1. In the administrative console, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Container Settings] Container Services** → **Compensation Service**.
2. Select the **Enable service at server startup** check box.
3. If required, modify the compensation handler retry interval and limit. These values control the frequency with which the compensation handler compensate and close methods are retried, when either throw a RetryCompensationHandlerException exception, and the number of times that these methods are retried.
4. Save your changes to the master configuration.
5. Repeat the previous steps for each server that you plan to use.
6. Restart all the servers for the changes to take effect.

Results

The business activity support is enabled for the application server. Verify a successful enablement by checking for the message, `CWSCP0005I: The Compensation service started successfully.` in the `SystemOut.log` file for the relevant server.

What to do next

Deploy the business-activity-enabled application to the server.

Creating an application that uses the Web Services Business Activity support

To create an application component that uses the business activity support, you must set **Run EJB methods under a Business Activity scope** in the deployment descriptor of the relevant application component, and if required, create and specify a compensation handler for the application to use if there is an error. You then build the component into the application and deploy the application onto a server that has the business activity support enabled. The application component can be either an enterprise bean or a Web service that is implemented as an enterprise bean.

Before you begin

For information about editing deployment descriptors, refer to topics about the Application Deployment Descriptor editor in the Application Server Toolkit information, in the navigation pane of this information center.

About this task

Perform this task for an application that runs on a business-activity-enabled sever to use the business activity support at run time, and to perform work that might later be compensated by a compensation handler. If the application requires compensation when a business activity scope ends, the application passes the data that is required by the compensation process to a compensation handler indirectly, by using the business activity API. The data that is required by the compensation process can be in the form of either a serializable object or a Service Data Object (SDO).

1. Design the application component that requires the business activity support. In particular, define the application component requirements for compensation and close activities. If the application component requires compensation, define the nature of the data in the serializable object or the SDO that the application component passes to the compensation handler.
2. Using the information from your application design, create the compensation handler for the application component, if required. This handler defines the close and compensation logic that runs upon completion of a business activity scope that has the handler added to it through an application component.
   a. Open your chosen WebSphere Application Server assembly tool.
   b. Create a new Java class that implements the appropriate interface, depending on the format of the data that is required by the compensation process:
      - For a serializable object, implement the com.ibm.websphere.wsba.serializable.CompensationHandler interface.
      - For an SDO, implement the com.ibm.websphere.wsba.CompensationHandler interface.
   c. Implement the close and compensate methods on the new compensation handler object, to perform appropriate actions depending on the serializable or SDO data that passes to the handler when it is invoked.

   The compensation handler class is now ready for the application component to reference, and for assembly into an application.
3. Open the application component in the assembly tool.
4. Open the deployment descriptor for the application component in the deployment descriptor viewer.
5. Scroll to the **Compensation** section and select the **Run EJB methods under a Business Activity scope** check box.
6. In the **Compensation handler class** text field, type the fully qualified class name of the compensation handler class that you created earlier.
7. Save the deployment descriptor.

8. Build the application, including both the application component and the compensation handler. If the application is a Web service, the application must be compliant with the Java Specification Request (JSR) 109 standard.
9. Deploy the application onto an application server that is business-activity-enabled.

Results

The application is now business-activity-enabled, and can use the business activity support at run time through the business activity API. The application component has a compensation handler associated with it, and can therefore call the setCompensationDataImmediate and setCompensationDataAtCommit methods at run time to add the compensation handler to the business activity scope. For more information about these methods, see “Business activity API” on page 702. If the unit of work with which the business activity scope is associated fails, the compensation handler performs actions to compensate for the error.

What to do next

Ensure that the compensation handler class is on the application class path for the WebSphere Application Server runtime environment.

Business activity API

Use the business activity application programming interface (API) to create business activities and compensation handlers for an application component, and to log data that is required to compensate an activity if there is a failure in the overall business activity.

Overview

The business activity support provides a UserBusinessActivity API and two interfaces: a serializable.CompensationHandler interface and a CompensationHandler interface. Each interface has two exceptions: RetryCompensationHandlerException and CompensationHandlerFailedException. You can look up the UserBusinessActivity interface from the application server Java Naming and Directory Interface (JNDI) at `java:comp/websphere/UserBusinessActivity`. For example:

```
InitialContext ctx = new InitialContext();
UserBusinessActivity uba = (UserBusinessActivity) ctx.lookup("java:comp/websphere/UserBusinessActivity");
```

You can use the getId method to access the unique identifier for the business activity that is currently associated with the calling thread. The identifier is the same as the one that is generated for the business activity scope at run time and that is used for information, warning, and error messages. For example, the application can use the identifier in audit or diagnostic messages, and it is possible to correlate between application-generated and runtime-generated messages.

```
InitialContext initialContext = new InitialContext();
UserBusinessActivity uba = initialContext.lookup("java:comp/websphere/UserBusinessActivity");
...
String activityId = uba.getId();
if (activityId == null)
// No activity on the thread
else
// Output audit message including activity id
```

If an application component runs work that might require compensating upon failure in the business activity, you must provide a compensation handler class that is assembled as part of the deployed application. This Java class must implement one of the following interfaces:

- com.ibm.websphere.wsba.serializable.CompensationHandler, which takes a takes a parameter of a serializable object
- com.ibm.websphere.wsba.CompensationHandler, which takes a parameter of a Service Data Object (SDO)

Typically, applications that already have their data available in DataObject format will use the CompensationHandler interface, and applications that do not will use the serializable.CompensationHandler interface. Both interfaces support the close and compensate methods.

An application must register a compensation handler implementation that works with the type of compensation data (serializable object or SDO) that the application uses. If there is a mismatch between the type of data that the application component uses and the compensation handler implementation, there is an error.

During normal application processing, the application can make one or more invocations to the `setCompensationDataImmediate` or `setCompensationDataAtCommit` methods, passing in either a serializable object or an SDO that represents the current state of the work performed.

When the underlying unit of work (UOW) that the root business activity is associated with completes, all registered compensators are coordinated to complete. During completion, either the compensate or the close method is called on the compensation handler, passing in the most recent compensation data logged by the application component as a parameter. Your compensation handler implementation must be able to understand the data that is stored in either the serializable object or the SDO DataObject; using this data, the compensation handler must be able to determine the nature of the work performed by the enterprise bean and compensate or close in an appropriate way, for example by undoing changes made to database rows if there is a failure in the business activity. You associate the compensation handler with an application component by using the assembly tooling, such as Rational Application Developer.

Active and inactive compensation handlers

You implement the serializable.CompensationHandler or CompensationHandler interface for any application component that executes code that might need to be compensated within a business activity scope. Compensation handler objects are registered implicitly with the business activity scope under which the application runs, whenever the application calls the UserBusinessActivity API to specify compensation data. Compensation handlers can be in one of two states, active or inactive, depending on any transactional UOW under which they are registered. A compensation handler that is registered within a transactional UOW might initially be inactive until the transaction commits, at which point the compensation handler becomes active (see the following section). A compensation handler that is registered outside a transactional UOW always becomes active immediately.

When a business activity completes, it drives only active compensation handlers. Any inactive compensation handlers that are associated with the business activity are discarded and never driven.

Logging compensation data

The business activity API specifies two methods that allow the application to log compensation data. This data is made available to the compensation handlers during their processing when the business activity completes. The application calls one of these methods, depending on whether it expects transactions to be part of the business activity.

`setCompensationDataAtCommit()`

Call the setCompensationDataAtCommit method when the application expects a global transaction on the thread.

- If a global transaction is present on the thread, the CompensationHandler object is initially inactive. If the global transaction fails, it rolls back any transactional work done within its transaction context in an atomic manner, and drives the business activity to compensate other completed UOWs. The compensation handler does not need to be involved. If the global transaction commits successfully, the compensation handler becomes active because if the overall business activity fails, the compensation handler is required to compensate the durable work that is completed by the global transaction. The setCompensationDataAtCommit method configures the CompensationHandler instance to perform this compensation function.

- If a global transaction is not present when the setCompensationDataAtCommit method is called, the compensation handler becomes active immediately.

For example, for an SDO, using the same business activity instance as in the previous example:

```
DataObject compensationData = doWorkWhichWouldNeedCompensating();
uba.setCompensationDataAtCommit(compensationData);
```

setCompensationDataImmediate()

Call the setCompensationDataImmediate method when the application does not expect a global transaction on the thread.

The setCompensationDataImmediate method makes a CompensationHandler instance active immediately, regardless of the current UOW context at the time that the method is invoked. The compensation handler is always able to participate during completion of the business activity.

The role of the setCompensationDataImmediate method is to compensate any non-transactional work, in other words, work that can be performed either inside or outside a global transaction, but that is not governed by the transaction. An example of this type of work is sending an e-mail. The compensation handler must be active immediately so that if a failure occurs in a business activity, this non-transactional work is always compensated.

For example, for a serializable object, using the same business activity instance as in the previous example:

```
Serializable compensationData = new MyCompensationData();
uba.setCompensationDataImmediate(compensationData);
```

Although these two compensation data logging methods, if called in the same enterprise bean, use the same compensation handler class, they create two separate instances of the compensation handler class at run time. Therefore, the actions of the methods are mutually exclusive; calling one of the methods does not overwrite any work carried out by the other method.

If a compensation handler instance is already added to the Business Activity using one of these methods, and then the same method is called, passing in `null` as a parameter, that compensation handler instance is removed from the business activity, and is not driven to close or compensate during completion of the business activity.

As described previously, the business activity support adds a compensation handler instance to the business activity when a compensation data logging method is called for the first time by the enterprise bean that uses that business activity. At the same time, a snapshot of the enterprise application context is taken and logged with the compensation data. When the business activity competes, all the compensation handlers that were added to the business activity are driven to compensate or close. The code that you create in the CompensationHandler or serializable.CompensationHandler class is guaranteed to run in the same enterprise application context that was captured in the earlier snapshot.

For details about the methods available in the business activity API, see Additional Application Programming Interfaces (APIs).

Using WS-Policy to exchange policies in a standard format

WS-Policy is an interoperability standard that is used to describe and communicate the policies of a Web service so that service providers can export policy requirements in a standard format. Clients can combine the service provider requirements with their own capabilities to establish the policies required for a specific interaction. WebSphere Application Server conforms to the WS-Policy specification, so that policy information can be exchanged and received in accordance with the WS-Policy standard.

About this task

For more information about using WS-Policy, see the following topics.

- Learn about WS-Policy
- Configure a service provider to share its policy configuration
- Configure the client policy using a service provider policy
- Configure a service provider to share its policy configuration using the wsadmin tool
- Configure the client policy based on a service provider policy using the wsadmin tool
- Configure security for a WS-MetadataExchange request

Learning about WS-Policy

WS-Policy is an interoperability standard that is used to describe and communicate the policies of a Web service so that service providers can export policy requirements in a standard format. Clients can combine the service provider requirements with their own capabilities to establish the policies required for a specific interaction.

WebSphere Application Server conforms to the Web services Policy Framework (WS-Policy) specification. You can use the WS-Policy protocol to exchange policies in standard format. A policy represents the capabilities and requirements of a Web service, for example whether a message is secure and how to secure it, and whether a message is delivered reliably and how this is achieved. You can communicate the policy configuration to any other client, service registry, or service that supports the WS-Policy specification, including non-WebSphere Application Server products in a heterogeneous environment.

For a service provider, the policy configuration can be shared in published Web Services Description Language (WSDL), WSDL that is obtained by a client using an HTTP Get request, or by using the Web Services Metadata Exchange (WS-MetadataExchange) protocol. The WSDL is in the standard WS-PolicyAttachments format.

For a client, the client can obtain the policy of the service provider in the standard WS-PolicyAttachments format and use this information to establish a configuration that is acceptable to both the client and the service provider. In other words, the client can be configured dynamically, based on the policies supported by its service provider. The provider policy can be attached at the application or service level.

The WS-Policy assertion specifications that are supported in this version of WebSphere Application server are:

- WS-Policy. See Web Services Policy 1.5
- WS-Addressing. See Web Services Addressing 1.0 - Metadata.
- WS-AtomicTransaction. See Web Services Atomic Transaction Version 1.0 and Web Services Atomic Transaction Version 1.1.
- WS-ReliableMessaging. See Web Services Reliable Messaging Policy Assertion Version 1.0 and Web Services Reliable Messaging Policy Assertion Version 1.1.
- WS-SecurityPolicy. See WS-SecurityPolicy 1.2.

For details of the WS-Policy domains that are supported, see the following topics:

- “WS-Addressing policy settings” on page 911
- “WS-ReliableMessaging settings” on page 908
- “WS-Security policy settings” on page 935
- “WS-Transaction policy settings” on page 932

Web service providers and policy configuration sharing

A WebSphere Application Server service provider can share its current policy configuration through its Web Service Description Language (WSDL). The policy configuration is in standard WSDL

WS-PolicyAttachment format so that it can be shared with other clients, service registries, or services that support the Web Services Policy (WS-Policy) specification.

You can make the policy configuration of a Java API for XML-Based Web Services (JAX-WS) service endpoint available to share in two ways:

- Include the policy configuration of the service provider in the WSDL. The WSDL is then available to publish, or to obtain using an HTTP Get request.
- Enable the Web Services Metadata Exchange (WS-MetadataExchange) protocol so that the policy configuration of the service provider is included in the WSDL and is available to a WS-MetadataExchange GetMetadata request. An advantage of using the WS-MetadataExchange protocol is that you can apply message-level security to WS-MetadataExchange GetMetadata requests by using a suitable system policy set.

The policy configuration in the WSDL is in the standard WS-PolicyAttachments format. Any WS-Policy attachments that were in the WSDL previously are removed. Note that policy configuration information becomes available in the WSDL to publish, but it is not available if you just view the WSDL document using the administrative console. Also, policy configuration information is not available in WSDL that is published remotely by using an administrative agent.

By default, the policy configuration of the service provider is not included in the WSDL. To include the policy configuration of the service provider in the WSDL, and specify how it is shared, you can use the administrative console or wsadmin commands.

Application developers can specify that a service provider shares its policy configuration, and how it is shared, using Rational Application Developer tools when a Web service is generated. For more information, see the Rational Application Developer documentation.

Transport policy information is not included in the policy configuration because transport policies such as HTTP, SSL, and JMS cannot be expressed in WS-PolicyAttachment format.

Bootstrap policy information, for example, the policy to access a WS-Trust service, can be included in the policy configuration if the bootstrap policy is expressed in WS-PolicyAttachment format.

You can configure a service provider to share its policy configuration at application or service level. The policy configuration that is represented by the policy sets attached to any lower levels will also be shared. Policy sets that are attached at lower levels override the policy set configuration attached at a higher level.

Troubleshooting policy configuration sharing

A service provider might not be able to share its policy configuration because the configuration cannot be expressed in the standard WS-PolicyAttachments format. One reason might be because multiple incompatible policies are defined for a particular attach point. Another reason might be because there is not enough binding information to generate the standard policy. Policy configuration might include bootstrap policy, for example, the policy to access a WS-Trust service, so the bootstrap policy must also be expressed in WS-PolicyAttachments format.

If the policy configuration cannot be shared, an error that describes the problem is written to the service provider error log, and the following policy is attached to the WSDL of the service provider:

```
<wsp:Policy>
<wsp:ExactlyOne>
</wsp:ExactlyOne>
</wsp:Policy>
```

This policy notifies the client that there is no acceptable policy configuration for the service. Other aspects of the WSDL are unaffected.

Web service clients and policy configuration using the service provider policy

If a service provider publishes its policy in its Web Services Description Language (WSDL), the policy configuration of a WebSphere Application Server service client can be configured dynamically, based on the policies supported by its service provider.

The service provider must publish its policy in WS-PolicyAttachment format in its WSDL and the client must be able to support those provider policies. The client can base its policy configuration entirely on the policy of the provider, or partly on the policy of the provider with restrictions that are defined by the policy set configuration of the client.

A client acquires the provider policy by using either an HTTP Get request or the Web Services Metadata Exchange (WS-MetadataExchange) protocol to obtain the WSDL of the provider. You can configure how the client obtains the provider policy, and the endpoint at which the policy is acquired, by using the administrative console or wsadmin commands. If you use the WS-MetadataExhange protocol to obtain the policy of the provider, this has the advantage that you can secure WS-MetadataExchange GetMetadata requests by using a suitable system policy set.

The Web application client-side policy is calculated and cached as a runtime configuration. This calculated policy is known as the effective policy and is used for subsequent outbound Web service requests to the endpoint or operation for which the calculation was performed. The original policy set configuration of the client does not change.

For a specific set of WSDL, dynamic policy configuration occurs once, and it is assumed that this configuration is the same for all endpoints that implement a service, because they have the same WSDL. The policy calculations that are based on this WSDL are cached in the client runtime (they are not persisted) and shared with each target service.

If you require a different policy configuration for each endpoint implementation, you must create a new port for each endpoint. Then you can specify a different policy configuration for each endpoint.

Transport policies such as HTTP, SSL, and JMS, cannot be expressed in WS-PolicyAttachment format, so the client cannot acquire the transport policies of the service provider. If the client requires transport policies, you must configure these policies as part of the policy set configuration of the client.

Policy inheritance

The provider policy can be attached at the application or service level. Endpoints and operations inherit their policy configuration from the relevant service.

Calculating policy

Policy intersection is the comparison of a client policy and a provider policy to determine whether they are compatible, and the calculation of a new policy that complies with both their requirements and capabilities. When you obtain the policy of a service provider, you can choose to use the provider policy only, or to use the client and the provider policy. The outcome of policy intersection is as follows:

- When you specify provider policy only, the calculated policy is based on all the policies that the WebSphere Application Server client supports intersected by the provider policy. Effectively, the provider determines the policy, as long as the client can support that policy. This policy configuration is available if the scope point (endpoint operation) where the provider policy is attached is not attached to a client policy set and does not inherit a policy set attachment from parent scope points.
- When you specify client and provider policy, the calculated policy is based on the policy that is acceptable to the client intersected by the provider policy. Effectively, the policy conforms to the client policy set, but might be restricted further by the policies dictated by the provider. The policy that is acceptable to the client is defined by the policy set that is either attached to the client scope point, or that the client scope point inherits from a parent scope point. This policy configuration is available if the

scope point (endpoint operation) where the provider policy is attached is attached to a client policy set or inherits a policy set attachment from parent scope points.

The WS-Policy language provides a way to express multiple policy choices, so the policy calculation might produce more than one result. For example, the service provider might support both WS-ReliableMessaging 1.0 and WS-ReliableMessaging 1.1. If the client also supports both versions, the client could use either version in its Web service requests to the provider. In this situation, where more than one specification version is acceptable to both the client and the provider, the effective policy is calculated using the most recent version.

Policy intersection in the JAX-WS dispatch client

Invocations that use the JAX-WS dispatch client (javax.xml.ws.Dispatch) use provider policy in their configuration if this is the administered behavior for the service. If the operation for the invocation is unknown, the client behaves as follows:

- The client complies with the provider policy scoped to the operation only if the provider policy is identical for all the operations provided by the service (both semantically and syntactically).
- If the provider policy is not identical for all the operations provided by the service, the client returns a JAX-WS WebserviceException with the cause WSPolicyException (CWPOL0106E), and an appropriate error message.
- If there is no policy on any of the operations, the client uses the effective provider policy for the service endpoint.

Refreshing the provider policy held by the client

The provider policy that the client holds for a service is refreshed the first time that the Web service is invoked after the application is loaded. After that, the provider policy is refreshed when the application restarts, or when you explicitly invoke an update of the provider policy.

You can invoke an update of the provider policy in the application code. This might be useful if a JAX-WS invocation fails; in the exception handling, you can force a retry with refreshed policy. You can set the following property (available in the WSPConstants class of the API) on the JAX-WS client proxy, then reissue the JAX-WS request: com.ibm.wsspi.wspolicy.refreshProviderPolicy.

When the com.ibm.wsspi.wspolicy.refreshProviderPolicy property is set, the provider policy that the client holds for a service is refreshed, and the effective policy is recalculated at the next request. After the refresh and recalculation have occurred, the com.ibm.wsspi.wspolicy.refreshProviderPolicy property is unset.

After an update of the policy provider is invoked, the next time that the Web service that is associated with the endpoint you selected is invoked, the policy of the service provider is obtained and the policy intersection is recalculated.

The following example of code for a dispatch client shows the identification of an exception that might be resolved by refreshing the provider policy, followed by the invocation of the refresh.

```
try
{
dispatch.invoke(params);
}
catch (javax.xml.ws.WebServiceException e)
{
Throwable cause = e.getCause();
if ((cause instanceof NullPolicyException) || (cause instanceof PolicyException) )
{
// The exception might be because the policy of the provider is not up to date.
//
// There is also a message on the console that starts with the characters CWPOL,
// which helps to decipher and debug the cause of the error.
// This message is also available by using
```

```
// String nlsedMessage = cause.getMessage();
Map<String, Object> requestContext = dispatch.getRequestContext();
requestContext.put(WSPConstants.REFRESH_PROVIDER_POLICY, Boolean.TRUE);
// The following method might cause another jax-ws invocation exception.
// The cause might still be policy, in which case, a message is written to the
// console.
dispatch.invoke(params);
}
// For all other exceptions, use the normal exception handling for the
// application. In this case, assume there are no other exceptions and rethrow the
// initial exception. Remember that the WebServiceException might be caused by a
// WSPolicyAdministrationException. In this situation, a message is written to the
// console, but forcing a refresh in the application cannot resolve the problem.
throw e;
}
```

WS-MetadataExchange requests

You can use the Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request to exchange Web Services Definition Language (WSDL) that is annotated with WS-Policy information. A service provider can use a WS-MetadataExchange request to share its policies, and a service client can use a WS-MetadataExchange request to apply the policies of a provider. You can secure WS-MetadataExchange requests by using transport-level or message-level security.

The WS-MetadataExchange specification defines a mechanism to retrieve metadata from an endpoint. WebSphere Application Server supports the use of the WS-MetadataExchange 1.1 GetMetadata request to return metadata in a response. A service provider can use this mechanism to make WSDL that is annotated with WS-Policy information available, that is, the service provider can share its policies. A service client can use this mechanism to obtain WSDL that is annotated with WS-Policy information from a service provider and then apply those policies. The policy configuration must be in WS-PolicyAttachments format in the WSDL of the service provider.

You can use a WS-MetadataExchange request as an alternative to using an HTTP Get request.

By default, a service provider or a service client does not use WS-MetadataExchange to share or obtain WS-Policy information. You must configure the service provider to share its policies, or configure the service client to apply the policies of a service provider, and specify that a WS-MetadataExchange request is used to share or obtain the policy configuration. WS-Policy information can be shared or obtained at the application or service level. You can configure the service provider or service client by using the administrative console or using wsadmin commands.

Application developers can configure the service provider or service client using Rational Application Developer tools when a Web service is generated. For more information, see the Rational Application Developer documentation.

When a service provider is configured to share its policies through WS-MetadataExchange, the service supports incoming WS-MetadataExchange GetMetadata requests that are limited to the WSDL dialect. When the service receives such a request, the WSDL of the service is returned inline through a conformant WS-MetadataExchange response. The WSDL of the service contains WS-PolicyAttachments annotations that represent the current policy configuration. The policy configuration is in WS-PolicyAttachments format in the WSDL so that it is then available to other clients, service registries or services that support the Web Services Policy (WS-Policy) specification and the WS-MetadataExchange GetMetadata request.

When a service client is configured to use WS-MetadataExchange to obtain the policy of a service provider, the service client sends a WS-MetadataExchange GetMetadata request that specifies the WSDL dialect whenever it needs to obtain or refresh the policy of the provider.

WS-MetadataExchange security

You must ensure that the GetMetadata request is secured so that there is effective authentication, authorization, integrity, and confidentiality. End-to-end authentication is particularly important for the exchange of security metadata (SecurityPolicy), because if an unauthorized party could access this information, security credentials could be sent to non-trusted endpoints.

The GetMetadata request is targeted at the same port as the application endpoint, so if the application uses transport-level security, the GetMetadata request is also be targeted at the secure port and will, by default, use the same transport-level security configuration of the application.

Additionally, you can apply message-level security (WS-Security) to the metadata exchange. You might want to apply message-level security if transport-level security is not available on the application endpoint, or if transport-level security is not adequate for your requirements. An advantage of message-level security is that it provides end-to-end security by incorporating security features in the header of the SOAP message.

To provide message-level security, you attach system policy sets and general (named) bindings to the endpoint when you configure the service provider or service client to exchange policy configurations.

System policy sets are used for system messages that are not business-related, whereas application policy sets specify policy assertions for business-related messages. For example, system policy sets are used for messages that apply qualities of service (QoS), which includes the messages that are defined in the WS-MetadataExchange protocol. To provide message-level security for a GetMetadata request, you must attach a system policy set that contains only Web Services Security (WS-Security) or Web Services Addressing (WS-Addressing) policies. You can specify general bindings that are scoped either to the global domain or to the security domain of the service.

When you apply message-level security, any transport policy of the application is always used.

Configuring a service provider to share its policy configuration

A WebSphere Application Server service provider can share its policy configuration in published Web Services Description Language (WSDL), or WSDL that is obtained using an HTTP Get request or the Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request.

Before you begin

You have developed a Web services service provider that contains all the necessary artifacts and deployed your Web services application into your application server instance. You have attached the policy sets and managed the associated bindings.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see “Learning about WS-Policy” on page 715.

About this task

You can make the policy configuration of a Java API for XML-Based Web Services (JAX-WS) service endpoint available to share in two ways:

- Include the policy configuration of the service provider in the WSDL. The WSDL is then available to publish, or to obtain using an HTTP Get request.
- Enable the Web Services Metadata Exchange (WS-MetadataExchange) protocol so that the policy configuration of the service provider is included in the WSDL and is available to a WS-MetadataExchange GetMetadata request. An advantage of using the WS-MetadataExchange protocol is that you can apply message-level security to WS-MetadataExchange GetMetadata requests by using a suitable system policy set.

The policy configuration in the WSDL is in the standard WS-PolicyAttachments format. Any WS-Policy attachments that were in the WSDL previously are removed. Note that policy configuration information becomes available in the WSDL to publish, but it is not available if you just view the WSDL document using the administrative console. Also, policy configuration information is not available in WSDL that is published remotely by using an administrative agent.

You must configure a service provider to share its policy configuration because by default the policy configuration is not available in its WSDL. You can configure the service provider to include the policy configuration in its WSDL, to use WS-MetadataExchange so that the policy configuration is available, or both. This topic describes how to configure a service provider to share its policy configuration using the administrative console. You can also configure a service provider to share its policy configuration by using wsadmin commands or Rational Application Developer tools.

You can configure a service provider to share its policy configuration at application or service level. The policy configuration that is represented by the policy sets attached to any lower levels will also be shared. Policy sets that are attached at lower levels override the policy set configuration attached at a higher level.

1. From the navigation pane of the administrative console, click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***service_provider_application_instance*** → **[Web services properties] Service provider policy sets and bindings**.
2. In the row for the application or service where the provider policy that you want to share is attached, click the link in the Policy sharing column. The link is either **Enabled** or **Disabled**. The Policy Sharing pane is displayed.
3. To include the policy configuration of the service provider in its WSDL so that it can be either published or obtained using an HTTP Get request, select **Exported WSDL**.
4. To enable WS-MetadataExchange and make the policy configuration of the service provider available to a WS-MetadataExchange GetMetada request, select **WS-MetadataExchange request**.
5. Optional: If you select **WS-MetadataExchange request** and you want to use message-level security, select **Attach a system policy set to the WS-MetadataExchange**, then select a suitable policy set and binding from the drop-down lists. See “Configuring security for a WS-MetadataExchange request” on page 729.
6. Click **OK** and save your changes to the master configuration.

Results

The policy configuration of the service provider is available to its clients. The WSDL of the service provider contains the current policy configuration in WS-PolicyAttachments format so that it is available to other clients, service registries, or services that support the Web Services Policy (WS-Policy) specification. The link in the Policy Sharing column on the Service provider policy sets and bindings pane changes to **Enabled**.

If the policy configuration cannot be shared, an error that describes the problem is written to the service provider error log, and the following policy is attached to the WSDL of the service provider:

```
<wsp:Policy>
<wsp:ExactlyOne>
</wsp:ExactlyOne>
</wsp:Policy>
```

This policy notifies the client that there is no acceptable policy configuration for the service. Other aspects of the WSDL are unaffected.

A service provider might not be able to share its policy configuration because the configuration cannot be expressed in the standard WS-PolicyAttachments format. One reason might be because multiple incompatible policies are defined for a particular attach point. Another reason might be because there is not enough binding information to generate the standard policy. Policy configuration might include

bootstrap policy, for example, the policy to access a WS-Trust service, so the bootstrap policy must also be expressed in WS-PolicyAttachments format.

Configuring a service provider to share its policy configuration using the wsadmin tool

A WebSphere Application Server service provider can share its policy configuration in published Web Services Description Language (WSDL), or WSDL that is obtained using an HTTP Get request or the Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request.

Before you begin

You have developed a Web services service provider that contains all the necessary artifacts and deployed your Web services application into your application server instance. You have attached the policy sets and managed the associated bindings.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see “Learning about WS-Policy” on page 715.

About this task

You can make the policy configuration of a Java API for XML-Based Web Services (JAX-WS) service endpoint available to share in two ways:

- Include the policy configuration of the service provider in the WSDL. The WSDL is then available to publish, or to obtain using an HTTP Get request.
- Enable the Web Services Metadata Exchange (WS-MetadataExchange) protocol so that the policy configuration of the service provider is included in the WSDL and is available to a WS-MetadataExchange GetMetadata request. An advantage of using the WS-MetadataExchange protocol is that you can apply message-level security to WS-MetadataExchange GetMetadata requests by using a suitable system policy set.

The policy configuration in the WSDL is in the standard WS-PolicyAttachments format. Any WS-Policy attachments that were in the WSDL previously are removed. Note that policy configuration information becomes available in the WSDL to publish, but it is not available if you just view the WSDL document using the administrative console. Also, policy configuration information is not available in WSDL that is published remotely by using an administrative agent.

You must configure a service provider to share its policy configuration because by default the policy configuration is not available in its WSDL. You can configure the service provider to include the policy configuration in its WSDL, to use WS-MetadataExchange so that the policy configuration is available, or both. This topic describes how to configure a service provider to share its policy configuration using wsadmin commands. You can also use the administrative console or Rational Application Developer (RAD) tools.

You can configure a service provider to share its policy configuration at application or service level. The policy configuration that is represented by the policy sets attached to any lower levels will also be shared. Policy sets that are attached at lower levels override the policy set configuration attached at a higher level.

1. Start the wsadmin tool if it is not already running.
2. Use the SetProviderPolicySharingInfo command. For example:

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WebServiceProviderApplication
-resource WebService:/WebServiceProvider.war:{http://example_path/}Service1
-sharePolicyMethods [httpGet ]]')
```

3. Save your changes to the master configuration.

   To save your configuration changes, enter the following command:

```
AdminConfig.save()
```

Results

The policy configuration of the service provider is available to its clients. The WSDL of the service provider contains the current policy configuration in WS-PolicyAttachments format so that it is available to other clients, service registries, or services that support the Web Services Policy (WS-Policy) specification.

If the policy configuration cannot be shared, an error that describes the problem is written to the service provider error log, and the following policy is attached to the WSDL of the service provider:

```
<wsp:Policy>
<wsp:ExactlyOne>
</wsp:ExactlyOne>
</wsp:Policy>
```

This policy notifies the client that there is no acceptable policy configuration for the service. Other aspects of the WSDL are unaffected.

A service provider might not be able to share its policy configuration because the configuration cannot be expressed in the standard WS-PolicyAttachments format. One reason might be because multiple incompatible policies are defined for a particular attach point. Another reason might be because there is not enough binding information to generate the standard policy. Policy configuration might include bootstrap policy, for example, the policy to access a WS-Trust service, so the bootstrap policy must also be expressed in WS-PolicyAttachments format.

What to do next

Optionally, you can publish the WSDL files.

Policy sharing settings

Use this pane to view and change whether the policy configuration of a Web services service provider is shared. You can configure the service provider to include the policy configuration in its Web Service Description Language (WSDL) so that it can be accessed using an HTTP Get request, or published. You can also make the policy configuration available to a Web Services Metadata Exchange (WS-MetadataExchange) request.

To view this administrative console page for an application or service, complete the following steps. The application must be a Web services service provider.

1. Click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***service_provider_application_name*** → **[Web Services Properties] Service provider policy sets and bindings**.
2. Select the link in the Policy Sharing column for the application or service you require. The link is available if the application or service has a policy set attached.

To view this administrative console page for a service, complete the following steps.

1. Click **Services** → **Service providers** → ***service_name***.
2. Select the link in the Policy Sharing column for the service. The link is available if the service has a policy set attached.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Exported WSDL:

Select **Exported WSDL** to include the policy configuration of the service provider in the WSDL. The policy configuration is in WS-PolicyAttachments format in the WSDL so that it is then available to other clients, service registries, or services that support the Web Services Policy (WS-Policy) specification. The policy

configuration will be available in published WSDL, or a client can use an HTTP Get request that is targeted at the target URL followed by `?WSDL` to obtain the provider policy.

WS-MetadataExchange request:

Select **WS-MetadataExchange** to make the policy configuration of the service provider available to a WS-MetadataExchange GetMetadata request. The policy configuration is in WS-PolicyAttachments format in the WSDL so that it is then available to other clients, service registries or services that support the Web Services Policy (WS-Policy) specification and the WS-MetadataExchange GetMetadata request.

When **WS-MetadataExchange** is selected, the **Attach a system policy set to the WS-MetadataExchange** option is available.

Attach a system policy set to the WS-MetadataExchange:

Select **Attach a system policy set to the WS-MetadataExchange** to set message-level security for the WS-MetadataExchange request. By default, this option is not selected and the transport policy of the application is used. This option is available only when **WS-MetadataExchange** is selected.

When **Attach a system policy set to the WS-MetadataExchange** is selected, the **Policy set** and **Binding** lists are available.

Policy set:

Select the policy set you require from the list to provide message-level security for the WS-MetadataExchange request. You can select from system policy sets that contain only WS-Security policies, only WS-Addressing policies, or both. The default policy set is SystemWSSecurityDefault.

System policy sets are used for system messages that are not business-related, for example, messages that apply qualities of service (QoS), including the messages that are defined in the WS-MetadataExchange protocol.

Note that any transport policy of the application is always used.

This option is available only when **Attach a system policy set to the WS-MetadataExchange** is selected.

Binding:

Select the binding you require from the list to provide message-level security for the WS-MetadataExchange request. You can select from general bindings that are scoped to the global domain, or scoped to the security domain of this service.

This option is available only when **Attach a system policy set to the WS-MetadataExchange** is selected.

Configuring the client policy using a service provider policy

An application that is a Web service client can obtain the policy configuration of a Web service provider and use this information to establish a policy configuration that is acceptable to both the client and the service provider.

Before you begin

You have developed a Web service client that contains all the necessary artifacts, and deployed your Web services application into your application server instance. If you require them, you have attached the policy sets and managed the associated bindings.

The service provider must publish its policy in its Web Services Description Language (WSDL) and that policy must contain its policy configuration at run time in WS-PolicyAttachments format. The client must be able to support those provider policies.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see “Learning about WS-Policy” on page 715.

About this task

The client can obtain the policy of the service provider in the standard WS-PolicyAttachments format. You can apply the provider policy at the application or service level. Endpoints and operations inherit their policy configuration from the relevant service.

Policy intersection is the comparison of a client policy and a provider policy to determine whether they are compatible, and the calculation of a new policy, known as the effective policy, that complies with both their requirements and capabilities.

This topic describes how to configure the client policy to use a service provider policy by using the administrative console. You can also configure the client policy to use a service provider policy by using wsadmin commands.

1. From the navigation pane of the administrative console, click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***service_client_application_instance*** → **[Web services properties] Service client policy sets and bindings**.
2. In the row for the application or service where you want to apply the policy, click the link in the Policies Applied column. The Policies Applied pane is displayed.
3. Select one of the following options from the drop-down list:
   - Provider policy only. Configure the client based solely on the policy of the service provider. This option is available when a client policy set is not attached.
   - Client and provider policy. Configure the client based on both the client policy set and the policy of the service provider. This option is available when a client policy set is attached.

   The other options in the list do not apply to this task.
4. To obtain the provider policy using an HTTP Get request, click **HTTP Get request**. By default, the HTTP Get request is targeted at the URL for the service endpoint followed by `?WSDL`. When you apply a policy to an application, you cannot change this value.
   a. Optional: If you are applying a policy to a service and you want to change the target of the HTTP Get request from the default, click **Specify request target**, then enter the URL you require, followed by `?WSDL`, in the field. For example:

```
http://service1/service1?WSDL
```

   b. Optional: If you are applying a policy to a service and you want to change the target of the HTTP Get request to the default, click **Use the default request target**. The HTTP Get request is targeted at the URL for the service endpoint followed by `?WSDL`.
5. To obtain the provider policy using a Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request, click **WS-MetadataExchange request**.
6. Optional: If you select **WS-MetadataExchange request** and you want to use message-level security, select **Attach a system policy set to the WS-MetadataExchange**, then select a suitable policy set and binding from the drop-down lists. See “Configuring security for a WS-MetadataExchange request” on page 729.
7. Click **OK**.
8. Save your changes to the master configuration.

Results

The Web application client-side policy is calculated based either on the policy of the service provider, or on the client policy set and the policy of the service provider, depending on which option you selected, and cached as a runtime configuration. The effective policy is used for subsequent outbound Web service requests to the endpoint or operation for which the dynamic policy calculation was performed. The policy set configuration of the client does not change.

The provider policy that the client holds for a service is refreshed the first time that the Web service is invoked after the application is loaded. After that, the provider policy is refreshed when the application restarts, or if the application explicitly invokes a refresh.

Configuring the client policy based on a service provider policy using the wsadmin tool

An application that is a Web service client can obtain the policy configuration of a Web service provider and use this information to establish a policy configuration that is acceptable to both the client and the service provider.

Before you begin

You have developed a Web service client that contains all the necessary artifacts, and deployed your Web services application into your application server instance. If you require them, you have attached the policy sets and managed the associated bindings.

The service provider must publish its policy in its Web Services Description Language (WSDL) and that policy must contain its policy configuration at run time in WS-PolicyAttachments format. The client must be able to support those provider policies.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see “Learning about WS-Policy” on page 715.

About this task

The client can obtain the policy of the service provider in the standard WS-PolicyAttachments format. You can apply the provider policy at the application or service level. Endpoints and operations inherit their policy configuration from the relevant service.

Policy intersection is the comparison of a client policy and a provider policy to determine whether they are compatible, and the calculation of a new policy, known as the effective policy, that complies with both their requirements and capabilities.

This topic describes how to configure the client policy to use a service provider policy by using the administrative console. You can also configure the client policy to use a service provider policy by using wsadmin commands.

1. Start the wsadmin tool if it is not already running.
2. Use the SetClientDynamicPolicyControl command. For example:

```
AdminTask.setClientDynamicPolicyControl('[-applicationName WebServiceClientApplication
-resource WebService:/ClientApplication.war:{http://example_path/}Service1
-acquireProviderPolicyMethod [httpGet ]
-httpGetProperties [httpGetTargetURI http://example_path?WSDL]]')
```

3. Save your changes to the master configuration.

   To save your configuration changes, enter the following command:

```
AdminConfig.save()
```

Results

The Web application client-side policy is calculated based either on the policy of the service provider, or on the client policy set and the policy of the service provider, depending on which option you selected, and cached as a runtime configuration. The effective policy is used for subsequent outbound Web service requests to the endpoint or operation for which the dynamic policy calculation was performed. The policy set configuration of the client does not change.

The provider policy that the client holds for a service is refreshed the first time that the Web service is invoked after the application is loaded. After that, the provider policy is refreshed when the application restarts, or if the application explicitly invokes a refresh.

Policies applied settings

Use this pane to view and change whether the policy configuration of a WebSphere Application Server service client is configured dynamically, based on the policies supported by its service provider. You can view or change how the client obtains the policy of the service provider; the client can use an HTTP Get request or a Web Services Metadata Exchange (WS-MetadataExchange) request. You can specify a policy set and binding to provide message-level security for WS-MetadataExchange.

To view this administrative console page for an application or service, complete the following steps. The application must be a Web services service client.

1. Click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***service_client_application_name*** → **[Web Services Properties] Service client policy sets and bindings**.
2. Select the link in the **Policies Applied** column for the application or service you require.

To view this administrative console page for a service, complete the following steps:

1. Click **Services** → **Service clients** → ***service_name***.
2. Select the link in the **Policies Applied** column for the service. The link is available if the service or the parent application has a policy set attached.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Apply the following policies:

Specifies whether the client policy is based on the policy of the service provider, and how that policy is used.

Select from the following options:

- Client policy only. Configure the client based solely on the client policy set. Do not use the policy of the service provider. This option is available when a client policy set is attached to the resource.
- Client and provider policy. Configure the client based on both the client policy set and the policy of the service provider. This option is available when a client policy set is attached to the resource.
- Inherit application attachment. Inherit the setting of the parent application. This option is available for a service when a client policy set is not attached to the service. If there is a policy set attached to the parent application, the inherited properties are displayed on this pane, but you cannot change them. If there is no policy set attached to the parent application, when you return to the Service clients policy sets and bindings pane, the Policies applied column shows a value of **None**.
- Provider policy only. Configure the client based solely on the policy of the service provider. This option is available when a client policy set is not attached to the resource.

HTTP GET request:

Click **HTTP GET request** to obtain the policy of the service provider by using an HTTP Get request. The policy configuration must be in WS-PolicyAttachments format in the WSDL of the service provider.

This option is available when **Apply the following policies** is set to Client and provider policy or Provider policy only.

By default, the HTTP Get request is targeted at the URL for each service endpoint followed by ?WSDL.

Use the default request target:

When you apply a policy to a service, click **Use the default request target** to target the HTTP Get request at the URL for each service endpoint followed by ?WSDL.

This option is available when **HTTP GET request** is selected and you apply a policy to a service.

When you apply a policy to an application, this option is not available.

Specify request target:

When you apply a policy to a service, click **Specify request target** to change the target of the HTTP Get request. Enter the URL you require, followed by `?WSDL`, in the field.

This option is available when **HTTP GET request** is selected and you apply a policy to a service.

When you apply a policy to an application, this option is not available.

WS-MetadataExchange request:

Click **WS-MetadataExchange** to obtain the policy of the service provider by using a WS-MetadataExchange GetMetadata request. The policy configuration must be in WS-PolicyAttachments format in the WSDL of the service provider.

This option is available when **Apply the following policies** is set to Client and provider policy or Provider policy only.

Attach a system policy set to the WS-MetadataExchange:

Select **Attach a system policy set to the WS-MetadataExchange** to set message-level security for the WS-MetadataExchange request. By default, this option is not selected and the transport policy of the application is used. This option is available when **WS-MetadataExchange** is selected.

When **Attach a system policy set to the WS-MetadataExchange** is selected, the **Policy set** and **Binding** lists are available. If you select **Attach a system policy set to the WS-MetadataExchange**, you must also select a policy set and a binding.

Policy set:

Select the policy set you require from the list to provide message-level security for the WS-MetadataExchange request. You can select from system policy sets that contain only WS-Security policies, only WS-Addressing policies, or both. The default policy set is SystemWSSecurityDefault.

System policy sets are used for system messages that are not business-related, for example, messages that apply qualities of service (QoS), including the messages that are defined in the WS-MetadataExchange protocol.

Note that any transport policy of the application is always used.

This option is available when **Attach a system policy set to the WS-MetadataExchange** is selected.

Binding:

Select the binding you require from the list to provide message level security for the WS-MetadataExchange request. You can select from general bindings that are scoped to the global domain or scoped to the security domain of this service.

This option is available when **Attach a system policy set to the WS-MetadataExchange** is selected.

Configuring security for a WS-MetadataExchange request

You can configure message-level security for a Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request by specifying a suitable policy set and binding. You do this when you configure a Web service provider to share its policies or a Web service client to obtain the policies of a service provider.

Before you begin

For a service provider, you have completed the procedure to configure a service provider to share its policy configuration, up to and including the step to enable WS-MetadataExchange.

For a service client, you have completed the procedure to configure the client policy using a service provider policy, up to and including the step to use WS-MetadataExchange.

About this task

By default, the WS-MetadataExchange GetMetadata request uses the transport-level security configuration of the application. You might want to apply message-level security if transport-level security is not available on the application endpoint, or if transport-level security is not adequate for your requirements. An advantage of message-level security is that it provides end-to-end security, which is especially important for the exchange of security metadata.

This topic describes how to configure security for a WS-MetadataExchange request using the administrative console. You can also configure security for a WS-MetadataExchange request using wsadmin commands.

1. For a service provider, in the Policy Sharing panel on the administrative console, select **Attach a system policy set to the WS-MetadataExchange**. For a service client, in the Policies Applied panel on the administrative console, select **Attach a system policy set to the WS-MetadataExchange**.
2. Select a system policy set to provide message-level security from the Policy set list. You can select from system policy sets that contain only WS-Security policies, only WS-Addressing policies, or both. The default policy set is SystemWSSecurityDefault. If the policy sets that are listed are not suitable for your requirements, create your own system policy set, then return to this procedure.
3. Select a general binding for the policy set attachment from the Binding list. You can select from general bindings that are scoped to the global domain, or the security domain of this service. If the bindings that are listed are not suitable for your requirements, create your own general binding, then return to this procedure.
4. Click **OK**.
5. Save your changes to the master configuration.

Results

Message-level security is applied to the WS-MetadataExchange GetMetadata request.

Administering deployed Web services applications

You can administer deployed Web services applications using the administrative console.

Before you begin

Before you can administer a Web service application, you need to deploy your Web service application.

About this task

You can use the administrative console to administer Java API for XML-Based Web Services (JAX-WS) service provider or service client applications or Java API for XML-based RPC (JAX-RPC) Web services.

- Administer service providers. You can administer your service providers using the following ways:
  - View service providers at the cell level using the administrative console. You can view the details of your service provider, manage the policy sets for the service, its endpoints and operations, and assign bindings for the policy set attachment at the cell level.
  - View service providers at the application level using the administrative console. You can view the details of your service provider, manage the policy sets for the service, its endpoints and operations, and assign bindings for the policy set attachment at the application level.
  - Manage policy sets and bindings for service providers. You can view the details of your service provider, manage the policy sets for the service, its endpoints and operations, and assign bindings for the policy set attachment.
  - Manage policy sets and bindings for service providers at the application level using the administrative console. You can manage policy sets for the provider, its endpoints, and operations, and assign bindings for the policy set attachment at the application level.
  - View WSDL document using the administrative console . You can view the WSDL document for your JAX-WS application.
- Administer service clients. You can administer your service clients using the following ways:
  - View service clients at the cell level . Your application server instance can have one or more applications deployed on it that contain service clients. You can view a list of your service clients at the cell level using the administrative console.
  - View service clients at the application level . Your application server instance can have one or more applications deployed on it that contains service clients. You can view the service client names that are referenced in an application.
  - Manage policy sets and bindings for service clients. You can view details of your service client reference, manage the policy sets for the service, its endpoints and operations, and assign bindings for the policy set attachment.
  - Manage policy sets and bindings for service clients at the application level. You can manage policy sets for your service client applications or its service references, endpoints, or operations and assign bindings for the policy set attachment at the application level.
- View the deployment descriptors.. View the Web services server and client deployment descriptors for a deployed Web services application. You can view the bindings in the deployment descriptors. The deployment descriptors are required for JAX-RPC Web services. You can optionally use the webservices.xml deployment descriptor to augment or override application metadata specified in annotations within your JAX-WS Web services.
- Configure the scope of a Web service port..**(JAX-RPC applications only)** When a Web service application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains deployment information for the Web module or enterprise bean module, including implementation scope and client bindings information. There are three levels of scope that you can set: application, session and request.

Overview of service and endpoint listeners

The administration function of the product is enhanced to support the service listener. This topics describes the service listener and endpoint listener.

The administrative enhancements to the product include the ability to control throughput by starting and stopping individual service and endpoint listeners. By stopping a service listener, it effectively throttles back the inbound requests to all the endpoints for that service, while the whole application and the other services run to serve requests.

Service listener

The service listener can be started or stopped. When a service listener is stopped, all the endpoints for the service are stopped and new inbound requests are no longer processed. The endpoints for the service send out 404 error message response code to indicate that the service listener is currently stopped and cannot service new inbound requests. When the service listener is started, all the endpoints for the service resume processing of new inbound requests.

Endpoint listener

The endpoint listener can be started or stopped. When a service endpoint listener is stopped, the specific endpoint stops listening to any new inbound request. The requests that are already being processed are not affected. The endpoint sends out a 404 error message response code to indicate that the endpoint is currently stopped and cannot service a new, inbound request. When the endpoint listener is started, the specific endpoint resumes listening on new inbound requests. The state of a particular service endpoint does not impact the listening function of other endpoints for the same service.

Administration of service and endpoint listeners

The administration function of the product is enhanced to support service and endpoint listeners. MBeans such as EndpointManager and the EndpointCentralManager can be used to invoke service and endpoint listeners.

After an application containing a Web service is installed, you want to verify that the service is installed correctly. You also want to monitor its service listener state, and update the listener state as needed to control the throughput. One option is to use the collection view of service providers in the administrative console of the product to locate the service provider of interest and observe its listener state.

If you do not want the listener state, then select the service and choose to start or stop the service listener. As the system starts or stops the service listener, the status indicator for the service is updated to show that it is started or stopped. This scenario helps you to throttle back traffic to a specific service as needed but leaves the containing application and other services in the application running. See service providers at the cell level using the administrative console. You can also reference service providers at the application level using the administrative console.

Note: You can only start or stop the service listener using the administrative console.

Another option is to use MBeans. With MBeans, you can invoke the startListener or stopListener operations in the EndpointCentralManager MBean or EndpointManager MBean to start or stop the listener service. The administrative console option does not expose the function of starting or stopping the listening state of a specific endpoint in a service. However, the MBeans option provides this capability. You can use scripting to invoke the MBean operations to start or stop the endpoint listener.

EndpointCentralManager MBean

There is an EndpointCentralManager MBean instance in the deployment manager, AdminAgent, and stand-alone server. The EndpointCentralManager MBean provides the administrative

convenience to start and stop the service or endpoint listeners across all the deployment targets such as the cluster members in a cluster. You do not have to know the target servers for the service application.

EndpointManager MBean

There is an EndpointManager MBean instance for each Web services application module in a server. This MBean instance is created when the application module is started. The MBean instance is deleted when the module is stopped. The MBean provides the start and stop operations to change the service and endpoint listener state. The MBean can also send a Java Management Extension (JMX) notification whenever the listener state has changed.

Viewing service providers at the cell level using the administrative console

You can use this administrative console page to view and manage your service providers at the cell level.

Before you begin

Before completing this task, you need to install one or more Java API for XML-Based Web Services (JAX-WS).

About this task

You can view a list of your installed service providers, such as JAX-WS Web services providers in a cell. You can start or stop the service listener.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

1. Open the administrative console.
2. In the navigation pane, expand **Services > Service providers**.
3. Locate the Web service of interest by name and the associated deployed asset in Deployed Asset column.
4. [Optional] Click the service of interest in the Name column to view the detail of the service and manage the policy sets and bindings for that service.
5. Click **Start Listener** or **Stop Listener** to start or stop the service listener. Starting the service listener makes all the endpoints for the service provider available and ready to receive messages. Stopping the listener makes all the endpoints for the service provider unavailable.

Results

When you finish this task, you have viewed the service providers at the cell level. You have also started or stopped the service listener.

What to do next

Proceed to view service providers at the application level using the administrative console.

Service providers collection at the cell level

Use this page to view and manage service providers at the cell level. Java Application Programming Interface (API) for XML-Based Web Services (JAX-WS) service providers are displayed in this view. Java API for XML Remote Procedure Call (JAX-RPC) service providers are not displayed in this view.

To view a service provider using this administrative console page, perform the following steps:

1. Expand **Services > Service Providers**.

2. Locate the service of interest by name in the Name column.
3. Click the service of interest in the Name column.
4. View the detail of the service.

To change the listening state of a service, perform the following steps:

1. Select the service of interest, and click **Start Listener** to start the listener service or click **Stop Listener** to stop the listener service. Starting the service listener makes all the endpoints for the service provider to be available and to receive messages. Stopping the listener makes all the endpoints for the service provider unavailable.
2. [Optional] Select the deployed asset link in the Deployed Asset column to access the deployed asset settings page.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

"Service provider policy sets and bindings collection" on page 746
Use this page to attach and detach policy sets to an application, a service provider, its endpoints, or operations. You can select the default bindings, create new application-specific bindings, or use bindings that you created for an attached policy set. You can view or change whether the service provider can share its current policy configuration.

Administrative roles
The Java Platform, Enterprise Edition (Java EE) role-based authorization concept is extended to protect the WebSphere Application Server administrative subsystem.

Name:

Specifies the name of the service provider. The service, *QName* (`Java class javax.xml.namespace.QName`), is displayed when you hover your mouse pointer over the Name field.

Type:

Specifies the type of service, such as a JAX-WS Web service and Web Services Notification (WSN) client service. You can filter by the type of service. If your service was migrated from the Feature Pack for Web Services, you can only filter by the name of the service.

Deployed Asset:

Represents a Java Platform, Enterprise Edition (Java EE) application or a WS-Notification service point.

	Java EE application
	Web Services Notification client service point application

Status:

Indicates the status for the service listener.

	Service endpoints are listening.
	Service endpoints are running, but the listener control is not supported because of the characteristics of this service; for example, the application is installed on a Feature Pack for Web Services server.
	Either the deployed asset is partially started or the service endpoints are listening on some, but not all the target servers.
	The deployed asset is partially started and the listener control is not supported.
	Service endpoints are not listening, but the deployed asset is running.
	Service endpoints are not listening because the deployed asset is not running.
	Service endpoints are not listening because the deployed asset is not running. Listener control is not supported.
	Deployed asset is partially stopped. Service endpoints are not listening.
	Deployed asset is partially stopped. Service endpoints are not listening. Listener control is not supported because of the characteristics of this service; for example, the application is installed on a Feature Pack for Web Services server.
	Status cannot be determined.

Viewing service providers at the application level using the administrative console

You can use this administrative console page to view and manage your service providers at the application level.

Before you begin

Before completing this task, you need to install a Java API for XML-Based Web Service.

About this task

You can view a list of your service providers, such as JAX-WS Web services providers at the application level. You can start the service listener to make all the endpoints for the service to be available and to receive messages. You can also stop the service listener.

1. Open the administrative console.
2. To view the service providers, click **Applications > Application Types > WebSphere enterprise applications** >*Service_provider_application_instance* > **Service providers**.
3. [Optional] Click a module that contains a service to view the module information.
4. Depending on the current application status, click **Start Listener** or **Stop Listener** to start or stop the service listener. Starting the service listener makes all the endpoints for the service available and ready to receive messages. Stopping the listener makes all the endpoints for the service unavailable. See Endpoint and service listeners overview.

Results

When you complete this task, you have viewed and managed the service providers at the application level.

What to do next

You can proceed to managing policy sets using the administrative console. You can click on a service provider to manage the policy sets and bindings for that service.

Service providers collection at the application level

Use this page to view and manage service providers at the application level.

To view a service provider using this administrative console page, perform the following steps:

1. Click **Applications > Application Types > WebSphere enterprise applications** >*Service_provider_application_instance* > **Service providers**.
2. Locate the service of interest by name in the Name column.
3. Click the service of interest in the Name column.
4. View the detail of the service.

To change the listening state of a service, perform the following steps:

1. Select the service of interest, and click **Start Listener**, to start the service listener or **Stop Listener**, to stop the service listener. Starting the service listener makes all the endpoints for the service provider to be available and to receive messages. Stopping the listener makes all the endpoints for the service provider to be unavailable.
2. [Optional] Click a module name in the Module column to access the module detail page.

Name:

Specifies the name of the service provider. The service *QName* (`Java class javax.xml.namespace.QName`) is displayed when you hover your mouse pointer over the Name field.

Type:

Specifies the type of service.

Module:

Specifies the name of the module that contains the service.

Status:

Indicates the status for the service listener.

	Service endpoints are listening.
	Service endpoints are running, but the listener control is not supported because of the characteristics of this service; for example, the application is installed on a Feature Pack for Web Services server.
	Either the deployed asset is partially started or the service endpoints are listening on some, but not all the target servers.
	The deployed asset is partially started and the listener control is not supported.
	Service endpoints are not listening, but the deployed asset is running.
	Service endpoints are not listening because the deployed asset is not running.
	Service endpoints are not listening because the deployed asset is not running. Listener control is not supported.
	Deployed asset is partially stopped. Service endpoints are not listening.
	Deployed asset is partially stopped. Service endpoints are not listening. Listener control is not supported because of the characteristics of this service; for example, the application is installed on a Feature Pack for Web Services server.
	Status cannot be determined.

Viewing the detail of a service provider and managing policy sets using the administrative console

Use this administrative console task to view the detail of your service provider and to manage the policy sets for the service, its endpoints and operations.

Before you begin

Before completing this task, you need to install one or more Java API for XML-Based Web Services (JAX-WS) artifacts.

About this task

You have developed a Web service that contains all the necessary artifacts and deployed your Web services application into your application server instance. Now, you can attach or detach policy sets and manage the associated bindings.

The policy set information is displayed in the Attached Policy Set column. If a policy set is directly attached, then the policy set name appears; for example, `WS-I RSP` is displayed. If there is no policy set attached, and a policy set is attached at a higher level, then the word *inherited* in parentheses is appended to the policy set name, as the following example demonstrates: `WS-I RSP (inherited)`. If there is no policy set attached directly or at a higher level, then `None` is displayed.

Every attachment of a policy set to a service artifact has an assigned binding. The binding information is displayed in the Binding column. The Binding column can contain the following values:

- Not applicable. There is no policy set attached, either directly or to a higher level service resource.
- *Binding_name* or Default. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. Default is displayed if a policy set is attached directly but the service resource uses the default bindings.
- *Binding_name* (inherited) or Default (inherited). A service resource inherits the bindings from an attachment to a higher level resource.

In Version 7.0, there are two types of bindings, application specific bindings and general bindings.

Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have very limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. See service providers policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

General bindings

General bindings are new for Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general provider policy set bindings by accessing **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings. General provider policy set bindings might also be used for trust service attachments.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

1. Open the administrative console.
2. In the navigation pane, expand **Services > Service providers >***Service_provider_application_instance* **Service providers**.
3. Select one or more service, endpoints and operations of interest and view the associated service, endpoints and operations.

4. Do one or more of the following actions:
   - Click **Attach**, to attach a policy to a selected service, endpoint or operation.
   - Click **Detach**, to detach a policy set from a list of attached policy sets for a service, endpoint or operation.
5. Click **Assign Binding** to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options:
   - Default
   - New Application Specific Binding
   - Provider sample

   Default

   Specifies the default binding for the selected service, endpoint or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the Default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used.

   For any policy set attachment, the runtime checks to see if the attachment includes a binding. If so, it uses that binding. If not, the runtime checks in the following order and uses the first available default binding:

   a. Default general bindings for the server
   b. Default general bindings for the domain that the server resides
   c. Default general bindings for the global security domain

   New Application Specific Binding

   Select this option to create a new application specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.

   Provider sample

   Select this option to use the provider sample binding.
6. To close the drop down list for the assign binding action, click **Assign Binding**.

Results

When you finish this task, a policy set is attached, detached or a binding is assigned to the service artifact.

Example

You have configured a service provider, `EchoService12` in the application instance, WSSampleServicesSei. Now you want to attach the WS-Security policy to the `EchoService12Port` endpoint of the `EchoService12` service provider. First locate **`EchoService12`** in the Services > Service providers collection. Click the **`EchoService12`** service provider. Select the check box for the `columoService12Port` resource. Click **Attach** and select **WSSecurity** default policy from the list. Click **Save**, to save your changes to the master configuration.

What to do next

You can now proceed to manage policy sets and bindings for service providers at the application level using the administrative console.

Service provider settings

Use the Service provider settings page to manage the settings for your service providers. You can attach and detach policy sets to an application, its service, endpoints or operations. You can create new bindings,

or use bindings that you have already created for an attached policy set. You can view or change whether the service provider can share its current policy configuration.

Use the **WSDL document** link to view the Web Services Description Language (WSDL) for the service. The Application and Module links provide access to the application and module settings page.

To view this administrative console page, click **Services** → **Service providers** → ***service_provider_instance***.

You can also view this page by clicking **Applications** → **Application Types** → **WebSphere enterprise applications** → ***service_provider_application_instance*** → **Service providers** → ***service_provider_instance***.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Administrative roles
The Java Platform, Enterprise Edition (Java EE) role-based authorization concept is extended to protect the WebSphere Application Server administrative subsystem.

Service provider:

Specifies the name of the service provider that is displayed.

Policy Set Attachments:

Service/Endpoint/Operation:

Specifies the name of the service provider, endpoint, or operation that is contained in a service.

Attached Policy Set:

Specifies the policy set that is attached to a service provider, endpoint, or operation.

The Attached Policy Set column can contain the following values:

- **None**. No policy set is attached, either directly or to a higher-level service resource.
- ***Policy_set_name***. The name of the policy set that is attached directly to the service resource, for example, `WS-I RSP`.
- ***Policy_set_name*** **(inherited)**. The name of the policy set that is not attached directly to a service resource, but that is attached to a higher-level service resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

Binding:

Specifies the binding configuration that is available for a service provider, endpoint, or operation.

The Binding column can contain the following values:

- **Not applicable**. No policy set is attached, either directly or to a higher-level service resource.
- ***Binding_name*** or **Default**. The binding name is displayed if a policy set is attached directly and an application specific binding or a general binding is assigned, for example, `MyBindings1`. **Default** is displayed if a policy set is attached directly but the service resource uses the default bindings.
- ***Binding_name*** **(inherited)** or **Default (inherited)**. A service resource inherits the bindings from an attachment to a higher-level resource.

When the value in the Binding column is a link, click the link to view or change settings about the binding.

About policy set bindings

In this release, there are two types of bindings: application-specific bindings and general bindings.

Application-specific bindings

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to, and constrained by, the characteristics of the defined policy. Application-specific bindings can provide configuration for advanced policy requirements such as multiple signatures; however, these bindings are reusable only within an application. Also, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding, and fully configure the bindings for each policy that you add. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service providers policy sets and bindings collection page, for

service provider resources that have an attached policy set. Similarly, for service clients, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service clients policy sets and bindings collection page, for service client resources that have an attached policy set.

General bindings

You can configure general bindings to be used across a range of policy sets and they can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they cannot provide configuration for advanced policy requirements such as multiple signatures. There are two types of general bindings: general provider policy set bindings and general client policy set bindings.

You can create general provider policy set bindings by clicking **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel, or by clicking **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. For details about defining and managing service client or provider bindings, see the related links. General provider policy set bindings might also be used for trust service attachments.

Policy Sharing:

Specifies whether the service provider can share its current policy configuration.

The Policy sharing column can contain the following values:

- **Not applicable**. The resource does not have a policy set attached, so there is no policy configuration to share.
- **Disabled**. The policy set of the resource cannot be shared. This is the default setting if a policy set is attached to a service.
- **Enabled**. The policy set of the resource can be shared.

When the value in the column is a link, click the link to view or change settings about how the policy configuration can be shared.

For a service, if the policy set is inherited from the parent application, the policy sharing value is also inherited, and you cannot change it. The value is not a link and it is followed by the term `inherited` in parentheses.

For an endpoint or operation, the value is not a link and it is followed by the term `inherited` in parentheses. The setting is inherited from the parent application or service and you cannot change it.

Buttons:

Attach Policy Set	Click this button to view a list of policy sets available for attachment to the selected service, endpoint, or operation. Select a policy set from the list to attach and it is attached to the selected service, endpoint, or operation. To close the menu list, click **Attach Policy Set**.
Detach Policy Set	Click this button to detach a policy set from a selected service, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper level service resource, the **Attached Policy Set** column displays **None** and the **Binding** column displays **Not Applicable**. If there is a policy set attached to an upper level service resource, the **Attached Policy Set** column displays***policy_set_name*** **(inherited)** and the binding used for the upper level attachment is applied. The binding name is displayed followed by **(inherited)**.

Assign Binding	Click this button to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options: • Default • New Application Specific Binding • Provider sample **Default** Specifies the default binding for the selected service, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used. For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain in which the server resides 3. Default general bindings for the global security domain **New Application Specific Binding** Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached. **Provider sample** Select this option to use the Provider sample binding. To close the menu list, click **Assign Binding**.

Managing policy sets and bindings for service providers at the application level using the administrative console

Use this administrative console task to manage policy sets for an application or its services, endpoints, and operations.

Before you begin

Before completing this task, you need to install one or more Java API for XML-Based Web Services (JAX-WS) and attach a policy set to each Web service.

About this task

You have developed a Web service that contains all the necessary artifacts and deployed your Web services application into your application server instance. Now, you can attach or detach policy sets and manage the associated bindings.

The policy set information is displayed in the Attached Policy Set column. If a policy set is directly attached, then the policy set name appears; for example, `WS-I RSP` is displayed. If there is no policy set attached, and a policy set is attached at a higher level, then the word *inherited* in parentheses is appended to the policy set name, as the following example demonstrates: `WS-I RSP (inherited)`. If there is no policy set attached directly or at a higher level, then `None` is displayed.

Every attachment of a policy set to a service artifact has an assigned binding. The binding information is displayed in the Binding column. The Binding column can contain the following values:

- Not applicable. There is no policy set attached, either directly or to a higher level service resource.
- *Binding_name* or Default. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. Default is displayed if a policy set is attached directly but the service resource uses the default bindings.
- *Binding_name* (inherited) or Default (inherited). A service resource inherits the bindings from an attachment to a higher level resource.

In Version 7.0, there are two types of bindings, application specific bindings and general bindings.

Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have very limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. See service providers policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

General bindings

General bindings are new for Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general provider policy set bindings by accessing **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings. General provider policy set bindings might also be used for trust service attachments.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

1. Open the administrative console.
2. **Applications > Application Types > WebSphere enterprise applications** >*Service_provider_application_instance* > **Service provider policy sets and bindings**.
3. Select the check box next to a service resource of interest.
4. Click **Attach** to attach a policy set to an application, service, endpoint or operation.

5. [Optional] Click **Detach** to detach a policy set from a list of attached policy sets for an application, service provider, endpoint or operation.
6. Click **Assign Binding** to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options:
   - Default
   - New Application Specific Binding
   - Provider sample

   Default

   Specifies the default binding for the selected service, endpoint or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the Default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used.

   For any policy set attachment, the runtime checks to see if the attachment includes a binding. If so, it uses that binding. If not, the runtime checks in the following order and uses the first available default binding:

   a. Default general bindings for the server
   b. Default general bindings for the domain that the server resides
   c. Default general bindings for the global security domain

   New Application Specific Binding

   Select this option to create a new application specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.

   Provider sample

   Select this option to use the provider sample binding.
7. To close the drop down list for the assign binding action, click **Assign Binding**.

Results

When you finish this task, a policy set is attached or detached, and a binding is assigned to the service artifact.

Example

If you have configured a service provider application instance, `app1` and you want, for example, to attach the`Username WSSecurity default` policy set to your application, first locate `app1` application in the **Applications > Application Types > WebSphere enterprise applications**. Click `app1` > **Service provider policy sets and bindings** under the Web Services Properties section. Select the check box next to the `app1` service application. Click **Attach** and select `Username WSSecurity default` policy set. Click **Save**, to save your changes to the master configuration. You are returned to the **Applications > Application Types > WebSphere enterprise applications** page.

To assign a binding to the attached policy set, click `app1` > **Service provider policy sets and bindings**. Select the check box next to the `app1` service application and click **Assign Binding**. Select **Provider sample** binding from the list. Click **Save**, to save your changes to the master configuration.

What to do next

You can proceed to view service providers at the cell level using the administrative console.

Service provider policy sets and bindings collection

Use this page to attach and detach policy sets to an application, a service provider, its endpoints, or operations. You can select the default bindings, create new application-specific bindings, or use bindings that you created for an attached policy set. You can view or change whether the service provider can share its current policy configuration.

This page provides detail information for an application and its associated Web service providers, endpoints, and operations. You can view and manage policy set attachments and bindings information using this page.

To view this administrative console page, click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***Service_provider_application_instance*** → **Service provider policy sets and bindings**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

You can select default bindings, create new application-specific bindings, or use existing bindings for an attached policy set. You can view or change whether the client uses the policy of the service provider.

"Service client policy set and bindings collection" on page 763
Use this page to attach and detach policy sets to an application, a service client, its endpoints, or operations. You can select the default bindings, create new application-specific bindings, or use existing bindings for an attached policy set. You can view or change whether the client uses the policy of the service provider.

Administrative roles
The Java Platform, Enterprise Edition (Java EE) role-based authorization concept is extended to protect the WebSphere Application Server administrative subsystem.

Administrative console buttons
This page describes the button choices that are available on various pages of the administrative console, depending on which product features you enable.

Administrative console preference settings
Use the preference settings to specify how you want information to display on an administrative console

panel. The preference settings vary from one administrative console panel to another.

Application/Service/Endpoint/Operation:

Specifies the name of the application and the associated service providers, endpoints or operations.

The Application/Service/Endpoint/Operation column lists the service application and the service providers, endpoints, or operations that the application contains.

Attached Policy Set:

Specifies the policy set that is attached to a service provider, endpoint, or operation.

The Attached Policy Set column can contain the following values:

- **None**. No policy set is attached, either directly or to a higher-level service resource.
- ***Policy_set_name***. The name of the policy set that is attached directly to the service resource, for example, WS-I RSP.
- ***Policy_set_name* (inherited)**. The name of the policy set that is not attached directly to a service resource, but that is attached to a higher-level service resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

Binding:

Specifies the binding configuration that is available for a service provider, endpoint, or operation.

The Binding column can contain the following values:

- **Not applicable**. No policy set is attached, either directly or to a higher-level service resource.
- ***Binding_name*** or **Default**. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. **Default** is displayed if a policy set is attached directly but the service resource uses the default bindings.
- ***Binding_name* (inherited)** or **Default (inherited)**. A service resource inherits the bindings from an attachment to a higher-level resource.

When the value in the Binding column is a link, click the link to view or change settings about the binding.

About policy set bindings

In this release, there are two types of bindings: application-specific bindings and general bindings.

Application-specific bindings

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to, and constrained by, the characteristics of the defined policy. Application-specific bindings can provide configuration for advanced policy requirements such as multiple signatures; however, these bindings are reusable only within an application. Also, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding, and fully configure the bindings for each policy that you add. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service providers policy sets and bindings collection page, for service provider resources that have an attached policy set. Similarly, for service clients, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service clients policy sets and bindings collection page, for service client resources that have an attached policy set.

General bindings

You can configure general bindings to be used across a range of policy sets and they can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they cannot provide configuration for advanced policy requirements such as multiple signatures. There are two types of general bindings: general provider policy set bindings and general client policy set bindings.

You can create general provider policy set bindings by clicking **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel, or by clicking **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. For details about defining and managing service client or provider bindings, see the related links. General provider policy set bindings might also be used for trust service attachments.

Policy Sharing:

Specifies whether the service provider can share its current policy configuration.

The Policy sharing column can contain the following values:

- **Not applicable**. The resource does not have a policy set attached, so there is no policy configuration to share.
- **Disabled**. The policy set of the resource cannot be shared. This is the default setting if a policy set is attached to a service.
- **Enabled**. The policy set of the resource can be shared.

When the value in the column is a link, click the link to view or change settings about how the policy configuration can be shared.

For a service, if the policy set is inherited from the parent application, the policy sharing value is also inherited, and you cannot change it. The value is not a link and it is followed by the term `inherited` in parentheses.

For an endpoint or operation, the value is not a link and it is followed by the term `inherited` in parentheses. The setting is inherited from the parent application or service and you cannot change it.

Buttons:

Attach Policy Set	Click this button to view a list of policy sets available for attachment to the selected service, endpoint, or operation. Select a policy set from the list to attach and it is attached to the selected service, endpoint, or operation. To close the menu list, click **Attach Policy Set**.
Detach Policy Set	Click this button to detach a policy set from a selected service, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper level service resource, the **Attached Policy Set** column displays **None** and the **Binding** column displays **Not Applicable**. If there is a policy set attached to an upper level service resource, the **Attached Policy Set** column displays ***policy_set_name*** **(inherited)** and the binding used for the upper level attachment is applied. The binding name is displayed followed by **(inherited)**.

Assign Binding	Click this button to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options: • Default • New Application Specific Binding • Provider sample **Default** Specifies the default binding for the selected service, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used. For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain in which the server resides 3. Default general bindings for the global security domain **New Application Specific Binding** Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached. **Provider sample** Select this option to use the Provider sample binding. To close the menu list, click **Assign Binding**.

Viewing WSDL document using the administrative console

You can locate and view a Web Services Description Language (WSDL) document from the administrative console.

Before you begin

Before completing this task, you need to install or deploy a Java API for XML Web Services (JAX-WS). Read about the JAX-WS application deployment model.

About this task

JAX-WS integration with the WebSphere Application Server provides the option to view a Web Services Description Language (WSDL) document that is associated with your Web service using the administrative console.

A Web service application that contains all the necessary artifacts has been developed and deployed to the Application Server. Now you can view the WSDL document for each service using the administrative console.

1. Open the administrative console.
2. In the navigation pane, expand **Services > Service providers**.
3. Select a Web service of interest in the **Service providers** collection view.
4. Click the **WSDL document** link to view the WSDL document.

Results

When you finish this task, you have viewed the WSDL document for a service artifact.

What to do next

You can attach and detach policy sets and configure bindings information for your application. See managing policy sets and bindings for service providers at the application level using the administrative console.

Viewing service clients at the cell level using the administrative console

You can view all your service clients at the cell level using the administrative console.

Before you begin

Before completing this task, you need to install one or more Java API for XML-Based Web Services (JAX-WS).

About this task

You can view a list of your service clients, such as JAX-WS Web services clients using the administrative consolel.The Name column displays the service client references. The Deployed Asset column displays the name of the deployed asset that contains the service client.

1. Open the administrative console.
2. In the navigation pane, expand **Services > Service clients**.
3. View the Web service client of interest in the Name column and the associated application in the Deployed Asset column. For JAX-WS (WSN) references, the name of the containing WS-Notification service that is a part of the System Integration (SI) is displayed. Hovering over this name displays the Bus:<busName>.

Results

When you complete this task, you have viewed the service clients at the cell level.

What to do next

Proceed to view service clients at the application level using the administrative console. Click each service to see and manage the policy sets and bindings associated with a particular service.

Service client collection at the cell level

Use this page to view and manage service clients at the cell level. Server-based Java API for XML-Based Web Services (JAX-WS) service clients are the only clients that are displayed in this view. Java API for XML-based RPC (JAX-RPC) service clients are not displayed in this view.

To view this administrative console page, click **Services > Service clients**. Select the service name link in the Name column to access the service client settings page. Select the deployed asset link in the Deployed Asset column to access the deployed asset settings page.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

“Service client settings” on page 756
Use this administrative console page to manage the settings for your service clients. You can attach and detach policy sets to a service, its endpoints, or operations. You can select default bindings, create new application-specific bindings, or use existing bindings for an attached policy set. You can view or change whether the client uses the policy of the service provider.

Administrative roles
The Java Platform, Enterprise Edition (Java EE) role-based authorization concept is extended to protect the WebSphere Application Server administrative subsystem.

Name:

Specifies the name of the service client, which is the name of the service provider that is referenced by the client. The full `QName`, Java class `javax.xml.namespace.QName`, is displayed when you hover the mouse pointer over the **Name** field.

Type:

Specifies the type of service such as a JAX-WS client service and Web Services Notification (WSN) client service. You can filter by the type of service.

Deployed Asset:

Represents a Java Platform, Enterprise Edition (Java EE) application or a WS-Notification service. For JAX-WS or WSN clients, the name of the containing WS-Notification service that is a part of the System Integration (SI) is displayed. Hovering over this name displays the Bus:<busName>.

	Java EE application
	WS-Notification service

Viewing service clients at the application level using the administrative console

You can view your installed service clients for an application using this task.

Before you begin

Before completing this task, you need to install a Java API for XML-based Web Service.

About this task

You can view a list of your service client references.

Your application server instance can have one or more applications deployed on it that contain service clients. Use this task enables you to view the service names that are referenced in an application.

1. Open the administrative console.
2. View the service clients in an application by expanding **Applications > Application Types > WebSphere enterprise applications** >*Service_client_application_instance* > **Service clients**.
3. Select a client from the Name column to view the client and to manage the policy sets and bindings associated with it.
4. [Optional] Select a module name from the Module column to access the module detail page.

Results

When you finish this task, you have viewed service clients at the application level.

What to do next

You can now proceed to managing policy sets using the administrative console.

Service clients collection at the application level

Use this page to view and manage service clients at the application level.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications** >*Service_client_application_instance* > **Service client**.

Name:

Specifies the name of the service client. The service *QName*, `Java class javax.xml.namespace.QName`, is displayed when you hover your mouse pointer over the **Name** field.

Type:

Specifies the type of service such as a Java™ API for XML-Based Web Services (JAX-WS) Web service. You can filter by the type of service.

Module:

Specifies the name of the module that contains the service. Selecting a module name accesses the module detail page.

Viewing detail of a service client and managing policy sets using the administrative console

Use this administrative console task to view the detail of your service client reference and to manage the policy sets for the service, its endpoints and operations.

Before you begin

Before completing this task, you need to install one or more Java API for XML-Based Web Service (JAX-WS) Web service and attach a policy set to that Web service.

About this task

You have developed a Web service that contains all the necessary artifacts and deployed your Web services application into your application server instance. Now, you can attach or detach policy sets and manage the associated bindings.

The policy set information is displayed in the Attached Policy Set column. If a policy set is directly attached, then the policy set name appears; for example, `WS-I RSP` is displayed. If there is no policy set attached, and a policy set is attached at a higher level, then the word *inherited* in parentheses is appended to the policy set name, as the following example demonstrates: `WS-I RSP (inherited)`. If there is no policy set attached directly or at a higher level, then `None` is displayed.

Every attachment of a policy set to a service artifact has an assigned binding. The binding information is displayed in the Binding column. The Binding column can contain the following values:

- Not applicable. There is no policy set attached, either directly or to a higher level service resource.
- *Binding_name* or Default. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. Default is displayed if a policy set is attached directly but the service resource uses the default bindings.
- *Binding_name* (inherited) or Default (inherited). A service resource inherits the bindings from an attachment to a higher level resource.

In Version 7.0, there are two types of bindings, application specific bindings and general bindings.

Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have very limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have

added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service clients policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

General bindings

General bindings are new for Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general client policy set bindings by accessing **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

1. Open the administrative console.
2. In the navigation pane, click **Applications > Application Types > WebSphere enterprise applications** >*Service_client_application_instance* > **Service clients**.
3.
4. Select one or more service, endpoints and operations of interest and view the associated service, endpoints and operations.
5. You can perform any of the following actions:
   - Click **Attach**, to attach a policy set to a selected service, endpoint or operation.
   - Click, **Detach**, to detach a policy set from a list of attached policy sets for a service, endpoint or operation. The service name is the service client reference in the application.
6. Click **Assign Binding** to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options:
   - Default
   - New Application Specific Binding
   - Client sample

   Default

   Specifies the default binding for the selected service, endpoint or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the Default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used.

   For any policy set attachment, the runtime checks to see if the attachment includes a binding. If so, it uses that binding. If not, the runtime checks in the following order and uses the first available default binding:

a. Default general bindings for the server
b. Default general bindings for the domain that the server resides
c. Default general bindings for the global security domain

New Application Specific Binding

Select this option to create a new application specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.

Client sample

Select this option to use the client sample binding.

7. To close the drop down list for the assign binding action, click **Assign Binding**.

Results

When you finish this task, a policy set is attached, detached or a binding is assigned to the service artifact.

Example

You have configured a service client reference, `EchoService12` in the application instance, WSSampleClientSei. Now you want to attach the WSSecurity default policy to the `EchoService12Port` endpoint of the `EchoService12` service client reference. First locate `EchoService12` in the Services > Service clients collection. Click the **`EchoService12`** service client reference. Select the check box for the `EchoService12Port` resource and click **Attach**. Select the **WSSecurity** default policy from the list. Click **Save**, to save your changes to the master configuration.

What to do next

You can now proceed to manage policy sets and bindings for service clients at the application level using the administrative console.

Service client settings

Use this administrative console page to manage the settings for your service clients. You can attach and detach policy sets to a service, its endpoints, or operations. You can select default bindings, create new application-specific bindings, or use existing bindings for an attached policy set. You can view or change whether the client uses the policy of the service provider.

This service client page displays configuration information for a service client and the associated endpoints and operations. You can view and manage policy set attachments, bindings information, and whether the client uses the policy of the service provider.

The Application and Module links provide access to the application and module settings page.

To view this administrative console page, click **Services** → **Service clients** → ***service_client_instance***.

You can also view this page by clicking **Applications** → **Application Types** → **WebSphere enterprise applications** → ***service_client_application_instance*** → **Service clients** → ***service_client_instance***.

You can specify a policy set and binding to provide message-level security for WS-MetadataExchange.

Administrative console buttons
This page describes the button choices that are available on various pages of the administrative console, depending on which product features you enable.

Administrative console preference settings
Use the preference settings to specify how you want information to display on an administrative console panel. The preference settings vary from one administrative console panel to another.

Administrative roles
The Java Platform, Enterprise Edition (Java EE) role-based authorization concept is extended to protect the WebSphere Application Server administrative subsystem.

Service client:

Specifies the name of the service client that is displayed.

Policy Set Attachments:

Service/Endpoint/Operation:

Specifies the name of the service client, endpoints or operations. The full `QName` (Java class `javax.xml.namespace.QName`) is displayed when you hover the mouse pointer over a service client name.

Attached Client Policy Set:

Specifies the policy set that is attached to the service client, endpoints or operations.

The Attached Client Policy Setcolumn can contain the following values:

- **None**. No policy set is attached, either directly or to a higher level service resource.
- ***policy_set_name***. The name of the policy set that is attached directly to the service resource, for example, `WS-I RSP`.
- ***policy_set_name* (inherited)**. The name of the policy set that is not attached directly to a service resource, but that is attached to a higher level service resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

Policies Applied:

Specifies the policies that are applied to the resource.

The Policies Applied column can contain the following values:

- **None**. No policies are applied to the service. This is the default setting if there is no policy set attached to the client.
- **Client only**. The client policy set is applied to the service. This is the default setting if a policy set is attached to the client.
- **Provider only**. The policy configuration of the service provider is applied to the service, as long as the client can support those policies.
- **Client and provider**. A policy that is based on both the client policy set and the policy of the service provider is applied to the service.

When the value in the column is a link, click the link to view or change settings about how the policies are applied.

For a service, if the value in the column is a link followed by the word `inherited` in parentheses, this shows a setting that is inherited from the parent application. You can click the link to change the setting for the service.

For an endpoint or operation, the value is not a link and it is followed by the word `inherited` in parentheses. The setting is inherited from the parent application or service and you cannot change it. If there is no applied policy, the entries in the column are None or None (inherited).

Binding:

Specifies the binding information available for a service client, endpoint, or operation.

The Binding column can contain the following values:

- **Not applicable**. There is no policy set attached, either directly or to a higher level service resource.
- ***Binding_name*** or **Default**. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. Default is displayed if a policy set is attached directly but the service resource uses the default bindings.
- ***Binding_name* (inherited)** or **Default (inherited)**. A service resource inherits the bindings from an attachment to a higher level resource.

When the value in the Binding column is a link, click the link to view or change settings about the binding.

About policy set bindings

In this release, there are two types of bindings: application-specific bindings and general bindings.

Application-specific bindings

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to, and constrained by, the characteristics of the defined policy. Application-specific bindings can provide configuration for advanced policy requirements such as multiple signatures; however, these bindings are reusable only within an application. Also, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding, and fully configure the bindings for each policy that you add. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service providers policy sets and bindings collection page, for service provider resources that have an attached policy set. Similarly, for service clients, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service clients policy sets and bindings collection page, for service client resources that have an attached policy set.

General bindings

You can configure general bindings to be used across a range of policy sets and they can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they cannot provide configuration for advanced policy requirements such as multiple signatures. There are two types of general bindings: general provider policy set bindings and general client policy set bindings.

You can create general provider policy set bindings by clicking **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel, or by clicking **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. For details about defining and managing service client or provider bindings, see the related links. General provider policy set bindings might also be used for trust service attachments.

Buttons:

Attach Client Policy Set	Click this button to view a list of policy sets available for attachment to the selected service, endpoint, or operation. Select a policy set from the list to attach and it is attached to the selected service, endpoint, or operation. To close the menu list, click **Attach Client Policy Set**.

Detach Client Policy Set	Click this button to detach a policy set from a selected service, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper level service resource, the Attached Client Policy Set column displays **None** and the Binding column displays **Not Applicable**. If there is a policy set attached to an upper level service resource, the Attached Client Policy Set column displays ***policy_set_name*** **(inherited)** and the binding used for the upper level attachment is applied. The binding name is displayed followed by **(inherited)**.
Assign Binding	**Default** Specifies the default binding for the selected service, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used. For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain in which the server resides 3. Default general bindings for the global security domain **New Application Specific Binding** Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached. **Provider sample** Select this option to use the Provider sample binding. To close the menu list, click **Assign Binding**.

Managing policy sets and bindings for service clients at the application level using the administrative console

Use this administrative console task to manage policy sets for service clients applications or its services, endpoints, or operations.

Before you begin

Before completing this task, you need to install one or more Java API for XML-Based Web Services (JAX-WS) applications.

About this task

You have developed a Web service that contains all the necessary artifacts and deployed your Web services application into your application server instance. Now, you can attach or detach policy sets and manage the associated bindings.

The policy set information is displayed in the Attached Policy Set column. If a policy set is directly attached, then the policy set name appears; for example, `WS-I RSP` is displayed. If there is no policy set attached, and a policy set is attached at a higher level, then the word *inherited* in parentheses is appended to the policy set name, as the following example demonstrates: `WS-I RSP (inherited)`. If there is no policy set attached directly or at a higher level, then `None` is displayed.

Every attachment of a policy set to a service artifact has an assigned binding. The binding information is displayed in the Binding column. The Binding column can contain the following values:

- Not applicable. There is no policy set attached, either directly or to a higher level service resource.
- *Binding_name* or Default. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. Default is displayed if a policy set is attached directly but the service resource uses the default bindings.
- *Binding_name* (inherited) or Default (inherited). A service resource inherits the bindings from an attachment to a higher level resource.

In Version 7.0, there are two types of bindings, application specific bindings and general bindings.

Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have very limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service clients policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

General bindings

General bindings are new for Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general client policy set bindings by accessing **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

1. Open the administrative console.
2. In the navigation pane, click **Applications > Application Types > WebSphere enterprise applications** >*Service_client_application_instance* > **Service client policy sets and bindings**.
3. Select the check box next to the **Application/Service/Endpoint/Operation** column. The service name is the service client reference in the application.
4. Click **Attach** to attach a policy set to an application, service, endpoint or operation.
5. [Optional] Click **Detach** to detach a policy set from a list of attached policy sets for an application, service client, endpoint or operation.
6. Click **Assign Binding** to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options:
   - Default
   - New Application Specific Binding
   - Client sample

   Default

   Specifies the default binding for the selected service, endpoint or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the Default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used.

   For any policy set attachment, the runtime checks to see if the attachment includes a binding. If so, it uses that binding. If not, the runtime checks in the following order and uses the first available default binding:

   a. Default general bindings for the server

   b. Default general bindings for the domain that the server resides

   c. Default general bindings for the global security domain

   New Application Specific Binding

   Select this option to create a new application specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.

   Client sample

   Select this option to use the client sample binding.

Results

When you finish this task, a policy set is attached or detached, and a binding is assigned to the service artifact.

Example

If you have configured a service client application instance, `app1` and you want, for example, to attach the Username WSSecurity default policy set to your application, first locate `app1` application in the **Applications > Application Types > WebSphere enterprise applications**. Click `app1` > **Service client policy sets and bindings** under the Web Services Properties section. Select the check box next to the `app1` service application. Click **Attach** and select **Username WSSecurity default** policy set. Click **Save**, to save your changes to the master configuration.

To assign a binding to the attached policy set, click `app1` > **Service client policy sets and bindings**. Select the check box next to the `app1` service application and click **Assign Binding**. Select **client sample** binding from the list. Click **Save**, to save your changes to the master configuration.

What to do next

You can proceed to view service clients at the cell level using the administrative console.

Service client policy set and bindings collection

Use this page to attach and detach policy sets to an application, a service client, its endpoints, or operations. You can select the default bindings, create new application-specific bindings, or use existing bindings for an attached policy set. You can view or change whether the client uses the policy of the service provider.

This page displays detail information for an application and its associated Web service clients, endpoints, and operations. You can view and manage policy set attachments and bindings information using this page.

To view this administrative console page, click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***service_client_application_instance*** → **Service client policy sets and bindings**.

This console page can also be viewed for WS-Notification service clients by clicking one of the following paths:

- **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional properties] Outbound request policy sets and bindings**
- **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional properties] Outbound request policy sets and bindings**

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

“Service provider policy sets and bindings collection” on page 746
Use this page to attach and detach policy sets to an application, a service provider, its endpoints, or operations. You can select the default bindings, create new application-specific bindings, or use bindings that you created for an attached policy set. You can view or change whether the service provider can share its current policy configuration.

Administrative roles
The Java Platform, Enterprise Edition (Java EE) role-based authorization concept is extended to protect the WebSphere Application Server administrative subsystem.

Administrative console buttons
This page describes the button choices that are available on various pages of the administrative console, depending on which product features you enable.

Administrative console preference settings
Use the preference settings to specify how you want information to display on an administrative console panel. The preference settings vary from one administrative console panel to another.

Application/Service/Endpoint/Operation:

Specifies the name of the application and the associated service client, endpoints, or operations. For WS-Notification service clients, the first entry is associated with the WS-Notification service, not an application.

Attached Client Policy Set:

Specifies the policy set that is attached to the application, service clients, endpoints, or operations.

The Attached Client Policy Set column can contain the following values:

- None. No policy set is attached directly, or is attached at an upper level.
- ***policy_set_name***. The name of the policy set that is directly attached, for example, WS-I RSP.
- *policy_set_name* (inherited). A policy set is not directly attached to the resource, but a policy set is attached to a higher-level resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

Policies Applied:

Specifies the policies that are applied to the resource. This column is not applicable and is not shown for WS-Notification service clients.

The Policies Applied column can contain the following values:

- **None**. No policies are applied to the application or service. This is the default setting if there is no policy set attached to the client.
- **Client only**. The client policy set is applied to the application or service. This is the default setting if a policy set is attached to the client.
- **Provider only**. The policy configuration of the service provider is applied to the application or service, as long as the client can support those policies.
- **Client and provider**. A policy that is based on both the client policy set and the policy of the service provider is applied to the application or service.

When the value in the column is a link, click the link to view or change settings about how the policies are applied.

For a service, if the value in the column is a link followed by the word `inherited` in parentheses, this shows a setting that is inherited from the parent application. You can click the link to change the setting for the service.

For an endpoint or operation, the value is not a link and it is followed by the word `inherited` in parentheses. The setting is inherited from the parent application or service and you cannot change it.

Binding:

Specifies the name of the binding associated with a policy set.

The Binding column can contain the following values:

- **Not applicable**. There is no policy set attached, either directly or to a higher-level service resource.
- ***Binding_name*** or **Default**. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. **Default** is displayed if a policy set is attached directly but the service resource uses the default bindings.
- ***Binding_name*** **(inherited)** or **Default (inherited)**. A service resource inherits the bindings from an attachment to a higher-level resource.

When the value in the Binding column is a link, click the link to view or change settings about the binding.

About policy set bindings

In this release, there are two types of bindings: application-specific bindings and general bindings.

Application-specific bindings

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to, and constrained by, the characteristics of the defined policy. Application-specific bindings can provide configuration for advanced policy requirements such as multiple signatures; however, these bindings are reusable only within an application. Also, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding, and fully configure the bindings for each policy that you add. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service providers policy sets and bindings collection page, for service provider resources that have an attached policy set. Similarly, for service clients, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service clients policy sets and bindings collection page, for service client resources that have an attached policy set.

General bindings

You can configure general bindings to be used across a range of policy sets and they can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they cannot provide configuration for advanced policy requirements such as multiple signatures. There are two types of general bindings: general provider policy set bindings and general client policy set bindings.

You can create general provider policy set bindings by clicking **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel, or by clicking **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. For details about defining and managing service client or provider bindings, see the related links. General provider policy set bindings might also be used for trust service attachments.

Buttons:

Attach Client Policy Set	Click this button to view a list of policy sets available for attachment to the selected service, endpoint, or operation. Select a policy set from the list to attach and it is attached to the selected service, endpoint, or operation. To close the menu list, click **Attach Client Policy Set**.

Detach Client Policy Set	Click this button to detach a policy set from a selected service, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper level service resource, the Attached Client Policy Set column displays **None** and the Binding column displays **Not Applicable**. If there is a policy set attached to an upper level service resource, the Attached Client Policy Set column displays ***policy_set_name*** **(inherited)** and the binding used for the upper level attachment is applied. The binding name is displayed followed by **(inherited)**.
Assign Binding	Click this button to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options: • Default • New Application Specific Binding • Client sample **Default** Specifies the default binding for the selected service, endpoint or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used. For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain that the server resides 3. Default general bindings for the global security domain **New Application Specific Binding** Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached. **Client sample** Select this option to use the Client sample binding. To close the menu list, click **Assign Binding**.

Viewing Web services deployment descriptors in the administrative console

You can view the Web services client and server deployment descriptors for a deployed Web services application. You can view the bindings in the deployment descriptors.

Before you begin

Before you can view the deployment descriptors, you need to complete all tasks required to implement a JAX-RPC Web service, create the deployment descriptor templates that were generated by the WSDL2Java command-line tool, configure the deployment descriptors and bindings, and deploy the Web service application into WebSphere Application Server. Review the implementing Web services application documentation for more information on developing and implementing Web services.

About this task

Deployment descriptors contain the information that is needed by a Web services client to communicate with the server for which the Web services is installed. This information is added to the deployment descriptor templates after a Web service is developed or an existing Web service is located. The data that you can view in the deployment descriptor includes the following:

- The Web service description including the name, WSDL file, WSDL file location and the mapping file.
- The port description, including the port component name, the WSDL port, the service endpoint interface that indicate the service's bindings, and the EJB that is used to implement the Web service.

After you have developed a Web service that contains all the necessary artifacts, created the deployment descriptors from the deployment descriptor templates, configured the deployment descriptors, and deployed the Web services application into WebSphere Application Server; now you can view the deployment descriptors and bindings in the administrative console.

Similar to Java API for XML-based RPC (JAX-RPC) Web services, you can use deployment descriptors to describe JAX-WS Web services. For JAX-WS Web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

1. Open the administrative console.
2. Click **Applications > Application Types > WebSphere enterprise applications > *application_name* > Manage Modules**.
   - Click **View Web services client deployment descriptor extension**.
   - Click **View Web services server deployment descriptor**.
   - Click **View Web services server deployment descriptor extension**.
3. Click **Expand All** to view the deployment descriptor contents.
4. Verify deployment descriptor and bindings configurations.

What to do next

You have viewed and verified the deployment descriptors and bindings for the Web services application.

Configuring the scope of a Web service port

When a Java API for XML-based RPC (JAX-RPC) Web service application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains

deployment information for the Web module or enterprise bean module, including implementation scope, client bindings and deployment descriptor information. There are three levels of scope that can be set: application, session and request.

Before you begin

Deploy a Web service into the WebSphere Application Server. To learn more, read about deploying Web services applications onto application servers.

About this task

The Web Services for Java Platform, Enterprise Edition (Java EE) specification states that Web services implementations must be stateless. Therefore, to maintain specification compliance, the scope can remain at the application level because the state relevant to the individual sessions level or the requests level is not supposed to be maintained in the implementation. If you want to deviate from the specification and want to access a different JavaBean instance, because you are looking for information that is located in another JavaBean implementation, the scope settings need to change.

The setting that you configure for the scope determines how frequently a new instance of a service implementation class is created for the Web service ports in a module. Use this task to configure the scope of a Web service port.

This task applies only to Java API for XML-based RPC (JAX-RPC) Web services.

To change the scope setting in the administrative console:

1. Open the administrative console.
2. Click **Applications > Application Types > WebSphere enterprise applications *application_name* > Manage Modules > *module instance* > Web services implementation scope**
3. Set the scope to application, session or request. The application scope causes the same instance of the implementation to be used for all requests on the application. The session scope causes the same instance to be used for all requests in each session. The request scope causes a new instance to be used for every request. For example, with the scope set to application, every message that comes to the server accesses the same JavaBean instance because that is the way the scope settings are configured.
4. Click **Apply**.
5. Click **OK**.

Results

The scope for a Web service port is configured.

What to do next

Now you can finish any other configurations, start or stop the application, and verify the expected behavior of the Web service.

Web services implementation scope

Use this page to view and manage the scope of the ports of a Web service application.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application_name* > Manage Modules > *module_instance* > Web services implementation scope**.

This administrative console panel applies only to Java API for XML-based RPC (JAX-RPC) applications.

Related tasks

“Configuring the scope of a Web service port” on page 768
When a Java API for XML-based RPC (JAX-RPC) Web service application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains deployment information for the Web module or enterprise bean module, including implementation scope, client bindings and deployment descriptor information. There are three levels of scope that can be set: application, session and request.

Port:

Specifies a port name for a Web service. A module can contain one or more Web services, each of which can contain one or more ports.

Web service:

Specifies the name of the Web service. A module can contain one or more Web services.

URI:

Specifies the Uniform Resource Identifier (URI) of the binding file that defines the scope. The URI is relative to the Web module.

Scope:

Specifies the scope of a port. The valid values for scope are request, session and application.

The scope value determines when a new instance of a service implementation is created for the Web service ports in a module. When the scope value is set to application, the same instance of the implementation is used for all requests on the application. When the scope value is set to session, the same instance is used for all requests on each session. When the scope value is set to request, a new instance is created for every request.

Making deployed Web services applications available to clients

You can publish WSDL files to the file system. If you are a client developer or a system administrator, you can use WSDL files to enable clients to connect to Web services.

Before you begin

The publish WSDL administrative console panel supports both JAX-RPC and JAX-WS services. The publish WSDL panel generates a zip file that contains WSDL files for all modules in an application that contains JAX-WS or JAX-RPC Web services. Read about providing the HTTP endpoint URL information to learn how the URL information affects the content of the published WSDL.

To publish a Web Services Description Language (WSDL) file you need an enterprise application, also known as an enterprise archive (EAR) file, that contains a Web services-enabled module and has been deployed into WebSphere Application Server. To learn how to deploy Web services, see the documentation on deploying Web services onto application servers.

About this task

The purpose of publishing the WSDL file is to provide clients with a description of the Web service, including the URL identifying the location of the service.

After installing a Web services application, and optionally modifying the endpoint information, you might need WSDL files containing the updated endpoint informations to make deployed Web services application to be available to clients.

Before you publish a WSDL file, you can configure Web services to specify endpoint information in the form of URL fragments to enable full URL specification of WSDL ports. Refer to the tasks describing configuring endpoint URL information.

The WSDL files for each Web services-enabled module are published to the file system location you specify. You can provide these WSDL files to clients that want to invoke your Web services.

You can specify endpoint information for HTTP ports, for Java Message Service (JMS) ports, or you can directly access enterprise beans that are acting as Web services.

1. Configure the Web services client bindings.
2. Configure the URL endpoint information for HTTP bindings. Do one of the following depending on what kind of bindings you are using:
   - Configure the URL endpoint information for JMS bindings.
3. Externalize or publish the WSDL file out of the application. You can complete this task in the following ways:
   - Publish a WSDL file with the **wsadmin** command tool.

What to do next

Apply security to the Web service.

Configuring Web services client bindings

When a Web services application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains deployment information for the Web module or enterprise JavaBean (EJB) module, including client bindings.

Before you begin

Deploy a Web service into your WebSphere Application Server instance. Read about deploying Web services applications onto application servers.

You must know the topology of the URL endpoint address of the Web services servers and which Web service the client depends upon. You can view the deployment descriptors in the administrative console to find the topology information. View Web services server deployment descriptors for more information.

About this task

The client bindings define the Web Services Description Language (WSDL) file name and preferred ports. The relative path of a Web service in a module is specified within a compatible WSDL file that contains the actual URL to be used for requests. The address is only needed if the original WSDL file did not contain a URL, or when a different address is needed. For a service endpoint with multiple ports, you need to define an alternative WSDL file name.

The following steps describe how to edit bindings for a Web service after these bindings are deployed on a server. When one Web service communicates with another Web service, you must configure the client bindings to access the downstream Web service.

To configure client bindings through the administrative console:

1. Open the administrative console.

2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Manage Modules** > *module_instance* > **Web services client bindings**.
3. Find the Web service you want to update.

   The Web services are listed in the **Web Service** field.
4. Select the WSDL file name from the drop down box in the WSDL file name field.
5. Click **Edit** in the Preferred port mappings field to configure the default port to use.
   a. Specify the port type and the preferred ports in the Port type and Preferred ports fields.

      Configuring the preferred port enables you to select an optimal port implementation use non-SOAP protocols. See RMI-IIOP Web services using JAX-RPC for more information about using non-SOAP protocols.
   b. Click **Apply** and **OK**.
6. Click **Edit** in the Port information field to configure the request timeout, the overridden endpoint, and the overridden binding namespace for a port.

   Configuring the request timeout accommodates complex topologies that can have multiple cascaded Web services that involve multiple hops or long-running services.

   You can configure Timeout values based on observed behavior of the overall system as integration proceeds. For example, a Web service client might time out because of changing network conditions or the performance of an external Web service. When you have applications containing Web services clients that timeout, you can change the request time out values for the clients.

   You can specify an endpoint URL to override the current endpoint. A client invoking a request on this port uses this endpoint instead of the endpoint specified in the WSDL file. You can specify the **Overridden endpoint URL** value for both Java API for XML-Based Web Services (JAX-WS) clients and Java API for XML-based RPC (JAX-RPC) clients.

   Note: The **Overridden endpoint URL** field is applicable for both JAX-WS and JAX-RPC clients. The other fields on this administrative console page are only applicable for JAX-RPC clients.
   a. Click **Apply** and **OK**.

Results

Your Web service client bindings are configured.

What to do next

Now you can finish any other configurations, start or restart the application, and verify the expected behavior of the Web service.

Web services client bindings

The client bindings define the Web Service Description Language (WSDL) file name, preferred ports and other port information. Use this page to specify the client bindings and the port mappings for the Web services in a module.

A Web service can specify the relative path within the module of a compatible WSDL file containing the actual URL to be used for requests. The relative path only needs to be specified if the original WSDL file does not contain a URL or when a different URL is needed. For a service endpoint with multiple ports defined, a preferred mapping specifies the default port to use for a port type.

To view this administrative console page, complete the following steps:

1. Click **Applications > Application Types > WebSphere enterprise applications > *application_name*** .
2. Click **Manage modules > *URI_file_name* > Web services client bindings** .

This administrative console panel applies only to Java API for XML-based RPC (JAX-RPC) applications.

Web service:

Identifies the name of this Web service. A module can contain one or more Web services.

EJB:

Identifies the name of the EJB for the EJB modules.

WSDL file name:

Specifies the WSDL file name, which is relative to the module. Locate the WSDL file name in the drop down menu.

Preferred port mappings:

Specifies and manages the preferred port type mapping for a Web service when a particular port type is requested.

Click **Edit** to edit the preferred port mapping information on the **Preferred port mappings** panel.

Port information:

Specifies additional configuration information for the ports of this Web service.

Click **Edit** to edit the port information on the **Port information** panel. You can set a request timeout, override an endpoint and override a binding namespace for each client port.

Preferred port mappings:

Use this page to view and manage a preferred portType mapping for a Web service.

This administrative console panel applies only to Java API for XML-based RPC (JAX-RPC) applications.

When you have multiple ports that reference the same portType (service endpoint interface), a preferred port specifies the port to use when the `Service.getPort(Class SEI)` method is called with only the service endpoint interface.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications *application_name* > Manage Modules > *module instance* > Web services client bindings > Edit > *preferred_port_instance***.

portType:

Specifies the portType.

The preferred port and the portType values are both of the type `java.xml.namespace.QName`.

Preferred port:

Specifies the preferred port to be associated with a particular portType. The `Service.getPort(Class)` method returns the preferred port associated with the specified service endpoint interface class (portType).

The preferred ports available are listed, as well as a value of `None`, which indicates no preferred port is selected.

Web services client port information:

Use this page to specify a request timeout, override an endpoint, and override a binding namespace for a Web services client port.

A Web service can have multiple ports. You can view and configure the port attributes for each defined Web service port. The Web services are listed on the Web services client bindings panel.

To view this page, click **Applications > Application Types > WebSphere enterprise applications *application_name* > Manage Modules > *module_instance* > Web services client bindings > Edit** .

This administrative console panel applies to both Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) Web services. The **Overridden endpoint URL** field is the only field supported for JAX-WS clients. The other fields are not applicable for JAX-WS clients.

Port:

Specifies the name of a port.

Request timeout:

Specifies the time, in seconds, that a Web service client waits for a request to complete on this port. If a timeout is not specified, the default request timeout for the client to wait is `360` seconds. If the value is set at `0` (zero), the client's request does not timeout. This field is supported only for JAX-RPC clients.

A typical use for this setting is to customize the client's behavior when it is configured to use a JMS transport to access a Web service to make it wait longer for an expected completion. Depending upon network conditions, or the nature of a Web service implementation, it might be necessary to tune the timeout.

Overridden endpoint URL:

Specifies the name of an endpoint that is used to override the current endpoint. A client invoking a request on this port uses this endpoint instead of the endpoint specified in the WSDL file. This field is supported for both JAX-WS and JAX-RPC clients.

If an assembled application contains a Web service client that is statically bound, the client is locked into using the implementation (service end point) identified in the WSDL file used during development. Overriding the endpoint is an alternative to configuring the deployed WSDL attribute.

The overridden endpoint URI attribute is specified on a per port basis. It does not require an alternative WSDL file within the module. The overridden endpoint URI takes precedence over the deployed WSDL attribute. The client uses this value for the service end point URI or SOAP address, instead of the value in the static client bindings.

Overridden binding:

Specifies the WSDL file binding namespace URI to use with this port, instead of the namespace in the WSDL file. This binding does not need to exist in the WSDL file. A client invoking a request on this port uses this binding instead of the binding specified in the WSDL file. An overridden binding namespace cannot be specified unless an overridden endpoint is specified. This field is supported only for JAX-RPC clients.

Configuring endpoint URL information for HTTP bindings

Configuring a service endpoint is necessary to connect Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) Web services clients to any Web services among the components being assembled or to any external Web services.

Before you begin

You can develop an HTTP accessible Java API for XML-based remote procedure call (JAX-RPC) or Java API for XML Web Services (JAX-WS) Web service when you already have a JavaBean object to enable as a Web service. For additional information, see the using HTTP to transport Web services requests documentation.

About this task

You can specify HTTP URL prefixes for Web services that are accessed through HTTP by using the Provide HTTP endpoint URL information panel in the administrative console. The HTTP URL prefixes provide location specific information and are used to form complete endpoint URLs that are included within published WSDL files.

Note: The Provide HTTP panel in the administrative console displays modules that contain Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) Web services. You can use the Provide HTTP panel to provide URL information for both types of Web services, however, the panel does not indicate which type of service that you are working with.

To configure these prefixes with the administrative console:

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Provide HTTP endpoint URL information**.
3. Specify the URL prefixes for the Web service.

   In this step you specify the protocol (HTTP or HTTPS), as well as the *host_name* and *port_number* used in the endpoint URL. You can select a prefix from a predefined list, by selecting the default HTTP URL prefix, or you can use a custom HTTP URL prefix.

   a. Select **Default HTTP URL prefix** or **Custom HTTP URL Prefix**.

      If you select the default HTTP URL prefix, a list provides you with a choice of endpoint URL prefixes. The list is a combination of two sets of ports in the module: the virtual host ports and the application server ports. Use a prefix from this list if the application server of the Web service is accessed directly. Select a value and also select the check box of the modules to use the prefix.

      If you want to use a custom HTTP URL prefix, type the value in the field. Select the check box to use in the prefix.

      If you configure a custom HTTP URL prefix, , you must also configure the custom JVM property, `com.ibm.ws.webservices.enableHTTPPrefix` in the administrative console and set the value to `true`. You must restart the application server after this custom property has been defined so that this property is used by the system. Setting this custom JVM property is required so the custom HTTP endpoint prefix information is correctly displayed in the ?WSDL query that is returned from the browser and the URL field of the WSDL file that is returned to the client. If this custom property is not defined with the value of `true`, the custom HTTP URL prefix is not reflected in the WSDL file that the service returns to the client. To learn how to configure this custom JVM property, see the documentation on configuring additional HTTP transport properties using the JVM custom property panel in the administrative console.

   b. Click **Apply**.

      The URL prefix, whether default or custom, is copied to the selected module HTTP URL prefix field.

   c. Click **OK**. The URL information is saved to your workspace.

Results

You have specified the partial URL information that is used to form the target endpoint addresses in the WSDL files that are published using the Publish WSDL files panel.

What to do next

Configure any other URL endpoint information for Java Message Service (JMS) bindings and direct Enterprise JavaBeans (EJB) access. Then publish the WSDL files to make the deployed Web services application available to clients.

Provide HTTP endpoint URL information

Use this page to specify endpoint URL prefix information for Web services accessed by HTTP. Prefixes are used to form complete endpoint addresses included in published Web Services Description Language (WSDL) files.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application_name* > Provide HTTP endpoint URL information**.

You can specify a portion of the endpoint URL to be used in each Web service module. In a published WSDL file, the URL defining the target endpoint address is found in the location attribute of the port's `soap:address` element.

This administrative console panel applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) Web services.

Specify endpoint URL prefixes for Web services:

Specifies the *protocol* (either http or https), *host_name*, and *port_number* to be used in the endpoint URL.

You can select a prefix from a predefined list using the **HTTP URL prefix** or **Custom HTTP URL prefix** field.

The URL prefix format is *protocol://host_name:port_number*, for example, http://*myHost*:9045. The actual endpoint URL that is contained in a published WSDL file consists of the prefix followed by the module's context-root and the Web service url-pattern, for example, http://*myHost*:9045/services/*myService*.

Select default HTTP URL prefix:

Specifies the drop down list associated with a default list of URL prefixes. This list is the intersection of the set of ports for the module's virtual host and the set of ports for the module's application server. Use items from this list if the Web services application server is accessed directly.

To set an HTTP endpoint URL prefix, select **Select default HTTP URL prefix** and select a value from the drop down list. Select the check box of the modules that are to use the prefix and click **Apply**. When you click **Apply**, the entry in the **Select default HTTP URL prefix** or **Select custom HTTP URL prefix** fields, depending on which is selected, is copied into the **HTTP URL prefix** field of any module whose check box is selected.

Select custom HTTP URL prefix:

Specifies the *protocol*, *host*, and *port_number* of the intermediate service if the Web services in a module are accessed through an intermediate node, for example the Web services gateway or an IHS server.

To set a custom HTTP endpoint URL prefix, you must also configure the custom JVM property, `com.ibm.ws.webservices.enableHTTPPrefix` in the administrative console and set the value to `true`. Setting this custom JVM property is required so the custom HTTP URL is correctly populated in the URL field of the WSDL file that is returned to the client. If this custom JVM property is not configured, the custom HTTP URL prefix is not in the URL field in the copy of the WSDL file that the service returns to the client. To learn how to configure this custom JVM property, see the documentation on configuring additional

HTTP transport properties using the JVM custom property panel in the administrative console. You must restart the application server after this custom property has been defined so that this property is used by the system.

After the `com.ibm.ws.webservices.enableHTTPPrefix` custom JVM property is configured, select **Select custom HTTP URL prefix** and enter a value. Select the check box of the modules that are to use the prefix and click **Apply**. When you click **Apply**, the entry in the **Select default HTTP URL prefix** or **Select custom HTTP URL prefix** fields, depending on which is selected, is copied into the **HTTP endpoint URL prefix** field of any module whose check box is selected.

Configuring endpoint URL information for JMS bindings

WebSphere Application Server supports the use of the Java Message Service (JMS) API to transport Web services requests, as an alternative to using HTTP.

Before you begin

The application server supports use of the Java Message Service (JMS) API to transport Web services requests, as an alternative to HTTP transport. Read about using the Java Message Service (JMS) to transport Web services requests to learn more about how Web service clients and servers can communicate through JMS queues and topics instead of through HTTP connections.

About this task

Configuring a service endpoint is necessary to connect Web service clients to any Web services among the components being assembled or to any external Web services. You can configure the endpoint URL information for JMS during application installation

In this task, enter the JMS endpoint URL prefix to use for each Web service-enabled Enterprise JavaBeans (EJB) Java archive (JAR) file that belong to the application. The JMS endpoint URLs are included in the Web Service Description Language (WSDL) files published for clients to use.

You can specify HTTP URL prefixes for Web services that are accessed through HTTP by using the Provide HTTP endpoint URL information panel in the administrative console. These prefixes are used to form complete endpoint addresses that are included in WSDL files when published.

You can specify JMS URL prefixes by using the Provide JMS and EJB endpoint URL information panel in the administrative console during or after application installation.

This task applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) Web services.

To configure JMS URL prefixes:

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Provide JMS and EJB endpoint URL information**.
3. Locate the list of Web services modules that are accessible through JMS transport.
4. Type the JMS URL fragment in the **URL fragment** field. Enter a URL fragment that is a prefix to the initial URL part that is obtained by examining the deployment information of the Web service. See the usage scenario following this task for more information.

   The value that you enter is used to define the location attribute of the port soap:address element within the WSDL file that is published using the *application_name*`_ExtendedWSDLFiles.zip` or the *application_name*`_WSDLFiles.zip` file on the Publish WSDL zip files panel.

Results

You have a Web service that is accessible through the JMS transport and configured with JMS bindings.

Example

Suppose an application called StockQuoteService contains an EJB JAR file that is named StockQuoteEJB, which contains one or more Web services that are accessible through the JMS transport. In Using SOAP over Java Message Service to transport Web services requests, you defined a queue with the Java Naming and Directory Interface (JNDI) name of `jms/StockQuote_Q`, and a connection factory with the JNDI name of `jms/StockQuote_CF`, for your application. In this example, you specify the following string as the JMS URL prefix within the Provide JMS and EJB endpoint URL information panel:

```
jms:/queue?destination=jms/StockQuote_Q&connectionFactory=jms/StockQuote_CF
```

The WSDL publisher uses this partial URL string to produce the actual JMS URL for each port component that is defined in the module. The `targetService=<port_name>` string is added to the end of the JMS URL, for example:

```
jms:/queue?destination=jms/StockQuote_Q&connectionFactory=jms/StockQuote_CF&targetService=getQuote
```

The published WSDL file is used by clients to invoke the Web service.

What to do next

Publish the WSDL files to make the deployed Web services application available to clients.

Provide JMS and EJB endpoint URL information

Use this page to specify endpoint URL fragments for Web services accessed through SOAP and Java Message Service (JMS) or directly as enterprise beans. Fragments are used to form complete endpoint addresses included in published Web Services Description Language (WSDL) files.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application_name* > Provide JMS and EJB endpoint URL information**.

You can specify a fragment of the endpoint URL to be used in each Web service module. In a published WSDL file, the URL defining the target endpoint address is found in the location attribute of the port's `soap:address` element.

If you are using Web services modules that are configured to use JMS or configured to access enterprise beans directly, these modules are listed on this panel.

This administrative console panel applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) Web services.

URL fragment for JMS:

Specifies a URL fragment for Web services accessed through a JMS transport. You can enter a value that is used to define the `soap:address` of a Web service. When WSDL files are published, a URL is formed using this fragment and is contained in the WSDL files.

The URL fragment that is entered as a value is a prefix to which the targetService=property is appended to form a complete JMS URL endpoint. The default value is obtained by examining the installed service's deployment information, for example, `jms:/queue?destination=jms/MyQueue&connectionFactory=jms/MyCF`.

This information is obtained from the Web service's configured JMS endpoint, which is a Message Driven Bean (MDB) defined by the **endpointEnabler** command-line tool. You can modify the URL fragment, for

example, by adding properties. The URL fragment is combined with the targetService property to form the complete URL, for example, `jms:/queue?destination=jms/MyQueue&connectionFactory=jms/MyCF &priority=5&targetService=GetQuote`.

URL fragment for EJB:

Specifies a URL fragment for Web services accessed through an EJB binding. You can enter a value used to define the location attribute of the port's `generic:address` element of a Web service. This port address is contained in the WSDL zip file when the zip file is published using the ***application_name_ExtendedWSDLFiles*.zip** field on the **Publish WSDL zip file** panel.

The URL fragment value entered is a suffix, which is appended to the initial part of the URL obtained by examining the Web service's deployment information. For example, the following URL fragment can be obtained from the EJB's deployment information: `wsejb:/ com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome`.

In this case, you can enter the following information in the URL fragment field, `jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2809`, which results in this endpoint URL, `wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome &jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2809`.

Configuring endpoint URL information to directly access enterprise beans

WebSphere Application Server supports directly accessing an enterprise bean as a Web service, as an alternative to using HTTP or Java Message Service (JMS) to transport requests between the server and the client. The EJB module that is used as a Web service contains a Web Services Description Language (WSDL) file that contains EJB bindings.

Before you begin

To learn more about the process of directly accessing an enterprise bean as a Web service, review the topic Using EJB bindings to invoke an enterprise bean from a Web services client .

About this task

Configuring a service endpoint is necessary to connect Web service clients to any Web services among the components being assembled or to any external Web services.

You can specify Web address endpoints of the enterprise bean for Web services that are accessed directly by EJB bindings using the Provide JMS and EJB endpoint Web address information panel in the administrative console.

If you have modules that are configured for using direct EJB access, the modules are listed on the Provide JMS and EJB endpoint Web address information panel in the administrative console. The EJB endpoint is only available in the WSDL that is found in the *application_name*_ExtendedWSDLfiles.zip file.

You can specify a fragment of the endpoint Web address for the Web services in each module.

To configure the Web address endpoints of the enterprise bean with the administrative console:

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Provide JMS and EJB endpoint URL information**.
3. Locate the list of EJB modules.
4. Select the application module.

5. Type the Web address fragment in the **URL fragment** field.

   Enter a Web address fragment that is a suffix to the initial Web address part that is obtained by examining the Web service deployment information. See the example following this task for more information.

   The value that you enter is used to define the location attribute of the port generic:address element within the WSDL file that is published using the *application_name*_ExtendedWSDLFiles.zip file name link on the Publish WSDL zip files panel. The zip file names are listed as links on the panel.
6. Click **OK**.
7. Click **Save**.

Results

You have configured endpoints of the enterprise bean for Web services that are accessed directly by EJB bindings.

Example

The following example illustrates a Web address fragment to enter in the URL fragment field.

The following Web address information can be obtained from the deployment descriptor of an enterprise bean:

```
wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome
```

Enter the following Web address fragment in the URL fragment field:

```
jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2089
```

The results are shown in the following example:

```
wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome&jndiProviderURL=
corbaloc:iiop:myhost.mycompany.com:2089
```

What to do next

Provide a description of the Web service to the service requestor by publishing WSDL files.

Publishing WSDL files using the administrative console

You can publish a Web Services Description Language (WSDL) file using the WebSphere Application Server administrative console.

Before you begin

Before completing this task, you need to install or deploy the Web service. After deployment, configure the URL endpoint tasks for your transport:

- Configure endpoint URL information for HTTP bindings.
- Configure endpoint URL information for JMS bindings.
- Configure endpoint URL information to directly access enterprise beans

About this task

By publishing a WSDL file, you are providing clients with a description of the Web service, including the URL identifying the location of the service.

The WSDL files in each Web services-enabled module are published to the file system location you specify. You can provide these WSDL files in the development and configuration process of the Web service clients so they can invoke your Web services.

This task applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) Web services.

Review Publishing WSDL files for more ways to publish WSDL files.

To publish an application's WSDL file with the administrative console:

1. Open the administrative console.
2. Click **Applications > Application Types > WebSphere enterprise applications > *application_name***.
3. Under Web Services Properties, click **Publish WSDL files**. This takes you to the **Publish WSDL zip files** page.
4. Click the WSDL zip file to download. The zip file contains the application's published WSDL files. The zip file `Extended`*`WDLFiles`*`.zip` contains EJB binding information. It can also contain JMS or HTTP binding information. The zip file *`WSDLFiles`*`.zip` only contains JMS or HTTP binding information.

What to do next

Apply security to your Web service.

Publish WSDL zip files settings

Use this page to publish Web Services Description Language (WSDL) files.

This administrative console panel applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) Web services.

The publish WSDL panel generates a zip file that contains WSDL files for all modules in an application that contains a JAX-WS or JAX-RPC Web service. Read about providing the HTTP endpoint URL information to learn how the URL information affects the content of the published WSDL.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application_name* > Publish WSDL files**.

When you click **OK**, a panel showing one or several zip file names displays. Each zip file contains a WSDL file that represents the Web services-enabled modules in the application. When you select a zip file to publish, a dialogue displays from which you can choose where to create the zip file. Within the published zip files, the directory structure is *application_name/module_name/[META-INF|WEB-INF]/wsdl/wsdl_file_name*.

In a published WSDL file, the location attribute of a port's `soap:address` element contains the endpoint URL through which the Web service is accessed. Using the **Provide HTTP endpoint URL information** and the **Provide JMS and EJB endpoint URL information** panels, configure the endpoint URLs to be used for the Web services in each module.

*application_name*_***WSDLFiles.zip:***

Specifies the *`application_name`*`_WSDLFiles.zip` file containing the WSDL that describes Web services that are accessible by standard SOAP-based ports.

*application_name*_***ExtendedWSDLFiles.zip:***

Specifies the *application_name*_ExtendedWSDLFiles.zip file containing the WSDL file that describes the Web services available, including SOAP-based and non-SOAP based (for example, EJB) ports.

If there are no Web services configured for direct EJB access, this zip file name is not displayed. Do not use this zip file if you want to produce a WSDL file compliant to standards.

Publishing WSDL files using a URL

You can publish a Web Services Description Language (WSDL) file using a URL.

Before you begin

Before you can publish a WSDL file using a URL, ensure the Web services-enabled application is installed and running.

The files referenced by the <wsdl-file> element in the webservices.xml might import other WSDL or XML Schema Definition (XSD) files. Typically, all WSDL or XSD files are initially placed into the META-INF/wsdl directory when using Enterprise JavaBeans (EJB) or the WEB-INF/wsdl directory when using JavaBeans. If your WSDL or XSD files are not placed in one of these directories, the file referenced by the <wsdl-file> and its imported files are copied to the wsdl directory for publishing purposes.

There are two different forms of URL query strings. The first appends /wsdl to the service and returns only HTTP and JMS bindings. The second appends /extwsdl to the service and returns the extended WSDL file, including HTTP, JMS, and EJB bindings. If a WSDL file contains only EJB bindings and the /wsdl query is used, an error message displays in the browser saying there are no HTTP or JMS bindings in the WSDL file. The error message suggests using the /extwsdl query instead. Publishing a WSDL file using a URL requires that the application have a Web module; either provided by the application or in the form of an HTTP router module. If an EJB application contains a WSDL file with only JMS or EJB Web service bindings, the **endptEnabler** command can be used to add an HTTP router module to the application.

Note: Only HTTP URLs are supported for publishing.

About this task

To publish a WSDL file using a URL:

1. Retrieve the outer-most WSDL file. The outer-most WSDL file is the WSDL file defined by the <wsdl-file> element in the webservices.xml file.

   Each Web service has an endpoint address, like http://example.com/services/stockquote. You can retrieve the outer-most WSDL file (defined by the <wsdl-file> element within the webservices.xml file) by appending the string "/wsdl" or "/wsdl/" to the endpoint address, for example,http://example.com/services/stockquote/wsdl.
2. Retrieve the imported WSDL files. When the outer-most WSDL file imports other WSDL or XSD files, these imported files can be retrieved by appending the relative path to the URL, which is used to retrieve the outer-most WSDL file. This is also true for WSDL files that import other files. This process is similar to the use of relative hyperlinks in HTML documents. If an HTML document contains a hyperlink to other documents, the relative path is appended to create the URL to access the hyperlinked documents.

Example

Suppose you have an application with the following directory structure:

```
<module-root>/
 WEB-INF/
  webservices.xml    /* the <wsdl-file> element points to "WEB-INF/wsdl/fooImpl.wsdl"*/
  web.xml
  ibm-webservices-bnd.xml
```

```
wsdl/
 fooImpl.wsdl   /* imports foo.wsdl which is an interface wsdl */
 foo.wsdl       /* type definition for the interface */
```

If the SOAP address for the foo service is `http://examples.com:9080/services/foo`, the simple way to retrieve the foo service's outer-most WSDL is with the following form: `http://examples.com:9090/services/foo/wsdl` or `http://examples.com:9090/services/foo/wsdl/`. The URL is redirected to `http://examples.com:9090/services/foo/wsdl/fooImpl.wsdl`, where `fooImpl.wsdl` is the name of the outer-most WSDL file.

Since the `fooImpl.wsdl` file has the import `<import namespace="http://examples.com/foo" location="a/b/foo.wsdl>`, use the URL `http://examples.com:9090/services/foo/wsdl/a/b/foo.wsdl` to obtain the `foo.wsdl` file.

Creating a monitor for WebSphere Application Server for WSDM resources (deprecated)

The Web Services Distributed Management (WSDM) monitoring support provided in the Version 6.1 Feature Pack for Web Services uses an external management software. It is, however, more useful to build a custom WebSphere Application Server monitor for WSDM. Use this task to create a WSDM monitor that is based on the Java API for XML Web Services (JAX-WS) programming model.

Before you begin

Note: IBM WebSphere Application Server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation Web services programming model extending the foundation provided by the JAX-RPC programming model. Using the strategic JAX-WS programming model, development of Web services and clients is simplified through support of a standards-based annotations model. Although the JAX-RPC programming model and applications are still supported, take advantage of the easy-to-implement JAX-WS programming model to develop new Web services applications and clients.

About this task

Complete the following steps to create a WSDM monitor:

1. Retrieve the relative URLs. The following table contains a list of URLs that you can use to retrieve the Web Services Description Language (WSDL) files for each supported resource that is in the product.

Table 6. Relative URLs to WSDM WSDL files

Resource	URL
Service group	/websphere-management/services/service-group?wsdl
Application	/websphere-management/services/application?wsdl
Application server	/websphere-management/services/applicationserver?wsdl
Data source	/websphere-management/services/datasource?wsdl
Enterprise JavaBeans	/websphere-management/services/ejb?wsdl
Java virtual machine (JVM)	/websphere-management/services/jvm?wsdl
Servlet	/websphere-management/services/servlet?wsdl
WebSphere cluster	/websphere-management/services/websphere cluster?wsdl
WebSphere domain	/websphere-management/services/ webspheredomain?wsdl

Table 6. Relative URLs to WSDM WSDL files (continued)

Resource	URL
Web service	/websphere-management/services/webservices?wsdl

2. Create a skeleton code for the service endpoint interface (SEI) files for the Web services client. After retrieving the relative URLs, create a skeleton code for the SEI files by running the WSDL to Java tooling against the WSDM WSDL files. You can use the IBM Rational Application Developer or wsimport command utility for this task. Run the wsimport utility against the retrieved WSDL file.

   Note: At a minimum, WSDL files for the service group resource and the resource that you want must be compiled.

   When you finish this step, you have created the client code that is used to communicate with the service provider, which is the WSDM service endpoint.
3. Write the code for the JAX-WS WSDM client. Review the following JAX-WS WSDM client sample code before you start writing the client code. The sample client code demonstrates a complete implementation of a client suitable for polling statistics for a resource and is used to delegate the setting up of WS-Addressing resource references and request and response processing.

   Sample WSDM JAX-WS client

 // Retrieve a list of available resources
 GetResourcePropertyResponse response = null;
 response = rp.getResourceProperty(property);

 // Return the property
 if (response != null) {
  return ((JAXBElement) response.getAny().get(0)).getValue();
 } else {
  return null;
 }
}

public String getResourceMBeanID(EntryType entry) {
 return findListMember(entry, WAS_MBEAN_ID);
}

public String getResourceMRID(EntryType entry) {
 return findListMember(entry, WAS_RESOURCE_ID);
}

public String getResourceType(EntryType entry) {
```

```
  return findListMember(entry, WAS_RESOURCE_TYPE);
 }

 /**
  * Extract the ERPs address
  */
 public String getResourceAddress(EntryType entry) {
  if (entry == null)
   return null;
  else
   return entry.getMemberServiceEPR().getAddress().getValue();
 }

 /**
  * EPRs cannot be looked up by their QName. This method does a linear search
  * of the EPR to find a particular reference parameter
  */
 private String findListMember(EntryType entry, QName name) {

  if (name == null || entry == null) return null;

  List<Object> res = entry.getMemberServiceEPR().getReferenceParameters()
    .getAny();

  for (Object ob : res) {
   Element e = (Element) ob;
   if (name.getLocalPart().equals(e.getNodeName()))
    return e.getTextContent();
  }

  return null;
 }
}
```

4. Create the WSDM monitor. The following example is used for polling a servlet for the number of requests that the servlet it is responding to.

   WSDM monitor

```
// Instantiate the client and instruct it to poll
// the server at localhost:9080
WsdmJaxWsClient wjc = new WsdmJaxWsClient("localhost:9080");

// Get a list of all available resources
List<EntryType> entries = wjc.getResources();

// Iterate through available resources until you find
// a servlet resource
EntryType servlet = null;
for (EntryType entry: entries){
 if ("servlet".equals(wjc.getResourceType(entry))){
  servlet = entry;
  System.out.println("URL " + wjc.getResourceAddress(entry));
  System.out.println("Type " + wjc.getResourceType(entry));
  System.out.println("MbeanID" + wjc.getResourceMBeanID(entry));
  System.out.println("ResourceID " + wjc.getResourceMRID(entry));
  break;
 }
}

// Request Concurrent Requests PMI statistics from this servlet
Object servletConcurrentRequests =
 wjc.getResourceProperty(servlet, J2EEConstants.CONCURRENT_REQUESTS_QNAME);

System.out.println(servletConcurrentRequests);
```

5. Obtain a list of available resources. The sample JAX-WS WSDM client provided in code example 1 shows a list of available resources. The list is filtered to obtain some resources and statistics from these resource objects. In this step, the client is initialized for an application server that is installed on a local machine and it is servicing HTTP requests on port 9080.

   Initialize WSDM client

```
// Instantiate the client and instruct it to poll
// the server at localhost:9080
WsdmJaxWsClient wjc = new WsdmJaxWsClient("localhost:9080");

// Get a list of all available resources
List<EntryType> entries = wjc.getResources();
```

6. Filter the available resources. The list of resources returned by getResources call is lengthy. This call returns a list of all resources that are currently available, not necessarily the particular resource type that you might be interested in.

   Filter resources

```
// Iterate through available resources until you find a servlet resource
EntryType servlet = null;
for (EntryType entry: entries){
 if ("servlet".equals(wjc.getResourceType(entry))){
  servlet = entry;
  System.out.println("URL " + wjc.getResourceAddress(entry));
  System.out.println("Type " + wjc.getResourceType(entry));
  System.out.println("MbeanID" + wjc.getResourceMBeanID(entry));
  System.out.println("ResourceID " + wjc.getResourceMRID(entry));
  break;
 }
}
```

You might want to expand this example to find a particular resource instead of finding the first available servlet. To complete this action, you need to do further filtering based on getResourceMBeanID. The string representing the resource is similar to the following code example:

Sample resource MBean identifier string

```
WebSphere:WebModule=WSDMDemo.war,name=myServlet,process=server1,Application=wsdm-demo,platform=dynamicproxy,
J2EEApplication=wsdmdDemo,node=demoNode01,J2EEName=wsdm-demo#WSDMDemo.war#mySelvlet,j2eeType=Servlet,
J2EEServer=server1,Server=server1,version=6.1.0.7,type=Servlet,mbeanIdentifier=
wsdm-demo#WSDMDemo.war#myServlet,cell=demoCell01,spec=1.0
```

7. Poll resources for statistics. Finally, you can now request the resource property. A list of available URLs for a given resource can be obtained from the WSDL file in Table 1. The following example is a list of properties for a servlet:

   Available properties for a servlet resource

```
<xsd:element name="ServletResourceProperties">
xsd:complexType>
 xsd:sequence>

 !--  WSDM MUWS Part 1 - Identity -->
 <xsd:element ref="muws1:ResourceId"></xsd:element>

 !--  WSDM MUWS Part 1 - ManageabilityCharacteristics -->
 <xsd:element ref="muws1:ManageabilityCapability" minOccurs="0" maxOccurs="unbounded"></xsd:element>

 !--  WSDM MUWS Part 2 - Description -->
 <xsd:element ref="muws2:Caption" minOccurs="0" maxOccurs="unbounded"></xsd:element>
 <xsd:element ref="muws2:Description" minOccurs="0" maxOccurs="unbounded"></xsd:element>
 <xsd:element ref="muws2:Version" minOccurs="0"></xsd:element>

 !--  WSDM MUWS Part 2 - Metrics -->
 <xsd:element ref="muws2:CurrentTime"></xsd:element>

 !--  J2EE Servlet -->
 <xsd:element ref="servlet:ConcurrentRequests"></xsd:element>
 <xsd:element ref="servlet:TotalRequests"></xsd:element>
 <xsd:element ref="servlet:NumberOfErrors"></xsd:element>
 <xsd:element ref="servlet:ResponseTime"></xsd:element>

 !--  J2EE ManagedObject -->
 <xsd:element ref="j2ee:ObjectName"></xsd:element>
 <xsd:element ref="j2ee:StateManageable"></xsd:element>
 <xsd:element ref="j2ee:EventProvider"></xsd:element>
 <xsd:element ref="j2ee:StatisticsProvider"></xsd:element>

 </xsd:sequence>
</xsd:complexType>
</xsd:element>
```

8. Obtain statistics. You can use the following code example to poll for the concurrent requests property. Then, you can resolve the property to a QName and pass the property onto the client.

   Obtain statistics

```
// Request Concurrent Requests PMI statistics from this servlet
Object servletConcurrentRequests =
 wjc.getResourceProperty(servlet, new QName("http://www.ibm.com/xmlns/prod/websphere/management/j2ee/servlet", "ConcurrentRequests"));

System.out.println(servletConcurrentRequests);
```

Results

You have created a custom WSDM monitor that you can use to manage and control resources.

Use the code examples to help you in creating your custom monitor, including the SOAP conversation code example.

In addition to these code examples, there is a built-in code sample in the product that you can use to retrieve the statistics for a servlet resource. To execute this sample, run `java –classpath wsdm-demo.jar;<install_root>/runtimes/com.ibm.jaxws.thinclient_7.0.0.jar samples.wsdm.servlet.WsdmDemo`.

Example

SOAP conversation example

Requesting available resources

The following code example demonstrates how to request for all available resources.

```
<soap:Envelope xmlns:soap="http://www.w3.org/2003/05/soap-envelope">

Request for concurrentRequests performance metrics from a servlet resource

This example shows how to request concurrentRequests metrics from a servlet resource. The resource that is of interest here is specified as reference parameters in the SOAP header. These parameters appear in bold font.

```
<?xml version="1.0" encoding="UTF-8"?>
<soap:Envelope xmlns:soap="http://www.w3.org/2003/05/soap-envelope">
    <soap:Header>
        <wsa:To xmlns:wsa="http://www.w3.org/2005/08/addressing">http://test.ibm.com:8080/websphere-management/services/servlet</wsa:To>
        <wsa:Action xmlns:wsa="http://www.w3.org/2005/08/addressing">http://docs.oasis-open.org/wsrf/rpw-2/GetResourceProperty/

Web Services Distributed Management

Web Services Distributed Management (WSDM) is an OASIS approved standard that supports managing resources through a standardized Web service interface. Your environment, such as WebSphere Application Server host or an operating system host that has an exposed resource as a Web service within a single interface is used to manage and control resources. WSDM is a distributed management model, but it does not replace any existing WebSphere Application Server administration models. WSDM provides a new way to expose the internal product administration functions for a Web service interface.

The existing administration interfaces, such as managed bean (MBean), wsadmin, and Java Application Programming Interface (API), are more language and platform specific. WSDM provides a common, flexible infrastructure to manage the product resources by leveraging the Web services protocols.

WSDM defines two specifications: Management Using Web Services (MUWS) and Management of Web Services (MOWS). MUWS defines how resources interact with the resources managed through a set of accessible Web services interfaces. MOWS extends the MUWS concepts to define how a Web service resource, itself, is managed. See Specifications and API documentation for MOWS and MUWS specifications. In addition to the manageability capabilities defined in the MUWS specifications, WebSphere Application Server WSDM also defines manageability capabilities unique to the product environment.

There is a general pattern that managed resources use to expose their manageability services through WSDM compliant Web services interfaces. First, you must create a model of the managed resource. Typically the model of the resource is created using a modeling tool such as the Test and Performance Tools Platform (TPTP), an eclipse plug-in tool; however, a simple text document is sufficient. Use the modeling tool to develop the model of WebSphere Application Server managed resources. The following graphic illustrates the process.

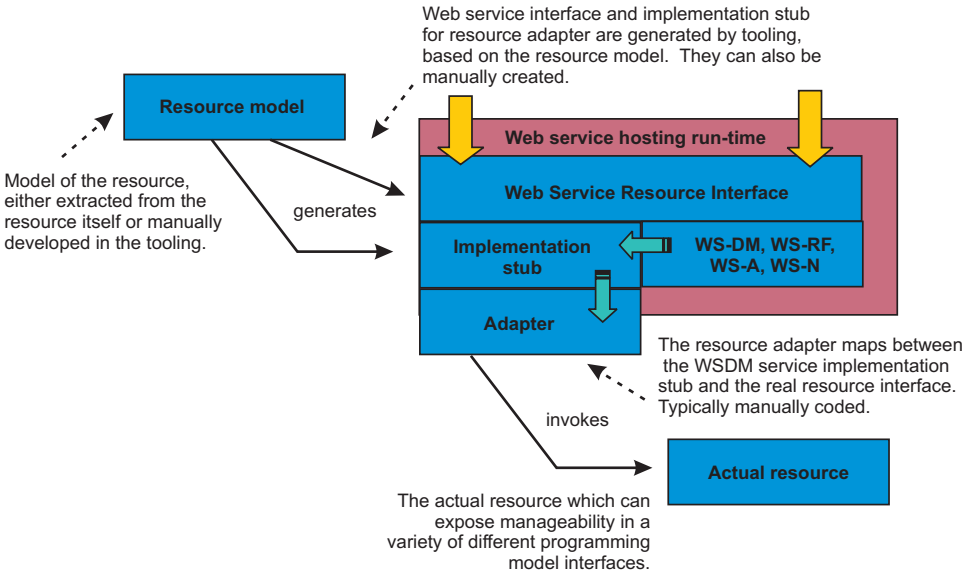

Figure 9. Generic WSDM Concept

Code artifacts are generated from the resource model. Generated artifacts for each resource model include:

- A Web Services Description Language (WSDL) document that describes the Web service interface for the management functions for that resource
- An implementation stub for the service implementation classes for that Web service
- A client proxy for the service that is used in a program that needs to invoke the management functions of that resource
- A unit test code for invoking test cases that exercises the functions of that service
- Additional XML documents and schema that describe the properties, operations, and notifications associated with the managed resource

The code generated from the resource model is essentially an empty shell of the management Web service for the modeled resource. The next step in the process is to enter code that acts as an adapter between the implementation stub for the service and the real resource management functions. In the case of the WSDM support implementation, this adapter code contain calls to theWebSphere Application Server AdminService APIs that expose normal product management functions. You must install the completed service implementation in a hosting Web service environment. To install your WSDM application, see Deploying and administering enterprise applications and follow the steps for installing enterprise application files on an application server.

Note: WSDM is a system application and it is disabled by default when the product is installed. You must first enable WSDM before you can use it to manage the product resources. Use scripting to enable WSDM.

Web Services Distributed Management resource management

Web Services Distributed Management (WSDM) is an OASIS approved standard that supports the management of resources through a standardized Web service interface. WSDM delivers Web services based interfaces to manage application server resources using a manageability endpoint.

The manageability endpoint contains manageability capabilities for the resources. A manageability capability uniquely identifies and associates with a set of properties, operations, and events. A resource that supports one or more manageability capabilities becomes a manageable resource. For example, a

manageable resource is a server or an application resource that supports a capability, which includes stop, start, and remove operations. To leverage the functions that a manageable resource provides, a manageability consumer is used. Manageability consumer queries and discovers the available manageable resources through the Web services endpoints. After the service is discovered, the manageability consumer exchanges messages to gather property information, invoke operations or receive notifications. The following graphics illustrates the relationships between the manageability consumer and manageable resources linked by the Web service endpoints.

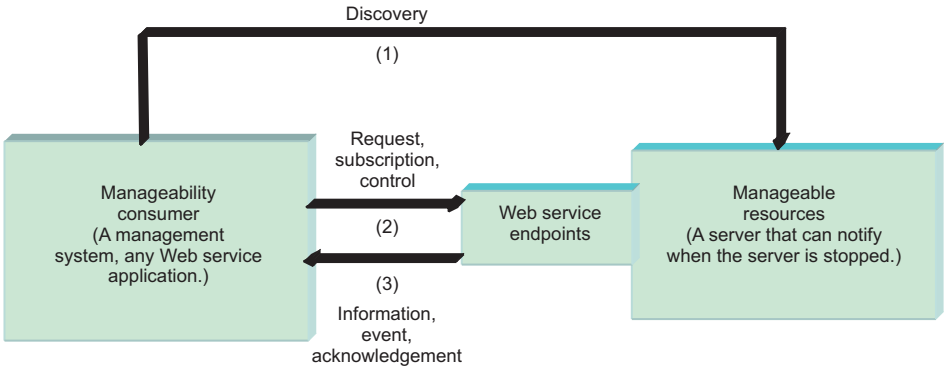

Figure 10. Relationship between the different parts of WSDM

Note: WSDM is a system application and it is disabled by default when the product is installed. You must first enable WSDM before you can use it to manage the product resources. Use scripting to enable WSDM.

WSDM manageability capabilities for WebSphere Application Server resource types

A resource that supports one or more manageability capabilities is a manageable resource. Each resource type that is exposed within the product supports a number of manageability capabilities.

Note: WSDM is a system application and it is disabled by default when the product is installed. You must first enable WSDM before you can use it to manage the product resources. Use scripting to enable WSDM.

A manageable resource is a server or an application that supports a capability which includes stop, start, and remove operations. A manageability capability includes some properties, operations, and notifications. You can obtain and view performance data about the managed resources when you enable Performance Monitoring Infrastructure (PMI) in your server environment.

Resource types

WSDM manageable resources, in general, are an aggregation of manageability capabilities. There are manageability capabilities that are globally applicable to many resource types. State management fits into this category. There are manageability capabilities that are unique to a single-managed resource, for example the Java virtual machine (JVM) manageability capability only applies to JVM-managed resources.

The autonomic manager (AC), which can be any client with management capability interact with the resources. Before the AC can interact with the resources, the AC needs to query what resources are available in the application server via the service group. The service group is an aggregation of WS-Resources within the same domain. The WebSphere Application Server WSDM service group contains all of the resources. Each resource becomes a member in the service group. The AC can get a

particular resources endpoint reference (EPR) from the service group based on the resource type or the reference parameters. After the EPR is obtained, the AC can send the request to the resource. The service group can be accessed using the following endpoint address: http://<hostname>:<port>/websphere-management/services/service-group.

After the AC gets the resources EPR list from the service group, the AC can send requests to the resource provider. Each resource endpoint is listed below. The associated Web Service Definition Language (WSDL) can be obtained by attaching `?wsdl` to the end of the endpoint address.

Resource type	Resource endpoint address
WebSphere Application Server profile, also called runtime configuration instance or WebSphere Application Server domain	http://<hostname>:<port>/websphere-management/services/webspheredomain
WebSphere Application Server	http://<hostname>:<port>/websphere-management/services/applicationserver
WebSphere Application Server cluster	http://<hostname>:<port>/websphere-management/services/websphere cluster
Java virtual machine	http://<hostname>:<port>/websphere-management/services/jvm
Application	http://<hostname>:<port>/websphere-management/services/application
WebSphere Application Server deployed object	http://<hostname>:<port>/websphere-management/services/deployedobject
Servlet	http://<hostname>:<port>/websphere-management/services/servlet
Enterprise JavaBeans	http://<hostname>:<port>/websphere-management/services/ejb
Web services	http://<hostname>:<port>/websphere-management/services/webservices
JAX-WS Web services	http://<hostname>:<port>/websphere-management/services/jaxwswebservices
JAX-RPC Web services	http://<hostname>:<port>/websphere-management/services/jaxrpcwebservices
Data source	http://<hostname>:<port>/websphere-management/services/datasource

Manageability capabilities of the resource types

Each resource type that is exposed in the product supports a number of manageability capabilities. These resources are defined by the WSDM specification, AC touchpoint, and the product's built-in management. A touchpoint is a combination of port types and operations defined in WSDL that exposes the manageability interface for a managed resource in a way that complies with different specifications for Web services. Each manageability capability includes a number of properties, operations, and notifications.

The following table lists the manageability capabilities that each resource aggregates. For information about an Application Programming Interface (API) or a specification that is listed with a manageability capability, see Specifications and API documentation.

Resource types and manageability capabilities

Resource type	Manageability capabilities	Specification
WebSphere Application Server domain	• J2EEDomain • J2EEManagedObject • Identity • Metrics • ManageabilityCharacteristics • Description • ResourceType • Configuration • ApplicationManagement • ConfigChangeNotifier • NotificationProducer	• JSR 77 – J2EE • JSR 77 – J2EE • MUWS – WSDM • MUWS – WSDM • MUWS • MUWS – WSDM • AC touchpoint • MUWS – WSDM • WebSphere Application Server unique • WebSphere Application Server unique • WSBN - WS-N

Specific application server manageability capabilities

The following table lists the attributes and operations for the product's manageability capabilities.

Manageability Capabilities	Attributes	Operations
J2EEDomain	None	• String getAttribute(String, String) • String[] queryNames(String queryString)
J2EEManagedObject	• objectName • stateMangeable • eventProvider • statisticsProvider	None
ConfigChangeNotifier	None	None (however, it has notification of ConfigChange)
ApplicationManagement	None	• String installApplication(String, String, HashMap) • String uninstallApplication(String) • String updateApplication(String, String, HashMap) • String, HashMap • EndpointReference listApplications(String applicationName)
J2EEServer	• serverVendor • serverVersion • DepolyedObjects • javaVMs	None
StateManageable	• state • startTime	• stop() • start() • startRecursive()
ApplicationServer	• name • versionsForAllEFixes • versionsForAllExtensions • VersionsForAllPTFs • shortName • threadMonitorInterval • threadMonitorthreshold • threadMonitorAdjustmentThreshold • ProcessId • cellName • nodeName • processType • platformName • platformVersion	• stopImmediate() • restart() • String getproductVersion(String)

Manageability Capabilities	Attributes	Operations
ClusterManagement	• clusterName • preferLocal • wlcId • state • backupName • backupBootstrapHost • backupBootstrapPort	• start() • stop() • stopImmediate() • rippleStarT() • exportRouteTable() • dumpClusterInfo() • boolean getAvailable(String, String) • boolean setAvailable(String, String) • boolean setUnavailable(String, String)
Java virtual machine	• javaVersion • javaVendor • node • stats • freeMemory • usedMemory • heapSize • upTime • GCCount • GCTime • GCInternalTime • waitsForLockCount • waitForLockTime • objectAllocatedCount • objectMovedCount • objectFreedCount • threadStartedCount • threadEndedCount	None
J2EEDeployedObject	• deploymentDescriptor • server	None
J2EE Application	module	None
Application	implementationVersion	None
Servlet	• concurrentRequest • responseTime • numErrors • totalRequests	None
EJB	• createCount • loadCount • storeCount • readyCount • liveCount • pooledCount • waitTime	None

Manageability Capabilities	Attributes	Operations
WebService	• payloadSize • replyPayloadSize • requestPayloadSize • requestResponseTime • replyResponseTime • responseTime • processRequestCount • dispatchedRequestCount • receivedRequestCount • loadedWebServiceCount	None
DataSource	• jdbcDriver • connectionFactoryType • dataSourceName • dataStoreHelperClass • loginTimeout • statementCacheSize • jtaEnabled • name • jndiName • testConnection • testConnectionInterval • stuckTimerTime • stuckTime • stuckThreshold • surgeThrehold • surgeCreationInterval • connectionTimeout • maxConnections • minConnctions • purgePolicy • reapTime • unusedTimeout • agedTimeout • freePoolDistributionTableSize • freePoolPartions • sharedPoolPartitions	• String showPoolContents() • void purgePoolContents() • void pause() • void resume() • String getStatus()

Web Services Distributed Management support in the application server

The Web Services Distributed Management (WSDM) support for a Web service in WebSphere Application Server runs within an application server that has exposed management functions.

In the application server implementation of WSDM, a WSDM application is packaged as a Java Platform, Enterprise Edition (Java EE) Enterprise archive (EAR) file. The EAR file is deployed as an application server system application.

Note: WSDM is a system application and it is disabled by default when the product is installed. You must first enable WSDM before you can use it to manage the product resources. Use scripting to enable WSDM.

WSDM support for the product consists of two parts:

- WSDM runtime environment and support
- WSDM resource model and service implementation

WSDM runtime environment and support

The WSDM runtime environment provides fundamental capabilities for the manageable resources. The WSDM runtime environment interacts with the underlying Web services platform and the WSDM resources to service the requests and responses. There are multiple specifications that the WSDM runtime environment uses in order to provide the WSDM functions, namely `WS-Addressing`, `WS-ResourceFramework`, and `WS-Notification`. For each request, the WSDM runtime environment routes the request to the appropriate resource service implementation based on the endpoint reference, (EPR). The EPR is defined by the `WS-Addressing` specification. Each EPR contains target address, runtime specific data and reference properties to uniquely identify an instance of a WSDM resource. After the resource service implementation returns a response, the WSDM runtime environment wraps the response into an appropriate SOAP message format specified in the Management Using Web Services (MUWS) specification and returns the response back to the requester. The application server leverages Apache Muse 2.0 to provide the runtime support for WSDM. The Apache MUSE 2.0 provides both the development tool and the WSDM runtime environment.

WSDM resource model and service implementation

The WSDM resource model for the application server identifies the elements of the product that are managed resources and further defines the specific properties, operations, and notifications that are managed resources support. The resource model defines the interfaces to interact with the resources and administrative functions in the product. The resource model includes appropriate capabilities defined in the two WSDM specifications, Management Using Web Services (MUWS) and Management of Web Services (MOWS). What this means is that the implementation is a mapping of the WSDM specification interfaces onto the product administration and programming interfaces. The implementation does not introduce new functions into the product, but rather, an alternative interface for accessing existing administration and programming functions in the product. In addition, the resource model defines specific capabilities to provide additional manageability functions. Each of the capabilities defines a set of properties, operations, and events for managed resources in an autonomically managed system. Each resource is associated with a Web Services Description Language (WSDL) file that contains the definition of its manageability capabilities.

Security

The implementation is attached to the WSSecurity default policy set and runs the administrative operations from the client user identity. This user identity must have privileges to perform any administrative action. It is the role of the autonomic computing (AC) manager that makes requests for the WSDM implementation to ensure that the user of that manager has appropriate authorization to perform administration and any other functions exposed by the AC manager.

The benefit of WSDM support in the application server is that the product can participate in multiple product management solutions in a standard way. By exposing the product management functions through a standard Web services interoperable interface, you can combine the application server with large management systems based on the WSDM specification.

Web Services Distributed Management in a standalone application server instance

In a standalone application server environment, there is one Web Services Distributed Management (WSDM) application deployed for each application server instance.

Note: WSDM is a system application and it is disabled by default when the product is installed. You must first enable WSDM before you can use it to manage the product resources. Use scripting to enable WSDM.

The WSDM application acts as an administrative client to the management code running inside the single Java virtual machine for that instance. Figure 1 illustrates an Autonomic Computing Manager (ACM) interacting with two application server instances, each with its own WebSphere Application Server WSDM application exposing the manageability for that individual instance.

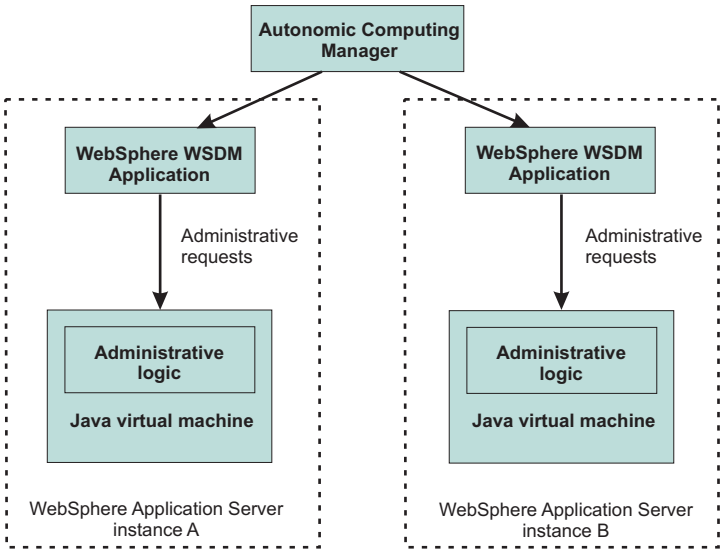

Figure 11. WSDM application in a stand-alone server instance

Web Services Distributed Management in a Network Deployment cell

You can use Web Services Distributed Management (WSDM) to manage application server instances within a Network Deployment cell. The administrative support and visibility for WSDM in a cell is obtained through interaction with each WSDM application deployed on the application server.

Note: WSDM is a system application and it is disabled by default when the product is installed. You must first enable WSDM before you can use it to manage the product resources. Use scripting to enable WSDM.

In the multinode Network Deployment environment, the management code runs across a distributed network of Java virtual machines with a central access point as the deployment manager process for the entire network or cell. Several different application server Java virtual machines might be managed within a cell. You can manage an application server Java virtual machines within a cell through the WSDM application installed on deployment manager. The WSDM application acts as an administrative client to the managed application server. Figure 1 illustrates this environment with an Autonomic Computing Manager interacting with the single application server implementation of WSDM to expose the manageability of that application server. You can build a federated deployment manager cell from individual application server instances by running the addNode utility program to add the application server instances to the centrally

managed cell. After a node is added to the cell, the manager can still manage each application server within the cell through the installed WSDM application on the deployment manager.

Figure 12. WSDM application in a Network Deployment cell

Web Services Distributed Management in an administrative agent environment

You can use Web Services Distributed Management (WSDM) to manage application server profiles in an administrative agent (AdminAgent) environment.

Note: WSDM is a system application and it is disabled by default when the product is installed. You must first enable WSDM before you can use it to manage the product resources. Use scripting to enable WSDM.

You can manage multiple base application servers within profiles using the AdminAgent. You can also use the Web Services Distributed Management (WSDM) to manage each profile within the AdminAgent. WSDM is deployed inside the AdminAgent as a system application. Each profile is represented as a domain resource within the product. You can get and manage the resources within a profile through the product's domain resource. Figure 1 illustrates the AdminAgent topology.

Figure 13. WSDM application in an AdminAgent environment

Notifications from the application server Web Services Distributed Management resources

Use this topic to learn about application server Web Services Distributed Management (WSDM) resources and their life cycle events.

Note: WSDM is a system application and it is disabled by default when the product is installed. You must first enable WSDM before you can use it to manage the product resources. Use scripting to enable WSDM.

There are different life cycle events that can occur for any resource. The notifications associated with these lifecycle events are resource definition events and resource state events. Resource definition events are:

- Created
- Deleted
- Changed

Resource state events are:

- Started
- Stopped
- Suspended

The following resources are discussed in detail. You can review WSDM manageability capabilities for application server resource types for information about each resource endpoint address and manageability capabilities.

Application server

The application server instances support definitional notifications. Whenever a resource definition event occurs, the configuration of an application server is created, modified, or deleted and a notification is generated by the WebSphere Application Server domain. The notification includes the configuration documents that have been changed.

Application server installation

The product installation is performed and managed by the underlying operating system. There is no runtime entity that represents the product installation. There are no life cycle notifications currently planned for events related to the product installation. There are no state event notifications associated with the lifecycle of the overall product installation.

Application server domain: profile or runtime configuration instance

There is an administrative agent process that is created as part of a WebSphere Application Server profile. This administrative agent process, once created, becomes available to emit life cycle notifications for the profile. Since any configuration modification might be considered a change to the profile, there is no generic *profile changed* notification. Instead, there are specific notifications for some configuration changes. In addition, there is no state change notification for profiles because a profile does not actually run, it simply exists or does not exist.

Hosted applications

Applications that are installed into the product support both definitional and operational notifications. Whenever an application is installed, a notification is produced to indicate that an instance of that application managed resource has been created. A notification is generated each time the application is started, stopped, or updated. When an application is uninstalled, the *resource destroyed* notification is produced.

Application server deployed object

Individual deployed modules have independent life cycles. There are create, modify, delete, start, and stop notifications for individual deployed objects in the product.

Web services

Even though Web services are not robust applications, there is a need to understand the life cycle for these essential deployed objects. Notifications are produced in accordance to the MOWS specification such as when a Web service is installed, modified, started, stopped or uninstalled.

Managing policy sets using the administrative console

You can use policy sets, or assertions that define services, to simplify your Web services configuration because policy sets group security and other Web services settings into reusable units. You can use the administrative console to create, modify, and delete custom policy sets.

Before you begin

Before creating policy sets, first identify the security and other requirements of the Web service.

Note: You can only use policy sets with JAX-WS applications that run on the Axis2 Web service engine. You cannot use policy sets for JAX-RPC applications.

About this task

You can use the administrative console to view and manage policy sets. From the administrative console, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**. The Application policy sets collection displays a listing of the custom (if you have created custom policy sets) and default policy sets. Use the Application or System policy sets collection page to create, copy, delete, export, and import policy sets.

The following policy sets are ready for you to use as is.

- LTPA WSSecurity Default
- Kerberos V5 HTTPS default
- SSL WSTransaction
- Username SecureConversation
- Username WSSecurity default
- WS-Addressing default
- WSHTTPS default
- WS-I RSP ND
- WS-ReliableMessaging persistent

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

- "Viewing policy sets using the administrative console" on page 805.

  This topic describes the process of viewing and evaluating policy sets.
- "Creating policy sets using the administrative console" on page 806.

  This topic describes two ways to create policy sets: creating new policy sets or copying and renaming policy set templates.
- "Modifying policy sets using the administrative console" on page 820.

  This topic describes how to edit custom policy sets you have created.
- "Importing policy sets using the administrative console" on page 816.

  This topic describes how to import policy sets from the default repository or from a selected location.
- "Exporting policy sets using the administrative console" on page 953.

  This topic describes how to export policy sets.
- "Deleting policy sets using the administrative console" on page 822.

  This topic describes how to delete custom policy sets. You can delete policy set templates and re-import them if needed.
- "Managing policies in a policy set using the administrative console" on page 902

  This topic describes how you can define policies with policy sets to secure messages.
- "Defining and managing policy set bindings" on page 824

  This topic describes configuring custom binding configurations.

Results

Using these tasks, you can determine how to create a new policy set and verify whether you can reuse an existing policy set. You can configure a policy set, and define policies for that policy set.

What to do next

Depending on how you are using policy sets, you might want to revisit some of the tasks listed in this topic to tweak the configuration for your policy set. You can also proceed to configure bindings for your policy set. See Defining binding information for policy sets.

Viewing policy sets using the administrative console

You can use the administrative console to view lists of policy sets. Policy sets can either be default policy sets that you cannot edit or custom policy sets that you have created and can edit. You can use policy sets, or assertions that define services, to simplify your Web services configuration because policy sets group security and other Web services settings into reusable units.

Before you begin

If you are creating a custom policy set by copying an existing default policy set, you might want to view the existing policy sets to choose a policy set with properties similar to the one you are planning to create.

About this task

You can view a list of policy sets to decide which policy sets can be reused or copied, modified and reused.

1. To view policy sets from the administrative console, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**.
2. Set the number of policy set rows that you want to view at a time using the Preferences settings. The default value is 20. The Editable column on the table in this view shows which policy sets you can edit. You can only edit the custom policy sets that you create. You cannot edit the provided default policy sets.
3. To view the details for any of the policy sets, click the name of the policy set in the Name column of the table. The Policy set settings page displays details about the selected policy set. If the policy set is a custom policy set you can edit the fields on the page. If the policy set is a provided default, then you can copy and reuse the policy set. You cannot edit the fields otherwise.

Results

After you have viewed the available policy sets and their settings, you can then decide if you want to create a new policy set, copy an existing policy set that you can rename, or use one of the existing policy sets that meets your needs.

Related tasks

"Creating policy sets using the administrative console"
You can use the administrative console to either create a policy set by specifying all the necessary information or by copying an existing policy set that you rename. You can use policy sets, or assertions that define services, to simplify your Web services configuration because policy sets group security and other Web services settings into reusable units.

"Modifying policy sets using the administrative console" on page 820
You can use the administrative console to modify existing custom policy sets that you have created. If you have copied an existing default policy set or created a policy set yourself, you can always go back and make changes to them to make them better suit the changing needs of your business.

"Application policy sets collection" on page 954
Use this page to manage policy sets. You can create, copy, export, and import policy sets. You can also view or delete existing policy sets. You can use policy sets, or assertions that define services, to simplify your Web services configuration because policy sets group security and other Web services settings into reusable units.

"Application policy set settings" on page 955
Use this page to view, create, enable or disable your policy sets. You can use policies, or assertions that define services, to simplify your Web services configuration.

Creating policy sets using the administrative console

You can use the administrative console to either create a policy set by specifying all the necessary information or by copying an existing policy set that you rename. You can use policy sets, or assertions that define services, to simplify your Web services configuration because policy sets group security and other Web services settings into reusable units.

Before you begin

To create a new policy set, you can either specify the information to create a new policy set or you can copy and rename an existing policy set. Using either method, you need basic information about the policy set that you want to create, such as the name, description, policies to include, policy details, attachments, and binding configurations. If you are creating a policy set by copying an existing policy set, then you should also view the existing policy sets to choose one with properties that are most similar to the one you plan to create.

About this task

Whether you choose to create a new policy set or copy and rename an existing one, start from the Applications policy sets collection in the administrative console.

1. From the administrative console, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**.
2. If the policy set you are creating is:
   - a new policy set, then click **New**.
   - an existing policy set to be copied and renamed, click the **Select** box beside the name of the policy set to be copied in the**Name** column and click **Copy**.

   Using either method, this action opens the Policy set settings view to specify the required information about the policy set being created or copied.
3. Enter the name of the policy set that you want to create or copy in the **Name** field.
4. Enter a brief description of the policy set in the **Description** field. This is the description that displays in the Application policy sets or the System policy set collection, so it must be meaningful to you and other potential users of this policy set.

5. Optional: If you created a new policy set, you do not have any policies to edit until you add them to the policy set. The policy set is initially empty.

Results

You have provided the basic information to create a policy set.

Example

After you have looked at your Web services, you might decide that the WS-I RSP default policy set most closely meets your needs. You would go to the administrative console and click **Services > Policy sets > Application policy sets** to access the Application policy sets collection. Locate the WS-I RSP default in the Name column of the table and click the box beside it (in the Select column). Click **Copy**. This opens the Policy set settings window. You might want to name your policy set by your company or division so you could provide a name like ABC WS-I RSP in the Name field. Because you know others in your organization might access and use it, you've chosen a name that is meaningful to those people too. You want to be sure everyone knows exactly what this copy of the WS-I RSP policy is used for, so you add a description in the Description field describing it. Now you want to customize the policy set so you edit the policy information by clicking the name of a policy to edit it.

When you identify the requirements of your web service, you might decide that none of the default policy sets meet your needs closely enough to use them as a template so you might decide to create your own policy set. You would first create the policy set with the name you choose to give it. As if you were reusing an existing template, you would go to the administrative console and click **Services > Policy sets > Application policy sets** and click **New**. The Policy set settings window opens but note that the Policy set name field is blank and there are not yet any associated policies in the table. Enter the name and add any policies necessary.

When you add policies to a policy set, the policies are set to their default values. You can then edit the policies to modify any attribute values that need to be changed and save the settings.

What to do next

If you are creating a new policy set without copying an existing policy set, you need to specify the policy information. If you are copying an existing policy set, you can either accept the default policies associated with the policy set or you can change the policies.

WS-I RSP default policy sets

The Reliable Asynchronous Message Profile (WS-I RSP) default policy sets are based on the Reliable Asynchronous Message Profile specification. The WS-I RSP default policy sets include the WS-I RSP default policy set, the Lightweight Third-Party Authentication (LTPA) WS-I RSP default policy set and the Username WS-I RSP default policy set. You can use these policy sets to simplify your Web services configuration.

The WS-I RSP default policy sets are composed of a set of policies to provide reliable and secure Web services. The WS-I RSP default policy sets use the WS-Addressing, WS-ReliableMessaging, and WS-Security specifications. Use the WS-I RSP default policy set, the LTPA WS-I RSP default policy set, or the Username WS-Security WS-I RSP default policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WS-I RSP default policy sets include the following policies:

WS-Addressing policy
: You can use the WS-Addressing policy to enable the addressing capability of the WS-Addressing specification.

WS-ReliableMessaging policy
: You can use the WS-ReliableMessaging policy to specify the quality of service for reliable delivery.

WS-Security policy
: The WS-Security policy in the WS-I RSP default policy set provides the following security:
  - Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications.
  - Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications.
  - Traditional RSA cryptography is used to secure a request to a Trust Server to obtain a Secure Context Token (SCT). Thereafter, the conversation is secured using symmetric keys derived from the SCT.

The application server provides additional policy sets that you can use or customize. To use the following default policy sets, you must import the policy sets from the default repository. Read about importing policy sets using the administrative console for more information.

The following WS-I RSP default policy sets exist:

WS-I RSP default
: This policy set provides:
  - Reliable message delivery to the intended receiver by enabling WS-ReliableMessaging.
  - Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications.
  - Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications.

LTPA WS-I RSP default
: This policy set provides the WS-I RSP default policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username WS-I RSP default

This policy set provides the WS-I RSP default policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

Related concepts

"Web services policy sets" on page 961
Policy sets are assertions about how services are defined. They are used to simplify your quality of service configuration for Web services.

Related tasks

"Importing policy sets using the administrative console" on page 816
You can import predefined policy sets or import policy sets from a selected location using the administrative console.

SecureConversation default policy sets

The SecureConversation default policy sets are based on the Web Services Secure Conversation Language (SecureConversation) standard that establishes a secure context, based on shared keys for the client and server to use for a series of messages. This standard provides a framework to define how to secure the message exchange across organizations. The SecureConversation default policy sets include the SecureConversation policy set, the Lightweight Third-Party Authentication (LTPA) SecureConversation policy set, and the Username SecureConversation policy set.

The SecureConversation default policy sets are based on the WS-SecureConversation, the WS-Security, and the WS-Addressing specifications. Use the SecureConversation policy set, the LTPA SecureConversation policy set, or the Username SecureConversation policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WS-SecureConversation specification alone does not provide a complete security solution. The WS-SecureConversation is built on the WS-Security and WS-Trust specifications to provide secure communication across one or more messages. Specifically, this specification defines mechanisms for establishing and sharing security contexts, and deriving keys from established security contexts or any shared secret.

WS-Security focuses on the message authentication model but not in a security context. The WS-SecureConversation specification defines mechanisms for establishing and sharing security contexts, and deriving keys from security contexts, to enable a secure conversation. By using the SOAP extensibility model, modular SOAP-based specifications are designed to be composed with each other to provide a rich messaging environment.

The following SecureConversation default policy sets exist:

SecureConversation

This policy set provides:

- Message integrity by digital signature that includes signing the body, timestamp, and WS-Addressing headers using WS-SecureConversation and WS-Security specifications.
- Message confidentiality by encryption that includes encrypting the body, signature and signature confirmation elements, using WS-SecureConversation and WS-Security specifications.

LTPA SecureConversation

This policy set provides the SecureConversation policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username SecureConversation

This policy set provides the SecureConversation policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request

Related concepts

"Web services policy sets" on page 961
Policy sets are assertions about how services are defined. They are used to simplify your quality of service configuration for Web services.

"WS-I RSP default policy sets" on page 809
The Reliable Asynchronous Message Profile (WS-I RSP) default policy sets are based on the Reliable Asynchronous Message Profile specification. The WS-I RSP default policy sets include the WS-I RSP default policy set, the Lightweight Third-Party Authentication (LTPA) WS-I RSP default policy set and the Username WS-I RSP default policy set. You can use these policy sets to simplify your Web services configuration.

WS-ReliableMessaging default policy sets

The WS-ReliableMessaging default policy sets are pre-configured to provide reliable message exchange between Web services. Two of these policy sets (WS-I RSP and WS-I RSP ND) are immediately available, and the rest are readily available for import from a default repository.

With WS-ReliableMessaging, you can make your SOAP over HTTP-based Web services reliable without writing custom code. You can use the provided non-editable default policy sets without change, or you can create customized copies of them.

All the default policy sets that include the WS-ReliableMessaging policy also include the WS-Addressing policy. The WS-ReliableMessaging policy provides the ability to deliver a message reliably to its intended receiver. The WS-Addressing policy provides a transport-neutral way to uniformly address Web services and messages, and WS-ReliableMessaging uses WS-Addressing to provide asynchronous request and reply capabilities.

Note: WS-ReliableMessaging Version 1.1 messaging requires WS-Addressing to be mandatory. If you use a policy set that includes WS-ReliableMessaging and WS-Addressing policies, and the WS-Addressing policy is configured as optional, then WebSphere Application Server overrides the WS-Addressing setting and automatically enables WS-Addressing.

The following default policy sets that include the WS-ReliableMessaging policy are immediately available, as described in "Viewing policy sets using the administrative console" on page 805:

WS-I RSP

This policy set enables WS-ReliableMessaging Version 1.1 and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. In-order delivery is set to "false", so messages are not necessarily delivered in the order in which they were sent. Message integrity is provided by digitally signing the body, the time stamp, and the WS-Addressing headers. Message confidentiality is provided by encrypting the body and the signature. This policy set follows the WS-SecureConversation and WS-Security specifications.

WS-I RSP ND

This is the network deployment version of the WS-I RSP policy set. This policy set provides the WS-I RSP default policy set and adds a *managed non-persistent* quality of service. This in-memory quality of service option uses a messaging engine to manage the sequence state, and messages are written to disk if memory is low. This quality of service allows for the re-sending of messages that are lost in the network, and can also recover from server failure. However, state is discarded after a messaging engine restart so in this case you will lose messages.

The following additional default policy sets that include the WS-ReliableMessaging policy are readily available for import, as described in “Importing policy sets using the administrative console” on page 816:

LTPA WS-I RSP
This policy set provides the WS-I RSP default policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username WS-I RSP
This policy set provides the WS-I RSP default policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

WSReliableMessaging 1_0
This policy set enables both WS-ReliableMessaging Version 1.0 and WS-Addressing and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

You can use this policy set with .NET-based Web services.

WSReliableMessaging default
This policy set enables both WS-ReliableMessaging Version 1.1 and WS-Addressing and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

WSReliableMessaging persistent
This policy set enables both WS-ReliableMessaging and WS-Addressing and uses the maximum quality of service, *managed persistent*. This quality of service supports asynchronous Web service invocations and uses a service integration messaging engine and message store to manage the sequence state. Messages are processed within transactions, are persisted at the Web service requester server and at the Web service provider server, and are recoverable in the event of server failure. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

Because this policy set specifies managed persistent quality of service, you need to define bindings to the service integration bus and messaging engine that you want to use to manage the WS-ReliableMessaging state. For more information, see “Attaching and binding a WS-ReliableMessaging policy set to a Web service application using the administrative console” on page 657 or using the wsadmin tool.

“Adding assured delivery to Web services through WS-ReliableMessaging” on page 634
WS-ReliableMessaging is an interoperability standard for the reliable transmission of messages between two endpoints. With WS-ReliableMessaging, you can make your SOAP over HTTP-based Web services reliable without having to write custom code. You can get different qualities of service with WS-ReliableMessaging. These range from protecting against loss of messages across a network, through to protecting against a server becoming unavailable.

“Learning about WS-ReliableMessaging” on page 635
WS-ReliableMessaging is an interoperability standard for the reliable transmission of messages between two endpoints. Use these topics to learn more about WS-ReliableMessaging.

WSAddressing default policy set

The WSAddressing default policy set provides a transport-neutral way to uniformly address Web services and messages.

The WSAddressing default policy set is based on the WS-Addressing specification. The WS-Addressing standard uses endpoint references and message addressing properties to facilitate the addressing of Web services in a standard and interoperable way.

Use the WSAddressing default policy set as provided with the application server. To customize the policy set, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

To learn more about the WS-Addressing standard, read about Web Services Addressing support.

Related concepts

“Web services policy sets” on page 961
Policy sets are assertions about how services are defined. They are used to simplify your quality of service configuration for Web services.

Web Services Addressing support
The Web Services Addressing (WS-Addressing) support in this product provides the environment for Web services that use the Worldwide Web Consortium (W3C) WS-Addressing specifications. This family of specifications provide transport-neutral mechanisms to address Web services and to facilitate end-to-end addressing.

WSSecurity default policy sets

The WSSecurity default policy sets are based on the Web Services Security (WS-Security) 1.0 and Web Services Addressing (WS-Addressing) specifications. The WSSecurity default policy sets include the WSSecurity default policy set, the Lightweight Third-Party Authentication (LTPA) WSSecurity policy set, and the Username WSSecurity policy set. Use the WSSecurity default policy sets to build secure Web services.

The WSSecurity default policy sets use the WS-Security 1.0 specification enhancements to SOAP messaging to provide quality of protection through message integrity, message confidentiality, and single message authentication. Providing quality of protection means to prevent the following potential threats to SOAP messages:

- The message being modified or read by antagonists
- An antagonist sending messages to a service that are formed correctly, but lack the appropriate security claims to be processed

The WSSecurity default policy sets provide message protection by using WS-Security to digitally sign the WS-Addressing headers, the time stamp and the body. This policy set also encrypts the signature and the body. RSA public key cryptography is used for the signature and for encryption operations.

The WS-Addressing specification defines XML 1.0 and XML Namespaces elements to identify Web services endpoints and to secure end-to-end endpoint identification in messages.

Use the WSSecurity default policy set, the LTPA WSSecurity policy set, or the Username WSSecurity policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The following WSSecurity default policy sets exist:

WSSecurity default
This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, and signature elements using WS-Security specifications.

LTPA WSSecurity default
This policy set provides the WSSecurity default policy set and adds aLightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username WSSecurity default
This policy set provides the WSSecurity default policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

"Web services policy sets" on page 961
Policy sets are assertions about how services are defined. They are used to simplify your quality of service configuration for Web services.

WSTransaction default policy sets

The WSTransaction default policy sets are based on the WS-Transaction specification and provide transactional integrity for Web services. The WSTransaction default policy sets include the WSTransaction policy set and the SSL WSTransaction policy set.

You can use the WSTransaction default policy sets to make your SOAP over HTTP-based Web services interoperable and coordinate atomic transactions or business activities without writing custom code. Use the WSTransaction policy set or the SSL WSTransaction policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WSTransaction default policy sets are:

WSTransaction
Use this policy set to coordinate distributed transactional work atomically and interoperably using

the WS-AtomicTransaction specification. Also, use this policy set to coordinate loosely coupled business processes that are distributed across the heterogenous Web service environment, with the ability to compensate actions if a failure occurs in the business activity, using the WS-BusinessActivity specification.

SSL WSTransaction

Use this policy set to coordinate distributed transactional work atomically, interoperably and securely using the WS-AtomicTransaction specification and SSL Transport security. Also, use this policy set to coordinate loosely coupled business processes, with the ability to compensate actions if a failure occurs in the business activity, securely, using the WS-BusinessActivity specification and SSL Transport security.

Related concepts

"Web services policy sets" on page 961
Policy sets are assertions about how services are defined. They are used to simplify your quality of service configuration for Web services.

"Web Services Atomic Transaction support in the application server" on page 689
The Web Services Atomic Transaction (WS-AT) support in the application server provides transactional quality of service to the Web services environment. Distributed Web services applications, and the resources they use, can take part in distributed global transactions.

"Web Services Business Activity support in the application server" on page 693
With Web Services Business Activity (WS-BA) support in the application server, Web services on different systems can coordinate activities that are more loosely coupled than atomic transactions. Such activities can be difficult or impossible to roll back atomically, and therefore require a compensation process if an error occurs.

WSHTTPS default policy set

The WSHTTPS default policy set provides SSL transport security for the HTTP protocol with Web services applications.

The WSHTTPS default policy set is provided with the application server and it contains the HTTP transport policy, the SSL transport policy and the WS-Addressing policy.

You can use the WSHTTPS default policy set as provided with the application server. You cannot edit the WSHTTPS default policy set. You can create a copy of the default policy set and then configure custom policy settings and bindings to meet your needs. Alternatively, you can create a new policy set and specify the policies for it.

Copy of default policy set and bindings settings

Use this page to copy a policy set that you select from a list of available policy sets.

To view this administrative console page:

1. Click **Services > Policy sets > Application policy sets**.
2. Select the policy set that you want to copy, and click **Copy**.
3. Enter a name for the copy of the policy set in the **Name** field.
4. [Optional] Enter a description for the copy of the policy set in the **Description** field.

Name:

Specifies the name of the policy set. Use this field to enter a name for the copy of the policy set.

Description:

Specifies a description of the policy set that you want to copy.

Transfer attachments:

If the policy set that you want to copy is attached to one or more applications, services, or endpoints, then the check box option for **Attach this policy set in place of the original for all attached applications, services, endpoints, and operations**, is available. The default setting for this check box is cleared. You can perform the following actions:

1. Select the **Attach this policy set in place of the original for all attached applications, services, endpoints, and operations** check box to move the attachments to a new policy set. Selecting the check box detaches the original policy set and attaches the replacement policy set in its place.
2. Select **Copy bindings** if you want to copy the bindings of the policy set that is currently attached.
3. [Optional] Select **Restore default bindings** if you want to restore the default bindings.

Importing policy sets using the administrative console

You can import predefined policy sets or import policy sets from a selected location using the administrative console.

Before you begin

Before you begin this task, review Application policy sets collection.

About this task

The policy sets panel has an Import button to allow the import of policy sets. You can import a policy set from the default repository or from a selected location.

1. From the administrative console navigation, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**. The policy sets collection page displays a listing of the custom and default policy sets. Custom policy sets are displayed only if you have created them. If you have not created a custom policy set, then only the default policy sets are displayed.
2. From the Application policy sets panel, click **Import**.
3. Choose the option for importing the policy set. You can choose to import a policy set from the default repository or from a selected location. Selecting **Import from Default Repository** accesses the next panel that displays a set of predefined default policy sets that are available for you to import. Some of the predefined policy sets have already been imported for you from the default repository. You can import additional predefined policy sets that are available in the predefined policy set repository.

   Select **Import from Selected Location** to provide a path or browse your file system for a policy set file to import.

   - To import a policy set from the default repository, select **Import from Default Repository** and perform task step 4.
   - To import a policy set from a selected location, select **Import from Selected Location** and perform task step 7.
4. Select **Import from Default Repository** and select either the **Import** or the **Import a Copy** radio button.

   The behavior of **Import** policy set:

   - Available for selection of one or more policy sets.
   - Imports the default, not editable, policy set. You are returned to the Application policy sets panel after the import of the policy set.
   - The imported policy set can be deleted, but it cannot be modified.

   The behavior of **Import a Copy** for a policy set:

- Not available for multiple selection. If multiple policy sets are selected and the **Import a Copy** radio button is selected, an error message is displayed, indicating that only one policy set can be copied at a time.
- Prompts you for a name and description for the copy. You are returned to the Application policy sets panel after you import the policy set.
- The imported policy set can be modified or deleted.

5. If you selected **Import** from the previous step, select one or more policy sets to import in the **Name** column.
   a. Click **OK**. You are returned to the Application policy set panel.
   b. Click **Save**, to save your changes to the configuration.
6. If you selected **Import a Copy** from step 4, select the policy set to import a copy in the **Name** column. You can only select one policy set in the Name column to import its copy.
   a. Provide a different name for the copy.
   b. Click **OK**. You are returned to the Application policy set panel.
   c. Click **Save**, to save your changes to the configuration.
7. Select **Import from Selected Location**.
   a. Specify the full path or browse for the policy set file in your file system.
   b. Select either **Use current policy set name** or **Specify a different name to use for this policy set**.
   c. Click **OK**. You are returned to the Application policy set panel.
   d. Click **Save** to save your changes to the configuration.

Results

When you finish this task, you have been able to import a policy set using either the default repository or from a selected location.

Example

If you have a policy set, `XYZ_ps` and you want to import it from a selected location, perform the following steps:

1. From the Application policy set panel, click **Import**.
2. Select **Import from Selected Location**.
3. Specify the full path or browse to where the `XYZ_ps` policy set file is located in your file system.
4. Select either **Use the current policy set name**, `XYZ_ps`, or **Specify a different name for the policy set**.
5. Click **OK**.
6. Click **Save**, to save your changes to the configuration.

What to do next

You can modify or use the policy set that you just imported.

Related tasks

“Importing and exporting policy sets to client or server environments using scripting” on page 539
Use the wsadmin tool, which supports the Jython and Jacl scripting languages, to export and import application or system policy sets for Web services. The exportPolicySet command creates an archive file based on the policy set configuration, and the importPolicySet command imports a default policy set or policy set from an archive file.

Use this page to manage policy sets. You can create, copy, export, and import policy sets. You can also view or delete existing policy sets. You can use policy sets, or assertions that define services, to simplify your Web services configuration because policy sets group security and other Web services settings into reusable units.

Import policy sets from default repository settings

Use this page to specify a policy set to import from a default repository. You can import predefined policy sets from the default repository.

To view this administrative console page, complete the following actions:

1. Click **Services > Policy sets > Application policy sets**.
2. Click **Import**.
3. Select **From Default Repository**.
4. You have the Import and Import a copy options. Select **Import a copy**.
5. In the **Name of copy** field, enter a name for the copy of the policy set that you select to import from the list of policy sets.

The behavior of **Import**:

- Available for selection of one or more policy sets.
- Imports the default, not editable, policy set. You are returned to the Application policy sets panel after the import of the policy set.
- The imported policy set can be deleted, but it cannot be modified.

The behavior of **Import a copy** policy set:

- Not available for multiple selection. If multiple policy sets are selected and the **Import a copy** radio button is selected, an error message is displayed, indicating that only one policy set can be copied at a time.
- Prompts you for a name for the copy. The description of the imported policy set is kept, but you can edit the description after you have imported the policy set. You are returned to the Application policy sets panel after the import of the policy set.
- The imported policy set can be modified or deleted.

You can use policy sets, or assertions that define services, to simplify your Web services configuration because policy sets group security and other Web services settings into reusable units. You can use the administrative console to create, modify, and delete custom policy sets.

“Importing and exporting policy sets to client or server environments using scripting” on page 539
Use the wsadmin tool, which supports the Jython and Jacl scripting languages, to export and import application or system policy sets for Web services. The exportPolicySet command creates an archive file based on the policy set configuration, and the importPolicySet command imports a default policy set or policy set from an archive file.

Related reference

“Application policy sets collection” on page 954
Use this page to manage policy sets. You can create, copy, export, and import policy sets. You can also view or delete existing policy sets. You can use policy sets, or assertions that define services, to simplify your Web services configuration because policy sets group security and other Web services settings into reusable units.

“Import policy sets from default repository settings” on page 818
Use this page to specify a policy set to import from a default repository. You can import predefined policy sets from the default repository.

Path and file name for the policy set file:

Specify a fully qualified path and file name to the policy set file or use the **Browse** to locate the file in your file system.

Select **Use current policy set name** if you are not changing the policy set name and click **OK**.

Select **Specify a different name for this policy set** if you are changing the policy set name. Provide a new name and click **OK**.

Button	Resulting action
OK	Imports the specified policy set file if valid or returns an error if an invalid file is provided. You are returned to the Application policy set panel after the import.
Cancel	Returns you to the Application policy set panel without importing a policy set.

Modifying policy sets using the administrative console

You can use the administrative console to modify existing custom policy sets that you have created. If you have copied an existing default policy set or created a policy set yourself, you can always go back and make changes to them to make them better suit the changing needs of your business.

Before you begin

You can create a copy of a policy set and modify the copy. You must first copy a default policy set before you can modify it. See copy of default policy set and bindings settings.

About this task

To modify a custom policy set, you can use the Policy set settings view to access configuration information for the policy set.

1. Create a policy set using the steps in “Creating policy sets using the administrative console” on page 806
2. From the administrative console, click **Services > Policy sets > Application policy sets** >*policy_set_name* or **Services > Policy sets > System policy sets** >*policy_set_name* where

policy_set_name is the custom policy set of interest that is displayed in the table. This opens the Policy set settings view. You must specify the required information about the policy set that you want to modify.

3. Change the description of the policy set. Edit the brief description of the policy set in the Description field. This is the description that displays in the Application policy sets collection so it must be meaningful to you and other potential users of this policy set.
4. Edit the policy information. You can include, exclude, add or delete policies from this policy set using the settings in the Policies table. To work more extensively with policies, see “Managing policies in a policy set using the administrative console” on page 902.
5. This step does not apply to system policy sets. Detach the policy set from an application or replace the policy set attached to the application with another policy set. Click the **Attached applications** link to access applications that are attached to this policy set and applications that contain attached service resources. To detach a policy set from an application, use the following steps:
   a. In the Filter list, click **Name**.
   b. Find the application. In the Search term(s) field, enter all or part of the name of the application you want to detach and click **Go**.
   c. Detach the application. Find and select the application in the listing and click **Detach Policy Set**.

   To change the policy set that is attached to an application, use the following steps:
   a. In the Filter list, click **Name**.
   b. Find the application. In the Search term(s) field, enter all or part of the name of the application and click **Go**.
   c. Replace the policy set for this application. Find and select the application in the listing and click **Replace Policy Set**. You then have one of the following options:
      - If there are fewer than 25 policy sets to choose from, the Replace Policy Set button is a drop down list and you can click a policy set to attach to the application.
      - If there are more than 25 policy sets to choose from, the Replace Policy Set button opens a collection of policy sets and you can select the policy set to replace from the listing.

Results

Performing these tasks modifies the application to which the custom policy set is attached.

Example

If you had a custom policy set ABC WS-I RSP, for example, that had a misleading description and you want to change the description so that other users know what the policy set really includes, you would access the Policy Set settings view for that policy set. To do this, from the administrative console, you would click **Services > Policy sets > Application policy sets** > ***ABC WS-I RSP***. Then you would click the description field and edit the text so that it better represents the scope of the policy set.

What to do next

If the policy set you have modified is an attached policy set, restart all affected applications to pick up the changes you made. If the policy set is unattached, then no further action is required.

You can use policy sets, or assertions that define services, to simplify your Web services configuration because policy sets group security and other Web services settings into reusable units.

“Application policy set settings” on page 955
Use this page to view, create, enable or disable your policy sets. You can use policies, or assertions that define services, to simplify your Web services configuration.

Deleting policy sets using the administrative console

You can use the administrative console to delete the default policy sets or the application specific policy sets that you have created.

Before you begin

If you are deleting an attached policy set, stop all applications and the associated endpoints or operations, then detach and delete the policy set. If the policy set is unattached, then you do not need to detach the policy set before deleting it.

About this task

If a application specific policy set is no longer needed, you might choose to delete it. To delete a application specific policy set, use the Application policy set collection panel.

1. From the administrative console, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**.
2. Click the box in the **Select** column next to the policy set that you want to delete.
3. Click **Delete**.
4. Verify that you want to delete this policy set.

Results

The selected application specific policy set is deleted from the list of policy sets and is no longer available.

Example

You might decide that the *ABC WS-I RSP* policy set that you created did not meet your needs as you had expected and you have already created the *DEF WS-I RSP* policy set to better meet your needs. You have detached all the applications and endpoints from the *ABC WS-I RSP* policy set and you want to delete the policy set. Click **Services > Policy sets > Application policy sets** and find the *ABC WS-I RSP* policy set in the listing. Select the *ABC WS-I RSP* policy set and click **Delete**. Confirm that you want to delete the policy set and it is removed from the listing of policy sets. Restart the applications that you detached the ABC WS-I RSP policy from, and you have successfully deleted the policy set.

Alternatively, and depending on your use case, you might want to reassign the attachment to another resource before deleting the policy set. Make a copy of the policy set that you are about to delete, then attach it later to your application or service artifact. See attaching a policy set to a service artifact. You can now delete the policy set.

What to do next

If you have detached and then deleted a policy set from an application, restart all affected applications to pick up this change.

Defining and managing policy set bindings

Policy set bindings contain platform specific information, like keystore, authentication information or persistent information, required by a policy set attachment. Use this task to create and manage bindings.

About this task

In Version 7.0, there are two types of bindings, application specific bindings and general bindings.

Application specific bindings

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have very limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. See service providers policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

General bindings

General bindings are new for Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general provider policy set bindings by accessing **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings. General provider policy set bindings might also be used for trust service attachments.

Note: The general bindings that are shipped with the product are provider and client sample bindings. These bindings are initially set as the cell default bindings. Do not use these bindings in their current state in a production environment. To use the sample bindings, modify them to meet your security needs in a production environment. Alternatively, create a copy of the bindings and then modify the copy. For example, change the key and keystore settings to ensure security, and modify other settings to match your environment. You must also configure the username and password for Username or LTPA token authentication. See the topic Configuring the username and password for WS-Security Username or LTPA token authentication for more information.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

To view or work with your current policy sets bindings, perform the following:

1. To view your current policy set and application specific bindings from the administrative console, click **Services > Policy sets > Application policy sets** >*policy_set_name* > **Attached applications** and then click an application. Depending on the application that you select, use one of the following topics for help with the bindings attached to policy sets:
   - Service provider policy sets and bindings
   - Service client policy sets and bindings

   Sort on the **Attached policy set** column on either of the policy sets and bindings pages to select the service resources with the same policy set attached. Likewise, sort on the **Binding** column to select the service resources that share the same custom binding to attach to a different policy set. If you sort on the **Policy Set** or the **Binding** column, the hierarchical relationship of the service resources in the first column is not accurate. You can sort again on the **Application/Service/Endpoint/Operation** column to restore the hierarchical relationship. The entries in the **Application/Service/Endpoint/ Operation** column display in ascending order.
2. To work with an existing bindings from the administrative console, click **Services > Policy sets > Application policy sets** >*policy_set_name* > **Attached applications**. Click an application name, and then click either the **Service provider policy sets and bindings** or the **Service client policy sets and bindings**. Then click a binding name in the Bindings column of the table.

   Note: If no applications appear when you click **Attached applications**, you do not have any applications attached to the selected policy set. To attach a policy set and binding to an application using the administrative console, click **Applications > Enterprise Applications > *application name***. Then, click either **Service provider policy sets and bindings** or **Server client policy sets and bindings** to attach resources to your policy set and to assign bindings.

   .
3. [Optional] To work with general bindings, click **Services > Policy sets > General client policy set bindings** or **Services > Policy sets > General provider policy set bindings**.

   You can complete the following actions for general bindings:
   - “Importing policy set bindings using the administrative console” on page 827
   - “Export policy sets bindings settings” on page 836
   - “Defining and managing service client or provider bindings” on page 831
   - “Creating new or configuring existing general binding settings” on page 835
   - “Copy policy set binding settings” on page 836
   - “Deleting policy set bindings” on page 837

Results

When you finish this task, you would have performed one or more of the following:

- Created an application specific or general policy set binding
- Imported a policy set binding
- Exported a policy set binding
- Deleted a policy set binding
- Modified an application attachment to apply an application specific binding for single security domain
- Modified an application attachment to apply an application specific binding for multiple security domain

The Java Platform, Enterprise Edition (Java EE) role-based authorization concept is extended to protect the WebSphere Application Server administrative subsystem.

“Service client policy set and bindings collection” on page 763
Use this page to attach and detach policy sets to an application, a service client, its endpoints, or operations. You can select the default bindings, create new application-specific bindings, or use existing bindings for an attached policy set. You can view or change whether the client uses the policy of the service provider.

“Service provider policy sets and bindings collection” on page 746
Use this page to attach and detach policy sets to an application, a service provider, its endpoints, or operations. You can select the default bindings, create new application-specific bindings, or use bindings that you created for an attached policy set. You can view or change whether the service provider can share its current policy configuration.

Importing policy set bindings using the administrative console

You can import predefined client or provider policy set bindings using the administrative console.

Before you begin

This task only applies to general client or provider bindings. Before you begin this task, review the defining and managing service client or provider bindings.

About this task

The general bindings panel has an Import button to allow the import of client or provider policy set bindings. You can import a policy set binding by specifying the full path and filename of the binding to import.

1. Navigate to the General client policy set bindings or the General provider policy set bindings panel using one of the following ways:
   - **Services > Policy sets > General client policy set bindings**
   - **Services > Policy sets > General provider policy set bindings**
2. Click **Import**.
3. Specify the full path and file name of the policy set binding to import.
4. Select either **Use current binding name** or **Specify a different name to use for this binding**. If you are importing a binding and that binding name already exists in the repository, you must specify a different name to use for the binding import.
5. Click **OK**.

Results

When you finish this task, you have been able to import a policy set binding using the administrative console.

Example

If you have a policy set binding, `XYZ_psbind` and you want to import it, perform the following steps:

1. From the General client or provider policy set bindings panel, click **Import**.
2. Specify the full path and file name of the policy set binding to import or use **Browse** to locate the binding in your file system.
3. Select either **Use current binding name** or **Specify a different name to use for this binding**.
4. Click **OK**.
5. Click **Save**, to save your changes to the configuration.

What to do next

You can export a policy set binding to reuse it.

Related tasks

Select **Use current binding name** if you are not changing the binding name and click **OK**.

Select **Specify a different name for this binding** if you are changing the binding name. Provide a new name and click **OK**.

Button	Resulting action
OK	Imports the specified binding file if valid or returns an error if an incorrect file is provided. You are returned to the General client or provider policy set binding panel after the import.
Cancel	Returns you to the General client or provider policy set binding panel without importing a binding.

Web services policy set bindings

A set of bindings is a named object that is associated with a specific policy set and service resource that is attached to the policy set.

Bindings contain environment and platform specific information, like the following types of information:

- Keys used for signature and encryption
- Keystore information

- Authentication information
- Persistent information

Typically, bindings are specific to the application or the platform, and they are not shared.

In Version 7.0, there are two types of bindings, application specific bindings and general bindings.

Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and defined by the characteristics of the policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. See service providers policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

General bindings

General bindings are new for Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they do not provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general provider policy set bindings by accessing **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings. General provider policy set bindings might also be used for trust service attachments.

Note:

The sample general bindings that are shipped with the product are provider and client sample. Do not use these sample bindings in their current state in a production environment. However, if they were modified to contain non-sample data, you can use these sample bindings in a production environment.

You cannot assign a binding to a service provider resource that does not have a policy set or has an inherited attachment. To assign a binding to such a service provider resource, you must first attach a policy set to the resource. Also, you cannot assign a binding to a service client resource

that does not have an effective policy configuration or has an inherited policy attachment. To assign a binding to such a service client resource, you must first attach a policy set or specify the use of the provider policy.

Defining and managing service client or provider bindings

Service client or provider bindings are general bindings. You can create, copy, and manage general bindings such as the client or provider policy set bindings. These bindings provide system-specific configuration and can be reused across policy set attachments.

Before you begin

You cannot assign a binding to a service provider resource that does not have a policy set or has an inherited attachment. To assign a binding to such a service provider resource, you must first attach a policy set to the resource. Also, you cannot assign a binding to a service client resource that does not have an effective policy configuration or has an inherited policy attachment. To assign a binding to such a service client resource, you must first attach a policy set or specify the use of the provider policy. See attaching a policy set to a service artifact.

About this task

In Version 7.0, there are two types of bindings, application specific bindings and general bindings.

Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and defined by the characteristics of the policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in an unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set.

General bindings

General bindings are new for Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they do not provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

Note: The general bindings that are included with the product are provider and client sample bindings. Do not use these bindings in their current state in a production environment. However, if they were modified to contain non-sample data, they could be used in a production environment.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

You can complete the following tasks to define and manage general client or provider policy set bindings.

1. To create a new general client or provider policy set binding or to manage the binding configuration from the administrative console, click **Services > Policy sets > General client policy set bindings** > **New**. You can also access this panel by clicking **Services > Policy sets > General provider policy set bindings** > **New**. Use the resulting detail panel to create a new client or provider policy set binding. See creating new or configuring existing general binding settings.
2. To copy a specific policy set binding, select the binding name from the table and click **Copy**. See copying a policy set binding settings.
3. To import a client or provider policy set binding, click **Import**. Use the importing policy set bindings using the administrative console to complete the import task that you select.
4. To export a client or provider policy set binding, select the binding name from the table, and click **Export**. See export policy set binding settings.
5. To delete a policy set binding, select the binding name from the table, and click **Delete**. See deleting policy set bindings.

Results

When you finish this task, you have created, copied, exported, imported or deleted a client or provider policy set binding.

Related tasks

"Attaching a policy set to a service artifact" on page 901
Attach a policy set to a service artifact, such as an application, service, or endpoint to define the quality of services that are supported. Policy sets can define the policies for WS-Addressing, WS-Security, WS-ReliableMessaging, WS-Transaction, HTTP transport, Java Messaging Service (JMS) transport, and Secure Sockets Layer (SSL) transport.

Administrative roles
The Java Platform, Enterprise Edition (Java EE) role-based authorization concept is extended to protect the WebSphere Application Server administrative subsystem.

Service client or provider policy set bindings collection:

Use this page to create, copy, and manage general policy set bindings, such as the service client or provider bindings. These bindings provide system-specific configuration, and can be reused across policy set attachments. You can select the general default bindings, create new general bindings, or use existing bindings for an attached policy set.

To view this administrative console page, click **Services** → **Policy Sets** → **General client policy set bindings**. You can also view this page by clicking **Services** → **Policy Sets** → **General provider policy set bindings**.

About policy set bindings

In Version 7.0, there are two types of bindings, application specific bindings and general bindings.

Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and defined by the characteristics of the defined policy. Application specific bindings can provide onfiguration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in an unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. See service providers policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

General bindings

General bindings are new for Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general provider policy set bindings by accessing **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings. General provider policy set bindings might also be used for trust service attachments.

Note:

The sample general bindings that are shipped with the product are provider and client sample. Do not use these sample bindings in their current state in a production environment. However, if they were modified to contain non-sample data, you can use these sample bindings in a production environment.

You cannot assign a binding to a service provider resource that does not have a policy set or has an inherited attachment. To assign a binding to such a service provider resource, you must first attach a policy set to the resource. Also, you cannot assign a binding to a service client resource

that does not have an effective policy configuration or has an inherited policy attachment. To assign a binding to such a service client resource, you must first attach a policy set or specify the use of the provider policy.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Administrative roles
The Java Platform, Enterprise Edition (Java EE) role-based authorization concept is extended to protect the WebSphere Application Server administrative subsystem.

Name:

Specifies the name of the service client or provider policy set binding.

The following list of buttons are available to create and manage service client or provider policy set bindings:

Button	Resulting Action
New	Creates a new client or provider policy set binding. This option accesses the New binding panel. The binding is empty initially; you must enter a name and an optional description for a new client or provider policy set binding.
Delete	Removes the selected client or provider general policy set binding. The default general bindings are being used as the default for a server or a security domain, including the global security domain. You cannot delete global security default bindings. An attempt to delete such default general binding generates an error message that the selected binding cannot be deleted because it is currently the default binding for the global security domain.
Copy	Creates a modifiable copy of the selected client or provider policy set binding using a new name that you provide.
Import	Imports a client or provider policy set binding. This is a menu item with the option of importing a binding with the same name or providing a different name for the import.
Export	Exports the selected client or provider policy set binding to an archive file.

Description:

Specifies the user-defined description for the client or provider policy set bindings.

Creating new or configuring existing general binding settings:

Use this page to create a new client or provider policy set binding. You can also use this page to configure an existing general binding. Empty bindings will be deleted. Scoping a binding to a security domain constrains the configuration options to those applicable to that domain and limits use of the binding to the specified domain.

To view this administrative console page, click **Services > Policy sets > General client policy set bindings** > **New**. You can also view this page by clicking **Services > Policy sets > General provider policy set bindings** > **New**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Administrative roles
The Java Platform, Enterprise Edition (Java EE) role-based authorization concept is extended to protect the WebSphere Application Server administrative subsystem.

Bindings configuration name:

Specifies the name of the new binding configuration.

You must enter a binding configuration name to proceed. The name of the binding is automatically applied when you add a policy type and provide additional configuration information. At that time, the initial **Cancel** button is replaced with an **OK** button. Each binding that you add is initially empty, and you are directed to the binding configuration panel to provide additional information for the binding.

Button	Resulting Action
Add	Adds a policy type, such as WS-Security, to a new binding that you create or to an existing binding. You can access the configuration of each policy type binding through the policy type name link. If you click **Cancel** without providing any configuration information for the policy type, that policy type is not saved or included in the list of policy types. You might receive an attention message that the policy type was not saved as part of the binding configuration.
Delete	Deletes a policy type from the list.

Button	Resulting Action
OK	Associates the name of the binding to the policy type information after you add a policy type and provide additional configuration information.
Cancel	Returns you to the General client or provider policy set bindings panel without creating a new binding configuration.

Security domain:

This field is only available in a multiple security domain environment and specifies a valid security domain. You can scope the binding to that particular security domain, which is scoped to the global security domain by default.

Description:

Specifies a brief description of the new client or provider policy set binding.

Export policy sets bindings settings

This task only applies to general client or provider bindings. Use this page to export either a client or provider policy set binding for reuse.

Navigate to the General client policy set bindings or the General provider policy set bindings panel using one of the following paths:

- **Services > Policy sets > General client policy set bindings**
- **Services > Policy sets > General provider policy set bindings**

1. Select a binding from the list and click **Export**.
2. Click the binding to download the archive file.
3. Use the file dialog box to select a location for the exported binding. The policy set binding file is exported as a compressed file.
4. Click **Done**.

Specifies a brief description of the copy of the policy set binding.

Deleting policy set bindings

Use this task to delete general policy set bindings using the administrative console.

About this task

You cannot delete general bindings specified as the default for any server or domain. You also cannot delete general bindings that are assigned to a policy set attachment. To delete other bindings, perform the following steps:

1. Click **Services > Policy sets > General client policy set bindings**. You can also access this page by clicking **Services > Policy sets > General provider policy set bindings**.
2. Select an existing binding from the list, and click **Delete**.
3. Click **Save**, to save your changes.

Results

When you finish this task, you have deleted a general policy set binding.

Creating application specific bindings for policy set attachment

After you attach a policy set to a service artifact such as an application, service, or endpoint, you can define application specific bindings for the attached policy set.

Before you begin

Before you can start this task, you must deploy an application containing Web services, and attach a policy set. See attaching a policy set to a service artifact.

About this task

The application specific binding panels display options based on the definitions in the attached policy set. For example, if the policy set does not have WS-ReliableMessaging configured, then the application specific binding panels do not display an option to configure WS-ReliableMessaging bindings. To create application specific bindings for an attached policy set, perform the following steps:

1. Open the administrative console.
2. To create application specific bindings for a service provider policy attachment, click **Applications > Application Types > WebSphere enterprise applications** >*Service_provider_application_instance* > **Service provider policy sets and bindings**.

   To create application specific bindings for a service client policy attachment, click **Applications > Enterprise applications** > ***application_name*** > **Service client policy sets and bindings**.
3. Select the check box for the service artifact with an attached policy set.
4. Click **Assign Binding** to see a list of available bindings to assign.
5. [Optional] Select a previously defined application specific attachment binding from the list.

   If you decide to create a new application specific binding, complete steps 6 through 9.
6. Click **New**.
7. Specify a name for the binding and select which policies that you want to include in this application specific binding. Click **Add**, and select the policies to add.
8. Complete the information for the specified policies to define associated configuration data.
9. Click **Save**, to save your changes to the master configuration.

Results

When you finish this task, a application specific binding is created for the service artifact with the attached policy set.

Example

You have the application, `app1` with the attached policy set `Username WSSecurity default`, and you want to define application specific bindings. First locate the application in the **Applications > Application Types > WebSphere enterprise applications** collection. Click the **app1** application. You can then click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** link. Select the check box for the `app1` application where the policy set is attached. Click **Assign Binding** and click **New**. Specify a name for the binding, such as `myBinding`. Click **Add** and select **WS-Security** from the list. Next, click the link for **WS-Security** policy and complete the panels with the appropriate information. Click **Save**, to save your changes to the master configuration.

What to do next

Restart the application that contains the service artifact with the application specific bindings you created.

Related tasks

"Attaching a policy set to a service artifact" on page 901
Attach a policy set to a service artifact, such as an application, service, or endpoint to define the quality of services that are supported. Policy sets can define the policies for WS-Addressing, WS-Security, WS-ReliableMessaging, WS-Transaction, HTTP transport, Java Messaging Service (JMS) transport, and Secure Sockets Layer (SSL) transport.

"Defining and managing service client or provider bindings" on page 831
Service client or provider bindings are general bindings. You can create, copy, and manage general bindings such as the client or provider policy set bindings. These bindings provide system-specific configuration and can be reused across policy set attachments.

Related reference

"Creating new or configuring existing general binding settings" on page 835
Use this page to create a new client or provider policy set binding. You can also use this page to configure an existing general binding. Empty bindings will be deleted. Scoping a binding to a security domain constrains the configuration options to those applicable to that domain and limits use of the binding to the specified domain.

Setting server default bindings for policy sets

You can set server default bindings if you want the policy set attachments for service providers and clients that are deployed to the server to use bindings that are different than those that are specified for the cell. If you use multiple security domains, your default server bindings will also override the security domain default bindings.

Before you begin

Before you can set server default bindings for your Java API for XML-Based Web Services (JAX-WS) application, you must first configure at least one general provider policy set binding or general client policy set binding. To define and manage these general bindings, use the administrative console and select **Services > Policy sets > General provider policy set bindings** or **Services > Policy sets > General client policy set bindings** .

About this task

Note: In WebSphere Application Server Version 7.0, the security model is enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product.

In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general bindings that are used as the default for an application server or a security domain.

General service provider and client bindings are not linked to a particular policy set, and they provide configuration information that you can reuse across multiple applications. You can create and manage general provider and client policy set bindings, and then select one of each binding type to use as the default for an application server. Setting the server default bindings is useful if you want the services that are deployed to a server to share binding configuration. You can also accomplish this sharing of binding configuration by assigning the binding to each application deployed to the server or by setting default bindings for a security domain and assigning the security domain to one or more servers.

You can specify default bindings for your service provider or client that are used at the global security (cell) level, for a security domain, for a particular server. The default bindings are used in the absence of an overriding binding specified at a lower scope. The following list is the order of precedence from lowest to highest that the application server uses to determine which default bindings to use:

1. Server level default
2. Security domain level default
3. Global security (cell) default

The sample general bindings that are provided with the product are initially set as the global security (cell) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. For trust service attachments, the default bindings are used when no trust specific bindings are assigned. If you do not want to use the provided **Provider sample** as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided **Client sample** as the default service client binding, you can select an existing general client binding or create a new general client binding. To specify your global security (cell) default bindings, use the administrative console, and click **Services > Policy sets > Default policy set bindings**. For environments with multiple security domains, you can optionally choose the general provider and general client bindings that you want to use as the default bindings for a domain.

In addition to choosing default bindings for the global security (cell), you can also choose the general provider and general client bindings that you want to use as the default bindings for a server. This is only necessary if you want to use different default bindings for a particular server than those used by the other servers in the security domain or cell.

To choose the default bindings for a server from the administrative console, click **Servers > Server Types > WebSphere application servers > *server_name*** and then under Security, click **Default policy set bindings**. If you do not choose a general binding as the default for a server, the default bindings for the domain in which the server resides is used. If you do not choose a binding as the default for a domain, the default bindings for the global security (cell) are used. You must choose a default service provider and default service client bindings for the cell. The general bindings that are included with the product are initially set as the global security (cell) default bindings. You cannot delete a binding that is used as part of any policy set attachment or specified as the default binding for server, a domain, or the cell. To learn more about defining default bindings for a server, see the server default bindings documentation.

Note:

If you have an application that contains one or more application specific bindings that are configured at the WebSphere Application Server V6.1 level, this application is a V6.1 application. If you have applications that are deployed to Version 6.1 servers within the Version 7.0 application

server environment or you have V6.1 applications that are deployed to V7.0 application servers, you can specify Version 6.1 default policy set bindings for the cell. These bindings are used for both client and provider policy set attachments within V6.1 applications and attachments to service applications that are deployed to a V6.1 server. Additionally, these default bindings are used for V6.1 attachments unless they are overridden at the attachment point by an application specific binding or a V6.1 server default binding. You can upgrade V6.1 bindings to WebSphere Application Server V7.0 bindings for by using the upgradeBindings command using the wsadmin tool, if the V6.1 application is not installed on WebSphere Application Server V6.1.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

1. Open the administrative console.
2. To set default policy set bindings for your server, select**Servers > Server Types > WebSphere application servers > *server_name* > Default policy set bindings**.
3. Select the server default provider binding.

   If you specify a server default provider binding, the selected binding overrides the default provider bindings that are specified for the cell or the security domain to which the server is deployed. The default setting is **None**.

   If multiple security domains are in use, the name of the security domain to which each binding is scoped displays beside the name of each available provider binding. Only the bindings that are scoped to the global security level or to the security domain to which the server is deployed are displayed.
4. Select the server default client binding.

   If you specify a server default client binding, the selected binding overrides the default client bindings that are specified for the cell or the security domain to which the server is deployed. The default setting is **None**.

   If multiple security domains are in use, the name of the security domain to which each binding is scoped displays beside the name of each available provider binding. Only the bindings that are scoped to the global security level or to the security domain to which the server is deployed are displayed.
5. Click **Apply** or **OK** to submit your changes.
6. Click **Save** to save your changes to the master configuration.
7. (optional) If you are using a Version 6.1 application, you can specify server V6.1 default policy set bindings. To set these bindings, select **Servers > Server Types > WebSphere application servers > *server_name* > Default policy set bindings > Version 6.1 default policy set bindings**.

   Note: Select the V6.1 default bindings for this server. If your application contains one or more application specific bindings that are configured at the WebSphere Application Server V6.1 level, this application is a V6.1 application. These default bindings are used for client and provider policy set attachments for applications that are deployed to V6.1 servers, and for V6.1 applications that are deployed to V7.0 servers. These bindings are used for both client and provider policy set attachments within V6.1 applications and attachments to service applications that are deployed to a V6.1 server. Additionally, these default bindings are used for V6.1 attachments unless they are overridden at the attachment point by an application specific binding or a V6.1 server default binding.

Results

When you complete these steps, the server default bindings are defined and all policy set attachments that specify use of the default binding for your Web service applications that are deployed to the server will use server level default bindings.

Example

Suppose you have configured an application server, `server1`, and you have deployed several Web service applications to the `server1` application server. Because these applications have similar security and quality of service requirements and you plan for them to share security configuration, you want to define the default bindings for policy set attachments to service providers and clients using the `server1`.

Suppose also that you want to modify the provided general provider binding, **Provider sample**. You can copy and modify this provided sample to take advantage of existing bindings.

1. Copy and modify the provided **Provider sample** and **Client sample** to meet your security and quality of service requirements. Include binding configuration for all policy types.
   - Click **Services > Policy sets > General provider policy set bindings**. Select **Provider sample > copy**. Name the new general provider binding, MyServiceProviderbinding , and provide a description for the new binding.
   - Click **Services > Policy sets > General client policy set bindings**. Select **Client sample > copy**. Name the new general client binding, MyServiceClientbinding, and provide a description for the new binding.
2. Locate *server1* in the Application servers collection and click the instance. From the administrative console, select **Servers > Server Types > WebSphere application servers** , and click the *server1* instance.
3. Click **Default policy set bindings**.
4. Select the bindings that you want to use for your provider and client policy set attachments. In this example, select your customized general bindings, MyServiceProviderbinding and MyServiceClientbinding.
5. Click **Apply** or **OK** to submit your changes.
6. Click **Save** to save your changes to the master configuration.

Each time you attach a policy set to a service or client deployed to the *server1* application server, it is initially set to use the specified bindings.

.

What to do next

After setting server default bindings, you can start deploying services to the server and start attaching policy sets. Alternatively, you might already have services deployed to the server, and the server is using the global default bindings because there is no server default binding. Now that you have set server default bindings, ensure that the server default bindings are used for the service messages as specified.

You can set provider and client default policy set bindings that are used as the global security default policy set bindings. The specified global security default bindings apply to all Web services unless the bindings are overridden at the attachment point, at the server, or at a security domain.

“Default policy set bindings collection” on page 850
Use this page to specify the service provider and client default bindings. The specified service provider and client bindings are used at the cell (global security) level unless these specified bindings are overridden at the attachment point, at the server, or at a security domain.

Related reference

Administrative roles
The Java Platform, Enterprise Edition (Java EE) role-based authorization concept is extended to protect the WebSphere Application Server administrative subsystem.

Server default binding settings:

Use this page to specify the server default bindings if you want to override the default bindings that are specified for the cell (global security) or the security domain to which the server is deployed.

To view this administrative console page, complete the following actions:

1. Click **Servers > Server Types > WebSphere application servers >** ***server_name***.
2. From Security, click **Default policy set bindings**.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Policy set bindings for servers

To understand default policy set bindings, it is important to first understand policy set bindings.

Policy set bindings contain platform-specific information, such as keystore, authentication information or persistent information that is required by a policy set attachment. A policy set attachment is a policy set that is attached to an application resource. In WebSphere Application Server Version 7.0, there are two types of bindings, general bindings and application specific bindings.

There are two types of general bindings, general service provider bindings and general service client bindings. You can configure one or more general service provider bindings and one or more general service client bindings across a range of policy sets. Additionally, you can re-use these general bindings across applications and for trust service attachments. To define and manage general bindings, in the administrative console click **Services > Policy sets > General provider policy set bindings** or **Services > Policy sets > General client policy set bindings**. The general service provider and client bindings have independent settings that you can customize to meet the needs of your environment. To learn more about general bindings, read about defining and managing policy set bindings.

You can create application specific bindings when you attach a policy set to an application resource. These bindings are specific to and defined to the characteristics of the policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets. To assign application specific bindings to an application for service providers, in the administrative console click **Applications > Applications Types > WebSphere**

enterprise applications > *application_name*> **Service provider policy sets and bindings > Assign Binding > New Application Specific Binding**. To assign application specific bindings to an application for service clients, in the administrative console click **Applications > Applications Types > WebSphere enterprise applications >** *application_name*> **Service client policy sets and bindings > Assign Binding > New Application Specific Binding**.

Default policy set bindings for servers

Note: In WebSphere Application Server Version 7.0, the security model is enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default cell (global security) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0, you can configure one or more general service provider bindings and one or more general service client bindings.

General service provider and client bindings are not linked to a particular policy set, and they provide configuration information that you can reuse across multiple applications. You can create and manage general provider and client policy set bindings and then select one of each binding to use as the default for an application server. Setting the server default bindings is useful if you want the services that are deployed to a server to share binding configuration. You can also accomplish this sharing of binding configuration by assigning the binding to each application deployed to the server or by assigning a security domain with a default binding to your server.

You can specify default bindings for your service provider or client that are used at the cell (global security) level, for a security domain, or for a particular server. The default bindings are used in the absence of an overriding binding specified at a lower scope. The application server uses the following order of precedence, from lowest to highest, when determining which default bindings to use:

1. Server level default
2. Security domain level default
3. Cell (global security) default

The general bindings that are provided with the product are initially set as the cell (global security) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. If you do not want to use the provided **Provider sample** as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided **Client sample** as the default service client binding, you can select an existing general client binding or create a new general client binding. To specify a cell (global security) default bindings, in the administrative console click **Services > Policy sets > Default policy set bindings**. For environments with multiple security domains, you can optionally choose the general provider and general client bindings that you want to use as the default bindings for a domain. To learn more about default policy set bindings for the cell (global security), see the default policy set bindings documentation.

In addition to choosing default bindings for the cell (global security), you can also choose the general provider and general client bindings that you want to use as the default bindings for a server. Use this page to choose the default bindings for a server from the administrative console. Click **Servers > Server Types > WebSphere application servers >** *server_name* and then from Security, click **Default policy set bindings**. If you do not choose a general binding as the default for a server, the default bindings for the domain in which the server resides is used. If you do not choose a binding as the default for a domain, the default bindings for the cell (global security) is used. You must choose a default service provider and default service client bindings for the cell. The general bindings that are included with the product are initially set as the cell (global security) default bindings. You cannot delete a binding that has been

selected as the default binding for server, a domain, or the cell. Before you delete the binding, you must select a different binding as the default or choose to use the defaults for the cell (global security).

Note:

If you have an application that contains one or more application specific bindings that are configured at the WebSphere Application Server V6.1 level, this application is a V6.1 application. If you have applications that are deployed to Version 6.1 servers within the Version 7.0 application server environment or you have V6.1 applications that are deployed to V7.0 application servers, you can specify Version 6.1 default policy set bindings for the cell. These bindings are used for both client and provider policy set attachments within V6.1 applications and attachments to service applications that are deployed to a V6.1 server. Additionally, these default bindings are used for V6.1 attachments unless they are overridden at the attachment point by an application specific binding or a V6.1 server default binding. You can upgrade V6.1 bindings to WebSphere Application Server V7.0 bindings for by using the upgradeBindings command using the wsadmin tool, if the V6.1 application is not installed on WebSphere Application Server V6.1.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Server default provider binding:

Specifies the default server binding. Select the name of the binding you want to use as the default for service providers deployed to this server.

If you are using multiple security domains, the name of the security domain to which the binding is scoped is specified with the name of the server default provider binding. Only bindings that are scoped to global security or to the security domain to which the server is assigned are available in the list.

Note: It is a best practice to specify a default binding that includes all of the policy types. This practice ensures that your default service provider binding has the necessary configuration for all policy types that you want to use.

Server default client binding:

Specifies the default client binding. Select the name of the binding you want to use as the default for service clients deployed to this server.

If you are using multiple security domains, the name of the security domain to which the binding is scoped is specified with the name of the server default client binding. Only bindings that are scoped to global security or to the security domain to which the server is assigned are available in the list.

Note: It is a best practice to specify a default binding that includes all of the policy types. This practice ensures that your default service client binding has the necessary configuration for all policy types that you want to use.

Version 6.1 default bindings:

If you have a Version 6.1 application that you want to use in the Version 7.0 application server environment and you want to specify Version 6.1 default bindings for this server, you can click this link to specify Version 6.1 default bindings.

Server Version 6.1 default policy set bindings:

Use this page to specify the server Version 6.1 default policy set bindings for this server. These default bindings are used for client and provider policy set attachments for applications that are deployed to Version 6.1 servers, and for Version 6.1 applications that are deployed to Version 7.0 servers. The default bindings are used for Version 6.1 attachments unless overridden at the attachment point.

To view this administrative console page, complete the following actions:

1. Click **Servers > Server Types > WebSphere application servers >** ***server_name***
2. Under Security, click **Default policy set bindings**
3. Click **Version 6.1 default policy set bindings**

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Version 6.1 default policy set bindings

You can install a WebSphere Application Server Version 6.1 Feature Pack for Web Services application within the WebSphere Application Server Version 7.0 environment. If your application contains Version 6.1 custom bindings, the application is defined as a Version 6.1 application to the application server. Additionally, if your application is installed on a WebSphere Application Server Version 6.1 Feature Pack for Web Services server within the WebSphere Application Server Version 7.0 environment, the custom binding is created as a Version 6.1 custom binding.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Bindings configuration name:

Specifies the name of the policy set bindings configuration. This field is read-only for default policy set bindings.

Button	Resulting action
Add	Adds a policy to the collection.
Delete	Removes a policy from the collection.

Setting default policy set bindings

You can set provider and client default policy set bindings that are used as the global security default policy set bindings. The specified global security default bindings apply to all Web services unless the bindings are overridden at the attachment point, at the server, or at a security domain.

Before you begin

You must first install and configure an application server. After the application server is installed, you must install a Java API for XML-Based Web Services (JAX-WS) application onto your server. Now, you are ready to attach a policy set to the Web service application. You can define and manage general service provider and client policy set bindings for your Web service resource by using the administrative console.

About this task

Policy set bindings for servers

After you understand policy set bindings, then it is easier to understand how the default bindings are used.

Policy set bindings contain platform-specific information, such as keystore, authentication information or persistent information that is required by a policy set attachment. A policy set attachment is a policy set

that is attached to an application resource. In WebSphere Application Server Version 7.0, there are two types of bindings, general bindings and application specific bindings.

There are two types of general bindings, *general service provider bindings* and *general service client bindings*. You can configure one or more general service provider bindings and one or more general service client bindings and then use them across a range of policy sets. Additionally, you can re-use these general bindings across applications and for trust service attachments. To define and manage general bindings, in the administrative console click **Services > Policy sets > General provider policy set bindings** or **Services > Policy sets > General client policy set bindings**. The general service provider and client bindings have independent settings that you can customize to meet the needs of your environment.

You can create *application specific bindings* when you attach a policy set to a Web service application resource. These bindings are specific to and defined by to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets. To assign application specific bindings to an application for service providers, in the administrative console click **Applications > Applications Types > WebSphere enterprise applications > *application_name* > Service provider policy sets and bindings**. Select a Web service resource with an attached policy and click **Assign Binding > New Application Specific Binding**. To assign application specific bindings to an application for service clients, in the administrative console click **Applications > Applications Types > WebSphere enterprise applications > *application_name* > Service client policy sets and bindings** . Select a Web services resource with an attached policy and click **Assign Binding > New Application Specific Binding**. You can additionally assign application specific bindings for service providers or service clients using the administrative console and click **Services > Service providers > *application_name*** or **Services > Service clients > *application_name*** and then select a Web services resource with an attached policy and assign your bindings.

To learn more about general bindings or application specific bindings, read about defining and managing policy set bindings.

Default policy set bindings

Note: In WebSphere Application Server Version 7.0, the security model is enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general bindings that are used as the default for an application server or a security domain.

General service provider and client bindings are not linked to a particular policy set, and they provide configuration information that you can reuse across multiple applications. You can create and manage general provider and client policy set bindings and then select one of each binding type to use as the default for an application server. Setting the server default bindings is useful if you want the services that are deployed to a server to share binding configuration. You can also share binding configuration by either assigning the binding to each application that is deployed to the server or by setting default bindings for a security domain and assigning the security domain to one or more servers.

You can specify default bindings for your service provider or client that are used at the global security (cell) level, for a security domain, for a particular server. The default bindings are used in the absence of an overriding binding specified at a lower scope. The following list is the order of precedence from lowest to highest that the application server uses to determine which default bindings to use:

1. Server level default
2. Security domain level default
3. Global security (cell) default

The sample general bindings that are provided with the product are initially set as the global security (cell) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. For trust service attachments, the default bindings are used when no trust specific bindings are assigned. If you do not want to use the provided **Provider sample** as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided **Client sample** as the default service client binding, you can select an existing general client binding or create a new general client binding. To specify your global security (cell) default bindings, in the administrative console click **Services > Policy sets > Default policy set bindings**. For environments with multiple security domains, you can optionally choose the general provider and general client bindings that you want to use as the default bindings for a domain.

In addition to choosing default bindings for the global security (cell), you can also choose the general provider and general client bindings that you want to use as the default bindings for a server. This is only necessary if you want to use different default bindings for a particular server than those used by the other servers in the security domain or cell. To choose the default bindings for a server from the administrative console, click **Servers > Server Types > WebSphere application servers >** *server_name* and then from Security, click **Default policy set bindings**. If you do not choose a general binding as the default for a server, the default bindings for the domain in which the server resides is used. If you do not choose a binding as the default for a domain, the default bindings for the global security (cell) are used. You must choose a default service provider and default service client bindings for the cell. The general bindings that are included with the product are initially set as the global security (cell) default bindings. You cannot delete a binding that is used as part of any policy set attachment or specified as the default binding for the server, a domain, or the cell. To learn more about defining default bindings for a server, see the server default bindings documentation.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

1. Open the administrative console.
2. To set global security default policy set bindings, select **Services > Policy sets > Default policy set bindings**.
3. Select the default service provider binding. The default service provider binding is used as the default for policy set attachments unless the provider or client binding is overridden at the attachment point, at the server, or at a security domain. The default setting is **Provider sample**.
4. Select the default service client binding. If you specify a default service client binding, the selected binding overrides the default bindings that are specified for the cell or the security domain to which the server is deployed. The default setting is **Client sample**.
5. If multiple security domains are enabled, you can view the default provider bindings and the default client bindings for each security domain that is defined in the security domain default bindings collection. You can select the security domain name link if you want to access the domain and select different default bindings. Additionally, you can select the default provider binding links or the default client binding links to access the default bindings and select different default binding settings.
6. Click **Apply** to apply selected bindings as the global default bindings.
7. Click **Save** to save your changes to the master configuration.
8. (optional) If you are using a Version 6.1 application, you can specify server V6.1 default policy set bindings. To set these bindings, select **Services > Policy sets > Default policy set bindings > Version 6.1 default policy set bindings**.

Note:

If you have an application that contains one or more application specific bindings that are configured at the WebSphere Application Server V6.1 level, this application is a V6.1 application. If you have applications that are deployed to Version 6.1 servers within the Version 7.0 application server environment or you have V6.1 applications that are deployed to V7.0 application servers, you can specify Version 6.1 default policy set bindings for the cell. These bindings are used for both client and provider policy set attachments within V6.1 applications and attachments to service applications that are deployed to a V6.1 server. Additionally, these default bindings are used for V6.1 attachments unless they are overridden at the attachment point by an application specific binding or a V6.1 server default binding. You can upgrade V6.1 bindings to WebSphere Application Server V7.0 bindings for by using the upgradeBindings command using the wsadmin tool, if the V6.1 application is not installed on WebSphere Application Server V6.1.

Results

When you complete these steps, you have defined your global security (cell) default policy set bindings and domain default policy set bindings, if applicable.

Example

Suppose that you do not want to use the provided general provider binding, **Provider sample**, as your default service provider binding. To take advantage of existing bindings, you can copy and modify the **Provider sample** to meet your business needs. This example assumes that your server environment has SecurityDomain1 and SecurityDomain2 defined.

1. Copy and modify the provided **Provider sample** general service provider binding. Click **Services > Policy sets > General provider policy set bindings**. Select **Provider sample > copy**. Name the new general provider binding, MyServiceProviderbinding, and provide a description for the new binding.
2. Copy and modify the provided **Client sample** general service client binding. Click **Services > Policy sets > General client policy set bindings**. Select **Client sample > copy**. Name the new general client binding, MyServiceClientbinding, and provide a description for the new binding.
3. To specify the default policy set bindings for your global security (cell) and for your domains, click **Services > Policy sets > Default policy set bindings**. From this page, select MyServiceProviderbinding as the default service provider binding, and select MyClientProviderbinding as the default service client binding.
4. Click **Apply** and **Save** to save your changes to the master configuration.

Assigning a domain default binding is optional. Generally, you assign domain default policy set bindings only when you want the servers in the domain to use different default bindings than the rest of the cell. In this example, suppose you have defined another general provider binding, MyServiceProviderbinding2, and you want to specify this binding as the domain default binding for your SecurityDomain1 domain.

1. From the security domain default bindings collection click **SecurityDomain1 > Default policy set bindings**. From this page, you can select MyServiceProviderbinding2 as the service provider domain default binding.
2. Click **Apply** and **Save** to save your changes to the master configuration.

Related tasks

“Managing policy sets using the administrative console” on page 803
You can use policy sets, or assertions that define services, to simplify your Web services configuration because policy sets group security and other Web services settings into reusable units. You can use the administrative console to create, modify, and delete custom policy sets.

“Server default binding settings” on page 843
Use this page to specify the server default bindings if you want to override the default bindings that are specified for the cell (global security) or the security domain to which the server is deployed.

“Setting server default bindings for policy sets” on page 839
You can set server default bindings if you want the policy set attachments for service providers and clients that are deployed to the server to use bindings that are different than those that are specified for the cell. If you use multiple security domains, your default server bindings will also override the security domain default bindings.

Administrative roles
The Java Platform, Enterprise Edition (Java EE) role-based authorization concept is extended to protect the WebSphere Application Server administrative subsystem.

Default policy set bindings collection:

Use this page to specify the service provider and client default bindings. The specified service provider and client bindings are used at the cell (global security) level unless these specified bindings are overridden at the attachment point, at the server, or at a security domain.

To view this administrative console page, click **Services > Policy sets > Default policy set bindings**.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Policy set bindings for servers

To understand default policy set bindings, it is important to first understand policy set bindings.

Policy set bindings contain platform-specific information, such as keystore, authentication information or persistent information that is required by a policy set attachment. A policy set attachment is a policy set that is attached to an application resource. In WebSphere Application Server Version 7.0, there are two types of bindings, general bindings and application specific bindings.

There are two types of general bindings, general service provider bindings and general service client bindings. You can configure one or more general service provider bindings and one or more general service client bindings across a range of policy sets. Additionally, you can re-use these general bindings across applications and for trust service attachments. To define and manage general bindings, in the administrative console click **Services > Policy sets > General provider policy set bindings** or **Services > Policy sets > General client policy set bindings**. The general service provider and client bindings have independent settings that you can customize to meet the needs of your environment. To learn more about general bindings, read about defining and managing policy set bindings.

You can create application specific bindings when you attach a policy set to an application resource. These bindings are specific to and defined to the characteristics of the policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets. To assign application specific bindings to an application for service providers, in the administrative console click **Applications > Applications Types > WebSphere enterprise applications >** *application_name*> **Service provider policy sets and bindings > Assign Binding > New Application Specific Binding**. To assign application specific bindings to an application for

service clients, in the administrative console click **Applications > Applications Types > WebSphere enterprise applications >** *application_name*> **Service client policy sets and bindings > Assign Binding > New Application Specific Binding**.

Default policy set bindings for servers

Note: In WebSphere Application Server Version 7.0, the security model is enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default cell (global security) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0, you can configure one or more general service provider bindings and one or more general service client bindings.

General service provider and client bindings are not linked to a particular policy set, and they provide configuration information that you can reuse across multiple applications. You can create and manage general provider and client policy set bindings and then select one of each binding to use as the default for an application server. Setting the server default bindings is useful if you want the services that are deployed to a server to share binding configuration. You can also accomplish this sharing of binding configuration by assigning the binding to each application deployed to the server or by assigning a security domain with a default binding to your server.

You can specify default bindings for your service provider or client that are used at the cell (global security) level, for a security domain, or for a particular server. The default bindings are used in the absence of an overriding binding specified at a lower scope. The application server uses the following order of precedence, from lowest to highest, when determining which default bindings to use:

1. Server level default
2. Security domain level default
3. Cell (global security) default

The general bindings that are provided with the product are initially set as the cell (global security) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. If you do not want to use the provided **Provider sample** as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided **Client sample** as the default service client binding, you can select an existing general client binding or create a new general client binding. To specify a cell (global security) default bindings, in the administrative console click **Services > Policy sets > Default policy set bindings**. For environments with multiple security domains, you can optionally choose the general provider and general client bindings that you want to use as the default bindings for a domain. To learn more about default policy set bindings for the cell (global security), see the default policy set bindings documentation.

In addition to choosing default bindings for the cell (global security), you can also choose the general provider and general client bindings that you want to use as the default bindings for a server. Use this page to choose the default bindings for a server from the administrative console. Click **Servers > Server Types > WebSphere application servers >** *server_name* and then from Security, click **Default policy set bindings**. If you do not choose a general binding as the default for a server, the default bindings for the domain in which the server resides is used. If you do not choose a binding as the default for a domain, the default bindings for the cell (global security) is used. You must choose a default service provider and default service client bindings for the cell. The general bindings that are included with the product are initially set as the cell (global security) default bindings. You cannot delete a binding that has been selected as the default binding for server, a domain, or the cell. Before you delete the binding, you must select a different binding as the default or choose to use the defaults for the cell (global security).

Note:

If you have an application that contains one or more application specific bindings that are configured at the WebSphere Application Server V6.1 level, this application is a V6.1 application. If you have applications that are deployed to Version 6.1 servers within the Version 7.0 application server environment or you have V6.1 applications that are deployed to V7.0 application servers, you can specify Version 6.1 default policy set bindings for the cell. These bindings are used for both client and provider policy set attachments within V6.1 applications and attachments to service applications that are deployed to a V6.1 server. Additionally, these default bindings are used for V6.1 attachments unless they are overridden at the attachment point by an application specific binding or a V6.1 server default binding. You can upgrade V6.1 bindings to WebSphere Application Server V7.0 bindings for by using the upgradeBindings command using the wsadmin tool, if the V6.1 application is not installed on WebSphere Application Server V6.1.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Default service provider binding:

Specifies the default service provider binding that is used as the default for policy set attachments. You can override this default at the attachment point or by a lower level default.

Note: It is a best practice to specify a default binding that includes all of the policy types. This practice ensures that your default service provider binding has the necessary configuration for all policy types that you want to use..

Default service client binding:

Specifies the default service client binding that is used as the default for policy set attachments. You can override this default at the attachment point or by a lower level default.

Note: It is a best practice to specify a default binding that includes all of the policy types. This practice ensures that your default service client binding has the necessary configuration for all policy types that you want to use.

Security domain default bindings:

Specifies a collection of security domain default bindings. This collection only displays if you are using multiple security domains.

If you are using multiple security domains, this collection displays the default client and provider bindings for each security domain. You can select the security domain name link if you want to access the domain and select different default bindings.

Security domain:

Specifies the name of a security domain.

Default provider binding:

Specifies the default service provider binding for the security domain. You can view the default provider binding settings by clicking on the name of default provider binding.

Default client Binding:

Specifies the default client binding for the security domain. You can view the default client binding settings by clicking on the name of default client binding.

Version 6.1 default bindings:

If you have a Version 6.1 application that you want to use in the Version 7.0 application server environment and you want to specify Version 6.1 default bindings for this server, you can click this link to specify Version 6.1 default bindings.

Version 6.1 default policy set bindings:

Use this page to specify Version 6.1 default policy set bindings for the cell (global security). These bindings are used for both client and provider policy set attachments within Version 6.1 applications and attachments to service applications that are deployed to a Version 6.1 server. These default bindings are used for Version 6.1 attachments unless they are overridden at the attachment point or by a Version 6.1 server default binding.

To view this administrative console page when you are specifying Version 6.1 cell level default policy set bindings, complete the following actions:

1. Click **Services > Policy sets > Default policy set bindings**
2. Click **Version 6.1 default policy set bindings**

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Version 6.1 default policy set bindings

You can install a WebSphere Application Server Version 6.1 Feature Pack for Web Services application within the WebSphere Application Server Version 7.0 environment. If your application contains Version 6.1 custom bindings, the application is defined as a V6.1 application to the application server. Additionally, if your application is installed on a WebSphere Application Server Version 6.1 Feature Pack for Web Services server within the WebSphere Application Server Version 7.0 environment, the custom binding is created as a V6.1 custom binding.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Bindings configuration name:

Specifies the name of the policy set bindings configuration. This field is read-only for default policy set bindings.

Policies – HTTP transport:

Links to the HTTP transport policy settings page where you define the HTTP transport settings. The HTTP features and HTTP connection polices are applied to outbound messages. The response listener policy is enforced on inbound messages.

Policies – SSL transport:

Links to the SSL transport policy configuration settings page where you define the SSL transport settings.

Policies – WS-Addressing:

Links to the configuration settings page for the WS-Addressing policy. In a network deployment environment, use this page to enable or disable workload management. Otherwise, you can attach the WS-Addressing policy set to service resources. No additional configuration is required.

Policies – WS-ReliableMessaging:

Links to the page where you configure the WS-ReliableMessaging bindings.

Policies – WS-Security:

Links to the WS-Security policy set bindings settings page where the WS-Security binding are configured.

Domain default bindings settings:

Use this page to specify the default policy set bindings for this security domain.

To view this administrative console page, complete the following actions:
1. Click **Security domains >** *domain_name*
2. From Web Services Bindings, click **Default policy set bindings**

Alternatively, you can view this administrative console page when multiple security domains are defined:
1. Click **Services > Policy sets > Default policy set bindings>*domain_name***
2. In the Security Domain Default Bindings collection, click *domain_name*
3. From Web Services Bindings, click **Default policy set bindings**

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Domain default provider binding:

Specifies the default provider binding for a specific security domain. You can specify `None` if you want to use the server or global default bindings for services deployed to this server. If you specify a server default binding, this binding takes precedence over the default bindings that are specified for the security domain to which the server is deployed. The name of the security domain to which each binding is scoped is displayed to the right of the name of the binding.

Note: It is a best practice to specify a binding that includes all of the policy types. This practice ensures that your default service provider binding has the necessary configuration for all policy types that you want to use.

Domain default client binding:

Specifies the default client binding for a specific security domain. You can specify `None` if you want to use the server or global default bindings for services deployed to this server. If you specify a server default binding, this binding will take precedence over the default bindings specified for the security domain to which the server is deployed. The name of the security domain to which each binding is scoped is displayed to the right of the name of the binding.

Note: It is a best practice to specify a binding that includes all of the policy types. This practice will ensure that your default client binding has the necessary configuration for all policy types that you want to use.

Modifying default bindings at the server level for policy sets

You can define default bindings for HTTP transport, JMS transport, Secure Sockets Layer (SSL) transport, WS-Addressing, WS-ReliableMessaging, and WS-Security policies.

Before you begin

To create or modify server default bindings, you must first install and configure an application server.

About this task

You can modify default cell bindings that are delivered with the product. Default bindings are not linked to a particular policy set and they provide default settings that might be used for sharing configuration information across multiple applications.

You can create default bindings for individual application servers and customize those bindings to meet your requirements. The policy set bindings are optional. If a policy set binding is not defined at the server level, then the default cell level bindings are used. To modify these default bindings, complete the following steps:

1. Open the administrative console.
2. To see which bindings are defined as the defaults for the cell or server, click **Services > Policy sets > Default policy sets bindings**.

   After seeing which bindings are defaults, you can select and edit them from the General provider or General client policy set bindings pages.
3. To edit the default bindings, see “Setting default policy set bindings” on page 846.

Results

When you finish these steps, the default policy set bindings are modified. If you created default bindings at the server level, those default bindings are used instead of the default bindings at the cell level.

What to do next

You can create application specific bindings for your policy sets. Read about creating application specific bindings for policy set attachments.

Related tasks

"Creating application specific bindings for policy set attachment" on page 838
After you attach a policy set to a service artifact such as an application, service, or endpoint, you can define application specific bindings for the attached policy set.

"Reassigning bindings to policy sets"
After you create a custom attachment binding, you can reassign that binding to another service artifact if necessary. You can reset a service artifact, such as an application, service, or endpoint to use the inherited bindings or default bindings.

Related reference

"Version 6.1 default policy set bindings" on page 853
Use this page to specify Version 6.1 default policy set bindings for the cell (global security). These bindings are used for both client and provider policy set attachments within Version 6.1 applications and attachments to service applications that are deployed to a Version 6.1 server. These default bindings are used for Version 6.1 attachments unless they are overridden at the attachment point or by a Version 6.1 server default binding.

"Default policy set bindings collection" on page 850
Use this page to specify the service provider and client default bindings. The specified service provider and client bindings are used at the cell (global security) level unless these specified bindings are overridden at the attachment point, at the server, or at a security domain.

Reassigning bindings to policy sets

After you create a custom attachment binding, you can reassign that binding to another service artifact if necessary. You can reset a service artifact, such as an application, service, or endpoint to use the inherited bindings or default bindings.

Before you begin

To reassign a application specific binding or a default binding, there must be an assigned binding for the service artifact.

About this task

You can assign bindings to policy sets and other service artifacts. If you created a policy set and attached it to a service artifact, you can reassign the binding that was initially assigned to that policy set.

1. Open the administrative console.
2. To reassign a binding for your service provider, click **Applications > Application Types > WebSphere enterprise applications*application_name*** > **Service provider policy sets and bindings**.

   To reassign a binding for your service client, click **Applications > Application Types > WebSphere enterprise applications*application_name*** > **Service client policy sets and bindings**.
3. Select the check box for the service artifact with an attachment binding.
4. Select **Assign Binding**.
5. Select the binding that you want to assign.
6. Click **Save**, to save your changes to the master configuration.

Results

The service artifact now inherits the policy set bindings that are indicated in either the **Service provider policy sets and bindings** or **Service client policy sets and bindings** panel.

Note: Reassigning the binding for a service artifact only reassigns it for that service artifact and any inherited artifacts. It does not reassign the binding for other non-related and non-inherited attachments to the same policy set or to a different policy set.

Example

If you have the application, `app1` with an attached policy set `Username WSSecurity default`, and you want to define custom bindings, then perform the following steps:

1. Locate the application in the **Applications > Application Types > WebSphere enterprise applications*application_name*** collection.
2. Click the **app1** application.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** link.
4. Select the check box for the**app1** application where the custom attachment binding is defined.
5. Click **Assign Binding** and select **New**.
6. Provide a name for the application specific bindings.
7. Add required policies to the new application specific bindings.
8. Configure the bindings.
9. Click **Save**, to save your changes to the master configuration.

What to do next

Restart the application that contains the policy set where you reassigned the bindings.

Related tasks

"Creating application specific bindings for policy set attachment" on page 838
After you attach a policy set to a service artifact such as an application, service, or endpoint, you can define application specific bindings for the attached policy set.

Transformation of policy and binding assertions for WSDL

Web Services security does not fully support the OASIS WS-SecurityPolicy Version 1.2 standard. However, several of the policy and binding assertions supported by WebSphere Application Server can be transformed and represented as WS-SecurityPolicy Version 1.2 assertions. The supported assertions are transformed when a Web Services Description Language (WSDL) or Web Services MetadataExhange (WS-MEX) request is received in a message, and also when the client receives a policy containing WS-SecurityPolicy 1.2 assertions.

When the WebSphere Application Server receives a WSDL or WS-MEX request, some policy and binding assertions are transformed into standard assertions and included in the policy that is embedded into the WSDL. In addition, when the client receives a policy containing these WS-SecurityPolicy assertions, the assertions are transformed back into product-specific assertions so that the Application Server run time can process them. This transformation provides interoperability between Application Server and other systems that support the WS-SecurityPolicy version 1.2 standard.

The following WS-SecurityPolicy 1.2 assertions can be represented in the policy returned on WSDL, or a WS-MEX request.

EncryptSignature
: Represented in the product using XPath expressions in the encrypted elements.

EncryptBeforeSigning
: The order attribute of the encryptionInfo and signingInfo elements on the outbound section of the bindings determines the order in which the transform takes place, and whether this assertion is set. The default behavior is to sign before encrypting.

ContentEncryptedElements
: Represented using XPath expressions ending with /node() in the encrypted elements. The Application Server can consume this policy assertion, but existing XPath expressions that end with /node() are not transformed.

KerberosToken

Represented using the custom token in the policy and bindings. The Kerberos custom token assertion specifies a local name of http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ, or http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ, depending on the desired Kerberos token type. Also, there is a custom property in the bindings, com.ibm.wsspi.wssecurity.krbtoken.requireDerivedKey, which specifies use of derived keys for Kerberos. Using the local name of the custom token, along with the derived key custom property from the product representation, an equivalent Version 1.2 representation can be created.

Require*<variable>***Reference, where** *<variable>* **is one of the following: KeyIdentifier, IssuerSerial, EmbeddedToken, or Thumbprint**

Rrepresented using the type attribute on keyInfo in the bindings.

MustSupportRef*<variable>***, where** *<variable>* **is one of the following: KeyIdentifier, IssuerSerial, EmbeddedToken, or Thumbprint**

This assertion is not represented in the WebSphere Application Server policies, but the product supports all four types of references.

Protection of the SignatureConfirmation element

The SignatureConfirmation element is implicitly signed and encrypted. However, if nothing is encrypted on the response, then the SignatureConfirmation element is not encrypted, and if nothing is signed on the response, then the SignatureConfirmation element is not signed. All XPath expressions representing the signing or encryption of the SignatureConfirmation element are removed from the policy during transformation. The explicitlyProtectSignatureConfirmation attribute in the Web services security binding is provided to disable implicit signature and encryption of the SignatureConfirmation element on the response message. This provides interoperability with WebSphere Application Server Version 6.1.x. To add the attribute, check the option **Disable implicit protection for Signature Confirmation** in the Authentication and protection panel for the default policy set bindings. If the explicitlyProtectSignatureConfirmation attribute is present in the binding, all XPath expressions representing the signing or encryption of the SignatureConfirmation element remain unchanged during transformation.

SC13SecurityContextToken

Version 1.3 of the Security Context Token is supported by specifying the local name http://docs.oasis-open.org/ws-sx/ws-secureconversation/200512, in the binding for the security context token.

RequireImpliedDerivedKeys

This is supported by adding the custom property, com.ibm.ws.wssecurity.token.generateImpliedDerivedKey, in the token generator bindings.

ExactlyOne

This assertion is transformed when callers are used. Callers specify which token to use for authentication. The ExactlyOne assertion communicates the caller tokens that the service expects. All caller options are enclosed inside the <ExactlyOne> assertion, and each option is enclosed inside the <wsp:All> assertion. As the name implies, the client sends only one of the token types. For example, in the server side bindings, using the product representation, the following caller options are specified:

```
<caller order="1">
       <jAASConfig configName="system.wss.caller"/>
       <callerIdentity uri="" localName="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken"/>
</caller>
<caller order="2">
       <jAASConfig configName="system.wss.caller"/>
       <callerIdentity localName="LTPA" uri="http://www.ibm.com/websphere/appserver/tokentype/5.0.2" />
</caller>
```

This assertion indicates that a UsernameToken token or an LTPA token is used as the caller. The requirement to use one of these two types of tokens is communicated to the client in the transformed policy, as in the following example:

```
<sp:ExactlyOne>
<wsp:All>
<sp:SupportingTokens>
   <wsp:Policy wsu:Id="request:token_auth">
     <sp:UsernameToken sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200512/IncludeToken/AlwaysToRecipient">
       <wsp:Policy>
         <sp:WssUsernameToken10 />
       </wsp:Policy>
     </sp:UsernameToken>
 </wsp:Policy>
</sp:SupportingTokens>
</wsp:All>
<wsp:All>
<sp:SupportingTokens>
<wsp:Policy wsu:Id="request:token_auth">
     <spe:LTPAToken sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200512/IncludeToken/AlwaysToRecipient" />
</wsp:Policy>
 </sp:SupportingTokens>
<wsp:All>
</sp:ExactlyOne>
```

The product-specific policy assertions LTPAToken and LTPAPropagationToken are not altered during transformation. These assertions are included in the embedded policy in the WSDL if they are present in the policy being transformed. This allows a WebSphere Application Server client and WebSphere Application Server service provider to interoperate.

Related concepts

"WSDL" on page 338
Web Services Description Language (WSDL) is an Extensible Markup Language (XML)-based description language. This language was submitted to the World-Wide Web Consortium (W3C) as the industry standard for describing Web services. The power of WSDL is derived from two main architectural principles: the ability to describe a set of business operations and the ability to separate the description into two basic units. These units are a description of the operations and the details of how the operation and the information associated with it are packaged.

Use the links on this page to configure authentication, signature, and encryption information that the policy requires when using general bindings.

Configuring the callers for general and default bindings

The caller specifies the token or message part that is used for authentication.

Before you begin

Before you can complete this task, you must create a new policy set and attach it to a service, or copy and edit one of the sample system policy sets. For more information, read the topics Creating policy sets using the administrative console and Attaching a policy set to a service artifact.

About this task

The caller is used to indicate which of the tokens on the incoming message is the caller of the request. This information is used to create authentication credentials. You can use the WebSphere Application Server administrative console to access, view and configure caller settings for tokens and message parts.

Note: WebSphere Application Server Version 7.0 provides support for multiple callers. The caller token used for authentication is the one with highest priority, based on decreasing order of preference. You can modify the order of the callers, as described in the topic Changing the order of the callers for a token or message part.

1. Create a new policy set and attach it to a service, or copy and edit a sample system policy set. Add the WS-Security policy, as described in the topic Creating policy sets using the administrative console.
2. Edit the general or default bindings for the WS-Security policy.

- To edit general provider bindings for WebSphere Application Server version 7.0, click **Services** → **Policy Sets** → **General Provider policy set bindings**. A caller is specified for the provider bindings only, not for the client bindings.
- To edit default bindings for WebSphere Application Server Version 6.x, click **Services** → **Policy Sets** → **Default policy set bindings**.

3. Navigate to the Callers panel by clicking on the **WS-Security** policy, then click the **Caller** link.
4. Click **New** to create a new caller.
5. Enter the Name and Caller identity local part information for the new caller. For more information, read about caller settings.
6. When you have finished entering the configuration information for the caller, click **Apply** to save the caller.
7. If this is the first caller created for the policy set, the caller is automatically assigned as the highest priority caller, with an order of 1 (one). If other callers are already defined, the new caller is added at the end of the ordered list and is automatically assigned the lowest priority. You can change the order of the callers using the Move up and Move down buttons.

Results

When assigning orders to callers for migrated bindings, the callers are initially displayed with no order attribute. You cannot save the bindings until you assign order attributes to all the callers. Use the **Move up** and **Move down** buttons to change the order of the callers until they are in the correct order.

Signing and encrypting message parts using policy sets

With Web services, you can sign message parts, encrypt message parts, or both, based on the quality of service defined for a policy set. You can accomplish these actions by defining the binding information in a custom attachment binding.

Before you begin

Before you begin this task, attach a policy set to a service artifact such as an application, service or endpoint and create a custom attachment binding. Read about creating custom attachment bindings for policy sets. The policy set that is attached to the service artifact must include a WS-Security policy that specifies message parts to be signed or encrypted. Read about securing message parts using the administrative console.

About this task

To sign message parts, encrypt message parts, or both, based on the quality of service defined for a policy set, perform the following steps:

1. Open the administrative console.
2. To sign and encrypt message parts for a service provider, click **Applications > Enterprise applications** > ***application_name*** > **Service provider policy sets and bindings**. To sign and encrypt message parts for a service client, click **Applications > Enterprise applications** > ***application_name*** > **Service client policy sets and bindings**.
3. Click the binding name link of the service artifact with a custom attachment binding.
4. If the binding does not contain WS-Security policy set bindings, then click **Add** and select **WS-Security** from the list.
5. Click **WS-Security** policy set bindings.
6. Click **Authentication and protection**. The resulting panel contains the following four tables:
   - Protection tokens: Specifies the tokens that are defined for the symmetric or asymmetric signature and encryption policies in the policy set.
   - Authentication tokens: Specifies the tokens that are defined for the request and response token policies.

- Request message signature and encryption protection: Specifies the message parts that are defined in the Request message part protection for the policy set.
- Response message signature and encryption protection: Specifies the message parts that are defined in the response message part protection in the policy set.

Initially, each table displays information that is generated based on the policy set which is attached to the service artifact. The possible configuration objects based on the policy set are displayed. The Status column indicates whether the object is currently configured in the custom attachment binding.

7. If the protection tokens have a status of **Not configured**, then create the protection tokens by clicking the default name, verifying the default values. Click **OK**.
8. [Optional] If you use the X.509 protection tokens, then you must configure the keystores and keys to be used to sign, verify, encrypt or decrypt message parts. You might need to also configure keystores and keys when using custom protection tokens, depending on the requirements of the custom tokens. When using a security context token for protection (secure conversation), you do not need to configure keystores or keys. If you need to configure the keystores and keys, then perform the following actions:
   a. Click the token name link.
   b. Click the **Callback handler** link under Additional bindings. If the Callback handler link is not click-able, click **Apply**, then click the **Callback handler** link.
   c. Either use a predefined keystore or custom keystore. To use a predefined keystore, select the keystore from the list. To use a custom keystore, select **Custom** from the list and click the **Custom key store configuration** link to specify the configuration.
   d. Click **OK**.
9. Click the name of the request or response message part reference to be signed or encrypted. The Protection column displays whether the message part is signed or encrypted based on the policy set.
10. Specify a name for the message part.
11. For encrypted parts, select the type of encryption from **Usage of key information references**. For asymmetric encryption, or X.509, select **Key encryption**. For symmetric encryption, or secure conversation, select **Data encryption**.
12. [Optional] For encrypted parts, select the **Include time stamp** or **Include nonce** options to include a time stamp or nonce in the encrypted message part. You can include one or both of these options in the encrypted message part.
13. For signed parts, specify one or more Message part references. Select a reference from the Available column and click **Add**.
14. [Optional] For signed parts, you can also choose to add a time stamp or nonce to the signed message part. Select a Message part reference from the Assigned column and click **Edit**. Select the **Include time stamp** or the **Include nonce** options to include a time stamp or nonce in the signed message part. You can select one or both of these options in the signed message part.
15. If there are no available key information entries, then create one using the following actions:
   a. Click **New**.
   b. Specify a name.
   c. Select a protection token from the Token generator or Consumer name list.
   d. Click **OK**.
16. Select a key information entry from the Available list and click **Add**.
17. [Optional] Specify custom properties if needed.
   a. To use Message Transmission Optimization Mechanism (MTOM) for the cipher text of the encrypted data, add the custom property, com.ibm.wsspi.wssecurity.enc.MTOM.Optimize, with value `true` to outbound encrypted parts for client requests or server responses.
   b. To use encryption headers as described in the WS-Security 1.0 specification instead of the encrypted header support described in WS-Security 1.1, add the custom property,

com.ibm.wsspi.wssecurity.encryptedHeader.generate.WSS1.0, with value `true` to outbound encrypted parts for client requests or server responses.

For Web Services Security Version 1.1 behavior that is equivalent to WebSphere Application Server versions prior to version 7.0, specify the com.ibm.wsspi.wssecurity.encryptedHeader.generate.WSS1.1.pre.V7 property with a value of true on the <encryptionInfo> element in the binding. When this property is specified, the <EncryptedHeader> element includes a wsu:Id parameter and the <EncryptedData> element omits the Id parameter. This property should only be used if compliance with Basic Security Profile 1.1 is not required.

18. Click **OK**.
19. Click **Save**, to save the changes to the master configuration.

Results

When you finish this task, the message parts are signed and encrypted, or both, based on the configuration used when communicating with the service artifact.

Example

You have an application, `app1`, with an attached policy set, RAMP default and a custom attachment binding, `myBinding`, and you want to sign and encrypt the message parts.

1. Click the `app1` application in the **Applications** > **Enterprise Applications** collection.
2. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** link.
3. Click the `myBinding` link.
4. [Optional] If WS-Security is not listed, then select **Add** > **WS-Security**.
5. Click the **WS-Security** link.
6. Click the **Authentication and protection** link.
7. In the Protection tokens table, click each of the four links and **OK** on the resulting panel. Each entry is now shown as **Configured** in the Status column.
8. In the Request message signature and encryption protection table, click **request:app_encparts**. Specify the name, `requestEncParts`.
9. Click **New** from Key information. Specify the name, `requestEncKeyInfo`.
10. Select **SymmetricBindingRecipientEncryptionToken**, and click **OK**.
11. Select **requestEncKeyinfo** in the Available list, and click **Add**. Click **OK**.
12. In the Request message signature and encryption protection table, click **request:app_signparts**.
13. Specify the name, `requestSignParts`.
14. Click **New** from Key information. Specify a name of `requestSignKeyInfo`.
15. Select **SymmetricBindingInitiatorSignatureToken**, and click **OK**.
16. Select **requestSignKeyinfo** in the Available list, and click **Add**. Click **OK**.
17. Repeat steps 8 to 16 for the links in the Response message signature and encryption protection table.
18. Click **Save**, to save the changes to the master configuration.

What to do next

Start the application.

Related tasks

“Attaching a policy set to a service artifact” on page 901
Attach a policy set to a service artifact, such as an application, service, or endpoint to define the quality of services that are supported. Policy sets can define the policies for WS-Addressing, WS-Security, WS-ReliableMessaging, WS-Transaction, HTTP transport, Java Messaging Service (JMS) transport, and Secure Sockets Layer (SSL) transport.

“Creating application specific bindings for policy set attachment” on page 838
After you attach a policy set to a service artifact such as an application, service, or endpoint, you can define application specific bindings for the attached policy set.

“Configuring the WS-Security policy” on page 933
When working with policy sets in the administrative console, you can customize policies to ensure message security. The WS-Security policy can be configured to apply a message security (WS-Security) profile to requests. Message security policies are applied to requests and enforced on responses to support interoperability.

“Securing message parts using the administrative console” on page 957
If you are working with policy sets, then you can secure message parts using the administrative console. To secure message parts with WS-Security using policy sets, you must define the elements for the message parts to be protected in the WS-Security policy within a policy set.

Signed or Encrypted message part settings:

Use this page to configure or create new signed or encrypted message parts. Message part bindings define how the part (which is defined in a policy set) is handled.

You can configure or create new signed or encrypted message parts when you are editing a default cell or server binding. You can also configure application specific bindings for tokens and message parts that are required by the policy set.

To view this administrative console page when you are editing a default cell binding, complete the following actions:

1. Click **Services > Policy sets > Default policy set bindings**.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Authentication and protection** link in the Main message security policy bindings section.
4. Select a signature or an encrypted message part in the Request message signature and encryption protection section or the Response message signature and encryption protection section.

To view this administrative console page when you are configuring application specific bindings for tokens and message parts that are required by the policy set, complete the following actions:

1. Click **Applications** → **Application Types** → **WebSphere enterprise applications**.
2. Select an application that contains Web services. The application must contain a service provider or a service client.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** in the Web Services Properties section.
4. Select a binding. You must have previously attached a policy set and assigned a application specific binding.
5. Click the **WS-Security** policy in the Policies table.
6. Click the **Authentication and protection** link in the Main message security policy bindings section.
7. Select a signature or an encrypted message part in the Request message signature and encryption protection section or the Response message signature and encryption protection section.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Name:

Specifies the name of the message part reference. The name field displays the name of the part reference you are editing, or you can enter a name if you are creating a message part reference.

Include time stamp:

This check box is available on this panel if you are configuring encryption protection and it specifies whether to include a time stamp. Select this check box to indicate that a time stamp is included or leave it unchecked to indicate that the time stamp is not included with the part reference.

For default bindings, to specify if a time stamp is included for signature protection, click the Signed part reference default link under the Additional bindings section.

For application specific bindings, to specify if a time stamp is included for signature protection, highlight an assigned signature message part reference and click **Edit**. The time stamp check box is located in the Reference section.

Include nonce:

This check box is available on this panel if you are configuring encryption protection and it specifies whether to include nonce. Select this check box to indicate that a nonce is to be used or leave it unchecked to indicate that nonce is not to be included with this part reference.

For default bindings, to specify if a nonce is included for signature protection, click the Signed part reference default link under the Additional bindings section.

For application specific bindings, to specify if a nonce is included for signature protection, highlight an assigned signature message part reference and click **Edit**. The nonce check box is located in the Reference section.

Usage of key information reference:

This field is available on this panel if you are configuring encryption protection and it specifies that the encryption key information is either data encryption key information or key encryption key information. Select **Data encryption** for symmetric algorithms and **Key encryption** for asymmetric algorithms.

Click one of the following radio buttons:

Data encryption
Indicates that the key information is used for data encryption.

Key encryption
Indicates that the key information is key encryption key information.

Key information (Request):

If you are configuring a request message signature or encryption protection, this field specifies the key information for a token request message part. This section provides interactive fields to assign the key information.

The **Available** field contains a listing of available key information entries for the message part. The **Assigned** field contains a listing of one or more of the key information entries that are assigned to the message part. Use the following actions to work with multiple request message part key information entries:

Button	Resulting action
Add >	Add the selected key information entry in the **Available** list to the **Assigned** list.
New...	Create a new key information entry.
< Remove	Remove the selected key information entry from the **Assigned** list.

Key information (Response):

If you are configuring a response message signature or a response encryption protection, this field specifies the key information for a token response message part. This field provides a menu used to assign the key information. You can only assign one key information entry for response message parts. The **New** button enables you to add a new key information entry to the menu for selection.

Custom properties – Name:

Specifies the name of the custom property to be used.

Custom properties are not initially displayed in this column. The following actions are available:

Button	Resulting Action
New	Creates a new custom property entry. To add a custom property, enter the name and value.
Edit	Specifies that you can edit the selected custom property. Select this action to provide input fields and create the listing of cell values for editing. The Edit button is not available until at least one custom property has been added.
Delete	Removes the selected custom property.

Custom properties – Value:

Specifies the value of the custom property to be used. With the Value entry field, you can edit, enter or delete the value for a custom property.

Additional bindings – Signed part reference default:

If you are configuring signature protection, this section is displayed on this panel. It links to a panel where you can configure part reference properties such as including a time stamp or nonce and transform algorithms. Part reference properties include the transform algorithms used to protect the message part.

Changing the order of the callers for a token or message part

Specifying a caller in default and general bindings indicates which token or tokens to use to create authentication credentials. When there are multiple tokens on an incoming message, the order of the callers determines which token is used for the credentials. You can rearrange the order of the callers using the administrative console.

Before you begin

Before you can complete this task, you must create a new policy set and attach it to a service, or copy and edit one of the sample system policy sets. For more information, read the topics Creating policy sets using the administrative console and Attaching a policy set to a service artifact. You can also create multiple new callers in the default provider bindings associated with the policy set, as described in the

topic Configuring the callers for general and default bindings

1. Edit the bindings for the policy by clicking **Services** → **Policy sets** → **General Provider policy set bindings**, then click on the name of the bindings. A caller is specified for the provider bindings only, not for the client bindings.
2. Navigate to the Callers panel by clicking on the policy name, then click the **Caller** link.
3. In the caller collection table, the callers are listed with the order of each caller displayed in the **Order** column. The order number indicates the order of preference in which the callers are used when multiple authentication tokens are received on an incoming message. Use the **Move up** and **Move down** buttons to change the order of the callers.
   a. To change the order of a caller to a higher priority, click the selection box next to the caller name, then click the **Move up** button. When a caller is moved up in priority, a caller that is above it will be moved down.
   b. To change the order of a caller to a lower priority, click the selection box next to the caller name, then click the **Move down** button.

Example

The order attribute is assigned only for callers on bindings in WebSphere Application Server Version 7.0. Bindings created with earlier versions of WebSphere Application server may have callers, but these callers do not have an order attribute. These callers can appear in the Callers collection table, but do not have an order number in the order column. If these bindings were migrated to Version 7.0, then order attributes must be assigned before saving and using these bindings. You can use the **Move up** and **Move down** buttons to assign orders to the callers.

Policy set bindings settings

Use this page to view or define general or application specific bindings configuration information that is specific to a system for policies that you can associate with the selected policy set. Use the links on this page to work with bindings for each specific policy.

To view this administrative console page when you are editing a general binding, click **Services > Policy sets > General provider policy set bindings** or **Services > Policy sets > General client policy set bindings**.

To view this administrative console page when you are creating or editing an application specific binding, complete the following actions:

1. Click **Applications > Application Types > WebSphere enterprise applications**.
2. Select an application that contains Web services. The application must contain a service provider or a service client.
3. Click **Service provider policy sets and bindings** or **Service client policy sets and bindings** in the Web Services Properties section.
4. Select a binding by clicking the binding name in the table if the binding has been assigned to an attachment. You must have previously attached a policy set and assigned an application specific binding.
5. [Optional] To edit a default cell binding or default server binding, click either**Services > Policy sets > General provider policy set bindings** or **Services > Policy sets > General client policy set bindings**.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

About Policy set bindings

Policy set bindings contain platform-specific information, like keystore, authentication information or persistent information, required by a policy set attachment. Each policy set attachment to a service provider or service client must have exactly one binding. When you create a policy set attachment, the

general default bindings are used initially. When general bindings are used in association with a policy set attachment, the cell-level general bindings are applied at run time. If application server level bindings exist, the server-level general bindings override the cell-level definition. General bindings specify configuration for both service client and service provider attachments and the general bindings are not tailored to a specific policy set or application. When you define server-level general bindings, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP Transport, that you want to override the general binding and you must fully configure the bindings for each policy that you have added.

An application specific binding is a named binding that you create. Application specific bindings enable you to provide platform-specific configuration information for specific policy set attachments. When you create an application specific binding, the available binding configuration options are tailored to the definitions in the attached policy set. You can reuse application specific bindings for multiple service resources within an application. For example, if you create a trust service specific binding, that binding can be reused only for trust service attachments. When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP Transport, that you want to override the general binding and you must fully configure the bindings for each policy that you have added.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Bindings configuration name:

Specifies the name of the policy set bindings configuration. The binding name is not editable when you are editing a binding. When you are creating a new binding, you must specify the binding name.

Note: If you are running a Version 6.1 application, the Binding configuration name is displayed as Version 6.1 default policy set bindings.

Use the following actions to create, edit, or delete policy set bindings.

Button	Resulting action
Add	Adds the selected policy set binding to the application.
Delete	Removes the selected policy set binding from the application.

Policies – HTTP transport:

Links to the HTTP transport policy configuration settings page where you define the HTTP transport settings. The HTTP features and HTTP connection polices are applied to outbound messages. The response listener policy is enforced on inbound messages.

Policies – SSL transport:

Links to the SSL transport policy configuration settings page where you define the SSL transport settings.

Policies – JMS transport:

Links to the JMS transport policy configuration settings page where you define the JMS transport settings.

Policies – WS-Addressing:

Links to the configuration settings page for the WS-Addressing policy. In a Network Deployment environment, use this page enable or disable workload management. Otherwise, you can attach the WS-Addressing policy set to service resources. No additional configuration is required.

Policies – WS-ReliableMessaging:

Links to the panel where the WS-ReliableMessaging bindings are configured.

Policies – WS-Security:

Links to the WS-Security policy set bindings settings page where the WS-Security bindings are configured.

Policy set bindings settings for WS-Security

Use this page to view, define or configure general bindings and application specific properties for the WS-Security policy. You can configure the main policy or the secure conversation bootstrap policy by editing the general bindings.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

To use this administrative console page to view the general default bindings, click **Services > Policy sets > Default policy set bindings**. You can use this navigation path for viewing only. To edit or configure the general default bindings, complete the following steps:

1. Navigate to the general bindings collection panel by clicking**Services > Policy sets > General client policy set bindings** or **Services > Policy sets > General provider policy set bindings** path.
2. Click a general binding in the Name column.
3. Click the **WS-Security** policy in the Policies table.

If you choose to use a sample binding that is provided in the product, you must edit the sample user name and password that are provided for the Username token and LTPA token. The values provided are only examples; to use them successfully, you must modify the values for your own environment. You can change the user ID and password for authentication using a scripting command or by editing a copy of the general binding.

The following configuration links are provided for both the main security policy and for secure conversation bootstrap policy bindings.

Authentication and protection:

Links to the collection of policy authentication and protection configuration settings. Click this link to access the collection of authentication and protection settings where you can configure authentication, signature, and encryption information that the policy requires.

Keys and certificates:

Links to the collection of WS-Security policy keys and certificates.

Caller:

Links to a panel to configure the caller settings. The caller specifies the token or message part that represents the identity to be set in the caller subject of the service.

The caller settings are available only for the service provider policy sets and bindings. The caller settings are not available for service client policy sets and bindings.

Message expiration:

Links to a panel to define settings for message expiration. When you enable message expiration, the message expires after the specified interval.

Custom properties:

Links to a panel where you can specify custom properties that apply to both inbound and outbound messages or specify properties that apply only to inbound or only to outbound messages.

Custom property settings:

Use this page to configure name-value pairs for custom binding properties, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. You can specify custom properties that apply to both inbound and outbound messages, or properties that apply only to inbound messages, or only to outbound messages.

To view this administrative console page, click **Applications** → **Application types** → **Websphere enterprise applications** → ***application name*** → **Service provider policy sets and bindings** → ***binding name*** → **WS-Security** → **Custom properties**.

Click **New** to create a new custom property, or click the check box for an existing property name. Click **Delete** to delete an existing property.

Name:

Specifies the name, or key, for the property.

Each property name must be unique. If the same name is used for multiple properties, the value specified for the first property that has that name is used.

Do not start your property names with `was.` because this prefix is reserved for properties that are predefined in the product.

Value:

Specifies the value paired with the specified name.

Keys and certificates

Use this page to link to key and certificate binding configuration panels. This panel defines key and certificate bindings for JAX-WS Web services only. These keys and certificates can be centrally managed by the product or in an external keystore.

You can define key and certificate bindings for message parts when you are editing a default cell or server binding. You can also configure application specific bindings for tokens and message parts that are required by the policy set.

To view this administrative console page when you are editing a default cell binding, complete the following actions:

1. Click **Services > Policy sets > General provider policy set bindings** (for provider bindings), or **Services > Policy sets > General client policy set bindings** (for client bindings).
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Keys and certificates** link in the Main message security policy bindings section.

To view this administrative console page when you are configuring application specific bindings for tokens and message parts that are required by the policy set, complete the following actions:

1. Click **Applications** → **Application Types** → **WebSphere enterprise applications**.

2. Select an application that contains Web services. The application must contain a service provider or a service client.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** in the Web Services Properties section.
4. Select a binding. You must have previously attached a policy set and assigned a application specific binding.
5. Click the **WS-Security** policy in the Policies table.
6. Click the **Keys and certificates** link in the Main message security policy bindings section.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Key information – Name:

Specifies the key information name. The key names listed in this field are links that are used to define key information attributes. Key information attributes define how cryptographic keys are generated or consumed.

Use the following buttons to work with this table:

Button	Resulting Action
New Inbound...	Creates a new inbound key information name.
New Outbound...	Creates a new outbound key information name.
Delete	Removes the selected key information name listing.

Key information – Type:

Specifies the type of key information.

Key information – Direction:

Specifies the whether the direction of the key is inbound or outbound. .

Certificate store – Name:

Specifies the certificate store name. The certificate store names listed in this table are used to configure certificate stores.

Use the following actions to work with this table:

Button	Resulting Action
New Inbound...	Creates a new inbound certificate store.
New Outbound...	Creates a new outbound certificate store.
Delete	Removes the selected certificate store.

Certificate store – Direction:

Specifies whether the direction of the certificate store is inbound or outbound.

Trust anchor – Name:

Specifies the trust anchor name. The trust anchor names in this table are links that are used to configure trust anchor certificate stores.

You can use the following buttons to work with this table:

Button	Resulting Action
New...	Creates a new trust anchor entry.
Delete	Removes the selected trust anchor.

Trust anchor – Keystore:

Specifies the type of keystore for the trust anchor.

Key information settings:

Use this page to configure the key information for the selected policy set binding. Key information attributes define how cryptographic keys are generated or consumed.

You can configure the key information for the selected policy set binding when you are editing a default cell or server binding. You can also configure application specific bindings for tokens and message parts that are required by the policy set.

To view this administrative console page when you are editing a default cell binding, complete the following actions:

1. Click **Services > Policy sets > General provider policy set bindings** or **General client policy set bindings**.
2. Click on a binding name in the **Name** column.
3. Click the **WS-Security** policy in the Policies table.
4. Click the **Keys and certificates** link in the Main message security policy bindings section.
5. Click a key in the **Name** column of the Key information table.

To view this administrative console page when you are configuring application specific bindings for tokens and message parts that are required by the policy set, complete the following actions:

1. Click **Applications** → **Application Types** → **WebSphere enterprise applications**.
2. Select an application that contains Web services. The application must contain a service provider or a service client.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** in the Web Services Properties section.
4. Select a binding. You must have previously attached a policy set and assigned a application specific binding.
5. Click the **WS-Security** policy in the Policies table.
6. Click the **Keys and certificates** link in the Main message security policy bindings section.
7. Click a key in the **Name** column of the Key information table.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Name:

Specifies the unique name for the key information configuration.

The key information name field displays the unique name of the key that is being configured if you are editing a key. If you are creating one, enter a unique name.

Type:

Lists the type of key reference.

This field appears only if you selected an encryption or signing key for the generator binding, such as gen_signkeyinfo, gen_signsctkeyinfo, gen_encsctkeyinfo, or gen_enckeyinfo.

You can select one of the following key types from this list:

Key identifier
The associated attribute in the binding file is KEYID.

Security token reference
The associated attribute in the binding file is STRREF.

Embedded token
The associated attribute in the binding file is EMB.

X.509 issuer name and issuer serial
The associated attribute in the binding file is X509ISSUER.

Thumbprint
The associated attribute in the binding file is THUMBPRINT.

The Thumbprint key information type requires a keystore with the public and private key pair instead of a shared key.

Data type: Selection list

Token generator or consumer name:

Specifies the name of the token generator or consumer. Specifies a unique name for the token configuration.

The token generator or consumer name field displays the name of the pre-configured tokens that can be used in the key information configuration if you are editing a key or creating a new key.

You can select a token generator or consumer name from this list. The list of names changes, depending on whether the key information selected is for inbound (consumer) keys or outbound (generator) keys. For keys with outbound direction, the list of defined token generators is displayed. For keys with inbound direction, the list of defined token consumers is displayed.

Data type: String

Direction:

Specifies whether the direction of the key is inbound or outbound.

The direction of generator tokens are outbound whereas the direction for consumer tokens and decryption keys are inbound.

Data type: String
Default values: Inbound (for consumer bindings) or Outbound (for generator bindings)

Requires derived keys:

Specifies whether the key information requires derived keys.

Explicit derived keys
Requires that derived keys be explicitly specified with a WS-SecureConversation <DerivedKeyToken> element.

Implicit derived keys
Requires that derived keys be implicitly specified with a WS-SecureConversation Nonce attribute on the WS-Security <SecurityTokenReference> element.

Override Defaults:

Specifying derived key values overrides the derived key information that the runtime generates by default.

Note: It is recommended that you do not override the following optional attributes. Web Services Security automatically provides default values for each attribute. Overriding the default values might be required if the service is running cross-vendors. The vendors can use different attribute values for derived key generation.

Key length
Specifies the derived key length. If an override value is not specified, the default value is provided based on the algorithm suite policy assertion. It is recommended that you leave this field empty so the default value can be used. Valid values for the key length range between 16 and 32.

Nonce length
Specifies the nonce length. A nonce is generated for each request, and included for derived key generation. This value is optional, and if an override value is not specified, a default value is used to generate the nonce. A valid value for the nonce length is any integer between 16 and 128.

Client label
Specifies the client label. The label is used in the P_SHA-1 function to generate the derived key. If unspecified, the default value used is `WS-SecureConversation`.

Service label
Specifies the service label. The label is used in the P_SHA-1 function to generate the derived key. If unspecified, the default value used is `WS-SecureConversation`.

Custom properties:

Specifies additional configuration settings that token types might require.

Custom properties are arbitrary name-value pairs of data.

This table lists custom properties. Use custom properties to set internal system configuration properties. You are not required to define a custom property when you define a custom token.

Select:

Specifies custom properties that you can add, edit, or delete from policy set bindings.

Click **New** to add and define a new custom property.

For existing custom properties, select the check box for the name of the custom property, and click one of the following actions:

Action	Description
New	Creates a new custom property entry. To add a custom property, enter the name and value.

Action	Description
Edit	Specifies that you can edit the selected custom property. Click this option to provide input fields and create the list of cell values to edit. At least one custom property must exist before the Edit option is displayed.
Delete	Removes the selected custom property.

Data type: Check box (unchecked)

Name:

Specifies the name of the custom property that you can use with default policy set bindings.

Custom properties are arbitrary name-value pairs of data. Custom properties are not initially displayed in this column until at least one custom property has been added.

Data type: String

Value:

Specifies the custom property value.

This column displays the value for the custom property (for example, `true`). The value can be a string or the value can be a true or false Boolean value.

Data type: String or Boolean

Certificate store settings:

Use this page to specify the location where certificates are stored. You can reference certificate revocation for service generators or consumers.

You can specify the location where certificates are stored when you are editing a default cell or server binding. You can also configure application specific bindings for tokens and message parts that are required by the policy set.

To view this administrative console page when you are editing a default cell binding, complete the following actions:

1. Click **Services > Policy sets > Default policy set bindings**.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Keys and certificates** link in the Main message security policy bindings section.
4. Click the ***certificate_store_name*** link in the Certificate store section.

To view this administrative console page when you are configuring application specific bindings for tokens and message parts that are required by the policy set, complete the following actions:

1. Click **Applications** → **Application Types** → **WebSphere enterprise applications**.
2. Select an application that contains Web services. The application must contain a service provider or a service client.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** in the Web Services Properties section.
4. Select a binding. You must have previously attached a policy set and assigned a application specific binding.

5. Click the **WS-Security** policy in the Policies table.
6. Click the **Keys and certificates** link in the Main message security policy bindings section.
7. Click the ***certificate_store_name*** link in the Certificate store section.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Name:

Specifies the name of the certificate store. The name field displays the name of the certificate store if you are editing a certificate store, or enter a name if you are creating a new certificate store.

Revoked certificates – Full path:

Specifies, in the Revoked certificates table, the paths for any certificates that are revoked. The Full Path column of this table lists any certificates that have been revoked.

You can add, edit, or remove these entries with the following buttons:

Button	Resulting Action
New	Creates a revoked generator or consumer certificate store.
Delete	Removes the selected revoked generator or consumer certificate store.
Edit	Allows you to edit the applied entries selected in the checkbox. This button is only displayed if revoked certificates exist in your configuration.

Intermediate X.509 certificates – Full Path:

Specifies, for the consumer certificate store only, the paths for any intermediate X.509 certificates. The Full Path column of this table lists any intermediate X.509 certificate stores. This table is only displayed for the consumer version of this panel. It is not valid for generator certificate stores.

Note: If the certificate store is outbound, the Intermediate X.509 certificates field is not displayed.

You can create, edit, or remove intermediate X.509 certificates with the following buttons:

Button	Resulting Action
New	Creates an intermediate X.509 consumer certificate store.
Delete	Removes an intermediate X.509 consumer certificate store.
Edit	Allows you to edit the applied entries selected in the checkbox.

Trust anchor settings:

Use this page to specify the trust anchor configuration. These trust anchor certificates are used to validate the X.509 certificate that is embedded in the SOAP message.

Use this information to configure a trust anchor. Trust anchors point to keystores that contain trusted root or self-signed certificates. This information enables you to specify a name for the trust anchor and the information that is needed to access a keystore. The application binding uses this name to reference a predefined trust anchor definition in the binding file (or the default).

You can configure a trust anchor when you are editing a default cell or server binding. You can also configure application specific bindings for tokens and message parts that are required by the policy set.

To view this administrative console page when you are editing a default cell binding, complete the following actions:

1. Click **Services > Policy sets > Default policy set bindings**.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Keys and certificates** link in the Main message security policy bindings section.
4. Click a name link in the **Name** column of the Trust anchor table.

To view this administrative console page when you are configuring application specific bindings for tokens and message parts that are required by the policy set, complete the following actions:

1. Click **Applications** → **Application Types** → **WebSphere enterprise applications**.
2. Select an application that contains Web services. The application must contain a service provider or a service client.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** in the Web Services Properties section.
4. Select a binding. You must have previously attached a policy set and assigned a application specific binding.
5. Click the **WS-Security** policy in the Policies table.
6. Click the **Keys and certificates** link in the Main message security policy bindings section.
7. Click a name link in the **Name** column of the Trust anchor table.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Name:

Specifies the unique name that is used by the application binding to reference a predefined trust anchor definition in the default binding.

A trust anchor specifies the keystore that contains trusted root certificates. This field displays the name for the trust anchor that is being edited. If you are creating a new trust anchor configuration, enter a unique name.

Keystore files contain public and private keys, root certificate authority (CA) certificates, the intermediate CA certificate, and so on. Keys that are retrieved from the keystore files are used to sign and validate or encrypt and decrypt messages or message parts.

Data type: String

Centrally managed keystore:

Specifies to use a centrally managed keystore. After selecting the **Centrally managed keystore** option, choose one of the centrally managed keystore names from the list. Centrally managed keystores can be managed in the administrative console by clicking these links: **Security > SSL certificate and key management > Key stores and certificates**.

Click the radio button to enable the **Name** field. Select a keystore from the list.

Data type: Radio button
Default value: Unselected

External keystore:

Specifies a keystore using a keystore path, keystore type and keystore password. The keystore file format is determined by the keystore type. The default trust anchor in the default binding uses an external keystore.

Select the radio button to enable an external keystore.

Data type: Radio button
Default value: Selected

Full path
Specifies the full path to the location of the keystore.

If the keystore is file-based, the location can reference any path in the file system of the node where the trust anchor keystore is located. The trust anchor defined in the default bindings is:

```
${USER_INSTALL_ROOT}/etc/ws-security/samples/dsig-receiver.ks
```

Note: Do not use the sample keystore files in a production environment. These samples are provided for testing purposes only.

Data type: String

Type Specifies the type of keystore when the external keystore is enabled.

The type specifies the implementation for keystore management. Click a keystore type from the list provided. The selection list is returned by java.security.Security.getAlgorithms(″KeyStore″).

The IBM Java Cryptography Extension (IBMJCE) supports the following file-based keystore types: JKS, JCEKS,PKCS12, and CMSKS.

- Use the JKS option if you are not using Java Cryptography Extensions (JCE).
- Use the JCEKS option if you are using Java Cryptography Extensions.
- Use the PKCS12 option if your keystore uses the PKCS#12 file format.
  - A key.p12 file or a trust.p12 file are examples of PKCS12 type keystores.
- Use the CMSKS option if your keystore uses the Certificate Management Services (CMS) format.

Password
Specifies the password that is needed to access the keystore file.

Use the password to protect the keystore. The password is used to access the named keystore and the password is also the default password that is used to store keys within the keystore.

The default trust anchor in default binding uses an external keystore. The password for the external keystore is: `server`. It is recommended that you change the default password as soon as possible.

Data type: String
Default value: WebAS or cell name

Confirm password
Confirms the password entered in the Password field.

Enter the password that is used to open the keystore file or device again. By entering the same password that was entered in the Password field again, you confirm the password.

Data type: String

WS-Security authentication and protection

Use the links on this page to configure authentication, signature, and encryption information that the policy requires.

You can configure authentication, signature, and encryption information for tokens and message parts when you are editing a default cell or server binding. You can also configure application specific bindings for tokens and message parts that are required by the policy set.

To view this administrative console page when you are editing a general provider policy set binding or general client policy set binding, complete the following actions:

1. Click **Services > Policy sets > General provider policy set bindings or General client policy set bindings**.
2. Click **Provider sample** or **Client sample**.
3. Click the **WS-Security** policy in the Policies table.
4. Click the **Authentication and protection** link in the Main Message Security Policy Bindings section.

To view this administrative console page when you are configuring application specific bindings for tokens and message parts that are required by the policy set, complete the following actions:

1. Click **Applications** → **Application Types** → **WebSphere enterprise applications**.
2. Select an application that contains Web services. The application must contain a service provider or a service client.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** link in the Web Services Properties section.
4. Select a binding. You must have previously attached a policy set and assigned an application specific binding.
5. Click the **WS-Security** policy in the Policies table.
6. Click the **Authentication and protection** link in the Main message security policy bindings section.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

WS-Security authentication and protection for general bindings:

Use the links on this page to configure authentication, signature, and encryption information that the policy requires when using general bindings.

You can configure authentication, signature, and encryption information for tokens and message parts when you are editing a general binding.

To view this administrative console page when you are editing a general binding at the cell level, complete the following actions:

1. Click **Services > Policy sets > General provider policy set bindings** or **General client policy set bindings**.
2. Click on the name of the bindings you want to edit.
3. Click the **WS-Security** policy in the Policies table.
4. Click the **Authentication and protection** link in the Main message security policy bindings section.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Disable implicit protection for Signature Confirmation:

Specifies whether implicit protection of the SignatureConfirmation element is enabled or disabled.

The explicitlyProtectSignatureConfirmation attribute in the Web services security binding is provided to disable implicit signature and encryption of the SignatureConfirmation element on the response message. If this checkbox is selected, the attribute is added and implicit protection is disabled. This provides interoperability with earlier versions of WebSphere Application Server.

Default: Not selected (implicit protection is enabled)

Protection tokens – Protection token name:

Specifies a list of protection tokens that can be configured in the Protection tokens table.

The following actions are available for general bindings:

Button	Resulting Action
New Token	Creates a new protection token type.
Delete	Removes the selected protection token type.

Protection tokens – Usage:

Specifies the policy assertion usage names that you can customize in the Protection tokens table.

For the usage field, the following options are available for the general bindings:

- Asymmetric encryption generator
- Asymmetric encryption consumer
- Asymmetric signature generator
- Asymmetric signature consumer
- Symmetric encryption generator
- Symmetric encryption consumer
- Symmetric signature generator
- Symmetric signature consumer

Authentication tokens – Authentication token name:

Specifies a list of authentication tokens that you can customize in the Authentication tokens table when using general bindings.

If you are working with a Username token or LTPA token that is using general bindings, the user names and passwords might have been provided as examples. When you click a Username token or LTPA token link, you need to update the values for these token types using the Callback handler link found on the Authentication token settings page.

The following actions are available for general bindings:

Button	Resulting Action
New Token	Creates a new authentication token type.
Delete	Removes the selected authentication token type.

Authentication tokens – Usage:

Specifies the usage names from the Authentication tokens table for general bindings.

The following options are available for general bindings:
- Inbound
- Outbound

Request message signature and encryption protection – Name:

Specifies a unique name to identify the request message part from the Request message signature and encryption protection table that is protected.

The following actions are available for general bindings. The Move up and Move down actions are available only when using service client policy sets and bindings.

Button	Resulting Action
New Signature	Creates a new signature.
New Encryption	Creates a new encryption protection.
Delete	Removes the selected request message part.
Move up	Moves the selected request message part up in the order.
Move down	Moves the selected request message part down in the order.

Request message signature and encryption protection – Protection:

Specifies the type of protection from the Request message signature and encryption protection table. This field displays the type of protection enabled for the general binding.

Response message signature and encryption protection – Name:

Specifies a unique name to identify the response message part from the Response message signature and encryption protection table that is protected.

The following actions are available for general bindings. The Move up and Move down actions are available only when using service provider policy sets and bindings.

Button	Resulting Action
New Signature	Creates a new response message signature.
New Encryption	Creates a new encryption.
Delete	Removes the selected response message part.
Move up	Moves the selected response message part up in the order.
Move down	Moves the selected response message part down in the order.

Response message signature and encryption protection – Protection:

Specifies the type of protection enabled from the Response message signature and encryption protection table. This field displays the type of protection enabled for the response message part.

Response message signature and encryption protection – Order:

Specifies the order in which the signatures and encryptions occur. Use the **Move up** and **Move down** actions to order the list of protection types in this table.

WS-Security authentication and protection for application specific bindings:

Use the links on this page to configure authentication, signature, and encryption information that the policy requires when using application specific bindings.

You can configure application specific bindings for tokens and message parts that are required by the policy set.

To view this administrative console page when you are configuring application specific bindings for tokens and message parts that are required by the policy set, complete the following actions:

1. Click **Applications** → **Application Types** → **WebSphere enterprise applications**.
2. Select an application that contains Web services. The application must contain a service provider or a service client.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** in the Web Services Properties section.
4. Select a binding. You must have previously attached a policy set and assigned a application specific binding.
5. Click the **WS-Security** policy in the Policies table.
6. Click the **Authentication and protection** link in the Main message security policy bindings section.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Disable implicit protection for Signature Confirmation:

Specifies whether implicit protection of the SignatureConfirmation element is enabled or disabled.

The explicitlyProtectSignatureConfirmation attribute in the Web services security binding is provided to disable implicit signature and encryption of the SignatureConfirmation element on the response message. If this checkbox is selected, the attribute is added and implicit protection is disabled. This provides interoperability with earlier versions of WebSphere Application Server.

Default: Not selected (implicit protection is enabled)

Protection tokens – Protection token name:

Specifies a list of protection tokens that can be configured in the Protection tokens table for application specific bindings.

The following actions are available for application specific bindings:

Button	Resulting Action
Unconfigure	Removes the selected protection token from the binding.

Protection tokens – Protection token type:

Specifies the protection token type for application specific bindings.

Protection tokens – Usage:

Specifies the policy assertion usage names that you can customize in the Protection tokens table.

For the usage field, the following options are available for the application specific bindings:

- Asymmetric encryption generator
- Asymmetric encryption consumer
- Asymmetric signature generator

- Asymmetric signature consumer
- Symmetric encryption generator
- Symmetric encryption consumer
- Symmetric signature generator
- Symmetric signature consumer

Protection tokens – Status:

Specifies the status of the protection token when using application specific bindings. The valid values are configured, not configured, or incompatible.

Authentication tokens – Security token reference:

Specifies a list of authentication tokens that you can customize in the Authentication tokens table when using application specific bindings.

The following actions are available for application specific bindings:

Button	Resulting Action
Unconfigure	Removes the selected authentication token from the binding.

Authentication tokens – Authentication token type:

Specifies the authentication token type for the security token reference when using application specific bindings.

Authentication tokens – Usage:

Specifies the usage names from the Authentication tokens table for application specific bindings.

The following options are available for application specific bindings:
- Inbound request
- Outbound request
- Inbound response
- Outbound response

Authentication tokens – Status:

Specifies the status of the authentication token form the Authentication tokens table for application specific bindings. The valid values are configured, not configured, or incompatible.

Request message signature and encryption protection – Request message part reference:

Specifies the name of the request message part in the policy from the Request message signature and encryption protection table that is protected.

The following actions are available for application specific bindings. The **Move up** and **Move down** actions are available only when using Service client policy sets and bindings.

Button	Resulting Action
Unconfigure	Removes the selected request message part from the binding.
Move up	Moves the selected request message part up in the order.

Button	Resulting Action
Move down	Moves the selected request message part down in the order.

Request message signature and encryption protection – Protection:

Specifies the type of protection from the Request message signature and encryption protection table. This field displays the type of protection enabled for the application specific binding.

Request message signature and encryption protection – Order:

Specifies the order in which signatures and encryptions occur when using service client policy sets and bindings. Use the **Move up** and **Move down** actions to order the list of protection types in this table.

Request message signature and encryption protection – Status:

Specifies the status of the request message signature and encryption protection token when using application specific bindings. The valid values are configured, not configured, or incompatible.

Response message signature and encryption protection – Response message part reference:

Specifies the name of the response message part in the policy from the Response message signature and encryption protection table that is protected.

The following actions are available for application specific bindings. The **Move up** and **Move down** actions are available only when using Service provider policy sets and bindings.

Button	Resulting Action
Unconfigure	Removes the selected response message part from the binding.
Move up	Moves the selected response message part up in the order.
Move down	Moves the selected response message part down in the order.

Response message signature and encryption protection – Protection:

Specifies the type of protection enabled from the Response message signature and encryption protection table. This field displays the type of protection enabled for the response message part.

Response message signature and encryption protection – Order:

Specifies the order in which signatures and encryptions occur when using service provider policy sets and bindings. Use the **Move up** and **Move down** actions to order the list of protection types in this table.

Response message signature and encryption protection – Status:

Specifies the status of the response message signature and encryption protection token when using application specific bindings. The valid values are configured, not configured, or incompatible.

Protection token settings (generator or consumer):

Use this page to configure protection tokens. Protection tokens sign messages to protect integrity or encrypt messages to provide confidentiality.

You can add protection token settings for message parts when you are editing general provider or client policy set bindings. You can also configure application specific bindings for tokens and message parts that are required by the policy set.

To view this administrative console page when you are editing a general provider binding, complete the following actions:

1. Click **Services** → **Policy sets** → **General provider policy set bindings**.
2. Click on the name of the binding you want to edit.
3. Click the **WS-Security** policy in the Policies table.
4. Click the **Authentication and protection** link in the security policy bindings section.
5. Click **New token** to create a new token generator or consumer, or click an existing consumer or generator token link from the Protection Tokens table.
6.

To view this administrative console page when you are editing a general client binding, complete the following actions:

1. Click **Services** → **Policy sets** → **General client policy set bindings**.
2. Click on the name of the binding you want to edit.
3. Click the **WS-Security** policy in the Policies table.
4. Click the **Authentication and protection** link in the Main message security policy bindings section.
5. Click **New token** to create a new token generator or consumer or click an existing consumer or generator token link from the Protection Tokens table.

To view this administrative console page when you are configuring application specific bindings for tokens and message parts that are required by the policy set, complete the following actions:

1. Click **Applications > Websphere enterprise applications**.
2. Select an application that contains Web services. The application must contain a service provider or a service client.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** in the Web Services Properties section.
4. Select a binding. You must have previously attached a policy set and assigned a binding.
5. Click the **WS-Security** policy in the Policies table.
6. Click the **Authentication and protection** link in the security policy bindings section.
7. Click a consumer or generator token link from the Protection Tokens table.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Name:

Specifies the token generator or consumer name. Enter a name in this field when you create a new token.

Token type:

Specifies the type of token. When using bindings, the token type is determined from the policy and cannot be edited.

Valid values are:

- LPTA Token V2.0
- Secure Conversation Token V1.3
- Secure Conversation Token V200502
- X509V3 Token V1.1

- X509V3 Token V1.0
- X509PKCS7 Token V1.1
- X509PKCS7 Token V1.0
- X509PkiPathV1 Token V1.1
- X509PkiPathV1 Token V1.0
- X509V1 Token V1.1
- Custom Token

The Secure Conversation Token v200502 token type for the WS-Security policy represents the requirement for a Security Context Token as defined in the February 2005 level of the WS-SecureConversation specification.

Enforce token version:

When LTPA Token v2.0 is selected as the token type, both LTPA version 1 and LTPA version 2 tokens can be consumed. Select this checkbox to restrict token consumption to the LTPA Token v2.0 token type.

Local name:

Specifies the local name of the custom token generator or consumer. The **Local name** field is populated based on the token type displayed. Use this field to edit custom token types only.

If the custom token type is used to generate a Kerberos token as defined in the OASIS Web Services Security Specification for Kerberos Token Profile V1.1, use one of the values listed below for the local name. The value you choose depends on the specification level of the Kerberos token generated by the Key Distribution Center (KDC). The following table lists the values and the specification level associated with each value. For purposes of interoperability, the Basic Security Profile V1.1 standard requires the use of the local name http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ.

Local Name Value for Kerberos Token	Associated Specification Level
http://docs.oasis-open.org/wss/oasiswss-kerberos-token-profile-1.1#Kerb erosv5_AP_REQ	Kerberos v5 AP-REQ as defined in the Kerberos specification. Use this value when the Kerberos ticket is an AP Request.
http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ	GSS-API Kerberos V5 mechanism token containing a KRB_AP_REQ message as defined in RFC-1964 [1964], Sec. 1.1 and its successor RFC-4121, Sec. 4.1. Use this value when the Kerberos ticket is an AP Request (ST + Authenticator).
http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ1510	Kerberos v5 AP-REQ as defined in RFC1510. Use this value when the Kerberos ticket is an AP Request per RFC1510.
http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ1510	GSS-API Kerberos V5 mechanism token containing a KRB_AP_REQ message as defined in RFC-1964, Sec. 1.1 and its successor RFC-4121, Sec. 4.1. Use this value when the Kerberos ticket is an AP Request (ST + Authenticator) per RFC1510.
http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ4120	Kerberos v5 AP-REQ as defined in RFC4120. Use this value when the Kerberos ticket is an AP Request per RFC4120.

Local Name Value for Kerberos Token	Associated Specification Level
http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ4120	GSS-API Kerberos V5 mechanism token containing an KRB_AP_REQ message as defined in RFC-1964, Sec. 1.1 and its successor, RFC-4121, Sec. 4.1. Use this value when the Kerberos ticket is an AP Request (ST + Authenticator) per RFC4120.

URI:

Specifies the uniform resource identifier (URI) of the custom token generator or consumer. The **URI** field is populated based on the token type displayed. Use this field to edit custom token types only.

Leave this field blank if the custom token type is used to generate a Kerberos token as defined in the OASIS Web Services Security Specification for Kerberos Token Profile V1.1.

JAAS login:

Specifies the Java Authentication and Authorization Service (JAAS) application login information. Click **New** to add a new JAAS application login or JAAS system login entry.

If the server is in a security domain that includes specific system or application logins, these logins are listed in the JAAS login menu, in addition to the global logins.

New Application Login:

Click to go to the effective JAAS login collection for the current security domain.

Custom properties – Name:

Specifies the name of the custom property. Custom properties are not initially displayed in this column until they are added.

Select one of the following actions for custom properties:

Button	Resulting Action
New	Creates a new custom property entry. To add a custom property, enter the name and value.
Edit	Specifies that you can edit the selected custom property. Select this action to provide input fields and create the listing of cell values for editing. The **Edit** button is not available until at least one custom property has been added.
Delete	Removes the selected property.

If the custom token type is used to generate a Kerberos token, specify the following custom properties:

Custom property name	Value
com.ibm.wsspi.wssecurity.krbtoken.targetServiceName	Specifies the name of the target service.
com.ibm.wsspi.wssecurity.krbtoken.targetServiceHost	Specifies the host name that is associated with the target service.
com.ibm.wsspi.wssecurity.krbtoken.targetServiceRealm	Specifies the name of the realm that is associated with the target service.

For the token generator, the combination of the target service name and target hostname forms a Service Principal Name (SPN), which represents the target Kerberos service principal name. The Kerberos client requests the initial Kerberos AP_REQ token for the SPN.

Custom properties – Value:

Specifies the value of the custom property. Use the **Value** field to enter, edit, or delete the value for a custom property.

Callback handler:

After all other configurations on the protection token page are applied or saved, this section is displayed and links to the configuration settings for the callback handler. Click this link to specify callback handler settings that determine how security tokens are acquired from message headers.

Tolerate secure conversation token V200502:

The secure conversation token V200502 token type for the WS-Security policy represents the requirement for a secure conversation token as defined the in the February 2005 level of the WS-SecureConversation specification. This option specifies whether the provider handles both secure conversation token V1.3 and secure conversation token V200502. By default, the provider handles both versions. You can change this behavior by clicking to remove the check box selection so that the provider handles only the V1.3 token.

Note: This checkbox is displayed only in the service provider token consumer panel.

Data type	Check box
Range	Selected or cleared
Default value	Selected

Authentication generator or consumer token settings:

Authentication tokens are used to prove or assert an identity. Use the administrative console to add authentication token settings for message parts when you are editing a general binding.

To configure authentication tokens, complete the following steps:

1. To view and select the general bindings that are set as the global security default policy set bindings, click **Services > Policy sets > Default policy set bindings**. The specified bindings are used unless overridden at the attachment point, at the server, or at a security domain.
2. To access and configure the general bindings and to add authentication token settings for message parts, click **Services > Policy sets > General provider policy set bindings**.
3. Click the **WS-Security** policy in the Policies table.
4. Click the **Authentication and protection** link in the Main message security policy bindings section.
5. Click **New token** to create a new token generator or consumer, or click an existing consumer or generator token link from the Authentication Tokens table.

To view and configure application-specific bindings for tokens and message parts that are required by a policy set, complete the following steps:

1. Click **Applications > Application Types > WebSphere enterprise applications**.
2. Select an application that contains Web services. The application must contain a service provider or a service client.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** link in the Web Services Properties section.
4. Select a binding. You must have previously attached a policy set and assigned an application specific binding.
5. Click the **WS-Security** policy in the Policies table.
6. Click the **Authentication and protection** link in the Main message security policy bindings section.

7. Click a consumer or generator token link from the Protection Tokens table.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Name:

Specifies the name of the token being configured. When using application specific bindings, this field is not displayed.

Token type:

Specifies the type of token being configured.

When you are using application specific bindings, the token type is obtained from the policy file and it is read-only. When you are using general bindings, select a token type from the list. The following token types are available:

- X509V3 Token V1.1
- X509V3 Token V1.0
- Username Token V1.1
- Username Token V1.0
- X509PKCS7 Token V1.1
- X509PKCS7 Token V1.0
- X509PkiPathV1 Token V1.1
- X509PkiPathV1 Token V1.0
- LTPA Propagation Token
- X509V1 Token V1.1
- LTPA Token
- LTPA Token V2.0
- Custom Token

Note: The LTPA Token V2.0 token type is available only for bindings using the new namespace in IBM WebSphere Application Server, Version 7.0 or later. When you select LTPA Token V2.0 as the token type for the token consumer, both LTPA tokens and LTPA V2.0 tokens can be consumed. To restrict the token consumer to LTPA V2.0 tokens only, select the **Enforce token version** check box.

If you select LTPA Token as the token type for the token generator, single sign-on interoperability mode must be enabled. This is a setting in global security from Web and SIP security. If the interoperability flag is not set to enabled (true), an error occurs when the application that is attached to these bindings is started. If you want to use the LTPA token without checking the state of the interoperability flag, you can set the custom property, com.ibm.wsspi.wssecurity.tokenGenerator.ltpav1.pre.v7, on the token generator.

Local name:

Specifies the local name for the authentication token generator or consumer. The **Local name** field is populated based on the token type displayed. Use this field to edit custom token types only.

URI:

Specifies the uniform resource identifier (URI) of the authentication token generator or consumer. The **URI** field is populated based on the token type displayed. Use this field to edit custom token types only.

Leave this field blank if the custom token type is used to generate a Kerberos token as defined in the OASIS Web Services Security Specification for Kerberos Token Profile v1.1.

Security token reference:

Specifies the security token reference. The security token reference field is displayed only for authentication tokens in application-specific bindings. This field is not available for default bindings.

JAAS login:

Specifies a list of application and system Java Authentication and Authorization Service (JAAS) logins that are effective for the domain to which the binding is scoped.

If an application is scoped to the global security or if it is scoped to a domain that does not customize its own JAAS logins, then the list of global logins are displayed in the menu list. Click **New Application Login** to access the global JAAS application login collection. The JAAS login menu list and **New Application Login** button behavior depend on whether the binding is being created in association with an attachment. Use caution when changing security domains, since a previously-referenced security configuration, such as JAAS logins, might not be accessible in a different security domain.

Custom properties – Name:

Specifies the name used for the custom property.

Custom properties are not initially displayed in this column. Click one of the following buttons to enable the actions described:

Button	Resulting Action
New	Creates a new custom property entry. To add a custom property, enter the name and value.
Edit	Enables the selected custom property to be edited. Clicking this button provides input fields and creates the listing of cell values to be edited. The Edit button is not available until at least one custom property has been added.
Delete	Removes the selected custom property.

Custom properties – Value:

Specifies the value of the custom property to be used. Use the **Value** field to enter, edit, or delete the value for a custom property.

If the custom token type is used to generate a Kerberos token, specify a custom property with the com.ibm.wsspi.wssecurity.krbtoken.targetServiceName target service name, the com.ibm.wsspi.wssecurity.krbtoken.targetServiceHost host name that is associated with the target service, and the com.ibm.wsspi.wssecurity.krbtoken.targetServiceRealm Kerberos realm that is associated with the target service. The com.ibm.wsspi.wssecurity.krbtoken.targetServiceName and com.ibm.wsspi.wssecurity.krbtoken.targetServiceHost custom properties are required. The com.ibm.wsspi.wssecurity.krbtoken.targetServiceRealm custom property is optional. For the token generator, the combination of the target service name and target hostname forms a Service Principal Name (SPN) which represents the target Kerberos service principal name. The Kerberos client requests the initial Kerberos AP_REQ token for the SPN.

Callback handler:

Links to the Callback handler page where you can configure callback handlers. Callback handler settings determine how security tokens are acquired from messages headers.

If you are working with a Username token or LTPA token that is using default bindings, the user names and passwords might have been provided as examples. You need to update the values for these token types.

Callback handler settings:

Use this page to configure callback handler settings, which determine how security tokens are acquired from messages headers.

You can configure callback handler settings when you are editing a default cell or server binding. You can also configure application specific bindings for tokens and message parts that are required by the policy set.

To view this administrative console page when you are editing a default cell binding, complete the following actions:

1. Click **Services > Policy sets > Default policy set bindings**.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Authentication and protection** link in the Main message security policy bindings section.
4. Click the ***name_of_token*** link in the Protection tokens section or the Authentication tokens section.
5. Click the **Callback handler** link.

To view this administrative console page when you are configuring application specific bindings for tokens and message parts that are required by the policy set, complete the following actions:

1. Click **Applications > Application Types > WebSphere enterprise applications**.
2. Select an application that contains Web services. The application must contain a service provider or a service client.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** in the Web Services Properties section.
4. Select a binding. You must have previously attached a policy set and assigned an application specific binding.
5. Click the **WS-Security** policy in the Policies table.
6. Click the **Authentication and protection** link in the Main message security policy bindings section.
7. Click the ***name_of_token*** link in the Protection tokens section or the Authentication tokens section.
8. Click the **Callback handler** link.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

The Callback Handler displays fields differently for different tokens being configured. Depending on whether you are configuring generator or consumer tokens for protection or you are configuring inbound or outbound tokens for authentication, the sections and fields on this panel display some or all of the fields explained in this topic, as noted in the description of each field.

Class name:

The fields in the Class name section are available for all types of token configuration.

Select the class name to use for the callback handler. Select the **Use built-in default** option for normal operation. Use the **Use custom** option only if you are using a custom token type.

For the Kerberos custom token type, use the class name, com.ibm.websphere.wssecurity.callbackhandler.KRBTokenGenerateCallbackHandler, for token generator configuration. Use com.ibm.websphere.wssecurity.callbackhandler.KRBTokenConsumeCallbackHandler for token consumer configuration.

Use built-in default:

Specifies that the default value is used for the class name. Use the default value (shown in the field) for the class name when you select this radio button. This name is based on the token type and whether the callback handler is for a token generator or a token consumer. This option is mutually exclusive to the **Use custom** option.

Use custom:

Specifies that a custom value is used for the class name. Select this radio button and enter the name in the field to use a custom class name.

No default value is available for this entry field. Use the information in the following table to determine this value:

Token Type	Consumer or Generator	Callback Handler Class Name
UsernameToken	consumer	com.ibm.websphere.wssecurity.callbackhandler.UNTConsumeCallbackHandler
UsernameToken	generator	com.ibm.websphere.wssecurity.callbackhandler.UNTGenerateCallbackHandler
X509Token	consumer	com.ibm.websphere.wssecurity.callbackhandler.X509ConsumeCallbackHandler
X509Token	generator	com.ibm.websphere.wssecurity.callbackhandler.X509GenerateCallbackHandler
LTPAToken/LTPAPropagationToken	consumer	com.ibm.websphere.wssecurity.callbackhandler.LTPAConsumeCallbackHandler
LTPAToken/LTPAPropagationToken	generator	com.ibm.websphere.wssecurity.callbackhandler.LTPAGenerateCallbackHandler
SecureConversationToken	consumer	com.ibm.ws.wssecurity.impl.auth.callback.SCTConsumeCallbackHandler
SecureConversationToken	generator	com.ibm.ws.wssecurity.impl.auth.callback.WSTrustCallbackHandler

This button is mutually exclusive to the **Use built-in default** option.

Certificates:

The fields in the Certificates section are available if you are configuring a protection token. For a consumer token, you can use the Trust any certificate or the Certificate store options to configure the certificate. For a generator token, you can click a certificate from the listing or click the **New** button to add one.

Certificates - Trust any certificate:

If the protection token has a certificate configured, this option specifies that the system will trust any certificate, and not define the certificate store. Select this option to trust each certificate. This option is mutually exclusive to the **Certificate store** option and is only applicable to the token consumer.

Certificates - Certificate store:

Specifies, if the protection token has a certificate configured, the certificate store to be trusted. Select this option to trust each certificate store specified in the entry field. This option is mutually exclusive to the **Trust any certificate** option. When you select this option, the **New** button is enabled so that you can configure a new certificate store. You can also add a second certificate store to the **Trusted anchor store** entry field when you click **Certificate store**. The **Trusted anchor store** field is only applicable to the token consumer.

Basic authentication:

The fields in the Basic authentication section are available if you are configuring an authentication token that is not an LTPA propagation token.

For the Kerberos custom token type, you must complete the Basic Authentication section for the Kerberos login.

User name:

Specifies the user name that you want to authenticate.

Password:

Specifies the password to be authenticated. Enter a password to authenticate in this entry field.

Confirm password:

Specifies the password that you want to confirm.

Keystore:

The fields in the Keystore section are available if you are configuring a protection token.

In the Keystore name list, you can click **Custom** to define a custom keystore, click one of the externally defined keystore names, or click **None** if no keystore is required.

Keystore - Name:

Specifies the name of the centrally managed keystore file that you want to use.

Click the name of a centrally managed keystore name from this menu or enter one of the following values:

NodeDefaultKeyStore
NodeDefaultTrustStore
NodeLTPAKeys
None Specifies to not use a centrally managed keystore file.

Custom
Specifies to use the centrally managed keystore file. Click the **Custom keystore configuration** link to configure custom keystore and key settings.

Keystore - Custom keystore configuration:

Specifies a link to create a custom keystore. Click this link to open a panel where you can configure a custom keystore.

Key:

The fields in the Key section are available if you are configuring a protection token.

Name:

Specifies the name of the key to use. Enter the name of the key to be used in this required field.

Alias:

Specifies the alias name of the key that you want to use. Enter the alias of the name of the key to use in this required field.

Password:

Specifies the password for the key that you want to use.

You cannot set a password for public keys for asymmetric encryption generator or asymmetric signature consumer.

Confirm password:

Specifies the confirmation of the password for the key that you want to use. Enter the password that you entered in the Password field to confirm.

Do not provide a key confirm password for public keys for asymmetric outbound encryption or inbound signature.

Custom properties:

The fields in the Custom properties section are available for all types of token configuration.

You can add custom properties needed by the callback handler here using name-value pairs.

To implement signer certificate encryption when using the JAX-WS programming model, add the custom property **com.ibm.wsspi.wssecurity.token.cert.useRequestorCert** with the value true on the callback handler of the encryption token consumer. This implementation uses the public key from the certificate of the signer. This custom property is used by the response generator.

For a Kerberos custom token based on OASIS Web Services Security Specification for Kerberos Token Profile V1.1, specify the following property for token generation: **com.ibm.wsspi.wssecurity.krbtoken.clientRealm**. This allows the Kerberos client realm to initiate the Kerberos login. If not specified, the default Kerberos realm name is used.

Name:

Specifies the name of the custom property to use.

Custom properties are not initially displayed in this column. Click one of the following actions for custom properties:

Button	Resulting Action
New	Creates a new custom property entry. To add a custom property, enter the name and value.
Delete	Removes the selected custom property.

Value:

Specifies the value of the custom property to use. With the **Value** entry field, you can enter or delete the value for a custom property.

Custom keystore settings:

Use this page to configure custom keystore files. Custom keystore files are alternatives to the key management support built into the WebSphere Application Server. The callback handler uses the custom version of the keystore configuration that includes keys.

You can configure custom keystore files for message parts when you are editing a default cell or server binding. You can also configure application specific bindings for tokens and message parts that are required by the policy set.

To view this administrative console page when you are editing a default cell binding, complete the following actions:

1. Click **Services > Policy sets > Default policy set bindings**.
2. Click the **WS-Security** policy in the Policies table.

3. Click the **Authentication and protection** link in the Main message security policy bindings section.
4. Click a ***protection_token*** link in the Protection tokens table.
5. Click the **Callback handler** link in the Additional bindings section.
6. Select **Custom** from the list in the Keystore section.
7. Click the **Custom keystore configuration** link.

To view this administrative console page when you are configuring application specific bindings for tokens and message parts that are required by the policy set, complete the following actions:

1. Click **Applications** → **Application Types** → **WebSphere enterprise applications**.
2. Select an application that contains Web services. The application must contain a service provider or a service client.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** in the Web Services Properties section.
4. Select a binding. You must have previously attached a policy set and assigned a application specific binding.
5. Click the **WS-Security** policy in the Policies table.
6. Click the **Authentication and protection** link in the Main message security policy bindings section.
7. Click a ***protection_token*** link in the Protection tokens table.
8. Click the **Callback handler** link in the Additional bindings section.
9. Select **Custom** from the list in the Keystore section.
10. Click the **Custom keystore configuration** link.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Keystore:

Use this section to specify information about the custom keystores.

Full path:

Specifies the full path to where the keystore file is located. Enter the path to the keystore file in this required field. You can use system variables for portions of the path. For example you might enter ${USER_INSTALL_ROOT}/etc/ws-security/myKeyStore.jks. This field is required for the custom keystore configuration.

Type:

Specifies the type of the keystore file to use.

Password:

Specifies the password to use.

Confirm password:

Specifies the password to be use and confirms the one entered in the **Password** field.

Key:

Use this section to specify information about the key.

Name:

Specifies the name of the key to use. Enter the name of the key to be used in this required field.

Alias:

Specifies the alias name of the key that you want to use. Enter the alias of the name of the key to use in this required field.

Password:

Specifies the password for the key that you want to use.

You cannot set a password for public keys for asymmetric signature inbound and encryption outbound. The Password and Confirm Password fields display only for the following:

client	asymmetric signature outbound	AsymmetricBindingInitiatorSignatureToken0
client	asymmetric encryption inbound	AsymmetricBindingInitiatorEncryptionToken0
server	asymmetric signature outbound	AsymmetricBindingRecipientSignatureToken0
server	asymmetric encryption inbound	AsymmetricBindingRecipientEncryptionToken0

Confirm password:

Specifies the confirmation of the password for the key that you want to use. Enter the password that you entered in the Password field to confirm.

Similar to the Password field, you cannot confirm the password for public keys for asymmetric signature inbound and encryption outbound.

Caller settings

Use this page to configure the caller settings. The caller specifies the token or message part that is used for authentication.

You can configure the caller settings for message parts when you are editing a default cell or server binding. You can also configure application specific bindings for tokens and message parts that are required by the policy set.

To view this administrative console page when you are editing a general provider binding, complete the following actions:

1. Click **Services > Policy sets > General provider policy sets bindings**.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Authentication and protection** link in the Main message security policy bindings section.
4. Click the **Caller** link in the Main message security policy bindings section.
5. Click **New**.

To view this administrative console page when you are configuring application specific bindings for tokens and message parts that are required by the policy set, complete the following actions:

1. Click **Applications** → **Application Types** → **WebSphere enterprise applications**.
2. Select an application that contains Web services. The application must contain a service provider or a service client.
3. Click the **Service provider policy sets and bindings** link in the Web Services Properties section. The caller settings are available only for the service provider policy sets and bindings. The caller settings are not available for service client policy sets and bindings.

4. Select a binding. You must have previously attached a policy set and assigned a application specific binding.
5. Click the **WS-Security** policy in the Policies table.
6. Click the **Caller** link in the Main message security policy bindings section.
7. Click **New**.

   Note: When you create a new caller it will automatically be assigned the next available order. You can change the order of preference, as described in the Order section below.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Name:

Specifies the name of the caller to use for authentication. Enter a caller name in this required field. This arbitrary name identifies this caller setting.

Order:

Specifies the order of preference for the callers. The order determines which caller will be utilized when multiple authentication tokens are received.

You can change the order of preference by moving a caller up or down in the list. Click the checkbox next to a caller name to select the caller, then click the **Move up** button to move the caller higher in the list, or click the **Move down** button to move the caller to a lower position in the preference order.

Button	Resulting Action
Move up	Moves the order of the selected caller up in the caller list.
Move down	Moves the order of the selected caller down in the caller list.

Note: The order column displays only for bindings using the new namespace. If a binding with multiple callers was migrated to the new namespace, then the callers do not have an order. In that case, an error message is displayed. When this occurs, select a caller in the table and then click either **Move up** or **Move down** to assign an order to each caller. Callers must have orders assigned before you save the bindings or use the bindings with an application.

Caller identity local part:

Specifies the local name of the caller to use for authentication. Enter a caller identity local name in this required field.

When specifying an LTPA caller, use LTPA as the local name for a caller that uses an older binding, prior to IBM WebSphere Application Server, Version 7.0. Newer bindings for IBM WebSphere Application Server, Version 7.0 and later should use LTPAv2 as the local name. Specifying LTPAv2 allows both LTPA and LTPAv2 tokens to be consumed, unless the Enforce token version option is selected on the token consumer.

Caller identity URI:

Specifies the uniform resource identifier (URI) of the caller to use for authentication. Enter a caller URI in this field.

When specifying an LTPA caller, use http://www.ibm.com/websphere/appserver/tokentype/5.0.2 as the URI for a caller that uses an older binding, prior to IBM WebSphere Application Server, Version 7.0. Newer

bindings for IBM WebSphere Application Server, Version 7.0 and later should use the http://www.ibm.com/websphere/appserver/tokentype URI.

Use identity assertion:

Specifies whether identity assertion is used when authenticating. Select this check box if you want to use identity assertion. Select this box to enable the **Trusted identity local name** and **Trusted identity URI** fields.

Trusted identity local name:

Specifies the trusted identity local name when the identity assertion is used. Enter a trusted identity local name in this entry field when the identity assertion is used.

Trusted identity URI:

Specifies the trusted identity uniform resource identifier (URI). Enter a URI in this entry field when the identity assertion is used.

Signing part reference:

When the trusted identity is based on a signing token, select the signing part reference that represents the message parts signed by that token.

Callback handler:

Specifies the class name of the callback handler. Enter the class name of the callback handler in this field.

JAAS login:

Specifies the Java Authentication and Authorization Service (JAAS) application login. You can enter a JAAS login, select one from the menu, or click **New** to add a new one.

Custom properties – Name:

Specifies the name of the custom property.

Custom properties are not initially displayed in this column. Select one of the following actions for custom properties:

Button	Resulting Action
New	Creates a new custom property entry. To add a custom property, enter the name and value.
Edit	Specifies that you can edit the custom property value. At least one custom property must exist before this option is displayed.
Delete	Removes the selected custom property.

Custom properties – Value:

Specifies the value of the custom property that you want to use. Use the Value field to add, edit, or delete the value for a custom property.

Caller collection

The caller specifies the token or message part that you want to use for authentication. Use this administrative console page to access, view and configure the caller settings for message parts.

To configure general bindings for tokens and message parts that are required by the policy set, complete the following steps.

1. To access and configure the general bindings, click **Services > Policy sets > General provider policy set bindings**. The caller settings are available only for the service provider policy sets and bindings. The caller settings are not available for service client policy sets and bindings.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Caller** link in the Main message security policy bindings section.

To view and configure application specific bindings for tokens and message parts that are required by a policy set, complete the following steps:

1. Click **Applications > Application Types > WebSphere enterprise applications**.
2. Select an application that contains Web services. The application must contain a service provider.
3. Click the **Service provider policy sets and bindings** link in the Web Services Properties section. The caller settings are available only for the service provider policy sets and bindings. The caller settings are not available for service client policy sets and bindings.
4. Select a binding. You must have previously attached a policy set and assigned an application specific binding.
5. Click the **WS-Security** policy in the Policies table.
6. Click the **Caller** link in the Main message security policy bindings section.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Name:

Specifies the name of the caller to use for authentication. Select a caller name from this field.

The following actions are available to work with callers.

Button	Resulting Action
New	Opens the Caller settings page, which you use to add a caller.
Delete	Removes the selected caller.

Order:

This number specifies the order of preference for the configured callers. If multiple caller tokens are found in an incoming message, the caller used for authentication will be the one with highest priority, based on decreasing order of preference.

You can change the order of preference using the **Move Up** and **Move Down** buttons.

Button	Resulting Action
Move Up	Moves the selected caller up in the order of preference, switching positions with the immediately preceding caller. The selected caller is now preferred over the caller that you demoted in the list.
Move Down	Moves the selected caller lower in the order of preference, switching positions with the caller following it. The demoted caller is now lower in preference than the caller that was previously below it.

Caller Identity Local Part:

Specifies the local identity part of the caller to use for authentication.

Caller Identity URI:

Specifies the uniform resource identifier (URI) of the caller to use for authentication.

Message expiration settings

Use this page to define settings for message expiration, if and when messages expire. When you specify message expiration, the message expires after the specified interval of time passes.

You can define message expiration settings for tokens and message parts when you are editing a default cell or server binding. You can also configure application specific bindings for tokens and message parts that are required by the policy set.

To view this administrative console page when you are editing a default cell binding, complete the following actions:

1. Click **Services > Policy sets > Default policy set bindings**.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Message expiration** link in the Main message security policy bindings section.

To view this administrative console page when you are configuring application specific bindings for tokens and message parts that are required by the policy set, complete the following actions:

1. Click **Applications** → **Application Types** → **WebSphere enterprise applications**.
2. Select an application that contains Web services. The application must contain a service provider or a service client.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** in the Web Services Properties section.
4. Select a binding. You must have previously attached a policy set and assigned a application specific binding.
5. Click the **WS-Security** policy in the Policies table.
6. Click the **Message expiration** link in the Main message security policy bindings section.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Message expiration:

Specifies whether message expiration is enabled. To enable message expiration, select this check box. Leave it unchecked to disable message expiration.

Message timeout interval:

Specifies the time, in minutes, for the message to time out if message expiration is enabled. This field is enabled only when you select the **Enable message expiration** check box.

Actor roles settings

Use this page to define settings for SOAP actor roles. The SOAP actor, also known as the SOAP role, defines the intermediary or ultimate recipient of a message.

To view this administrative console page use one of the following options:

1. Click **Applications** → **Application Types** → **WebSphere enterprise applications**.
2. Select an application that contains Web services. The application must contain a service provider or a service client.

3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** in the Web Services Properties section.
4. Select a binding. The binding must have previously attached a policy set and assigned a application specific binding.
5. Click the **WS-Security** policy in the Policies table.
6. Click the **Actor roles** link in the Main message security policy bindings section.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Inbound actor role URI:

Specifies the name of the uniform resource identifier (URI) for the inbound actor role.

Outbound actor role URI:

Specifies the name of the uniform resource identifier (URI) for the outbound actor role.

Web Services Addressing policy set binding

Use this page to modify the endpoint reference binding for Web Services Addressing (WS-Addressing). The product enforces this binding on JAX-WS Web service applications that use WS-Addressing. This panel applies only to the Network Deployment version of the product.

To view this administrative console page, click **Services** → **Policy Sets** → **Default policy set bindings** → **WS-Addressing**.

Prevent workload management of referenced endpoints in clusters:

By default, when an application uses the WS-Addressing API createEndpointReference(service, port) method to create an endpoint reference in a cluster environment, that endpoint reference is workload managed. Select this option to prevent the workload management of such endpoint references.

If you select this option, messages that are targeted at such an endpoint reference are always sent to the node on which the endpoint reference was created. This behavior is useful when the endpoint contains in-memory state that is held on a single node, for example, in Web Services Resource Framework (WS-RF) applications.

Note: Although the endpoint reference always represents the same endpoint, the state that is held at that endpoint is not reliable. If the node that is hosting the endpoint fails, the state could be lost. Note also that if the node fails, the endpoint reference is no longer valid.

Data type Check box

Default Cleared

Range

Cleared
Endpoint references that are created by the application in a cluster environment are workload managed.

Selected
Endpoint references that are created by the application in a cluster environment are not workload managed.

Attaching a policy set to a service artifact

Attach a policy set to a service artifact, such as an application, service, or endpoint to define the quality of services that are supported. Policy sets can define the policies for WS-Addressing, WS-Security, WS-ReliableMessaging, WS-Transaction, HTTP transport, Java Messaging Service (JMS) transport, and Secure Sockets Layer (SSL) transport.

Before you begin

Before you can start this task, you must deploy an application containing Web services. Also, if none of the default policy sets contain the necessary policy definitions, then you must create a custom policy set with the necessary definitions.

About this task

Develop a Web service that contains each of the necessary artifacts, and deploy your Web services application into your application server instance. Now you can attach policy sets to your service artifacts, such as an application, service, or endpoint. To attach a policy set to a service artifact perform the following steps:

1. Open the administrative console.
2. To attach a policy set to a service provider, click **Applications > Enterprise applications** > ***application_name*** > **Service provider policy sets and bindings**.

   To attach a policy set to a service client, click **Applications > Enterprise applications** > ***application_name*** > **Service client policy sets and bindings**.
3. Select the check box for the service artifact.
4. Select **Attach** to display a list of available policy sets to attach. Select a policy set from the list.
5. Click **Save**, to save your changes to the master configuration.
6. [Optional] To see what attachments are defined for a given policy set, select **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name*** > **Attached applications**.

Results

When you finish these steps, a policy set is attached to the service artifact.

Example

If you have the application, `app1` and you want to attach the policy set, `WSSecurity default`, then perform the following steps:

1. Locate the `app1` application in the **Applications** > **Enterprise applications** collection.
2. Click the **`app1`** application.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** link.
4. Select the check box for the service artifact where the policy set is to be attached.
5. Click **Attach**. Select **`WSSecurity default`** policy set.
6. Click **Save**, to save your changes to the master configuration.

What to do next

You can create custom bindings for policy set attachments. Read about creating custom bindings for policy set attachments.

You can configure the service client or service provider to share their policies. Read about using WS-Policy to exchange policies in a standard format.

Related tasks

"Creating application specific bindings for policy set attachment" on page 838
After you attach a policy set to a service artifact such as an application, service, or endpoint, you can define application specific bindings for the attached policy set.

"Reassigning bindings to policy sets" on page 856
After you create a custom attachment binding, you can reassign that binding to another service artifact if necessary. You can reset a service artifact, such as an application, service, or endpoint to use the inherited bindings or default bindings.

"Modifying default bindings at the server level for policy sets" on page 855
You can define default bindings for HTTP transport, JMS transport, Secure Sockets Layer (SSL) transport, WS-Addressing, WS-ReliableMessaging, and WS-Security policies.

"Using WS-Policy to exchange policies in a standard format" on page 714
WS-Policy is an interoperability standard that is used to describe and communicate the policies of a Web service so that service providers can export policy requirements in a standard format. Clients can combine the service provider requirements with their own capabilities to establish the policies required for a specific interaction. WebSphere Application Server conforms to the WS-Policy specification, so that policy information can be exchanged and received in accordance with the WS-Policy standard.

Managing policies in a policy set using the administrative console

When working with policy sets in the administrative console, you can customize the included policies to ensure message security. You can enable, disable, customize, add, or delete policies from a policy set. With your policy sets, you can define policies for WS-Addressing, WS-Security, WS-ReliableMessaging, WS-Transaction, HTTP transport, Java Messaging Service (JMS) transport, and Secure Sockets Layer (SSL) transport. The policies for all but WS-Security are relatively straightforward to define.

Before you begin

You can customize the policies for custom policy sets. The provided default policy sets cannot be edited. Make sure that you have created a copy of the default policy set or created a completely new policy set to specify the policies for this policy set.

About this task

Customize policies associated with a policy set using the administrative console.

1. Click one of the following:
   - **Services > Policy sets > Application policy sets** >*policy_set_name*
   - **Services > Policy sets > System policy sets** >*policy_set_name*

   You can also click **Services > Policy sets > Application policy sets** > **New** or **Services > Policy sets > System policy sets** > **New**. Follow this path when you want to create a new policy set and the associated policy or policies.
2. Add a policy to a custom policy set. To do this, see "Adding policies to policy sets using the administrative console" on page 903.
3. Enable a policy for a custom policy set. To do this, see "Enabling policies for policy sets using the administrative console" on page 950.
4. Optional: You can also disable a policy from a custom policy set. To do this, see "Disabling policies from policy sets using the administrative console" on page 951.
5. Optional: You can also delete a policy from a custom policy set. To do this, see "Deleting policies from policy sets using the administrative console" on page 904.

Results

After you have customized your policies, the associated policy set can protect messages according to the policy or policies defined.

What to do next

If the policy set you have modified is an attached policy set, restart all affected applications to pick up the changes you made. If the policy set is unattached, then no further action is required.

Adding policies to policy sets using the administrative console

You can use the administrative console to add policies to policy sets. Adding and configuring policies to a policy set further defines the rules governing the policy set.

Before you begin

Before adding a policy to a policy set, check that it is not listed as disabled in the **Policies** table. A disabled policy can be listed for the policy set and only need to be enabled to be included in the policy set. If this is the case, the policy does not need to be added and it is not available to be added.

About this task

All policies are initially set to their default values. These values can be edited and the attributes changed using the administrative console.

1. Click **Services > Policy sets > Application policy sets** > ***policy_set_name*** or **Services > Policy sets > System policy sets > *policy_set_name***. This displays a listing of available policies in the **Policies** table for the policy set selected. If you created a new policy set and did not copy and rename an existing policy set, this table might contain no policies and you must add them.
2. Add a policy. To add a policy not listed in the **Policies** table of the Policy set settings page, click the **Add** drop down button. This button displays a list of available policies that are not already listed in the **Policies** table and therefore not included in the policy set.
3. Click the policy to be added. The selected policy is added to the **Policies** table. Each policy you add has default settings that can be modified.

Results

After you have added a policy, it is then included in the policy set.

Example

If you were working on policy set ABC_ps (that you created and it therefore has no policies associated with it) you would click the ABC_ps name in the **Policy Sets** collection and then click the **Add** button in the **Policies** table on the **Policy set** settings window. The drop down list displays all available policies for you to choose from. You might decide you want to include the WS-Addressing and WS-Security policies for this policy set. You would select each of those from the list. Then, click the policy name in the table to edit the properties of these policies.

What to do next

If the modified policy set is an attached policy set, restart all affected applications to apply the changes. If the policy set is unattached, then no further action is required.

Use this page to view, create, enable or disable your policy sets. You can use policies, or assertions that define services, to simplify your Web services configuration.

Deleting policies from policy sets using the administrative console

You can use the administrative console to delete policies from policy sets. Deleting the policy removes the policy that further defined the rules governing the policy set.

Before you begin

Before deleting a policy from a policy set, be sure that you no longer want the policy to be available to the policy set. Otherwise, consider disabling it so that it is still available to the policy set but not currently associated with the policy set. You can disable the policy and leave it available for the policy set by clicking the **Select** button by the policy to be disabled and then clicking the **Disable** button. That policy (and any configuration changes you have made to it) is still available to the policy set but is not currently included in the policy set.

About this task

To delete a policy from a policy set, use the administrative console.

1. Click **Services > Policy sets > Application policy sets** > ***policy_set_name*** or **Services > Policy sets > System policy sets > *policy_set_name***. The Policy set settings page displays a listing of available policies in the **Policies** table of the Policy set settings page for the policy set selected. If you created a new policy set and did not copy and rename an existing policy set, this table might contain no policies to delete.
2. Delete the policy from the policy set.
   a. Click the **Select** box beside the policy that you want to delete in the **Policies** table of the Policy set settings page.

b. Click the **Delete** button.

3. Verify that you want to delete the selected policy from the policy set.

Results

You have deleted the policy from the policy set.

Example

If you have a policy set containing a policy that you no longer want included in that policy set, you have two options: disable it or delete it. In some cases, you might want to disable the policy if you have configured attributes for it that you might want to enable at a later time. You can disable the policy and leave it available for the policy set by clicking the **Select** button by the policy to be disabled and then clicking the **Disable** button. But for this example, you have decided that the policy WS-Addressing is no longer valid for your custom policy set ABC_ps and you and you want to delete it. To delete it, click the **Select** button beside the WS-Addressing policy and then click **Delete**. Confirm that you want to delete the policy.

What to do next

You can now add other policies to the policy set or enable or disable existing policies.

Modifying policies using the administrative console

With your policy sets, you can define policies for WS-Addressing, WS-Security, WS-ReliableMessaging, WS-Transaction, HTTP transport, Java Messaging Service (JMS) transport, and Secure Sockets Layer (SSL) transport. The policies for all but WS-Security are relatively straightforward to define.

Before you begin

The provided default policy sets cannot be edited. You can create a copy of the default policy set or create a completely new policy set in order to specify the policies for it.

About this task

Polices are associated with policy sets, so you can change an instance of a policy for a particular policy set.

1. Select the policy set containing the policy you want to modify. To customize the policies associated with a policy set, from the administrative console, click:
   - **Services > Policy sets > Application policy sets** >*policy_set_name*. Click a policy name in the Policies table.
   - Or **Services > Policy sets > System policy sets** >*policy_set_name*. Click a policy name in the Policies table.
2. Modify the settings. Depending on which Policy you choose, different settings can be modified.
3. [Optional] If the policy to be modified is not already in the Policies table, click **Add** and select a policy from the list to modify.
4. Save the changes you have made. Once you change the settings on a policy, you need to save the changes to return to the policy set.

Results

The policy set configuration is saved with the selected modifications.

Example

You have created a copy of the WSReliableMessaging persistent policy set and named it `WSRM_p1`. You want to change the settings on the WSReliableMessaging policy that is included, by default, in the copy of this policy set. So you click your `WSRM_p1` policy set from the Application policy sets window and then click the WSReliableMessaging policy from the Policies table. You can then alter the following settings:

Standard
The default setting is WSReliableMessaging 1.1.

Deliver messages in the order that they were sent
The default setting is false. Valid values are true or false.

Quality of service
The default is Unmanaged non-persistent

Enable 'MakeConnection' for synchronous two-way message exchange
This setting is selected by default.

Save your changes and return to the Application policy sets window for the WSRM_p1 policy set.

What to do next

You can use the policy set as you have configured or you can change the bindings, attach or detach the policy set from applications.

Note: Because this policy set specifies managed persistent quality of service, you need to define bindings to the service integration bus and messaging engine that you want to use to manage the WS-ReliableMessaging state. For more information, see "Attaching and binding a WS-ReliableMessaging policy set to a Web service application using the administrative console" on page 657 or using the wsadmin tool.

Configuring the WS-ReliableMessaging policy:

When working with policy sets in the administrative console, you can customize some policies.

Before you begin

This task assumes that you are working with a policy set to which the WS-ReliableMessaging policy has been added.

Do not edit the policies associated with the provided default policy sets. If you need to modify the reliable messaging policy settings, use a copy of a default policy set or create a new policy set.

At any stage - that is, before or after you have built your reliable Web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

About this task

To configure the WS-ReliableMessaging policy for a given policy set, use the administrative console to complete the following steps:

1. In the navigation pane, click **Services** → **Policy sets** → **Application policy sets** → ***policy_set_name*** → **WS-ReliableMessaging**. The "WS-ReliableMessaging settings" on page 908 form is displayed.
2. Modify one or more of the following properties:

   Standard

   Select the WS-ReliableMessaging specification to use for reliable transmission of your messages. WS-ReliableMessaging Version 1.1 is the default value. Details of the supported WS-ReliableMessaging specifications are available at the following Web addresses:

   - The WS-ReliableMessaging specification Version 1.0, February 2005.
   - The OASIS WS-ReliableMessaging specification Version 1.1, February 2007.

   Note: If you plan to invoke a .NET-based Web service, you must select WS-ReliableMessaging Version 1.0.

   Deliver messages in the order that they were sent

   Select this option if the sender of a request has to receive a response before it sends the next request, or if you want to enable transaction support for inbound (provider) message exchanges as described in "Providing transactional recoverable messaging through WS-ReliableMessaging" on page 653, or if you want to marginally increase reliability as described in "A message is not recovered after a server becomes unavailable, even with the managed persistent quality of service" on page 668.

   Note: When you enable this option, WS-ReliableMessaging ensures that the messages are made available to the requester application in the order that they were sent. That is, if WS-ReliableMessaging cannot make a given message available, it will not make any subsequent messages available. However, the requester application must also poll for the messages in the order in which it wants to receive them. For example:

   a. WS-ReliableMessaging makes message 1 available, then message 2, then message 3.
   b. The requester application uses asynchronous polling to deliberately poll for message 2, then message 3, then message 1. All three messages are available, so this polling out of order is successful.

   Even though WS-ReliableMessaging is delivering the messages in the order that they were sent, the requester application is choosing to receive them out of order.

Quality of service

Click a radio button to choose the required quality of service. The three choices are:

Unmanaged non-persistent

You can configure Web service applications to use WS-ReliableMessaging with a default in-memory store. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages.

Managed non-persistent

This in-memory quality of service option uses a messaging engine to manage the sequence state, and messages are written to disk if memory is low. This quality of service allows for the re-sending of messages that are lost in the network, and can also recover from server failure. However, state is discarded after a messaging engine restart so in this case you will lose messages.

Managed persistent

This quality of service for asynchronous Web service invocations is recoverable. This option also uses a messaging engine and message store to manage the sequence state. Messages are persisted at the Web service requester server and at the Web service provider server, and are recoverable if the server becomes unavailable. Messages that have not been successfully transmitted when a server becomes unavailable can continue to be transmitted after the server restarts.

The default is unmanaged non-persistent.

Note: All three qualities of service are supported when applications are deployed to the application server. Thin client and client container applications use the first option only.

3. Click **OK**.
4. Save your changes to the master configuration.

Results

After you have customized the reliable messaging policy, the associated policy set uses this policy to help ensure reliable delivery of messages.

WS-ReliableMessaging settings:

For the WS-ReliableMessaging policy you can configure the version of the WS-ReliableMessaging standard that you want to use, the order in which messages are delivered, and the required quality of service (the reliability level) for message delivery. The product can enforce these policies on inbound messages and applies them to outbound messages.

To view this pane in the console, click the following path: **Services** → **Policy sets** → **Application policy sets** → ***policy_set_name*** → **WS-ReliableMessaging**.

With WebSphere Application Server, you can use WS-ReliableMessaging with Java API for XML-Based Web Services (JAX-WS) 2.1 Web services applications that use a SOAP over HTTP binding. To configure a Web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent.

Do not edit the policies associated with the provided default policy sets. If you need to modify the reliable messaging policy settings, use a copy of a default policy set or create a new policy set.

At any stage - that is, before or after you have built your reliable Web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

Standard: Select the WS-ReliableMessaging specification to use for reliable transmission of your messages. WS-ReliableMessaging Version 1.1 is the default value. Details of the supported WS-ReliableMessaging specifications are available at the following Web addresses:

- The WS-ReliableMessaging specification Version 1.0, February 2005.
- The OASIS WS-ReliableMessaging specification Version 1.1, February 2007.

Note: If you plan to invoke a .NET-based Web service, you must select WS-ReliableMessaging Version 1.0.

Deliver messages in the order that they were sent:

Select this option if the sender of a request has to receive a response before it sends the next request.

If you enable in-order delivery, you must also ensure that the requester application polls for the messages in the order in which it wants to receive them. For more information, see “Configuring the WS-ReliableMessaging policy” on page 907.

Specifying in-order delivery also marginally increases reliability if you are using the managed persistent quality of service. For more information, see “A message is not recovered after a server becomes unavailable, even with the managed persistent quality of service” on page 668.

Quality of Service: Select one of the following qualities of service:

Unmanaged non-persistent - Tolerates network and remote system failures
You can configure Web service applications to use WS-ReliableMessaging with a default in-memory store. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. The default is Unmanaged Non-Persistent.

Managed non-persistent - Tolerates system, network, and remote system failures, but state is discarded after messaging engine restart
This in-memory quality of service option uses a messaging engine to manage the sequence state, and messages are written to disk if memory is low. This quality of service allows for the re-sending of messages that are lost in the network, and can also recover from server failure. However, state is discarded after a messaging engine restart so in this case you will lose messages.

Managed persistent - Tolerates system, network, and remote system failures
This quality of service for asynchronous Web service invocations is recoverable. This option also uses a messaging engine and message store to manage the sequence state. Messages are persisted at the Web service requester server and at the Web service provider server, and are recoverable if the server becomes unavailable. Messages that have not been successfully transmitted when a server becomes unavailable can continue to be transmitted after the server restarts.

Note:

- All three qualities of service are supported when applications are deployed to the application server. Thin client and client container applications use the first option only.
- For the unmanaged non-persistent quality of service, the messages are stored only in memory. For both of the managed qualities of service, the messages are managed by a messaging engine backed by a message store. You specify a binding to a bus and messaging engine on the

"WS-ReliableMessaging policy binding" form. If your chosen quality of service is Unmanaged Non-Persistent, which does not use a binding to a messaging engine, then any binding that you specify is ignored.

WS-ReliableMessaging policy binding:

To configure a Web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent. The managed qualities of service, managed persistent and managed non-persistent, are supported by the service integration bus. Use this page to select the bus and messaging engine to use for the reliable messaging protocol state.

To view this pane in the console, click one of the following paths:

- **Services** → **Policy sets** → **Default policy set bindings** → **Version 6.1 default policy set bindings** → **WS-ReliableMessaging** (This is the default binding for client and provider policy set attachments within WebSphere Application Server Version 6.1 applications, and attachments to service applications that are deployed to a Version 6.1 server.)
- **Services** → **Policy sets** → **General provider policy set bindings** → ***provider_policy_set_binding_name*** → **WS-ReliableMessaging** (This binding is used for the specified provider policy set.)
- **Services** → **Policy sets** → **General client policy set bindings** → ***client_policy_set_binding_name*** → **WS-ReliableMessaging** (This binding is used for the specified client policy set.)

Note:

- You only need to specify a binding to a bus and messaging engine if you are using a managed quality of service. If your chosen quality of service is Unmanaged Non-Persistent, any binding that you specify is ignored. The quality of service is defined on the "WS-ReliableMessaging settings" on page 908 form for your chosen policy set. For more information, see "Configuring the WS-ReliableMessaging policy" on page 907.
- When many applications use the same messaging engine, it can impact performance. Factors to consider include the number of applications that are already binding to the messaging engine, the CPU utilization, and the message throughput. To improve performance for a single server configuration, create a new messaging engine to bind to your application.

Bus name:

Specifies a list of available service integration buses in the cell. Use the list to select a bus, or click **Manage buses, bus members, and messaging engines** to add a new bus. The bus that you add is selected for this binding configuration when you return to this panel.

Messaging engine name:

Specifies a list of each bus member for the selected bus. Use the list to select a bus member, or click **Manage buses, bus members, and messaging engines** to add a new bus member. The bus member that you add is selected for this binding configuration when you return to this panel.

Configuring the WS-Addressing policy:

When working with policy sets in the administrative console, you can add and configure policies to enable standard addressing of Web services.

Before you begin

You can specify policies for custom policy sets. The provided default policy sets cannot be edited. You must create a copy of the default policy set or create a completely new policy set in order to specify the policies for it.

About this task

Adding a WS-Addressing policy enables the support for WS-Addressing. This support provides a standard way to address Web services and include addressing information in messages. Adding a WS-Addressing policy is equivalent to configuring the WSDL file for the Web service to specify that WS-Addressing should be used.

To specify or configure the policies associated with a policy set, use the administrative console.

1. In the navigation pane of the administrative console, click **Services Policy sets** → **Application policy sets** > ***policy_set_name*** → **[Policies] WS-Addressing**. The WS-Addressing settings pane is displayed.
2. Select **WS-Addressing is mandatory** to specify that WS-Addressing information must be included in SOAP message headers. For servers, this setting means that the server returns a fault if it receives a message that does not contain a WS-Addressing header. For clients, this setting means that WS-Addressing headers are always added to SOAP messages. If you have enabled WS-Policy, this requirement is communicated between servers and clients that support WS-Policy.
3. In the **Messaging style** box, select the message exchange pattern to use:
   - **Synchronous and asynchronous**. The targeting of response messages is not restricted.
   - **Synchronous only**. Response messages must be targeted at the WS-Addressing anonymous URI.
   - **Asynchronous only**. Response messages must not be targeted at the WS-Addressing anonymous URI.
4. Click **OK**.
5. Save your changes to the master configuration.

Results

After you have included the WS-Addressing policy in a policy set, the associated policy set uses this policy to address Web services.

WS-Addressing policy settings:

Use this panel to define the appropriate WS-Addressing policy assertions for this policy set.

To view this administrative console page, click **Services** → **Policy sets** → **Application policy sets** → ***policy_set_name*** → **[Policy] WS-Addressing**, when the policy set includes the WS-Addressing policy type.

You can configure the WS-Addressing policy type for both client-side and provider-side policy sets. If you enable WS-Policy, this configuration is communicated between servers and clients that support WS-Policy.

WS-Addressing is mandatory:

Specifies whether a WS-Addressing SOAP header is included on messages.

Data type	Check box
Default	Cleared

Range

Cleared
WS-Addressing is not mandatory. Servers will not generate a fault if they receive a message that does not contain a WS-Addressing header. Clients might not include WS-Addressing headers in SOAP messages, for example, if WS-Policy is enabled and the server does not specify that WS-Addressing is mandatory.

Selected
WS-Addressing is mandatory. Servers return a fault if they receive a message that does not contain a WS-Addressing header. Clients always include WS-Addressing headers in SOAP messages.

Messaging style:

Specifies the messaging style supported by this policy set.

Use the radio buttons to configure the messaging style.

- Select **Synchronous and asynchronous** to specify that there is no restriction on the targeting of response messages.
- Select **Synchronous only** to specify that response messages must be targeted at the WS-Addressing anonymous URI. You might want to use this messaging style in the following situations:
  - The SOAP headers are not signed, and WS-Security is not enabled. Specifying the synchronous message exchange pattern prevents the server sending messages to a third party, thereby preventing the server from potentially taking part in a Denial of Service attack.
  - Clients with a NAT device between themselves and the endpoint. In this configuration, non-anonymous URIs cannot be routed. Use this setting to prevent the client from sending a message containing a ReplyTo endpoint reference with a non-anonymous URI.
- Select **Asynchronous only** to specify that response messages must not be targeted at the WS-Addressing anonymous URI. This setting does not mean that all non-anonymous URIs are supported, therefore a server can return a fault if it receives a response endpoint reference that it cannot process. You might want to use this messaging style if the endpoint has a very long-running invocation time, and you do not want to hold the connection open while waiting for a response.

The following table shows how the messaging style options correspond to WS-Policy assertions.

Table 7.

Messaging style	WS-Policy mapping
Synchronous and asynchronous	wsam:AnonymousResponses or wsam:NonAnonymousResponses
Synchronous only	wsam:AnonymousResponses
Asynchronous only	wsam:NonAnonymousResponses

Required No
Data type Radio button

Configuring the HTTP transport policy:

When working with policy sets in the administrative console, you can customize policies to ensure message security. You can customize the Hypertext Transfer Protocol (HTTP) transport policy configuration or use the policy as it is provided with the default settings.

Before you begin

You can configure some settings for default policies for custom policy sets. The provided default policy sets cannot be edited. To customize a policy set, you must create a copy of the default policy set or create a new policy set and specify the policies for the custom policy set.

About this task

You can configure HTTP transport with the HTTP transport policy. HTTP is an application-level protocol for distributed, collaborative, hypermedia information systems. It is a generic, stateless, protocol that can be used for many tasks beyond its use for hypertext, such as name servers and distributed object management systems, through extension of request methods, error codes and headers. A feature of HTTP is the typing and negotiation of data representation, allowing systems to be built independently of the data being transferred. HTTP features and HTTP connections properties are applied to outbound messages for both the service client and service provider.

You can only configure a policy through a policy set. Therefore, before you can configure the HTTP transport policy, a policy set must exist that contains the HTTP transport policy. The provided default WSHTTPS policy set is read only and it cannot be edited. To customize a policy set that contains the HTTP transport policy, you must first create a copy of the WSHTTPS default policy set or create a new policy set and add the HTTP transport policy to the new policy set.

Note: The WSHTTPS default policy set contains the HTTP transport policy, the SSL transport policy and WS-Addressing policy. If you do not require the SSL transport policy or the WS-Addressing policy, you can customize your copy of the WSHTTPS default policy set to delete the policies that you do not require.

After you have created a copy of the WSHTTPS default policy set or created a new policy set with the HTTP transport policy added, you can customize the HTTP transport policy. Use the HTTP transport policy settings panel to customize the values of the HTTP transport policy properties such as read or write timeout values. Your customized values for the HTTP transport policy now apply for your policy set that contains that custom HTTP transport policy. You can attach this policy set containing your customized HTTP transport policy to your Java API for XML-Based Web Services (JAX-WS) application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that policy set is attached. To learn more about attaching policy sets to applications, see the documentation for managing policy sets for service providers and service clients at the application level.

For example, if you have multiple policy sets, *mypolicyset1* and *mypolicyset2*, containing the HTTP transport policy, you can customize the HTTP transport policy for each policy set to reflect different properties, such as timeout values. Now, you can attach these customized policy sets to one or more applications and these applications will use the HTTP property values associated with the HTTP transport policy that is contained within the attached policy set.

1. Create a policy set that contains the HTTP transport policy.
   a. Create a custom policy set.

      From the administrative console, click **Services > Policy Sets > Application policy sets** . From this panel you can create a new policy set, copy an existing default policy set such as WSHTTPS, import a copy of a policy set from the default repository or you can import an existing policy set from your specified location.

b. Add the HTTP transport policy to the policy set. From the administrative console, click **Services > Policy Sets > Application policy sets > *policy_set_name***. In the policy collection, click **HTTP transport**. The HTTP transport window displays options for configuring the HTTP settings for the transport policy.

c. In the **Protocol Version** drop down list, click the HTTP version to use. HTTP 1.1 is the default setting but HTTP 1.0 is also available. Selecting HTTP 1.1 enables more of the function on the rest of the HTTP transport window as some of the options are not available for HTTP version 1.0.

d. Complete the HTTP Features section. The following check boxes determine which HTTP features are enabled for this transport:

Session Enabled
Whether the HTTP session is enabled when a message is sent.

Enable chunked transfer encoding
Whether chunked transfer encoding is enabled when a message is sent. This option is only available if HTTP 1.1 is selected in the **Protocol version** field (it is greyed out and disabled if HTTP 1.0 is selected).

Send expect ″100-request″ header
Displays whether the expect ″100-request″ header is enabled when a message is sent. This option is only available if HTTP 1.1 is selected in the **Protocol version** field (it is greyed out and disabled if HTTP 1.0 is selected).

Accept URL redirection automatically
Displays whether the URL is automatically redirected when a message is sent.

Compress request content
Displays whether the request content is compressed when a message is sent.

Compress response content
Displays whether the response content is compressed when a message is sent.

e. Complete the HTTP Connections section. The following fields determine how HTTP connections are configured for this transport:

Read timeout
Displays the length of time, in seconds, for the read to time out when a message is sent.

Write timeout
Displays the length of time, in seconds, for the write to time out when a message is sent.

Connection timeout
Displays the length of time, in seconds, for the connection to time out when a message is sent.

Use persistent connection
Displays whether a persistent connection is to be used when a message is sent. This option is only available if HTTP 1.1 is selected in the **Protocol version** field.

Resend enabled
Displays whether or not a message can be resent. Click this check box to enable a message to be sent again.

2. Customize the HTTP transport provider bindings.

a. Navigate to the HTTP transport provider bindings. From the administrative console, click **Services > Policy Sets > General provider policy set bindings > *provider_policy_set_binding_name* > HTTP transport**.

The HTTP transport (bindings) window displays options for configuring the HTTP transport bindings.

b. Specify the properties for the Proxy for outbound asynchronous service responses.

The following fields determine proxy specifications for outbound asynchronous service responses:

Host Displays the host name for the outbound asynchronous service responses proxy.

Port Displays the port number for the outbound asynchronous service responses proxy. You can enter or edit the port number.

User name
Displays the user name for the outbound asynchronous service responses proxy.

Password
Displays a placeholder for the password for the outbound asynchronous service responses proxy. You can enter or edit the password. The actual password is masked.

Confirm password
Displays a placeholder for the password for the outbound asynchronous service responses proxy that must match the one in the **Password** field. The actual password is masked.

c. Specify the properties for the Basic authentication for outbound asynchronous responses.

The following fields determine authentication specifications for outbound asynchronous responses:

User name
Displays the user name for basic authentication of outbound asynchronous responses.

Password
Displays a placeholder for the password for basic authentication of outbound asynchronous responses. The actual password is masked.

Confirm password
Displays a placeholder for the password for basic authentication of outbound asynchronous responses that must match the one in the **Password** field. The actual password is masked.

3. Customize the HTTP transport client bindings.

a. Navigate to the HTTP transport client bindings. From the administrative console, click **Services > Policy Sets > General client policy set bindings > *provider_policy_set_binding_name* > HTTP transport**.

The HTTP transport (bindings) window displays options for configuring the HTTP transport bindings.

b. Specify the properties for the Proxy for outbound service requests. The following fields determine proxy specifications for outbound service requests:

Host Displays the host name for the outbound service request proxy.

Port Displays the port number for the outbound service request proxy.

User name
Displays the user name for the outbound service request proxy.

Password
Displays a placeholder for the password for the outbound service request proxy. The actual password is masked.

Confirm password
Displays a placeholder for the password for the outbound service request proxy that must match the one in the **Password** field. The actual password is masked.

c. Specify the properties for Basic authentication for outbound service requests. The following fields determine authentication specifications for outbound service requests:

User name
Displays the user name for basic authentication of outbound service requests.

Password
Displays a placeholder for the password for basic authentication of outbound service requests. The actual password is masked.

Confirm password
Displays a placeholder for the password for basic authentication of outbound service requests that must match the one in the **Password** field. The actual password is masked.

a.

Results

After you have customized the HTTP transport policy, the associated policy set uses this policy to protect message transmission.

Example

You can attach policy sets to an application, its services, endpoints, or operations. In this example scenario, suppose you have two different JAX-WS service clients for your application, but you want to use different HTTP transport property values for each service client. Specifically, you want to configure a different read or write timeout value for each service client. To modify the HTTP timeout values, you can edit the values of the HTTP transport policy that is contained within the policy set that is attached to your application or in this case, your service client. This change affects all applications to which the policy set containing the custom HTTP transport policy is attached.

This example describes the steps for configuring different read, write, and connection timeout values for service clients deployed in the same application server. This example makes the following assumptions:

- There are two JAX-WS service clients, ServiceClient1 and ServiceClient2, that are deployed in the application server.
- The HTTP transport policy has not been previously attached to these applications.

1. Create two new policy sets and add the HTTP transport policy to them. For example: *HTTPServiceClient1Policy* and *HTTPServiceClient2Policy*
   a. Click **Services > Policy sets > Application policy sets > New** .
   b. Enter the name of the new application policy set, *HTTPServiceClient1Policy*.
   c. From the Policies collection, click **Add > HTTP transport**.
   d. Click **Apply** and **Save** to save your changes to the master configuration.
   e. Repeat these steps to create the HTTPServiceClient2Policy.
2. Customize the HTTP transport policy settings for the newly created HTTPServiceClient1Policy and HTTPServiceClient2Policy policy sets. For example, customize the read and write timeout values for the HTTP transport policy contained in the HTTPServiceClient1Policy policy set and the connection timeout value for the HTTP transport policy contained in the HTTPServiceClient2Policy policy set.
   a. Click **Services > Policy sets > Application policy sets >***HTTPServiceClient1Policy* .
   b. From the Policies collection, click **HTTP transport**.
   c. From the HTTP transport policy configuration panel, change the HTTP connection read and write timeout values to 500 seconds.
   d. Click **Apply** and **Save** to save your changes to the master configuration.
   e. Click **Services > Policy sets > Application policy sets >***HTTPServiceClient2Policy* .
   f. From the Policies collection, click **HTTP transport**.
   g. From the HTTP transport policy configuration panel, change the HTTP connection timeout value to 360 seconds.
   h. Click **Apply** and **Save** to save your changes to the master configuration.
3. Attach the custom HTTP transport policy, HTTPServiceClient1Policy, to your application, ServiceClient1. Similarly, attach the custom HTTP transport policy, HTTPServiceClient2Policy, to ServiceClient2.
   a. Click **Services > Service clients >** *ServiceClient1*.
   b. From the Policy set attachments collection, select the service, *ServiceClient1*.

c. Click **Attach Client Policy Set** and click on *HTTPServiceClient1Policy*.
d. Click **Save** to save your changes to the master configuration.
e. Click **Services > Service clients >** *ServiceClient2*.
f. From the Policy set attachments collection, select the service, *ServiceClient1*.
g. Click **Attach Client Policy Set** and click on *HTTPServiceClient2Policy*.
h. Click **Save** to save your changes to the master configuration.

As a result, the ServiceClient1 application now has the HTTPServiceClient1Policy attached and the HTTP sessions will use a read and write timeout value of 500 seconds. The ServiceClient2 application has the HTTPServiceClient2Policy attached and the HTTP sessions will use a connection timeout value of 360 seconds.

What to do next

You can customize policies to ensure message security by configuring the SSL transport policy.

HTTP transport policy settings:

Use this page to define HTTP transport policy configuration. HTTP features and HTTP connection policies are applied to outbound messages. Any changes to the HTTP transport policy from this console page affects all Java API for XML-Based Web Services (JAX-WS) applications to which this custom HTTP transport policy is attached.

To view this administrative console page, click **Services > Policy sets > Application policy sets** >*policy_set_name* > **HTTP transport**, where *policy_set_name*, applies to any policy set that contains HTTP transport policy.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

You can only configure a policy through a policy set. Therefore, before you can configure the HTTP transport policy, a policy set must exist that contains the HTTP transport policy.

The WSHTTPS default policy set is provided with the application server and it contains the HTTP transport policy, the SSL transport policy and the WS-Addressing policy. The provided default WSHTTPS policy set is read only and it cannot be edited. To customize a policy set that contains the HTTP transport policy, you must first create a copy of the WSHTTPS default policy set or create a new policy set and add the HTTP transport policy to the new policy set.

After you customize values for the HTTP transport policy, these values now apply for your policy set that contains that custom HTTP transport policy. You can attach this policy set that contains your customized HTTP transport policy to your application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that policy set is attached. To learn more about attaching policy sets to applications, see the documentation for managing policy sets for service providers and service clients at the application level.

Protocol version:

Specifies the version of HTTP protocol to use. Use this list to specify the version of HTTP protocol. The default value is `HTTP 1.1`. The `HTTP 1.0` value is also a valid option.

Some of the remaining options on the HTTP Transport panel only work with HTTP Version 1.1. The following brief descriptions compare these options:

HTTP 1.0
Allows messages to be in MIME-like format, containing meta information about the data

transferred and modifiers on the request, response, or both. However, HTTP 1.0 does not sufficiently address the effects of hierarchical proxies, caching, the need for persistent connections, or virtual hosts.

HTTP 1.1
Enables each of two communicating applications to determine the true capabilities or the other. This protocol includes more stringent requirements than HTTP 1.0 to ensure reliable implementation of features.

Session enabled:

Specifies whether the HTTP session is enabled when a message is sent. Select this check box to enable an HTTP session.

If this property is used within a policy set that is attached to a service client, then it indicates whether HTTP session information is propagated to subsequent requests invoked by the same client application. If the property is enabled, the HTTP session information is returned to the service client in a response message is sent in subsequent requests invoked using the same RequestContext object.

If this property is used within a policy set that is attached to a service provider, then it indicates whether or not a new HTTP session is created when a request is being processed. If the property is enabled, then as a request is being processed, a new HTTP session is created if one does not already exist. This HTTP session information is then returned to the service client in the response message.

Enable chunked transfer encoding:

Specifies whether chunked transfer encoding is enabled when a message is sent. Select this check box to enable a chunked transfer encoding. This option is only available if you select HTTP 1.1 in the **Protocol version** field. This option is disabled if you selected the HTTP 1.0 protocol.

The default for this property is `true`.

Send expect ″100-request″ header:

Specifies whether the `expect "100-request"` header is enabled when a message is sent. Select this check box to enable the `expect "100-request"` header. This option is only available if you selected HTTP 1.1 in the **Protocol version** field. This option is disabled if you selected the HTTP 1.0 protocol.

The purpose of the 100 status is to allow a client that is sending a request message with a request body to determine if the origin server accepts the request, based on the request headers, before the client sends the request body. In some cases, you might not want the client to send the body if the server rejects the message without looking at the body.

The Expect request-header field is used to indicate that particular server behaviors are required by the client. A server that cannot comply with any of the expectation values in the Expect field if a request responds with an appropriate error status.

Accept URL redirection automatically:

Specifies whether the automatic URL redirection is accepted when a message is sent. Select this check box to enable a URL that has been automatically redirected to be accepted.

Compress request content:

Specifies whether the request content is compressed when a message is sent. Content coding is used to allow a document to be compressed without losing the identity of its underlying media type and without loss of information. Select this check box to enable request content that you want to compress. Clicking

the Compress request content button enables the **Compression format** option to select the compression method. The default value for the compression format is `gzip`.

Compress response content:

Specifies whether the response content is compressed when a message is sent. Content coding is used to allow a document to be compressed without losing the identity of its underlying media type and without loss of information. Select this check box to enable response content that you want to compress. Clicking the Compress response content button enables the **Compression format** option as he compression method. The default value for the compression format is `gzip`.

Read timeout:

Specifies the length of time, in seconds, for the Web services client to completely read the SOAP response. If the read process does not complete within the specified time, a SOAP fault error is generated on the client machine.

Write timeout:

Specifies the length of time, in seconds, for the write action to time out when a message is sent. Specify the time, in seconds, to enable the write to time out length of time.

Connection timeout:

Specifies the length of time, in seconds, for the connection to time out when a message is sent. Specify the time, in seconds, to enable the connection to time out length of time.

Use persistent connection:

Specifies whether a persistent connection is used when a message is sent. Select this check box to enable use of a persistent connection. This option is only available if you selected HTTP 1.1 in the **Protocol version** field. This option is disabled if you selected the HTTP 1.0 protocol.

Resend enabled:

Specifies whether a message can be resent. Select this check box to resend a message.

HTTP transport bindings settings:

Use this page to define the HTTP transport bindings for the HTTP transport policy.

To configure the HTTP transport bindings for the HTTP transport policy, perform the following:

1. Navigate to the general bindings collection panel using either the **Services > Policy sets > General client policy set bindings** or **Services > Policy sets > General provider policy set bindings** path.
2. Click a general binding in the Name column.
3. Click the **HTTP transport** policy in the Policies table.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Note: You can also configure HTTP transport properties such as read or write timeout values for JAX-WS applications that are deployed in the same application server. If you want to customize these HTTP properties, you must edit the HTTP transport policy. To customize the HTTP transport policy settings, click **Services > Policy sets > Application policy sets >*policy_set_name*>HTTP transport policy** where *policy_set_name* applies to any policy set that contains the HTTP transport policy. Your customized values for the HTTP transport policy now apply for your policy set that contains that custom HTTP transport policy. You can attach this policy set that contains your

customized HTTP transport policy to your application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that policy set is attached. To learn more about attaching policy sets to applications, see the documentation for managing policy sets for service providers and service clients at the application level.

Proxy for outbound service requests – Host:

Specifies the host name for the outbound service request proxy. In this field, you can change the name of the host if you are editing an existing set of application specific bindings or you can enter the host name for the outbound service request proxy.

Proxy for outbound service requests – Port:

Specifies the port number for the outbound service request proxy. You can edit an existing port number, or enter a new port number for the outbound service request proxy in this field.

Proxy for outbound service requests – User name:

Specifies the user name for the outbound service request proxy. Enter a user name in this field.

Proxy for outbound service requests – Password:

Specifies a placeholder for the outbound service request proxy password. The actual password is masked.

Proxy for outbound service requests – Confirm password:

Specifies a placeholder for the outbound service request proxy password. Re-enter the password you entered in the **Password** field. The actual password is masked.

Basic authentication for outbound service requests – User name:

Specifies the user name for basic authentication of outbound service requests. Enter or edit the user name.

Basic authentication for outbound service requests – Password:

Specifies a placeholder for basic authentication of outbound service requests password. The actual password is masked.

Basic authentication for outbound service requests – Confirm password:

Specifies a placeholder for basic authentication of outbound service requests password. Re-enter the same password as in the **Password** field. The actual password is masked.

Proxy for outbound asynchronous service responses – Host:

Specifies the host name for the outbound asynchronous service responses proxy. You can enter or edit the host name.

Proxy for outbound asynchronous service responses – Port:

Specifies the port number for the outbound asynchronous service responses proxy. You can enter or edit the port number.

Proxy for outbound asynchronous service responses – User name:

Specifies the user name for the outbound asynchronous service responses proxy. You can enter or edit the user name.

Proxy for outbound asynchronous service responses – Password:

Specifies a placeholder for the outbound asynchronous service responses proxy password. You can enter or edit the password. The actual password is masked.

Proxy for outbound asynchronous service responses – Confirm password:

Specifies a placeholder for the outbound asynchronous service responses proxy password. You can re-enter or edit the password. The actual password is masked.

Basic authentication for outbound asynchronous service responses – User name:

Specifies the user name for basic authentication of outbound asynchronous responses. You can enter or edit the user name.

Basic authentication for outbound asynchronous service responses – Password:

Specifies a placeholder for basic authentication of outbound asynchronous responses password. You can enter or edit the password in this field. The actual password is masked.

Basic authentication for outbound asynchronous service responses – Confirm password:

Specifies a placeholder for basic authentication of outbound asynchronous responses password. Re-enter the password in this field. The actual password is masked.

Custom Properties – Name:

Specifies the name of custom property. Custom properties are not initially displayed in this column until you define them.

Custom Properties – Value:

Specifies the value of the custom property. With the **Value** entry field, you can enter, edit, or delete the value for a custom property.

Click one of the following buttons to enable the action described:

Button	Resulting Action
New	Creates a new custom property entry. To add a custom property, enter the name and value.
Delete	Removes the selected custom property.
Edit	You can edit a selected custom property. It is only displayed when one or more properties exist.

Configuring the Java Message Service (JMS) transport policy:

You can define a Java Message Service (JMS) transport policy configuration if you are using SOAP over JMS with your Java API for XML-Based Web Services (JAX-WS) applications.

Before you begin

You can configure some settings for policies for custom policy sets. The provided default policy sets cannot be edited. You must create a copy of the default policy set or create a new policy set in order to specify the policies for it.

About this task

When using the SOAP over JMS transport with JAX-WS applications, you can customize the transport by configuring the JMS transport policy. The SOAP over JMS transport provides an alternative to HTTPS for transporting SOAP requests and response messages between clients and servers. See the documentation on using SOAP over JMS to transport Web services to learn more about this transport protocol.

You can only configure a policy through a policy set. Therefore, before you can configure the JMS transport policy, a policy set must exist that contains the JMS transport policy. To customize a policy set that contains the JMS transport policy, you must first create a policy set and add the JMS transport policy to the new policy set.

Use the JMS transport policy settings panel to customize the values of the JMS transport policy properties, such as the request timeout value. Your customized values for the JMS transport policy now apply for your policy set that contains that custom JMS transport policy. You can attach this policy set containing your customized JMS transport policy to your JAX-WS application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that policy set is attached. To learn more about attaching policy sets to applications, see the documentation for managing policy sets for service providers and service clients at the application level.

1. Create a policy set that contains the JMS transport policy.
   a. Create a custom policy set. From the administrative console, click **Services > Policy Sets > Application policy sets**. From this panel you can create a new policy set, import a copy of a policy set from the default repository, or you can import an existing policy set from your specified location.
   b. Add the JMS transport policy to the policy set. From the administrative console, click **Services > Policy Sets > Application policy sets > *policy_set_name***. In the policy collection, click **JMS transport**. The JMS transport window displays options for configuring the JMS settings for the transport policy.
   c. Specify the JMS connection properties for the JMS transport requests. The following fields configure the JMS features for this transport:

      Request timeout
      Specifies whether to enable a request timeout value. The request timeout value is the amount of time that the client waits for a response after sending the request to the server. The range is from 0 to 2147483647.

      Allow transactional messaging for one-way and asynchronous operations
      Specifies to enable a client to use transactions in one-way or asynchronous two-way requests. Select this check box to enable transactional messaging.

      When this option is selected, the client runtime environment exchanges SOAP request and response messages with the server over the JMS transport in a transactional manner if the client is operating under a transaction. This process indicates that the clients transaction is used to send the SOAP request message to the destination queue or topic, and the server receives the request message only after the client commits the transaction. Similarly, the server receives the request message under the control of a container-managed transaction and sends the reply message, if applicable, back to the client using that same transaction. The client then receives the reply message only after the server transaction has been committed.

If this option is not selected, then the client and server runtime environments perform messaging operations in a non-transactional manner as transactions are temporarily suspended for the JMS request. The transactions are enabled again after the request has completed.

Note: Transactional messaging operations are not supported for two-way synchronous operations as this leads to a deadlock condition.

2. Customize the JMS transport provider bindings.
   a. Navigate to the JMS transport provider bindings. From the administrative console, click **Services > Policy Sets > General provider policy set bindings > *provider_policy_set_binding_name* > JMS transport**.

      The JMS transport provider bindings window displays options for defining basic authentication for asynchronous service responses and custom properties for the JMS service provider binding configuration.

   b. Specify the properties for basic authentication for asynchronous service responses.

      You can use the JMS transport provider policy bindings to configure a service that uses the JMS transport to send asynchronous response messages back to the client. The application server runtime environment uses the user name and password that you configure when connecting to the JMS messaging provider and this configuration enables the service to send an asynchronous response message to the client in a secure manner.

      The following fields determine the authentication requirements for responses from the server:

      User name
      Specifies the user name for the asynchronous service responses for the service provider.

      Password
      Specifies a placeholder for the password for the asynchronous service responses from the service provider. You can enter or edit the password in this field. The actual password is masked.

      Confirm password
      Specifies a placeholder for the password for the asynchronous service responses from the service provider that must match the one in the **Password** field. The actual password is masked.

   a.

3. Customize the JMS transport client bindings.
   a. Navigate to the JMS transport client bindings. From the administrative console, click **Services > Policy Sets > General client policy set bindings > *client_policy_set_binding_name* > JMS transport**.

      The JMS transport provider bindings window displays options for defining basic authentication for outbound service requests and custom properties for the JMS client binding configuration.

   b. Specify the Basic Authentication for Outbound Service Requests properties.

      You can use the JMS transport client policy bindings to configure a client that uses the JMS transport to send a request message to the server. The client runtime environment uses the user name and password that you configure when connecting to the JMS messaging provide. This configuration enables the client to send the request message to the server in a secure manner.

      The following fields determine the authentication requirements for requests sent to the server:

      User name
      Specifies the user name that is used by the client runtime when connecting to the JMS messaging provider to send an outbound request to the destination queue or topic. Enter a user name in this field.

      Password
      Specifies a placeholder for the password that is used by the client runtime when

connecting to the JMS messaging provider to send an outbound request to the destination queue or topic. You can enter or edit the password in this field. The actual password is masked.

Confirm password
Specifies a placeholder for the password that is used by the client runtime when connecting to the JMS messaging provider to send an outbound request to the destination queue or topic. Re-enter the password in this field. This password must match the one in the **Password** field. The actual password is masked.

Results

After you have customized the JMS transport policy, the associated policy set uses this policy to configure the runtime behavior of the SOAP over JMS transport.

Example

You can attach policy sets to an application, its services, endpoints, or operations. In this example scenario, suppose you have two different JAX-WS service clients for your application, but you want to use different JMS transport request timeout values for each service client. To modify the JMS request timeout values, you can edit the values of the JMS transport policy that is contained within the policy set that is attached to your application or in this case, your service client. This change affects all applications to which the policy set containing the custom JMS transport policy is attached.

This example describes the steps for configuring different request timeout values for service clients deployed in the same application server. This example includes the following assumptions:

- Two JAX-WS service clients exist, ServiceClient1 and ServiceClient2, that are deployed in the application server.
- The JMS transport policy has not been previously attached to these applications.

1. Create two new policy sets and add the JMS transport policy to them. For example: *JMSServiceClient1Policy* and *JMSServiceClient2Policy*
   a. Click **Services > Policy sets > Application policy sets > New** .
   b. Enter the name of the new application policy set, `JMSServiceClient1Policy`.
   c. From the Policies collection, click **Add > JMS transport**.
   d. Click **Apply** and **Save** to save your changes to the master configuration.
   e. Repeat these steps to create the JMSServiceClient2Policy.
2. Customize the JMS transport policy settings for the newly created JMSServiceClient1Policy and JMSServiceClient2Policy policy sets. For example, set the request timeout value to `180` seconds for the JMS transport policy contained in the JMSServiceClient1Policy. The JMS transport policy contained in the JMSServiceClient2Policy specifies `300` seconds as the request timeout value.
   a. Click **Services > Policy sets > Application policy sets > *JMSServiceClient1Policy*** .
   b. From the Policies collection, click **JMS transport**.
   c. From the JMS transport policy configuration panel, specify `180` seconds for the request timeout value.
   d. Click **Apply** and **Save** to save your changes to the master configuration.
   e. Click **Services > Policy sets > Application policy sets > *JMSServiceClient2Policy*** .
   f. From the Policies collection, click **JMS transport**.
   g. From the JMS transport policy configuration panel, specify 300 seconds for the request timeout value.
   h. Click **Apply** and **Save** to save your changes to the master configuration.
3. Attach the custom JMS transport policy, JMSServiceClient1Policy, to your application, ServiceClient1. Similarly, attach the custom JMS transport policy, JMSServiceClient2Policy, to ServiceClient2.

a. Click **Services > Service clients >** *ServiceClient1*.
b. From the Policy set attachments collection, select the service, *ServiceClient1*.
c. Click **Attach Client Policy Set**, and click *JMSServiceClient1Policy*.
d. Click **Save** to save your changes to the master configuration.
e. Click **Services > Service clients >** *ServiceClient2*.
f. From the Policy set attachments collection, select the service, *ServiceClient1*.
g. Click **Attach Client Policy Set**, and click *JMSServiceClient2Policy*.
h. Click **Save** to save your changes to the master configuration.

As a result, the ServiceClient1 application now has the JMSServiceClient1Policy attached, and the JMS sessions use a request timeout of 180 seconds. The ServiceClient2 application has the policy, JMSServiceClient2Policy, attached and the JMS sessions use a request timeout of 300 seconds.

What to do next

You can customize other policies that you might need for your application.

JMS transport policy settings:

Use this page to configure settings for the Java Message Service (JMS) transport policy. You can configure a client that is using the JMS transport policy to exchange request and response messages with the server.

To view this administrative console page:
1. Click **Services > Policy Sets > Application policy sets**
2. Click ***policy_set_name***
3. In the policy collection, click **JMS transport**

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

You can only configure a policy through a policy set. Therefore, before you can configure the JMS transport policy, a policy set must exist that contains the JMS transport policy.

To customize a policy set that contains the JMS transport policy, you must create a new policy set, import a copy of a policy set from the default repository, or you can import an existing policy set from your specified location. After you have an editable policy set, you can add the JMS transport policy to your policy set.

After you customize values for the JMS transport policy, these values now apply for your policy set that contains that customized JMS transport policy. You can attach this policy set that contains your customized JMS transport policy to your application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that policy set is attached. To learn more about attaching policy sets to applications, read about managing policy sets for service providers and service clients at the application level.

Client JMS connection properties - Request timeout:

Specifies the request timeout value. The request timeout value is the amount of time that the client waits for a response after sending the request to the server. The default value is 300 seconds.

Client JMS connection properties - Allow transactional messaging for one-way and asynchronous operations:

Specifies to enable a client to use transactions in one-way or asynchronous two-way requests. Select this check box to enable transactional messaging.

If this option is selected, the client runtime exchanges SOAP request and response messages with the server over the JMS transport in a transactional manner if the client is operating under a transaction. Therefore, the client transaction is used to send the SOAP request message to the destination queue or topic, and the server receives the request message only after the client commits the transaction. Similarly, the server receives the request message under the control of a container-managed transaction and sends the reply message, if applicable, back to the client using that same transaction. The client then receives the reply message only after the server transaction is committed.

If this option is not selected, the client and server runtimes perform messaging operations in a non-transactional manner.

Note: Transactional messaging operations are not supported for two-way synchronous operations as this leads to a deadlock condition.

.

JMS transport bindings:

Use this page to define the Java Message Service (JMS) transport provider or client bindings configuration.

If you are using JMS transport provider bindings, to view this administrative console page, complete the following actions:

1. Click **Services > Policy Sets > General provider policy set bindings**.
2. Click ***provider_policy_set_binding_name***.
3. In the policy collection, click **JMS transport**.

If the JMS transport policy has not been added to the selected general provider policy set, then use the create general provider bindings panel to add the JMS transport policy to the selected general provider policy set.

You can use the JMS transport provider policy bindings to configure a service that uses the JMS transport to send asynchronous response messages back to the client. The application server run time uses the user name and password that you configure when connecting to the JMS messaging provider and this configuration enables the service to send an asynchronous response message to the client in a secure manner.

If you are using JMS transport client bindings, to view this administrative console page, complete the following actions:

1. Click **Services > Policy Sets > General client policy set bindings**.
2. Click ***client_policy_set_binding_name***.
3. In the policy collection, click **JMS transport**.

If the JMS transport policy has not been added to the selected general client policy set, then use the create general client bindings panel to add the JMS transport policy to the selected general client policy set.

You can use the JMS transport client policy bindings to configure a client that uses the JMS transport to send a request message to the server. The client run time uses the user name and password that you specify when connecting to the JMS messaging provider, and this configuration enables the client to send the request message to the server in a secure manner.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Note: You can also configure JMS transport properties, such as request timeout values or whether to enable transactional messaging for one-way asynchronous operations for JAX-WS applications that are deployed in the same application server. If you want to customize these JMS properties, you must edit the JMS transport policy. To customize the JMS transport policy settings, click **Services > Policy sets > Application policy sets > *policy_set_name* >JMS transport policy**, where *policy_set_name* applies to any policy set that contains the JMS transport policy. Your customized values for the JMS transport policy now apply for your policy set that contains that custom JMS transport policy. You can attach this policy set that contains your customized JMS transport policy to your application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that policy set is attached. To learn more about attaching policy sets to applications, see the documentation for managing policy sets for service providers and service clients at the application level.

Related tasks

"Modifying policies using the administrative console" on page 905
With your policy sets, you can define policies for WS-Addressing, WS-Security, WS-ReliableMessaging, WS-Transaction, HTTP transport, Java Messaging Service (JMS) transport, and Secure Sockets Layer (SSL) transport. The policies for all but WS-Security are relatively straightforward to define.

"Defining and managing policy set bindings" on page 824
Policy set bindings contain platform specific information, like keystore, authentication information or persistent information, required by a policy set attachment. Use this task to create and manage bindings.

"Managing policy sets and bindings for service providers at the application level using the administrative console" on page 743
Use this administrative console task to manage policy sets for an application or its services, endpoints, and operations.

"Managing policy sets and bindings for service clients at the application level using the administrative console" on page 760
Use this administrative console task to manage policy sets for service clients applications or its services, endpoints, or operations.

Using SOAP over Java Message Service to transport Web services
You can use the SOAP over Java Message Service (JMS) transport protocol as an alternative to SOAP over HTTP for communicating SOAP messages between clients and servers.

Related reference

"JMS transport policy settings" on page 925
Use this page to configure settings for the Java Message Service (JMS) transport policy. You can configure a client that is using the JMS transport policy to exchange request and response messages with the server.

Basic Authentication – User name:

For the service provider, this field specifies the user name for the asynchronous service responses. For the client, this field specifies the user name that is used by the client runtime when connecting to the JMS messaging provider to send an outbound request to the destination queue or topic. Enter a user name in this field.

Basic Authentication – Password:

For the service provider, this field specifies a placeholder for the password of the asynchronous service responses. For the client, this field specifies the password that is used by the client runtime when connecting to the JMS messaging provider to send an outbound request to the destination queue or topic. You can enter or edit the password in this field. The actual password is masked.

Basic Authentication – Confirm password:

For the service provider, this field specifies a placeholder for the password for the asynchronous service responses. For the client, this field specifies the password that is used by the client runtime when connecting to the JMS messaging provider to send an outbound request to the destination queue or topic. Re-enter the password in this field. The actual password is masked.

Custom Properties – Name:

Specifies the name of custom property. Custom properties are not initially displayed in this column until you define them.

Click one of the following buttons to enable the described action:

Button	Resulting Action
New	Creates a new custom property entry. To add a custom property, enter the name and value.
Delete	Removes the selected custom property.
Edit	Edit a selected custom property. This button is only displayed when one or more properties exist.

Custom Properties – Value:

Specifies the value of the custom property. With the **Value** entry field, you can enter, edit, or delete the value for a custom property.

Configuring the SSL transport policy:

When working with policy sets in the administrative console, you can customize policies to ensure message security by configuring the SSL transport policy.

Before you begin

The default policy sets provided with the product cannot be edited. To configure custom policy sets, you must first copy the default policy set or create a completely new policy set in order to specify the policies for it. See creating policy sets using the administrative console.

About this task

The SSL transport policy provides the SSL transport security for the Hypertext Transfer Protocol (HTTP) protocol with Web services applications. To view the default SSL transport policy set with the SSL transport policy, click **Services > Policy sets > Application policy sets > WSHTTPS default > SSL transport**.

1. To edit the SSL transport policy, click a policy set that you have created or customized from the default. Select the SSL transport policy applicable check boxes to enable the SSL functions. The following check boxes determine how SSL security is configured for this transport:
   - **Enable for outbound service requests**

     Displays whether the SSL security transport is enabled for outbound service requests.
   - **Enable for outbound asynchronous service responses**

     Displays whether the SSL security transport is enabled for outbound asynchronous service responses.
   - **Enable for inbound service responses**

     Displays whether the SSL security transport is enabled for inbound service responses.
2. To configure the binding for the SSL transport policy, click **Services > Policy sets > General client policy set bindings** > *binding_name* > **SSL transport** or **Services > Policy sets > General provider policy set bindings** > *binding_name* > **SSL transport**. Select the setting to configure the SSL bindings. The SSL transport window displays options for configuring the SSL security bindings.

a. Select the setting to configure the SSL bindings for the **Outbound service requests**.
   - **SSL settings**

     Specifies the SSL security transport binding that is enabled for outbound service requests. The default value for this field is **CellDefaultSSLSettings**.
   - **SSL properties file path**

     Specifies the path of the SSL properties file that is enabled for asynchronous service responses. Enter the location of the SSL properties file to enable for asynchronous service responses.

b. Select the setting to configure the SSL bindings for the **Inbound service responses**.
   - **SSL settings**

     Specifies the SSL security transport binding that is enabled for inbound service responses. The default value for this field is **CellDefaultSSLSettings**.
   - **SSL properties file path**

     Specifies the path of the SSL properties file that is enabled for inbound service responses. Enter the location of the SSL properties file to enable for inbound service responses.

c. Select the setting to configure the SSL bindings for the **Outbound asynchronous service responses**.
   - **SSL settings**

     Specifies the SSL security transport binding that is enabled for asynchronous service responses. The default value for this field is **CellDefaultSSLSettings**.
   - **SSL properties file path**

     Specifies the file path of the SSL properties file that is enabled for outbound service requests. Enter the location of the SSL properties file to enable for outbound service requests.

   Custom properties

   Click one of the following buttons to enable the action described:

Button	Resulting Action
New	Creates a new custom property entry. To add a custom property, enter the name and value.
Delete	Removes the selected custom property.
Edit	Enables you to edit a selected custom property. It is only displayed when one or more properties exist.

Results

Once you have customized the SSL transport policy, the associated policy set uses this policy to protect message transmission. Similarly, you can also configure HTTP transport with the HTTP transport policy. Read about configuring the HTTP transport policy to learn how to configure the HTTP transport with the HTTP transport policy.

What to do next

Depending on how you are using policies, you might want to configure the HTTP transport policy or the SSL transport security bindings.

SSL transport security policy settings:

Use this page to define the secure sockets layer (SSL) transport policy configuration for policy sets.

To configure the SSL transport security for a policy set, click **Services > Policy sets > Application policy sets** > *policy_set_name* > **SSL transport**, where *policy_set_name*, applies to any policy set that contains SSL transport security. An example of such SSL transport security is WSHTTPS default.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Enable for outbound service requests:

Specifies whether the SSL security transport is enabled for outbound service requests when the client sends out requests.

Enable for outbound asynchronous service responses:

Specifies whether the SSL security transport is enabled for outbound asynchronous service responses when the service or server sends back the response.

Enable for inbound service responses:

Specifies whether the SSL security transport is enabled for inbound service responses when the client receives responses.

SSL transport security settings:

Use this page to define the secure sockets layer (SSL) transport policy binding configuration.

1. Navigate to the general bindings collection page by clicking either **Services > Policy sets > General client policy set bindings** or **Services > Policy sets > General provider policy set bindings** path.
2. Click a general binding in the Name column.
3. Click the **SSL transport** policy in the Policies table.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Outbound service requests – SSL settings:

Specifies the SSL security transport binding that is enabled for outbound service requests when the client sends out requests. The default value for this field is `CellDefaultSSLSettings`.

Outbound service requests – SSL properties file path:

Specifies the file path of the SSL properties file that is enabled for outbound service requests. Enter the location of the SSL properties file to enable for outbound service requests.

Inbound service responses – SSL settings:

Specifies the SSL security transport binding that is enabled for inbound service responses when the client receives responses. The default value for this field is `CellDefaultSSLSettings`.

Inbound service responses – SSL properties file path:

Specifies the SSL security transport binding that is enabled for inbound service responses. Enter the location of the SSL properties file to enable for inbound service responses.

Outbound asynchronous service responses – SSL settings:

Specifies the SSL security transport binding that is enabled for asynchronous service responses when the service or server sends back the response. The default value for this field is `CellDefaultSSLSettings`.

Outbound asynchronous service responses – SSL properties file path:

Specifies the path of the SSL properties file that is enabled for asynchronous service responses. Enter the location of the SSL properties file to enable for asynchronous service responses.

Outbound asynchronous service responses – Custom properties:

Specifies the name and value pair that you define for the outbound asynchronous service responses. Click **New** to add a new custom property, or click **Delete** to delete an existing SSL custom property.

Configuring the WS-Transaction policy:

When you work with policy sets in the administrative console, you can configure the WS-Transaction policy type for the WS-AtomicTransaction (WS-AT) and the WS-BusinessActivity (WS-BA) protocols. You can configure whether a client propagates, and a server receives, a WS-AT context, and whether a client propagates, and a server receives, a WS-BA context.

Before you begin

You must be working with a policy set that includes the WS-Transaction policy type.

Do not edit the policies associated with the provided default policy sets. If you need to modify the WS-Transaction policy settings, use a copy of a default policy set or create a new policy set.

About this task

You can configure the policies for the WS-AtomicTransaction and WS-BusinessActivity protocols. The WS-AT protocol supports coordination of activities so that either all the activities occur, or none of them occur. The WS-BA protocol supports coordination of activities that are more loosely coupled than atomic transactions and that therefore require a compensation process if a failure occurs in the business activity.

When you add a WS-Transaction policy, it is equivalent to setting the following deployment descriptors that are associated with an EJB or Web module:

- Use Web Services Atomic Transaction
- Send Web Services Atomic Transaction on requests
- Execute using Web Services Atomic Transaction on incoming requests

A WS-BA context is sent if the client is running in a BusinessActivity scope (BAScope). A provider runs in a BAScope if it receives a message that contains a WS-BA context, as long as the provider is set to run Enterprise JavaBeans (EJB) methods in a Business Activity scope.

1. In the navigation pane of the administrative console, click **Services** → **Policy sets** → **Application policy sets** → ***policy_set_name*** → **[Policies] WS-Transaction**. The WS-Transactions settings pane is displayed.
2. In the WS-AtomicTransaction section, select the option you require:
   - **Mandatory**. For a client, the client always propagates a WS-AT context on an outbound request. For a server, any request that is received must include a WS-AT context, otherwise the request is rejected.
   - **Supports**. For a client, the client can propagate a WS-AT context on an outbound request when that context is available. For a server, if a request includes a WS-AT context, the context is imported and established on the thread before the request is processed.
   - **Never**. For a client, the client never propagates a WS-AT context on an outbound request. For a server, any request that is received must not include a WS-AT context, otherwise the request is rejected.
3. In the WS-BusinessActivity section, select the option you require:
   - **Mandatory**. For a client, the client always propagates a WS-BA context on an outbound request. For a server, any request that is received must include a WS-BA context, otherwise the request is rejected.

- **Supports**. For a client, the client can propagate a WS-BA context on an outbound request when that context is available. For a server, if a request includes a WS-BA context, the context is imported and established on the thread before the request is processed.
- **Never**. For a client, the client never propagates a WS-BA context on an outbound request. For a server, any request that is received must not include a WS-BA context, otherwise the request is rejected.

4. Click **OK**.
5. Save your changes to the master configuration.

Results

After you configure the WS-Transaction policy, the associated policy set uses this policy to support WS-AtomicTransaction and WS-BusinessActivity.

WS-Transaction policy settings:

Use this page to specify the policies for the WS-AtomicTransaction (WS-AT) and WS-BusinessActivity (WS-BA) protocols. WS-AT supports coordination of activities so that either all the activities occur, or none of them occur. WS-BA supports coordination of activities that are more loosely coupled than atomic transactions, and that therefore, require a compensation process if an error occurs.

To view this pane in the console, click the following path: **Services** → **Policy sets** → **Application policy sets** → ***policy_set_name*** → **[Policy] WS-Transaction**, when the policy set includes the WS-Transaction policy type.

You can configure the WS-Transaction policy type for both client and provider policy sets.

WS-AtomicTransaction: Specifies behavior with the WS-AT policy. The options are:

Mandatory
For a client, the client always propagates a WS-AT context on an outbound request. If there is no transaction on the thread when the request is made, the attempt to make the request fails.

For a server, any request that is received must include a WS-AT context, otherwise the request is rejected. If any Web Services Description Language (WSDL) is generated for the Web service with which the policy type is associated, a policy assertion is included that indicates that an operation must be invoked with an atomic transaction context.

Supports
For a client, the client can propagate a WS-AT context on an outbound request when it is available. For example, a transaction is associated with the thread that makes the request, and the policy of the provider requires WS-AT context.

For a server, if a request includes a WS-AT context, the context is imported and established on the thread before the request is processed. If a request does not include a WS-AT context, the request is processed as normal. If any WSDL is generated for the Web service with which the policy type is associated, a policy assertion is included that indicates that an operation supports invocation with an atomic transaction context when that context is available.

Never For a client, the client never propagates a WS-AT context on an outbound request.

For a server, any request that is received must not include a WS-AT context, otherwise the request is rejected with a MustUnderstand error. If any WSDL is generated for the Web service with which the policy type is associated, that WSDL does not include a policy assertion for an atomic transaction context.

WS-BuinessActivity: Specifies behavior with the WS-BA policy. The options are:

Mandatory

For a client, the client always propagates a WS-BA context on an outbound request. If there is no business activity scope on the thread when the request is made, the attempt to make the request fails.

For a server, any request that is received must include a WS-BA context, otherwise the request is rejected. If any WSDL is generated for the Web service with which the policy type is associated, a policy assertion is included that indicates that an operation must be invoked with a business activity context.

Supports

For a client, the client can propagate a WS-BA context on an outbound request when it is available. For example, a business activity scope is associated with the thread that makes the request, and the policy of the provider requires a WS-BA context.

For a server, if a request includes a WS-BA context, the context is imported and established on the thread before the request is processed. If a request does not include a WS-BA context, the request is processed as normal. If any WSDL is generated for the Web service with which the policy type is associated, a policy assertion is included that indicates that an operation supports invocation with a business activity context when that context is available.

Never For a client, the client never propagates a WS-BA context on an outbound request.

For a server, any request that is received must not include a WS-BA context, otherwise the request is rejected with a MustUnderstand error. If any WSDL is generated for the Web service with which the policy type is associated, that WSDL does not include a policy assertion for a business activity context.

Configuring the WS-Security policy:

When working with policy sets in the administrative console, you can customize policies to ensure message security. The WS-Security policy can be configured to apply a message security (WS-Security) profile to requests. Message security policies are applied to requests and enforced on responses to support interoperability.

Before you begin

You can configure some settings for default policies for custom policy sets. The provided default policy sets cannot be edited. You must create a copy of the default policy set or create a completely new policy set in order to specify the policies for it.

About this task

Message security policies are applied to requests and enforced on responses to support interoperability.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

1. Use the WS-Security policy panel to begin configuring the WS-Security policy. To access the WS-Security policy panel, from the administrative console, click **Services > Policy sets > Application policy sets > *policy_set_name* > WS-Security policy**.
2. Choose which type of message security to configure.
   - Click the Main policy link to specify how message security policies are applied to requests and enforced on responses to support interoperability.
   - Click the Bootstrap policy link to configure how secure conversations are established. A bootstrap policy might already be configured. If no bootstrap policy is currently configured, first ensure that you have enabled message security with symmetric signature and encryption policies and secure conversation tokens for both integrity and confidentiality protection.

3. Use the Main policy settings panel or the Bootstrap policy settings panel to specify how message security policies are applied to requests and enforced on responses. Assertions for WS-Security versions are already generated based on assertions in the policy set. If the policy set includes a WS-S 1.1 assertion, then WS-S 1.1 itself is asserted. Configure the settings on this panel to configure main or bootstrap policy settings:
   a. Select whether Message level protection is required. Select this check box if any of the message parts should be digitally signed or encrypted or if a timestamp should be inserted in the message. It this box is unchecked, the Signature confirmation, Key symmetry, and Timestamp and Security header layout options are disabled.
   b. Specify whether signature confirmation is required. Click this check box to require signature confirmation.
   c. Configure the settings in the Key Symmetry® section. The following fields can be configured in the Key symmetry section:

      Use symmetric tokens
      Click this radio button to use symmetric tokens. You can then configure symmetric tokens with the **Symmetric signature and encryption policies** link. Click this link to access the Symmetric Signature and Encryption Policies panel where you can create the trust context in which to use symmetric tokens. Using the same token for signing and validating messages and encrypting and decrypting messages provides better performance than can be achieved with asymmetric tokens. Symmetric tokens should be used within a trust context.

      Use asymmetric tokens
      Click this link to access the Asymmetric Signature and Encryption Policies panel where you can create the trust context (message integrity and confidentiality) in which to use asymmetric tokens. You can do this by specifying which token type to use for the initiator and recipient signature as well as the initiator and recipient encryption.

      Include timestamp in header
      Click this check box to include a timestamp in the header. You can then specify if the timestamp is positioned first or last in the header by using the Security header layout radio button options:
      - **Strict: Declarations must precede use**
      - **Layout (Lax): Order of contents can vary**
      - **Lax but timestamp required first in header**
      - **Lax but timestamp required last in header**

   d. Optional: Click the **Algorithms** link under the **Policy Details** section if you want to access the Algorithms panel to view and select from available algorithms. The available algorithms include cryptographic algorithms and their key lengths, as well as canonicalization algorithms for reconciling XML differences. Click this link to view the cryptographic and cannonicalization algorithms that are supported.
   e. Optional: Configure the request settings. Click either of the following links to configure request settings:

      Request message part protection
      Links to configuration for request message part protection. Click this link to define which message parts are to be protected and how that protection is provided.

      Request token policies
      Links to configuration for request token policies. Click this link to define policies that specify which types of security tokens are supported and the properties of those token types.

   f. Optional: Configure the response settings. Click either of the following links to configure response settings:

Response message part protection
Links to configuration for response message part protection. Click this link to define which message parts are to be protected and how that protection is provided.

Response token policies
Links to configuration for response token policies. Click this link to define policies that specify which types of security tokens are supported and the properties of those token types.

Results

Once you have customized the WS-Security policy, the associated policy set uses this policy to protect messages.

WS-Security policy settings:

Use this page to configure the WS-Security policy and apply a message security WS-Security profile to requests. WS-Security policies are applied to requests and enforced on responses to support inter-operability.

To view this administrative console page, click **Services > Policy sets > Application policy sets > *policy_set_name* > WS-Security policy**.

Main policy:

Links to configuration settings for a main policy. Use the Main policy link if you want to configure how WS-Security policies are applied to requests and enforced on responses to support interoperability.

Secure conversation bootstrap policy:

Links to configuration settings for a secure conversation bootstrap policy. Use the bootstrap policy link if you want to configure how secure conversations are established. To configure a secure conversation bootstrap policy, first ensure that you have enabled message security in the main policy with symmetric signature and encryption policies and secure conversation tokens for both integrity and confidentiality protection.

Click **Remove bootstrap policy** to discontinue using secure conversation policy settings.

Configuring the request or response token policies:

You can configure the request and response token policies that are part of the WS-Security policy using the administrative console. Message requests token policies are applied to requests and enforced on responses to support both quality and interoperability.

Before you begin

You can configure some settings for the policies within your policy sets. The default policy sets provided in the product cannot be edited. You must create a copy of the default policy set or create a completely new policy set in order to specify the policies for it.

About this task

Use this administrative console task to define policies that specifically support security tokens and properties.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation

to learn more about the valid roles for the application server.

1. Click **Services > Policy sets > Application policy sets > *policy_set_name* > WS-Security policy**.
2. Click one of the following links:
   - **Main policy** or
   - **Bootstrap policy**
   - Click the Main policy link to specify how message security policies are applied to requests and enforced on responses to support interoperability.
   - Click the Bootstrap policy link to configure how secure conversations are established. A bootstrap policy might already be configured. If no bootstrap policy is currently configured, first ensure that you have enabled message security with symmetric signature and encryption policies and secure conversation tokens for both integrity and confidentiality protection. See Configuring the WS-Security policy.
3. Click **Request token policies** under Request Policies or **Response token policies** under Response Policies. Use this to panel to define policies that specify which types of security tokens are supported for the properties of each token type.

Results

Once you have customized the WS-Security policy with the associated properties, including the request and response token policies, you can then send and receive protect messages.

Request or Response token policies collection:

Use this page to define policies that specify supported security tokens and properties.

To view this administrative console page, complete the following:

1. Click **Services > Policy sets > Application policy sets** >*policy_set_name*.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.
4. Click **Request token policies** or **Response token policies** from the Policy Details section.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Add token type:

Specifies a list of token types that you can add to the selected token name. You can only add a token type for a custom policy set.

This option provides the following supported token types:

- Username
- X.509
- LTPA
- Custom

Delete:

Removes the selected token name. This action is only available for a custom policy set.

Token name:

Specifies the name of the token.

Type:

Specifies the token type in the Supported token types table. This list displays a token type for each token name in the list.

Version:

Specifies the version of the token in the Supported token types table. This list displays the version of each token in the list.

Token type settings:

Use the administrative console to define the details about the token types. This panel is displayed differently for each different token type. Policies can be defined that specify which types of security tokens are supported as well as properties for the token type.

To view token types for a policy set, complete the following steps:

1. Click **Services > Policy sets > Application policy sets > *policy_set_name***.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.
4. Click one of the following:
   - **Request token policies** from the Policy detail section.
   - **Response token policies** from the Policy detail section.
   - **Symmetric signature and encryption policies** from the Key symmetry section.
   - **Asymmetric signature and encryption policies** from the Key symmetry section.
5. For a Request token policy or a Response token policy, click a token from the Supported Token Types table or click the **Add Token Type** button to select the type of token to add.
6. For a symmetric signature and encryption policy or an asymmetric signature and encryption policy, click **Edit Selected Type Policy**.

This panel is displayed for each token type you are configuring or adding. It displays fields for some token types and not for others. This help panel contains all of the fields for each of the token types and describes which token is being configured for each field.

Custom token name:

For a custom token, specifies the name of the token being configured. Enter or edit the name for the custom token in this entry field.

Local name:

For a custom token, specifies the local name.

If the custom token type is used to generate a Kerberos token as defined in the OASIS Web Services Security Specification for Kerberos Token Profile v1.1, use one of the values in the following table for the local name. The value you choose depends on the specification level of the Kerberos token generated by the Key Distribution Center (KDC). The table lists the values and the specification level associated with each value. For purposes of interoperability, the Basic Security Profile V1.1 standard requires the use of the local name, http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ.

Local Name Value for Kerberos Token	Associated Specification Level
http://docs.oasis-open.org/wss/oasiswss-kerberos-token-profile-1.1#Kerb erosv5_AP_REQ	Kerberos V5 AP-REQ as defined in the Kerberos specification. This value is used when the Kerberos ticket is an AP Request.
http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ	GSS-API Kerberos V5 mechanism token containing a KRB_AP_REQ message as defined in RFC-1964 [1964], Sec. 1.1 and its successor RFC-4121, Sec. 4.1. This value is used when the Kerberos ticket is an AP Request (ST + Authenticator).
http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ1510	Kerberos V5 AP-REQ as defined in RFC1510. This value is used when the Kerberos ticket is an AP Request per RFC1510.
http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ1510	GSS-API Kerberos V5 mechanism token containing a KRB_AP_REQ message as defined in RFC-1964, Sec. 1.1 and its successor RFC-4121, Sec. 4.1. This value is used when the Kerberos ticket is an AP Request (ST + Authenticator) per RFC1510.
http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ4120	Kerberos V5 AP-REQ as defined in RFC4120. This value is used when the Kerberos ticket is an AP Request per RFC4120.
http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ4120	GSS-API Kerberos V5 mechanism token containing an KRB_AP_REQ message as defined in RFC-1964, Sec. 1.1 and its successor RFC-4121, Sec. 4.1. This value is used when the Kerberos ticket is an AP Request (ST + Authenticator) per RFC4120.

URI:

For a custom token, specifies the uniform resource identifier (URI).

Leave this field empty, if the custom token type is used to generate a Kerberos token as defined in the OASIS Web Services Security Specification for Kerberos Token Profile v1.1.

LTPA token name:

For an LTPA token, specifies the name of the token being configured. Enter or edit the name for the LTPA token in this entry field.

Propagate the JAAS subject:

For an LTPA token, specifies whether the associated Java Authentication and Authorization Service (JAAS) subject is propagated. Select this check box to propagate the JAAS subject. The default value is not selected. Therefore, the JAAS subject is not propagated by default.

Username token name:

For a Username token, specifies the name of the token being configured. Enter or edit the name for the user name token in this entry field.

WS-Security version:

For a Username token, specifies the version of Web services security, the WS-Security specification, that is used to secure the message transmission.

The following versions are available:

- WS-Security V1.0
- WS-Security V1.1

X.509 token name:

For a X.509 token, specifies the name of the token being configured. Enter or edit the name for the X.509 token in this entry field.

WS-Security version:

For a X.509 token, specifies the version of Web services security that is used to secure the message transmission.

The following versions are available:
- WS-Security V1.0
- WS-Security V1.1

X.509 type:

For a X.509 token, specifies the type of X.509 token being configured.

The following types are available for the X.509 token:
- X.509 Version 1. This option is available with WS-Security Version 1.1 only.
- X.509, Version 3
- X.509 PKCX7
- PKI Path Version 1

Secure conversation token: The secure conversation token is available only when using symmetric signature and encryption policies.

Key derivation requirements:

For a secure conversation token, specifies whether derived keys are required.

Require reference to secure context token issuer:

For a secure conversation token, select this option to specify a reference to the issuer of the security context token.

After selecting the **Require reference to secure context token issuer** option, specify the URI of the security context token issuer.

Require an external URI reference:

For a secure conversation token, select this option to specify that an external URI reference is required when referencing the security context token.

Transform algorithms settings:

Use this administrative console page to select the uniform resource locator (URL) for the transform algorithms that are needed to protect the message part.

To view this administrative console page, complete the following:

1. Click **Services > Policy sets > General provider policy set bindings** or **General client policy set bindings**.

2. Click the name of the binding you want to edit.
3. Click **WS-Security** policy in the Policies table
4. Click the **Authentication and Protection** link in the Main message security policy bindings section.
5. Select a signature protection in the Request message and encryption protection section or the Response message signature and encryption protection section.
6. Click the **Additional bindings > Signed part reference default** at the end of the panel.
7. Click a URL in the Transform algorithms table.

You can also get to this administrative console page by completing the following actions:

1. Click **Applications > Application Types > WebSphere enterprise applications**.
2. Select an application that contains Web services.
3. Select **Service provider policy sets and bindings** or **Service client policy sets and bindings**.
4. Select a binding.

   Note: You must have previously attached a policy set and assigned an application specific binding before you can do this step.
5. Select **WS-Security**.

   Note: You must have previously added WS-Security to the bindings.
6. Click the **Authentication and Protection** link in the Main message security policy bindings section.
7. Select a signature protection in the Request message and encryption protection section or the Response message signature and encryption protection section.
8. Click the **Additional bindings > Signed part reference default** at the bottom of the panel.
9. Click **New** to add a transform.
10. [Optional] Click a URL in the Transform algorithms table. This step assumes that a transform algorithm has previously been configured.

URL:

Specifies the URL for the transform algorithms that are used to protect the message part.

The URLs of the supported transform algorithms are listed in the table. The recommended transform is *http://www.w3.org/2001/10/xml-exc-c14n#* and it is the Exclusive XML Canonicalization, as well as the default value provided in the URL field when a transform is added.

List of URLs for the transform algorithms
http://www.w3.org/2001/10/xml-exc-c14n#
http://www.w3.org/TR/1999/REC-xpath-19991116
http://www.w3.org/2002/06/xmldsig-filter2
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
http://www.w3.org/2002/07/decrypt#XML
http://www.w3.org/2000/09/xmldsig#enveloped-signature

Custom properties:

Specifies the custom properties name and value pair for the transform algorithms. Click **New** to add a new custom property. Click **Delete** to delete a custom property.

Name Specifies the name of a custom property that you choose to set to protect the message part.

Value Specifies the value of a custom property that you choose to set to protect the message part.

Signed part reference default bindings settings:

Use this administrative console page to configure the signed part reference general bindings and the uniform resource locator (URL) for the transform algorithms that are needed to protect the message part.

You can view and configure bindings for WS-Security using this administrative console page:

1. Click **Applications > Application Types > WebSphere enterprise applications**.
2. Select an application that contains Web services
3. Select **Service provider policy sets and bindings** or **Service client policy sets and bindings**
4. Select a binding.

   Note: You must have previously attached a policy set and assigned an application specific binding before you can do this step.
5. Select **WS-Security**.

   Note: You must have previously added WS-Security to the bindings.
6. Click the **Authentication and Protection** link in the Main message security policy bindings section.
7. Select a signature protection in the Request message and encryption protection section or the Response message signature and encryption protection section.
8. Click the **Additional bindings - Signed part reference default** at the bottom of the panel. For the custom, select an assigned message part and click **Edit**. In the custom version, there is also a reference field, **Specifies the name of the signature protection in the policy set**. Use this field to specify the name of the signature protection in the policy set.
9. Check the **Include timestamp** check box to include the timestamp when the message part is signed.
10. Check the **Include nonce** check box to include the nonce when the message part is signed.

Part reference properties:

Specifies the name of the part reference properties that include the transform algorithms used to protect the message part.

1. Check the **Include timestamp** check box to include the timestamp for the message part.
2. Check the **Include nonce** check box to include the nonce when the message part is signed.

Transform algorithms:

Specifies the uniform resource locator (URL) description for the transform algorithms. Click the URL to view the transform algorithms.

Main policy and bootstrap policy settings:

Use this page to specify how message security policies are applied to requests and enforced on responses, as defined by the main policy settings and the bootstrap policy settings. Assertions for Web Services Security (WS-Security) versions are already generated based on assertions in the policy set. If the policy set includes a Web Services Security Version 1.1 assertion, then Web Services Security Version 1.1, itself, is asserted.

To view this administrative console page, use one of the following steps:

1. Click **Services > Policy sets > Application policy sets > *policy_set_name***.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.

Message level protection:

Specifies whether message level protection, using digital signatures and encryption, is required.

Require signature confirmation

Specifies whether the signature confirmation is required. Select this check box to require a signature confirmation.

Message part protection:

Specifies whether message part protection, using digital signatures and encryption, is required.

Request message part protection
Click this link to define which request message parts you want protected and how that protection is provided.

Response message part protection
Click this link to define policies that specify which response message parts you want protected and how that protection is provided.

When the Message level protection check box is cleared, the link to Request message part protection is disabled, because the configuration information associated with message level security is removed when message level protection is cleared.

Key symmetry – Use symmetric tokens:

Specifies whether to use symmetric tokens. Select this radio button to use symmetric tokens. You can then configure symmetric tokens using the **Symmetric signature and encryption policies** link. Click this link to access the Symmetric signature and encryption policies panel where you can create the trust context in which to use symmetric tokens. Using the same token for signing and validating messages and encrypting and decrypting messages provides higher performance than can be achieved with asymmetric tokens. Use symmetric tokens within a trust context. If a custom Kerberos token type is used, you must select the Use symmetric tokens option.

Key symmetry – Use asymmetric tokens:

Specifies whether to use asymmetric tokens. Select this button to use asymmetric tokens. You can then configure asymmetric tokens using the **Asymmetric signature and encryption policies** link. Click this link to access the Asymmetric signature and encryption policies panel where you can create the trust context (message integrity and confidentiality) in which to use asymmetric tokens. Specify which token type to use for the initiator and recipient signature as well as the initiator and recipient encryption.

Include time stamp in security header:

Specifies whether to use a time stamp in the header. Select this check box to include a time stamp in the header. You can then specify where in the header to place the time stamp by using the **Security header layout** radio buttons.

Security header layout:

Specifies the layout rules for the security header.

You can use the following radio buttons for the security header layout:

Strict: declarations must precede use
The declarations in the header must precede the use.

Layout (Lax): order of contents can vary
The order of contents in the header can vary.

Lax but timestamp required first in header
The timestamp must be first in the header, but the order of the remaining elements can vary.

Lax but timestamp required last in header
The timestamp must be last in the header, but the order of the remaining elements can vary.

Policy details:

Specifies links for accessing the request token policies, response token policies, and algorithms for asymmetric tokens. Click these links to view token policies and cannonicalization algorithms that are supported. Algorithms are used to reconcile XML differences.

Request token policies:

Click this link to define policies that specify which types of supporting authentication tokens are used in the request and the properties of those token types.

Response token policies:

Click this link to define policies that specify which types of supporting authentication tokens are used in the response and the properties of those token types.

Algorithms for symmetric or asymmetric tokens:

Links to a view of available algorithms. Click this link to view the cryptographic and cannonicalization algorithms that are supported. Algorithms are used to reconcile XML differences.

Asymmetric signature and encryption policies settings:

Use this page to create the trust context, message integrity and confidentiality, to use asymmetric tokens. You can create the trust context by specifying which token type to use for the initiator and recipient signature as well as the initiator and recipient encryption.

To view this administrative console page complete the following actions:
1. Click **Services > Policy sets > Application policy sets > *policy_set_name* > WS-Security policy type**.
2. Click **Main policy** or **Bootstrap policy**.
3. Click the **Asymmetric signature and encryption policies** link.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Message integrity policies – Initiator signature token:

Specifies the token type of the initiator signature token. To add a token type or change the current token type that is displayed in the **Initiator signature token** field, or to edit the displayed token type, click **Action**.

Message integrity policies – Recipient signature token:

Specifies the token type of the recipient signature token. To add a token type or change the current token type that is displayed in the **Recipient signature token** field, or to edit the displayed token type, click **Action**.

Message confidentiality policies – Use the same token types that are used for integrity protection:

Specifies whether the token type set for initiator signature token and recipient signature token are used for the initiator encryption token and the recipient encryption token. When the box is checked the fields are empty and are cleared of data when **Ok** or **Apply** is selected.

Message confidentiality policies – Initiator encryption token:

Specifies the initiator encryption token type. To add a token type or change the current token type that is displayed in the **Initiator encryption token** field, or to edit the displayed token type, click **Action**.

Message confidentiality policies – Recipient encryption token:

Specifies recipient encryption token type. To add a token type or change the current token type that is displayed in the **Recipient encryption token** field, or to edit the displayed token type, click **Action**.

Action:

Specifies an option for each of the signature and encryption token fields. Use the **Action** button to change, delete, add, or edit the listed token type.

The Action button lists supported token types and provides the following options:

Edit selected type policy
Opens a page to edit the token type shown in the signature or encryption token fields.

Delete selected type policy
Removes the token type from the signature or encryption token fields.

Change to custom type
Opens the Custom type page to specify the uniform resource identifier (URI) for a custom token type.

Add custom type
Adds the custom type entry in the signature or encryption token fields.

Change to X.509
Changes the listed token type to X.509.

Add X.509
Adds the X.509 token type.

When you change the token type, any values you specified for the former token type are lost and the default values for the newly assigned token type are used.

Symmetric signature and encryption policies settings:

Use this page to create the trust context to use symmetric tokens. Using the same token for signing and validating messages and encrypting and decrypting messages increases performance. Use symmetric tokens within a trust context.

To view this administrative console page, complete the following options:

1. Click **Services > Policy sets > Application policy sets**.
2. Select a ***policy_set_name*** in the policy sets table that contains WS-Security content.
3. Click **WS-Security** in the policies table.
4. Click the **Main policy** link or the **Bootstrap policy** link.
5. Click the **Symmetric signature and encryption policies** link.

Message Integrity – Token type for signing and validating messages:

Specifies the current token type used for signing and validating messages.

To change the current token type that is displayed in the **Token type for signing and validating messages** field or to edit the displayed token type, click **Action**.

Message Confidentiality – Use same token type for confidentiality that is used for integrity:

Specifies whether the token type set for signing and validating messages is also used for encrypting and decrypting messages. For a Kerberos token, message confidentiality uses the same token that is used for the message integrity.

If you select this check box, then the **Token type for encrypting and decrypting messages** field is blank. If you clear this check box, then a different token can be used for message confidentiality.

Message Confidentiality – Token type for encrypting and decrypting messages:

Specifies the current token type that is used for encrypting and decrypting messages.

To change the current token type that is displayed in the **Token type for encrypting and decrypting messages** field or to edit the displayed token type, verify that the **Use the same token type for confidentiality that is used for integrity protection** check box is cleared, and click **Action**.

Action:

Enables the token type selected to be changed or edited.

The **Action** button lists supported token types and provides the following options:

Edit selected type policy
Opens a page to edit the token type for signing or encrypting fields.

Change to Secure Conversation
Changes the token type to Secure Conversation.

Change to custom type
Opens the custom type page to specify the Uniform Resource Identifier (URI) for a custom token type.

When you change the token type, any values that you specified for the former token type are lost, and the default values for the newly assigned token type are used.

Algorithms settings:

Use this page to view the supported cryptographic and cannonicalization algorithms. Algorithms are used to reconcile XML differences.

To view this administrative console page:

1. Click **Services > Policy sets > Application policy sets > *policy_set_name***.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.
4. Click the **Algorithms for symmetric tokens** link or the **Algorithms for asymmetric tokens** link.

This administrative console panel applies only to Java API for XML Web Services (JAX-WS) applications.

Algorithm suite:

Specifies the supported algorithms that are required for performing cryptographic operations with symmetric or asymmetric key-based security tokens.

All of the algorithm values in this field specify an algorithm suite. Algorithm suites and the values they each represent are detailed in the *Web Services Security Policy Language (WS-SecurityPolicy) July 2005 Version 1.1* specification. Select a supported algorithm from the following list:

- Basic256
- Basic192
- Basic128
- TripleDes
- Basic256Rsa15
- Basic192Rsa15
- Basic128Rsa15
- TripleDesRsa15
- Basic256Sha256
- Basic192Sha256
- Basic128Sha256
- TripleDesSha256
- Basic256Sha256Rsa15
- Basic192Sha256Rsa15
- Basic128Sha256Rsa15
- TripleDesSha256Rsa15

This table defines values for the components for each algorithm suite.

Table 8. Algorithm suite components

Algorithm Suite	Digest	Encryption	Symmetric Key Wrap	Asymmetric Key Wrap	Encryption key Derivation	Signature key Derivation	Minimum Symmetric Key Length
Basic256	Sha1	Aes256	KwAes256	KwRsaOaep	PSha1L256	PSha1L192	256
Basic192	Sha1	Aes192	KwAes192	KwRsaOaep	PSha1L192	PSha1L192	192
Basic128	Sha1	Aes128	KwAes128	KwRsaOaep	PSha1L128	PSha1L128	128
TripleDes	Sha1	TripleDes	KwTripleDes	KwRsaOaep	PSha1L192	PSha1L192	192
Basic256Rsa15	Sha1	Aes256	KwAes256	KwRsa15	PSha1L256	PSha1L192	256
Basic192Rsa15	Sha1	Aes192	KwAes192	KwRsa15	PSha1L192	PSha1L192	192
Basic128Rsa15	Sha1	Aes128	KwAes128	KwRsa15	PSha1L128	PSha1L128	128
TripleDesRsa15	Sha1	TripleDes	KwTripleDes	KwRsa15	PSha1L192	PSha1L192	192
Basic256Sha256	Sha256	Aes256	KwAes256	KwRsaOaep	PSha1L256	PSha1L192	256

When using a Kerberos custom token based on the OASIS Web Services Security Specification for Kerberos Token Profile V1.1, only Aes128, Aes256, and TripleDes encryption-based algorithm suites are supported.

Cannonicalization algorithm:

Specifies whether to use inclusive or exclusive cannonicalization.

The following supported cannonicalization algorithms are available in this list:

- Exclusive cannonicalization
- Inclusive cannonicalization

The default value is `Exclusive cannonicalization`.

XPath version:

Specifies the version of the XPath filter to use.

The following supported XPath versions are available:

- XPath 1.0
- XPathfilter 2.0

The `XPathfilter 2.0` version is the default value.

Use security token reference transformation:

Specifies whether the security token reference is transformed. Indicate whether the security token reference transform is either `True` or `False`.

Message part protection settings:

Use this page to define the message parts that you want protected and how that protection is provided.

To view this administrative console page, complete the following actions:

1. Click **Services > Policy sets > Application policy sets** >*policy_set_name*.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.
4. Click the **Request message part protection** link or the **Response message part protection** link from the Message Part Protection section.

Integrity protection – Signed parts:

Specifies the signed parts that you have added for message integrity protection. You can select parts to edit or delete, or add new signed parts.

Button	Resulting Action
Add	Specifies each element of a new signed part and to add those elements to the Signed parts listing.
Edit	Loads the specific part you selected for editing.
Delete	Removes the selected signed part from the list.

Confidentiality protection – Encrypted parts:

Specifies the encrypted parts that have been added for message confidentiality protection. You can select parts to edit or delete, or add new encrypted parts.

Button	Resulting Action
Add	Enables you to specify each of the elements of a new encrypted part and to add those elements to the Encrypted parts listing.
Edit	Loads the specific part you selected for editing.
Delete	Removes the selected encrypted part from the list.

Signed part settings:

Use this page to define the elements of a signed part. Signed parts are used to protect message integrity and, in this case, the signed parts are being defined as part of the policy set process.

To view this administrative console page, complete the following actions:

1. Click **Services > Policy sets > Application policy sets > *policy_set_name***.
2. Click the **WS-Security** policy in the Policies table.
3. Click either the **Main policy** link or the **Bootstrap policy** link.
4. Click the **Request message part protection** link or the **Response message part protection** link in the Message Part Protection section.
5. In the Integrity protection section, complete one of the following actions:
   - Click **Add** to add a new signed part.
   - Select an existing signed part and click **Edit**.

Name of part to be signed:

Specifies the name of this set of one of more message parts that you have selected to sign. The name you choose is a label and must be unique within the Response message part protection or Request message part protection collections for this WS-Security policy.

Elements in part:

Specifies a list of the message elements included in the signed part. The **Elements in part** field contains a listing of message elements that are included in this signed part to provide message integrity.

Click **Add** to add an element to the signed part of the message. To remove a message element from a signed part of a message, first click the selection box next to the element to be removed, then click **Remove**. Use the **OK**, **Apply**, **Reset** or **Cancel** buttons for the text entry fields. The QName or the Xpath expression value is required and can be edited at any time, such as when adding a new element, or after the element is added.

Protect message body:

Specifies if the message body is protected in this part. To protect the message body in this part, click **Protect message body**.

XPath expression:

Specifies if the displayed XPath expression is used as the method for specifying that a specific element is included in this part.

Select **XPath** from the **Add** menu list and provide an expression in the new XPath entry that is displayed in the table. Any Xpath expression row on the table that has no corresponding value is removed when you click **OK** or **Apply**.

QName for SOAP header elements only:

Specifies the Qname type for a namespace value for the SOAP header element that you want to encrypt. To encrypt a SOAP header element, select **Qname** and provide the **namespace** and optionally the **localname** of the SOAP header element in the **Value** field. When specifying the Qname, if using the optional localname, a comma must be inserted between the namespace and the localname, for example **<namespace>,<localname>**. If the **localname** is omitted, all SOAP header elements with the specified **namespace** are encrypted. To use the **Qname** selection method, the SOAP header elements must be the immediate children of the SOAP header. Any Qname row in the table that has no corresponding value is removed when you click **OK** or **Apply**.

Note:
You cannot select header elements that are sub-elements of other elements in the SOAP header using **Qname**. In this case, you must use an **Xpath expression** to select these header elements.

Encrypted message part settings:

Use this page to define the elements of an encrypted part of a message. Encrypted parts are used to protect message confidentiality, and in this case, the encrypted parts are being defined as part of the policy set process. A message part is a named set of one or more message elements.

To view this administrative console page, complete the following actions:

1. Click **Services > Policy sets > Application policy sets > *policy_set_name***.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.
4. Click the **Request message part protection** link or the **Response message part protection** link in the Message Part Protection section.
5. In the Confidentiality protection section, you can perform any of the following:
   - Click **Add** to add a new encrypted part.
   - Select an existing encrypted part, and click **Edit**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Name of part to encrypt:

Specifies the name of the set of one or more message parts that you have selected to encrypt. The name you choose is a label and must be unique within the Response message part protection or Request message part protection collections for this WS-Security policy.

Elements in part:

Specifies a list of the message elements that are included in the encrypted part. The **Elements in part** field contains a listing of message elements that are included in this encrypted part to provide message confidentiality.

Click **Add** to add an element to the encrypted part of the message. To remove a message element from an encrypted part of a message, first click the selection box next to the element to be removed, then click **Remove**. The value of the Qname namespace, or the Xpath expression, is required and can be edited at any time, while adding a new element or after the element is added.

Body Specifies the body of the message part.

Qname for SOAP header elements only
Specifies the Qname type for a namespace value for the SOAP header element that you want to encrypt. To encrypt a SOAP header element, select **Qname** and provide the **namespace** and

optionally the **localname** of the SOAP header element in the **Value** field. When specifying the Qname, if using the optional localname, a comma must be inserted between the namespace and the localname, for example **<namespace>,<localname>**. If the **localname** is omitted, all SOAP header elements with the specified **namespace** are encrypted. To use the **Qname** selection method, the SOAP header elements must be the immediate children of the SOAP header. Any Qname row in the table that has no corresponding value is removed when you click **OK** or **Apply**.

Note: You cannot select header elements that are sub-elements of other elements in the SOAP header using Qname. In this case, you must use an Xpath expression to select these header elements.

Xpath expression
Specifies if the displayed Xpath expression is used as the method for specifying that a specific element is included in this part. Select **XPath** from the **Add** menu list, and provide an expression in the new XPath entry that is displayed in the table. Any Xpath expression row on the table that has no corresponding value is removed when you click **OK** or **Apply**.

Enabling policies for policy sets using the administrative console

Policies can be listed in a policy set in the disabled state so that they are not currently included in the policy set. You can enable a policy to be included in a policy set using the administrative console.

Before you begin

To enable a policy for a policy set, be sure the policy is listed in the policy set and shown in the **Disabled** state in the **State** column of the **Policies** table on the Policy set settings page.

About this task

To enable a policy in a policy set, use the administrative console.

1. Click **Services > Policy sets > Application policy sets** > ***policy_set_name*** or **Services > Policy sets > System policy sets** > ***policy_set_name***. The Policy Set Settings page displays a listing of available policies in the **Policies** table for the policy set selected. If this table contains no policies to enable, no policies exist for the policy set of interest. In this case, you must add the policies to the policy set.
2. Click the **Select** box beside the disabled policy that you want to enable. You can select multiple policies if you want to enable more than one.
3. Click the **Enable** button. The **State** column of the **Policies** table is updated to display the selected policy as enabled.

Results

You have enabled a policy for the selected policy set.

What to do next

If the policy is not listed in the Policies table, it cannot be enabled and must be added. You can modify the policy after it is enabled.

Disabling policies from policy sets using the administrative console

You can have policies listed in a policy set that are in the enabled state so that they are currently included in the policy set. You can disable a policy from being included in a policy set without deleting it from the policy set. You might want to do this if you want the policy included in the policy set in the future. You can use the administrative console to change this setting.

Before you begin

To disable a policy for a policy set, be sure the policy is listed in the policy set and shown in the **Enabled** state in the **State** column of the **Policies** table on the Policy set settings page. If the policy is not listed, it might have been deleted and you must add it again and then disable it.

About this task

You can disable a policy in a policy set, from the menu of the administrative console.

1. Click **Services > Policy sets > Application policy sets** >***policy_set_name*** or **Services > Policy sets > System policy sets** >***policy_set_name***. Clicking a policy set name from the listing in the policy sets collection opens the Policy set settings panel for that policy set. This panel displays a listing of available and enabled policies in the **Policies** table for the policy set you selected. If this table contains no policies, there are no existing policies to disable.
2. Click the**Select** box beside the enabled policy to be disabled. You can select multiple policies if you want to disable more than one.

3. Click **Disable**. The **State** column of the **Policies** table is updated to display the selected policy as disabled. The policy was not deleted from the policy set and is still available to be enabled.

Results

You have disabled a policy for the selected policy set.

What to do next

You could now enable other policies or add or modify existing policies for this policy set.

Web services policies

Policies define the type of Web service policy based on the quality of service type. Policies are initially set with default settings but the attributes can be edited and changed.

Provided policies include:

WS-Addressing
: Based on the Worldwide Web Consortium (W3C) WS-Addressing specifications for Web services. This family of specifications provide transport-neutral mechanisms to address Web services and to facilitate end-to-end addressing. This specification provides asynchronous support.

WS-Security
: Based on the WS-Secure Conversation (WS-SC) and WS-Security specifications along with the associated token profiles. The WS-Security specification and its associated token profiles define a way to send security tokens and provide message integrity and confidentiality. The WS-Secure Conversation specification establishes a secure context, based on shared keys, for the client and server to use for a series of messages. This standard provides a framework across organizations

that defines how to secure the entire conversation. Use the WS-Security policy to define how the SOAP messages are secured. It has options such as:

- which message parts are signed and encrypted
- the tokens types to be included
- whether to use symmetric or asymmetric cryptography

You can also use WS-Security policies to define the bootstrap policy that is used to acquire security context tokens. Security context tokens are used by secure conversation.

WS-Reliable Messaging (WS-RM)
This specification enables the sender and receiver to assure the quality of services in a set of messages. It helps the application developer deal with latency issues, maintenance interruption, and other problems that prevent messages from being completed. This quality assurance is critical for stateful applications.

WS-Transaction
This specification provides support for coordination of atomic transactions or business activities for Web services applications. You can enable WS-Transaction on both the client (outbound) and server (inbound) side by attaching a policy set that enables the WS-Transaction policy as part of the policy set. This policy is based on the WS-AtomicTransaction specification and the WS-BusinessActivity specification, together with the WS-Coordination specification.

HTTP Transport
The HTTP transport policy applies the HTTP features and HTTP connections polices to outbound messages. The response listener policy is enforced on inbound messages.

SSL Transport
Provides SSL transport security for the HTTP protocol with Web services applications.

Exporting policy sets using the administrative console

You can export policy sets between a client and a provider or between servers using the administrative console.

Before you begin

Before you begin this task, select the policy set to be exported. Read about the application policy sets collection and exporting policy sets to client or server environments using the wsadmin tool.

About this task

Static export is used in development environment to exchange a policy sets between a client and a provider. You can also export between servers. The exported format is a .zip file.

1. From the administrative console navigation, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**. The Application policy sets collection page displays a listing of the custom and default policy sets. Custom policy sets are displayed only if you have created them. If you have not created a custom policy set, then only the default policy sets are displayed.
2. From the Application policy sets panel, select a policy set and click **Export**.
3. Locate the export archive file. From the Export policy set archive file settings panel, click the archive file to export.
4. Choose a location to export the file. Do not export the file to a browser.

Results

When you finish this task, the policy set archive file has been exported to the location you specified.

Example

If you have a policy set, `ABC_ps` and you want to move it from `ServerA` to `ClientA`, you can use the export function. The export policy set can be used by importing it into another application server. Read about the command task for importing an exported policy set zip file.

What to do next

You can import the policy set to reuse it.

Related tasks

“Importing and exporting policy sets to client or server environments using scripting” on page 539
Use the wsadmin tool, which supports the Jython and Jacl scripting languages, to export and import application or system policy sets for Web services. The exportPolicySet command creates an archive file based on the policy set configuration, and the importPolicySet command imports a default policy set or policy set from an archive file.

Related reference

“Application policy sets collection”
Use this page to manage policy sets. You can create, copy, export, and import policy sets. You can also view or delete existing policy sets. You can use policy sets, or assertions that define services, to simplify your Web services configuration because policy sets group security and other Web services settings into reusable units.

Application policy sets collection

Use this page to manage policy sets. You can create, copy, export, and import policy sets. You can also view or delete existing policy sets. You can use policy sets, or assertions that define services, to simplify your Web services configuration because policy sets group security and other Web services settings into reusable units.

To view this administrative console page, click **Services > Policy sets > Application policy sets**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Name

Specifies a list of available policy sets. Click a policy set name to access the details panel for that policy set. Use the buttons on the page to create a new policy set or manage the existing policy sets. You can also import a policy set to display in the list of available policy sets.

The following list of buttons are available to you for creating and managing policy sets:

Button	Resulting action
New	Creates a new policy set. This option opens an empty policy set and allows you to provide additional details, such as the name, description, and policy configuration options.
Delete	Removes the selected policy set.
Copy	Creates a copy of the policy set that is selected from a list. After you create a copy, you can provide a name and a description for the copy. You must also specify whether to transfer attachments and binding information, where these options are available, from the original to the copy.

Button	Resulting action
Import	Imports a policy set. This is a menu item with the option of importing a policy set from a default repository or a selected location. You can select and import the default policy sets from the default repository. The default repository for the import function in the administrative console is the directory that contains the default policy sets. Initially, up to four default, pre-configured policy sets are exposed. However, there are other default policy sets that are available to import when you select **Import > From Default Repository**. The administrative console also displays the default policy sets in a list that includes descriptions, that you can use to select the policy set that you want to import.
Export	Exports the selected policy set to an archive file.

Editable
This column shows whether the policy set is a user-defined, custom policy set that can be edited or whether the policy set is a default policy set that is not editable.

Values displayed in this field are `Editable` or `Not editable`. Even though a policy set is identified as not editable, it is deletable. For example, you cannot edit information for the default system policy set, but you can delete the policy set. You can change the properties for a default, not editable policy set by copying it, and then modifying the properties of the copy. For more information on modifying a default policy set, see copy of default policy set and bindings settings document.

Data type: String
Default: Not editable

Description
Provides a brief description of the application policy sets that currently exist. You cannot edit information for the default application policy sets; however, you can delete the policy sets. The list of contained policies for each policy set that it relates to are displayed in the Name column. The contained policies that are displayed are only those that are enabled. From this panel, the field is not editable.

For custom policy sets that you create or modify, you can edit this description when you create or customize policy sets on the details panel. The description is the same one that you entered in the **Description** field when you created that policy set. For default policy sets, the included and enabled policies appear at the top followed by a bulleted list of the key attributes of the policy set.

Application policy set settings
Use this page to view, create, enable or disable your policy sets. You can use policies, or assertions that define services, to simplify your Web services configuration.

To view this administrative console page, click one of the following paths:
- **Services > Policy sets > Application policy sets** >*policy_set_name*
- **Services > Policy sets > Application policy sets** > **New**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Note: You can only edit the fields on this page if you open this page for a custom policy set. You cannot edit default policies.

Policy set name
Specifies the name of a selected policy set. This field is empty if you are creating a new policy set and you can enter a policy set name. If you select an existing policy set from the Policy set page, then this field displays the name of that policy set. This field is also not editable for existing custom policy sets and default policy sets.

Description
Specifies a brief description of the policy set being viewed, modified or created. This field displays a brief description of the policy set displayed in the Policy set name field or is empty if a new policy set is being created. You can edit this field for custom policy sets only.

Policies
The Policies table displays a list of policies that are contained in the policy set. This table initially contains no policies when you are creating a new custom policy set. If this is a default policy set, then you cannot add, delete, enable or disable the policy. The configuration of a policy in a default policy set cannot be altered but you can view a policy by clicking on the policy name link. If the policy is a custom policy, you can modify the configuration of the policy by clicking the policy name link. You can alter the policies contained in a custom policy set using the following buttons:

Button	Resulting Action
Add	Provides a list of valid policies, instances of which are not already included in the collection, that can be added to the policy set collection. The following policies are available: • WS-Addressing • WS-Security • WS-ReliableMessaging • WS-Transaction • HTTP transport • JMS transport • SSL transport
Delete	Removes the selected policy from the policy set and from the listing in the Description column of the table.
Enable	The policy is enabled for the policy set and displayed as enabled in the State column.
Disable	The policy is disabled for the policy set. The policy remains in the list but the State field shows the policy as Disabled.

Policies - Policy
Specifies the name of a policy. This field is empty if you are creating a new policy set. If you select an existing policy, then this field displays the name of that policy. If this policy is a default policy, then this field is read only. If you are creating a new policy, then this field is empty and you can enter a policy name.

Policies - State
Specifies an Enabled or Disabled status for each policy in the policy set. You cannot change the state for default policy sets. To change the state of the policy, select the policy and click **Enable** or **Disable**. The state is refreshed in this column to reflect your change.

If you disable a policy, you are temporarily removing the policy from the policy set without losing the configuration details for that policy. When a policy is disabled, you can easily enable the policy again by selecting **Enable**. If the policy is deleted, the configuration for that policy no longer exists. After you delete a policy, to enable that policy in a policy set, you must add the policy to the policy set and enter the configuration details for that policy.

Policies - Description
Specifies a brief description of each policy in the policies table. The product does not support custom policies; therefore, this field is not editable. You cannot create a new policy.

Attachments – Attached applications
Click this link to search for applications to which this policy set is attached. You can also find applications that contain service resources to which the policy set is attached.

Search attached applications collection
Use this page to search for applications and other resources that are attached to a specific policy set or to search for applications and other resources that have attached service resources.

To view this administrative console page, complete the following actions:

1. Click **Services > Policy sets > Application policy sets** >*policy_set_name*.
2. Click **Attached applications** link in the Additional Properties section.

Name
Specifies a list of applications that match the search text. The application names that are displayed in the Name column are either attached explicitly to the specified policy set or have service resources attached to this policy set.

To alter the policy set that is attached to an application, select an application, and click a button to enable the following options:

Button	Resulting Action
Detach Policy Set	Detaches the current policy set from the selected application or applications. This action also detaches any attached application service resources. This action does not detach other policy sets from the application or application service resources.
Replace Policy Set	Displays a list of policy sets that can be attached to the selected application or applications and any contained attached service resources. The policy set is replaced with the one selected. This action does not replace other policy sets that are attached to resources in the application that you select.

Click the application name to complete actions such as attaching policy sets to the application, its services, or its endpoints.

Securing message parts using the administrative console
If you are working with policy sets, then you can secure message parts using the administrative console. To secure message parts with WS-Security using policy sets, you must define the elements for the message parts to be protected in the WS-Security policy within a policy set.

Before you begin

Before you can start this task, you must have a policy set defined for your application or service artifact. Also, if none of the default policy sets contain the necessary policy definitions, then you must create a custom policy set with the necessary definitions.

About this task

This task assumes that you are using policy sets and you want to secure message parts within that context.

1. Open the administrative console.
2. Select the policy set containing the message parts that you want to secure.
   - To secure message parts using application policy sets click **Services > Policy sets > Application policy sets**.
   - To secure message parts using system policy sets click**Services > Policy sets > System policy sets**.
3. Select the policy set that you want to use.
4. If the WS-Security policy is not listed, then click **Add** and select that policy from the list.
5. Click the **WS-Security** link.
6. Click **Main policy** or **Bootstrap policy**. The bootstrap policy is available when Secure Conversation is used. If you want to use the bootstrap policy, then select the SecureConversation policy set in step three.
7. Make sure that Message level protection is selected, then click **Request message part protection** or **Response message part protection**. When the Message level protection checkbox is unchecked, the link to Response message part protection is not available, because the configuration information associated with message level security is removed when Message level protection is deselected.
8. Click **Add** for either Encrypted parts or Signed parts depending on the level of security that you want.
9. Specify a part name and add the elements to be signed or encrypted, or both. The elements can be the message body, XPath expression, or a QName which is for SOAP header elements only. Click **OK**. Recommendation for when to use QName or XPath: If you are encrypting or signing SOAP headers, you can use QName to select which SOAP headers to be signed or encrypted.

   Note: The elements must be a direct child of the SOAP headers.

   If you wanted to sign and encrypt other elements in the SOAP message, then you can use XPath expression. Use this XPath example to select, `MyElement` in a namespace, `http://xyz.acme.com` with `MyHeader`, `http://acme.com`.

```
/*[namespace-uri()='http://www.w3.org/2003/05/soap-envelope' and local-name()='Envelope']/*[namespace-uri()=
'http://www.w3.org/2003/05/soap-envelope' and local-name()='Header']/*[namespace-uri()='http://acme.com' and local-name()=
'MyHeader']/*[namespace-uri()='http://xyz.acme.com' and local-name()='MyElement']
```

10. Repeat steps 8 and 9 to sign or encrypt each message part.
11. To save your changes to the master configuration, click **Save**.

Results

When you finish this task, you have configured the policy set that contains the quality of service definitions required for signing and encrypting message parts.

Example

If you have the policy set, **myPolicy** and you want to specify request message bodies that must be signed, you can perform the following:

1. Locate the policy set in the **Services > Policy sets > Application policy sets** collection and click the policy set name.
2. Click the **WS-Security** link. If the link does not exist, click **Add** and then select **WS-Security** from the list.
3. Click **Main policy** > **Request message part protection**
4. Click **Add** under the Integrity protection and Signed parts section.
5. Specify the name, `messageBody`.
6. Select **Protect message body**, click **Add Specified Elements**, and click **OK**.
7. Click **Save** to save your changes to the master configuration.

What to do next

You can proceed to signing and encrypting message parts using policy sets.

Related concepts

"Web services policy set bindings" on page 829
A set of bindings is a named object that is associated with a specific policy set and service resource that is attached to the policy set.

Encrypted SOAP headers
The encrypted header element provides a standard way of encrypting SOAP headers. As one of the extensions to the OASIS SOAP message security specification, the encrypted header element indicates that the responder has processed the request. Encrypting SOAP headers and parts help to provide more secure message-level security.

Related tasks

"Signing and encrypting message parts using policy sets" on page 860
With Web services, you can sign message parts, encrypt message parts, or both, based on the quality of service defined for a policy set. You can accomplish these actions by defining the binding information in a custom attachment binding.

"Creating application specific bindings for policy set attachment" on page 838
After you attach a policy set to a service artifact such as an application, service, or endpoint, you can define application specific bindings for the attached policy set.

"Modifying default bindings at the server level for policy sets" on page 855
You can define default bindings for HTTP transport, JMS transport, Secure Sockets Layer (SSL) transport, WS-Addressing, WS-ReliableMessaging, and WS-Security policies.

"Reassigning bindings to policy sets" on page 856
After you create a custom attachment binding, you can reassign that binding to another service artifact if necessary. You can reset a service artifact, such as an application, service, or endpoint to use the inherited bindings or default bindings.

"Configuring the WS-Security policy" on page 933
When working with policy sets in the administrative console, you can customize policies to ensure message security. The WS-Security policy can be configured to apply a message security (WS-Security) profile to requests. Message security policies are applied to requests and enforced on responses to support interoperability.

"Service client policy set and bindings collection" on page 763
Use this page to attach and detach policy sets to an application, a service client, its endpoints, or operations. You can select the default bindings, create new application-specific bindings, or use existing bindings for an attached policy set. You can view or change whether the client uses the policy of the service provider.

"Service provider policy sets and bindings collection" on page 746
Use this page to attach and detach policy sets to an application, a service provider, its endpoints, or operations. You can select the default bindings, create new application-specific bindings, or use bindings that you created for an attached policy set. You can view or change whether the service provider can share its current policy configuration.

"Policy set bindings settings" on page 866
Use this page to view or define general or application specific bindings configuration information that is specific to a system for policies that you can associate with the selected policy set. Use the links on this page to work with bindings for each specific policy.

"Policy set bindings settings for WS-Security" on page 868
Use this page to view, define or configure general bindings and application specific properties for the WS-Security policy. You can configure the main policy or the secure conversation bootstrap policy by editing the general bindings.

"WS-Security authentication and protection" on page 878
Use the links on this page to configure authentication, signature, and encryption information that the policy requires.

"Caller settings" on page 895

Use this page to configure the caller settings. The caller specifies the token or message part that is used for authentication.

"Message expiration settings" on page 899
Use this page to define settings for message expiration, if and when messages expire. When you specify message expiration, the message expires after the specified interval of time passes.

"Actor roles settings" on page 899
Use this page to define settings for SOAP actor roles. The SOAP actor, also known as the SOAP role, defines the intermediary or ultimate recipient of a message.

"Keys and certificates" on page 869
Use this page to link to key and certificate binding configuration panels. This panel defines key and certificate bindings for JAX-WS Web services only. These keys and certificates can be centrally managed by the product or in an external keystore.

Related information

"Web Services Addressing policy set binding" on page 900
Use this page to modify the endpoint reference binding for Web Services Addressing (WS-Addressing). The product enforces this binding on JAX-WS Web service applications that use WS-Addressing. This panel applies only to the Network Deployment version of the product.

Web services policy sets

Policy sets are assertions about how services are defined. They are used to simplify your quality of service configuration for Web services.

Note: You can use policy sets only with Java API for XML-Based Web Services (JAX-WS) applications. You cannot use policy sets with Java API for XML-based RPC (JAX-RPC) applications.

Policy sets combine configuration settings, including those for transport and message level configuration, such as WS-Addressing, WS-ReliableMessaging, and WS-Security.

There are two main types of policy sets; application policy sets and system policy sets. Application policy sets are used for business-related assertions. These assertions are related to the business operations that are defined in the Web Services Description Language (WSDL) file. System policy sets, on the other hand, are used for non-business-related system messages. These messages are not related to the business operations that are defined in the WSDL, but instead refer to messages that are defined in other specifications which apply qualities of service (QoS). Such QoS are the request security token (RST) messages that are defined in WS-Trust, or create sequence messages that are defined in WS-Reliable Messaging metadata exchange messages of the WS-MetadataExchange.

Policies are defined based on a quality of service. Policy definition is typically based on WS-Policy standard language, for example, the WS-Security policy is based on the current WS-SecurityPolicy from the Organization for the Advancement of Structured Information Standards (OASIS) standards.

An instance of a policy set consists of a collection of policies. For example, the WS-I RSP default policy set consists of instances of the WS-Security, WS-Addressing, and WS-ReliableMessaging policy types. A policy set is identified by a unique name that is unique across the cell. An empty policy set is a policy set with no policies defined.

You can use a default policy set after it is imported. If you want to change the properties for a default, not editable policy set, you need to copy the policy set to create an editable version to modify. See copy of default policy set and bindings settings. You can perform the following actions on policy sets:

- create
- copy
- edit
- delete

- attach to service resources like applications
- detach from service resources like applications
- export
- import

Note which functions you can configure using policy sets and the relationship of the security information that is configured. A set of default policy sets are included that you can import; then copy and rename for reuse. You can use a default policy set after it is imported, but if you want to change any of the settings, you need to copy the policy set to create an editable version. The configuration can then be altered and customized on the copy.

Note: You can only copy and customize policy sets using the administrative console or administrative commands. Policy sets do not function correctly if they are copied manually.

On the application server, policy sets are stored at the cell level. Policy sets are centrally located so that they are available to all applications on the server.

The following application policy sets are installed on the base or network deployment (ND) profile by default: WS-I RSP or WS-I RSP (ND), Username WSSecurity default, and WSHTTPS default. The WS-I RSP (ND) is installed in a network deployment environment.

The following policy sets are ready for you to use as is.
- LTPA WSSecurity Default
- Kerberos V5 HTTPS default
- SSL WSTransaction
- Username SecureConversation
- Username WSSecurity default
- WS-Addressing default
- WSHTTPS default
- WS-I RSP ND
- WS-ReliableMessaging persistent

The application server also provides other default policy sets that you can use or customize. To use the additional policy sets, you must import them from the default repository. Read about importing policy sets from the administrative console for more information.

The following default policy sets are provided:

WS-I RSP default

This policy set provides:
- Reliable message delivery to the intended receiver by enabling WS-ReliableMessaging
- Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications
- Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications

LTPA WS-I RSP default

This policy set provides:
- Reliable message delivery to the intended receiver by enabling WS-ReliableMessaging
- Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications

- Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications
- A Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service

Username WS-I RSP default

This policy set provides:

- Reliable message delivery to the intended receiver by enabling WS-ReliableMessaging
- Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications
- Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications
- A username token included in the request message to authenticate the client to the service. The username token is encrypted in the request

SecureConversation

This policy set provides:

- Message integrity through digital signature that includes signing the body, time stamp, and WS-Addressing headers using WS-SecureConversation and WS-Security specifications
- Message confidentiality through encryption that includes encrypting the body, signature and signature confirmation elements, using WS-SecureConversation and WS-Security specifications

LTPA SecureConversation

This policy set provides:

- Message integrity through digital signature that includes signing the body, time stamp, and WS-Addressing headers using WS-SecureConversation and WS-Security specifications
- Message confidentiality through encryption that includes encrypting the body, signature and signature confirmation elements, using WS-SecureConversation and WS-Security specifications
- A Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service

Username SecureConversation

This policy set provides:

- Message integrity through digital signature that includes signing the body, time stamp, and WS-Addressing headers using WS-SecureConversation and WS-Security specifications
- Message confidentiality through encryption that includes encrypting the body, signature and signature confirmation elements, using WS-SecureConversation and WS-Security specifications
- A username token included in the request message to authenticate the client to the service. The username token is encrypted in the request

WSAddressing default

Enables WS-Addressing support, which uses endpoint references and message addressing properties to facilitate the addressing of Web services in a standard and interoperable way.

WSHTTPS default

Provides SSL transport security for the HTTP protocol with Web services applications.

Kerberos V5 HTTPS default

This policy set provides message authentication with a Kerberos Version 5 token. Message integrity and confidentiality are provided by Secure Sockets Layer (SSL) transport security. This policy set follows the OASIS Kerberos Token Profile V1.1 and WS-Security specifications.

When you use this policy set, configure the basic authentication data and custom properties such as the com.ibm.wsspi.wssecurity.krbtoken.targetServiceName and

com.ibm.wsspi.wssecurity.krbtoken.targetServiceHost custom properties in the client bindings. For more information, see the Authentication generator or consumer token settings and Protection token settings (generator or consumer) topics.

WSReliableMessaging default

This policy set enables both WS-ReliableMessaging Version 1.1 and WS-Addressing and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. In-order delivery is set to "false", so messages are not necessarily delivered in the order in which they were sent.

WSReliableMessaging persistent

This policy set enables both WS-ReliableMessaging and WS-Addressing and uses the maximum quality of service, *managed persistent*. This quality of service supports asynchronous Web service invocations and uses a service integration messaging engine and message store to manage the sequence state. Messages are processed within transactions, are persisted at the Web service requester server and at the Web service provider server, and are recoverable in the event of server failure. In-order delivery is set to "false", so messages are not necessarily delivered in the order in which they were sent.

Because this policy set specifies managed persistent quality of service, you need to define bindings to the service integration bus and messaging engine that you want to use to manage the WS-ReliableMessaging state. For more information, see "Attaching and binding a WS-ReliableMessaging policy set to a Web service application using the administrative console" on page 657 or using the wsadmin tool.

WSReliableMessaging 1_0

This policy set enables both WS-ReliableMessaging Version 1.0 and WS-Addressing and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. In-order delivery is set to "false", so messages are not necessarily delivered in the order in which they were sent.

You can use this policy set with .NET-based Web services.

WSSecurity default

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.

LTPA WSSecurity default

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.
- A Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username WSSecurity default

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.

- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.
- A username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

WSTransaction

This policy set enables WS-Transaction, which provides:

- The ability to coordinate distributed transactional work atomically and interoperably using the WS-AtomicTransaction specification.
- The ability to coordinate loosely coupled business processes that are distributed across the heterogenous Web service environment, with the ability to compensate actions if a failure occurs in the business activity, using the WS-BusinessActivity specification.

SSL WSTransaction

This policy set enables WS-Transaction, which provides:

- The ability to coordinate distributed transactional work atomically, interoperably, and securely, using the WS-AtomicTransaction specification and SSL Transport security.
- The ability to coordinate loosely coupled business processes, with the ability to compensate actions if a failure occurs in the business activity, securely, using the WS-BusinessActivity specification and SSL Transport security.

Policy sets do not include environment or platform-specific information, such as keys for signing, keystore information, or persistent store information. This type of information is defined in the binding. A policy set attachment defines how a policy set is attached to service resources and bindings. The attachment definition is outside the policy set definition and is defined as meta-data associated with application data.

Bindings are made up of environment and platform-specific information. General bindings such as the service client or provider bindings for the global security domain can be shared across applications.

To enable policy sets to work with applications, bindings are needed. Use the administrative console to configure general bindings and application specific bindings. Read about defining binding information for policy sets for more information about working with attachments and bindings.

Related concepts

“WS-I RSP default policy sets” on page 809
The Reliable Asynchronous Message Profile (WS-I RSP) default policy sets are based on the Reliable Asynchronous Message Profile specification. The WS-I RSP default policy sets include the WS-I RSP default policy set, the Lightweight Third-Party Authentication (LTPA) WS-I RSP default policy set and the Username WS-I RSP default policy set. You can use these policy sets to simplify your Web services configuration.

“WS-ReliableMessaging default policy sets” on page 811
The WS-ReliableMessaging default policy sets are pre-configured to provide reliable message exchange between Web services. Two of these policy sets (WS-I RSP and WS-I RSP ND) are immediately available, and the rest are readily available for import from a default repository.

Web Services Addressing support
The Web Services Addressing (WS-Addressing) support in this product provides the environment for Web services that use the Worldwide Web Consortium (W3C) WS-Addressing specifications. This family of specifications provide transport-neutral mechanisms to address Web services and to facilitate end-to-end addressing.

“WSSecurity default policy sets” on page 813
The WSSecurity default policy sets are based on the Web Services Security (WS-Security) 1.0 and Web Services Addressing (WS-Addressing) specifications. The WSSecurity default policy sets include the WSSecurity default policy set, the Lightweight Third-Party Authentication (LTPA) WSSecurity policy set, and the Username WSSecurity policy set. Use the WSSecurity default policy sets to build secure Web services.

“SecureConversation default policy sets” on page 810
The SecureConversation default policy sets are based on the Web Services Secure Conversation Language (SecureConversation) standard that establishes a secure context, based on shared keys for the client and server to use for a series of messages. This standard provides a framework to define how to secure the message exchange across organizations. The SecureConversation default policy sets include the SecureConversation policy set, the Lightweight Third-Party Authentication (LTPA) SecureConversation policy set, and the Username SecureConversation policy set.

“WSHTTPS default policy set” on page 815
The WSHTTPS default policy set provides SSL transport security for the HTTP protocol with Web services applications.

“WSTransaction default policy sets” on page 814
The WSTransaction default policy sets are based on the WS-Transaction specification and provide transactional integrity for Web services. The WSTransaction default policy sets include the WSTransaction policy set and the SSL WSTransaction policy set.

Related tasks

“Defining and managing policy set bindings” on page 824
Policy set bindings contain platform specific information, like keystore, authentication information or persistent information, required by a policy set attachment. Use this task to create and manage bindings.

“Importing policy sets using the administrative console” on page 816
You can import predefined policy sets or import policy sets from a selected location using the administrative console.

“Defining and managing service client or provider bindings” on page 831
Service client or provider bindings are general bindings. You can create, copy, and manage general bindings such as the client or provider policy set bindings. These bindings provide system-specific configuration and can be reused across policy set attachments.

“Creating policy set attachments using the wsadmin tool” on page 515
Use the wsadmin tool, which supports the Jython and Jacl scripting languages, to define the policy set configuration for your Web services applications. You can attach policy sets to an application, Web service, endpoint, or specific operation.

OASIS WS-SX Technical Committee

Overview of migrating policy sets and bindings

Policy sets are migrated during the product migration from Version 6.1 Feature Pack for Web Services to Version 7.0. This topic describes the different rules that apply to migrating policy sets and bindings.

For information about migrating the version of the product that you are running to Version 7.0, see migrating and coexisting.

Migration rules for policy sets

For the following policy sets, the migration code first checks for any application attachment for a policy set. If there is an application attachment, the migration code upgrades and renames the policy set to *oldPolicySet_wsfep*; then updates the policy set attachments from *oldPolicySet* to *oldPolicySet_wsfep* in Version 7.0. If there is no attachment for the policy set, then the policy set is not migrated or renamed to Version 7.0.

- LTPA RAMP default
- LTPA SecureConversation
- LTPA WSSecurity default
- Username RAMP default
- Username SecureConversation
- Username WSSecurity default

Other policy sets are migrated to Version 7.0 only if there is no other policy set in Version 7.0 with the same name.

Migration rules for bindings

In Version 7.0, custom bindings are called application specific bindings. Read Web services policy set bindings.

The following migration rules apply to application specific bindings, cell level default bindings, server level default bindings, and trust service bindings:

Application specific bindings

During migration, the Version 6.1 application specific bindings in the applications are not upgraded. They are copied with the applications to the Version 7.0 system. After migration, you can upgrade the Version 6.1 application specific bindings in an application using the administrative command, `upgradeBindings`.

Cell level default bindings

During migration, the cell level default bindings from the Version 6.1 Feature Pack for Web Services are copied to the Version 7.0 system, and they replace any existing Version 6.1 cell default bindings in the Version 7.0 system. The Version 6.1 cell default bindings are migrated to general bindings in Version 7.0.

Note:
There is a security fix for the Version 6.1 cell level default WSSecurity bindings. Run the script, *updateBindings.py* that is located in WAS_HOME/bin to fix issues with the Version 6.1 cell level default WSSecurity bindings.

You can install a WebSphere Application Server Version 6.1 Feature Pack for Web Services application within the WebSphere Application Server Version 7.0 environment. If your application contains Version 6.1 application specific bindings, the application is defined as a Version 6.1 application to the application server. Additionally, if your application is installed on a WebSphere Application Server Version 6.1 Feature Pack for Web Services server within the WebSphere Application Server Version 7.0 environment, the application specific binding is created as a Version 6.1 application specific binding.

When you create an application specific binding, the system checks to see if the application is installed on a Version 6.1 server or if the application contains any Version 6.1 application specific bindings. If either of these conditions is true, the system creates Version 6.1 application specific bindings. In addition, you are not allowed to assign a general binding to a policy set attachment for that application because general bindings are for Version 7.0 level of the product.

Server level default bindings

During migration, the server default bindings in the Version 6.1 Feature Pack for Web Services are copied over to the Version 7.0 server. The server default bindings are also migrated to general bindings. You can decide whether or not to use these general bindings as the Version 7.0 server default bindings. The Version 6.1 applications and other applications that are installed on a Version 6.1 server use the Version 6.1 default bindings.

Trust service bindings

Trust service bindings are migrated during the product migration. The migrated trust service bindings replace the trust service bindings in Version 7.0.

Installing and managing WSIF

An overview of where and how the Web Services Invocation Framework (WSIF) is installed as part of WebSphere Application Server, and a set of links to specific information about other aspects of managing your WSIF system.

About this task

WSIF is provided in a JAR file named `com.ibm.ws.runtime.jar`. The JAR file contains the core WSIF classes, and the Java, EJB, SOAP over HTTP and SOAP over JMS providers. Additional providers are packaged as separate JAR files.

When you install WebSphere Application Server, the `com.ibm.ws.runtime.jar` file is put on the WebSphere or Java virtual machine (JVM) class path.

WSIF requires no further configuration. WSIF is a thin abstraction layer between application code and the relevant invocation infrastructure.

For information about managing your WSIF system, see the following topics:

- wsif.properties file - Initial contents
- Enable security for WSIF

- Trace and log WSIF
- Troubleshoot the Web Services Invocation Framework
- WSIF messages
- WSIF - Known restrictions

wsif.properties file - Initial contents

The Web Services Invocation Framework (WSIF) properties are stored in the `com.ibm.ws.runtime.jar` file, in a properties file named `wsif.properties`. You might need to modify the contents of this file, for example to change the default SOAP provider, so for reference here is a copy of the “as shipped” contents of the `wsif.properties` file.

The `com.ibm.ws.runtime.jar` file is located in the *app_server_root*`/plugins` directory, where *app_server_root* is the root directory for your installation of IBM WebSphere Application Server.

You must keep the `wsif.properties` file on the class path, so that WSIF can find it and the client administrator can use it to configure WSIF. However if you make any changes to the file, you do not replace the original copy in the `com.ibm.ws.runtime.jar` file. Instead, you save the modified version in the *app_server_root*`/lib/properties` directory.

The following code is the initial contents of the `wsif.properties` file. All the possible properties are listed and described.

```
# Two properties are used to override which WSIFProvider is selected when there
# exists multiple providers supporting the same namespace URI. These properties are:
#
#    wsif.provider.default.CLASSNAME=N
#    wsif.provider.uri.M.CLASSNAME=URI
#
# CLASSNAME is the WSIFProvider class name
# N is the number of following default wsif.provider.uri.M.CLASSNAME properties
# M is a number from 1 to N to uniquely identify each wsif.provider.uri.M.CLASSNAME
#   property key.
# For example the following two properties would override the default SOAP provider
# to be the Apache SOAP provider:
#
# wsif.provider.default.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=1
# wsif.provider.uri.1.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=\
# http://schemas.xmlsoap.org/wsdl/soap/
#

# maximum number of milliseconds to wait for a response to a synchronous request.
# Default value if not defined is to wait forever.
# Timeout properties are only used by providers which support timeouts.
wsif.syncrequest.timeout=10000

# maximum number of seconds to wait for a response to an async request.
# if not defined on invalid defaults to no timeout
# Timeout properties are only used by providers which support timeouts.
wsif.asyncrequest.timeout=60
```

To enable your legacy Web services to continue to work with WSIF, you might need to change the default WSIF SOAP provider back to the former Apache SOAP provider.

Enabling security for WSIF

The steps to be taken to enable the Web Services Invocation Framework (WSIF) to interact with a security manager.

About this task

WSIF interacts with a security manager in the following ways:
- WSIF runs in the Java Platform, Enterprise Edition (Java EE) security context without modification.
- When WSIF is run under a Java EE container, port implementations can use the security context to pass on security tokens or credentials as necessary.
- WSIF implementations can automatically convert Java EE security context into appropriate context for onward services.

For WSIF to interact effectively with the WebSphere Application Server security manager, complete the following step:

To load the WSDL file, enable the **FilePermission** attribute in the `was.policy` file. This permission is required when a WSDL file is referred to using the `file://` protocol.

Web Services Invocation Framework troubleshooting tips

A set of specific tips to help you troubleshoot problems you experience with the Web Services Invocation Framework (WSIF).

For information about resolving WebSphere-level problems, see Diagnosing and fixing problems.

To identify and resolve Web Services Invocation Framework (WSIF)-related problems, you can use the standard WebSphere Application Server trace and logging facilities. If you encounter a problem that you think might be related to WSIF, you can check for error messages in the WebSphere Application Server administrative console, and in the application server `stdout.log` file. You can also enable the application server debug trace to provide a detailed exception dump.

A list of the WSIF run-time system messages, with details of what each message means, is provided in Message reference for WSIF.

A list of the main known restrictions that apply when using WSIF is provided in WSIF - Known restrictions.

Here is a checklist of major WSIF activities, with advice on common problems associated with each activity:

Create service

Handcrafted Web Services Description Language (WSDL) can cause numerous problems. To help ensure that your WSDL is valid, use a tool such as WebSphere Development Studio for iSeries (WDS) to create your Web service. For more details about creating services with WSDL in an iSeries environment, read the WSIF and WSDL chapter of *Developing and deploying applications* PDF book.

Define transport mechanism

For the Java Message Service (JMS), check that you have set up the Java Naming and Directory Interface (JNDI) correctly, and created the necessary connection factories and queues.

For SOAP, make sure that the deployment descriptor file `dds.xml` is correct - preferably by creating it using WebSphere Development Studio for iSeries (WDS) or similar tooling.

Create client - Java code

Follow the correct format for creating a WSIF service, port, operation and message. For examples of correct code, refer to the Address Book Sample in the *Developing and deploying applications* PDF book.

Compile code (client and service)

Check that the build path against code is correct, and that it contains the correct levels of JAR files.

Create a valid EAR file for your service in preparation for deployment to a Web server.

Deploy service

When you install and deploy the service EAR file, check carefully any messages given when the service is deployed.

Server setup and start

Make sure that the WebSphere Application Server `server.policy` file (in the `/properties` directory) has the correct security settings. For more information about setting up security, see the Enabling security for WSIF topic in the *Securing applications and their environment* PDF book.

WSIF setup

Check that the `wsif.properties` file is correctly set up. For more information about this file, refer to the Maintaining the WSIF properties file topic in the *Administering applications and their environment* PDF book.

Run client

Either check that you have defined the class path correctly to include references to your client classes, WSIF JAR files and any other necessary JAR files, or (preferably) run your client using the WebSphere Application Server launchClient tool.

Either check that you have defined the class path correctly to include references to your client classes, WSIF JAR files and any other necessary JAR files, or (preferably) run your client using the WebSphere Application Server launch client tool. For more information about this tool, refer to the Running application clients chapter of the *Developing and deploying applications* PDF book.

Here is a set of tips to help you troubleshoot commonly-experienced problems:

- "No class definition errors received when running client code."
- "Cannot find WSDL error."
- "Your Web service EAR file does not install correctly onto the application server." on page 972
- "There is a permissions problem or security error." on page 972
- "Using WSIF with multiple clients causes a SOAP parsing error." on page 972
- "JNDI lookup errors occur when using the same names for JMS messaging queues and queue connection factories that run on application servers on different machines." on page 972
- "A JAX-RPC client running on WebSphere Application Server Version 5 uses SOAP over JMS to invoke a Web service running on a Version 5 application server. No user ID or password is required on the target MQ Series queue. After the application server is migrated to Version 6, and using Version 6 default messaging, client requests fail because basic authentication is now enabled." on page 973
- "The current WSIF default SOAP provider (the IBM Web Service SOAP provider) does not interoperate fully with services that are running on the former (Apache SOAP) provider." on page 973

"No class definition" errors received when running client code.

This problem usually indicates an error in the class path setup. Check that the relevant JAR files are included.

"Cannot find WSDL" error.

Some likely causes are:

- The application server is not running.
- The server location and port number in the WSDL are not correct.
- The WSDL is badly formed (check the error messages in the application server `stdout.log` file).
- The application server has not been restarted since the service was installed.

You might also try the following checks:

- Can you load the WSDL into your Web browser from the location specified in the error message?
- Can you load the corresponding WSDL binding files into your Web browser?

Your Web service EAR file does not install correctly onto the application server.

It is likely that the EAR file is badly formed. Verify the installation by completing the following steps:
- For an EJB binding, run the WebSphere Application Server tool `\bin\dumpnamespace`. This tool lists the current contents of the JNDI directory.
- For a SOAP over HTTP binding, open the `http://pathToServer/WebServiceName/admin/list.jsp` page (if you have the SOAP administration pages installed). This page lists all currently installed Web services.
- For a SOAP over JMS binding, complete the following checks:
  - Check that the queue manager is running.
  - Check that the necessary queues are defined.
  - Check the JNDI setup.
  - Use the "display context" option in the `jmsadmin` tool to list the current JNDI definitions.
  - Check that the Remote Procedure Call (RPC) router is running.

There is a permissions problem or security error.

Check that the WebSphere Application Server `server.policy` file (in the `/properties` directory) has the correct security settings. For more information about setting up security, see the Enabling security for WSIF topic in the *Securing applications and their environment* PDF book.

Using WSIF with multiple clients causes a SOAP parsing error.

Before you deploy a Web service to WebSphere Application Server, you must decide on the scope of the Web service. The deployment descriptor file `dds.xml` for the Web service includes the following line:

```
<isd:provider type="java" scope="Application" ......
```

You can set the `Scope` attribute to `Application` or `Session`. The default setting is `Application`, and this value is correct if each request to the Web service does not require objects to be maintained for longer than a single instance. If `Scope` is set to `Application` the objects are not available to another request during the execution of the single instance, and they are released on completion. If your Web service needs objects to be maintained for multiple requests, and to be unique within each request, you must set the scope to `Session`. If `Scope` is set to `Session`, the objects are not available to another request during the life of the session, and they are released on completion of the session. If scope is set to `Application` instead of `Session`, you might get the following SOAP error:

```
SOAPException: SOAP-ENV:ClientParsing error, response was:
FWK005 parse may not be called while parsing.;
nested exception is:

[SOAPException: faultCode=SOAP-ENV:Client; msg=Parsing error, response was:

FWK005 parse may not be called while parsing.;
        targetException=org.xml.sax.SAXException:
FWK005 parse may not be called while parsing.]
```

JNDI lookup errors occur when using the same names for JMS messaging queues and queue connection factories that run on application servers on different machines.

You should not use the same names for messaging queues and queue connection factories that run on application servers on different machines, because WSIF always looks first for JMS destinations locally, and only uses the full JNDI reference if it cannot find the destination locally. For example, if you run a Web service on a remote machine, and have an application server running locally that uses the same names for the messaging queues and queue connection factories, then WSIF will find and use the local queues even if the remote JNDI destination is provided in full in the WSDL service definition.

A JAX-RPC client running on WebSphere Application Server Version 5 uses SOAP over JMS to invoke a Web service running on a Version 5 application server. No user ID or password is required on the target MQ Series queue. After the application server is migrated to Version 6, and using Version 6 default messaging, client requests fail because basic authentication is now enabled.

The problem appears as a log message:

```
SibMessage W [:] CWSIT0009W: A client request failed in the application server
with endpoint <endpoint_name> in bus <your_bus> with reason: CWSIT0016E:
The user ID null failed authentication in bus <your_bus>.
```

For the steps to take to resolve the problem, see the following service integration technologies troubleshooting tip: “After you migrate an application server to WebSphere Application Server Version 6, existing Web services clients can no longer use SOAP over JMS to access services hosted on the migrated server”. This tip can be found in the Tips for troubleshooting service integration bus security section.

The current WSIF default SOAP provider (the IBM Web Service SOAP provider) does not interoperate fully with services that are running on the former (Apache SOAP) provider.

This restriction is due to the fact that the IBM Web Service SOAP provider is designed to interoperate fully with a JAX-RPC compliant Web service, and Apache SOAP cannot provide such a service. To enable interoperation, modify either your Web service or the WSIF default SOAP provider. For information about how to modify your provider, read the chapter “WSIF SOAP provider: working with legacy applications” in the *Developing and deploying applications PDF* book.

WSIF (Web Services Invocation Framework) messages

This topic contains a list of the WSIF run-time system messages, with details of what each message means.

WebSphere system messages are logged from a variety of sources, including application server components and applications. Messages logged by application server components and associated IBM products start with a unique message identifier that indicates the component or application that issued the message.

For more information about the message identifier format, see the topic Message reference.

WSIF0001E: An extension registry was not found for the element type “{0}”

Explanation: Parameters: {0} element type. No extension registry was found for the element type specified.

Action: Add the appropriate extension registry to the port factory in your code.

WSIF0002E: A failure occurred in loading WSDL from “{0}”

Explanation: Parameters: {0} location of the WSDL file. The WSDL file could not be found at the location specified or did not parse correctly

Action: Check that the location of the WSDL file is correct. Check that any network connections required are available. Check that the WSDL file contains valid WSDL.

WSIF0003W: An error occurred finding pluggable providers: {0}

Explanation: Parameters: {0} specific details about the error. There was a problem locating a WSIF pluggable provider using the J2SE 1.3 JAR file extensions to support service providers architecture. The WSIF trace file will contain the full exception details.

Action: Verify that a META-INF/services/org.apache.wsif.spi.WSIFProvider file exists in a provider jar, that each class referenced in the META-INF file exists in the class path, and that each class implements org.apache.wsif.spi.WSIFProvider. The class in error will be ignored and WSIF will continue locating other pluggable providers.

WSIF0004E: WSDL contains an operation type "{0}" which is not supported for "{1}"

Explanation: Parameters: {0} name of the operation type specified. {1} name of the portType for the operation. An operation type which is not supported has been specified in the WSDL.

Action: Remove any operations of the unsupported type from the WSDL. If the operation is required then make sure all messages have been correctly specified for the operation.

WSIF0005E: An error occurred when invoking the method "{1}" . ("{0}")

Explanation: Parameters: {0} name of communication type. For example EJB or Apache SOAP. {1} name of the method that failed. An error was encountered when invoking a method on the Web service using the communication shown in brackets.

Action: Check that the method exists on the Web service and that the correct parts have been added to the operation as described in the WSDL. Network problems might be a cause if the method is remote and so check any required connections.

WSIF0006W: Multiple WSIFProvider found supporting the same namespace URI "{0}" . Found ("{1}")

Explanation: Parameters: {0} the namespace URI. {1} a list of the WSIFProvider found.. There are multiple org.apache.wsif.spi.WSIFProvider classes in the service provider path that support the same namespace URI.

Action: A following WSIF0007I message will be issued notifying which WSIPFProvider will be used. Which WSIFProvider is chosen is based on settings in the wsif.properties file, or if not defined in the properties, the last WSIFProvider found will be used. See the wsif.properties file for more details on how to define which provider should be used to support a namespace URI.

WSIF0007I: Using WSIFProvider "{0}" for namespaceURI "{1}"

Explanation: Parameters: {0} the classname of the WSIFProvider being used. {1} the namespaceURI the provider will be used to support.. Either a previous WSIF0006W message has been issued or the SetDynamicWSIFProvider method has been used to override the provider used to support a namespaceURI.

Action: None. See also WSIF0006W.

WSIF0008W: WSIFDefaultCorrelationService removing correlator due to timeout. ID:"{0}"

Explanation: Parameters: {0} the ID of the correlator being removed from the correlation service. A stored correlator is being removed from the correlation service due to its timeout expiring.

Action: Determine why no response has been received for the asynchronous request within the timeout period. The wsif.asyncrequest.timeout property of the wsif.properties file defines the length of the timeout period.

WSIF0009I: Using correlation service - "{0}"

Explanation: Parameters: {0} the name of the correlation service being used. This identifies the name of the correlation service that will be used to process asynchronous requests.

Action: None. If a correlation service other than the default WSIF supplied one is required, ensure that it is correctly registered in the JNDI java:comp/wsif/WSIFCorrelationService namespace.

WSIF0010E: Exception thrown while processing asynchronous response - "{0}"

Explanation: Parameters: {0} the error message string of the exception. While processing the response from an executeRequestResponseAsync call an exception was thrown.

Action: Use the exception error message string to determine the cause of the error. The WSIF trace will have more details on the error including the exception stack trace.

WSIF0011I: Preferred port "{0}" was not available

Explanation: Parameters: {0} the user's preferred port. The preferred port set by the user on org.apache.wsif.WSIFService is not available

Action: None unless this message appears for long periods of time in which case the user might want to pick a different port as their preferred port.

WSIF - Known restrictions

This topic lists the main known restrictions that apply when using WSIF.

Threading

WSIF is not thread-safe.

External Standards

WSIF supports:

- SOAP Version 1.1 (not 1.2 or later).
- WSDL Version 1.1 (not 1.2 or later).

WSIF does not provide WS-I compliance, and it does not support the Java API for XML-based Remote Procedure Calls (JAX-RPC) Version 1.1 (or later).

Full schema parsing

WSIF does not support full schema parsing. For example, WSDL references in complex types in the schema are not handled, and attributes are not handled.

XML Schema “redefine” elements are not handled and are ignored.

SOAP WSIF does not support:

- SOAP headers that are passed as `<parts>`.
- Unreferenced attachments in SOAP responses, or the scenarios detailed in SOAP attachments - scenarios that are not supported.
- Document Encoded style SOAP messages.

  Note: This is not primarily a WSIF restriction. Although you can specify Document Encoded style in WSDL, it is not generally considered to be a valid option and is not supported by the Web Services Interoperability Organization (WS-I).

SOAP provider interoperability

The current WSIF default SOAP provider (the IBM Web Service SOAP provider) does not fully interoperate with services that are running on the former (Apache SOAP) provider. This restriction is due to the fact that the IBM Web Service SOAP provider is designed to interoperate fully with a JAX-RPC compliant Web service, and Apache SOAP cannot provide such a service. For information on how to overcome this restriction, see WSIF SOAP provider: working with legacy applications.

WSIF’s support for SOAP faults is restricted to SOAP faults originating from a Web service that runs using the IBM Web Service SOAP provider.

Note: This is not primarily a WSIF restriction. The current SOAP faults specification does not prescribe how to encode a SOAP fault so that it maps to a Java exception. Consequently, each Web service run-time environment currently decides on its own SOAP fault format. The IBM Web Service SOAP provider can understand its own response SOAP faults, but not the SOAP faults from another provider.

Type mappings

The current WSIF default SOAP provider (the IBM Web Service SOAP provider) conforms to the JAX-RPC type mapping rules that were finalized after the former (Apache SOAP) provider was created. The majority of types are mapped the same way by both providers. The exceptions are: `xsd:date`, `xsd:dateTime`, `xsd:hexBinary` and `xsd:QName`. Both client and service need to use the same mapping rules if any of these four types are used. Below is a table detailing the mapping rules for these four types:

XML Data Type	Apache SOAP Java Mapping	JAX-RPC Java Mapping
xsd:date	java.util.Date	Not supported
xsd:dateTime	Not supported	java.util.Calendar
xsd:hexBinary	Hexadecimal string	byte [ ]
xsd:QName	org.apache.soap.util.xml.QName	javax.xml.namespace.QName

Arrays and complex types

WSIF does not support general complex types, it only handles complex types that map to Java

Beans. To use schema complex types, you must write your own custom serializers. The specific complex type and array support for WSIF outbound invocation of Web services is as follows:

- WSIF supports Java classes generated by WebSphere Studio Application Developer - Integration Edition (WSAD-IE) message generators (the normal case when WSDL files are downloaded from somewhere else). The WSAD-IE-based generation happens automatically when you use the BPEL editor, or the generation actions available on the Enterprise Services context menu, or the Business Integration toolbar.
- WSIF does not support Java beans generated by other tools, including the base WSAD tool.
- For WSAD-IE generated Java beans, attributes defined in the WSDL do not work. That is to say that these attributes, although they appear in the Java beans generated to represent the complex type, do not appear in the SOAP request created by WSIF.
- WSIF does not support arrays when they are a field of a Java bean. That is to say, WSIF only supports an array that is passed in as a named `<part>`. If an array is wrappered inside a Java bean, the array is not serialized in the same way.

Object Serialization
WSIF does not support serialization of objects across different releases.

Asynchronous invocation
WSIF supports synchronous invocation for all providers. For the JMS and the SOAP over JMS providers, WSIF also supports asynchronous invocation. You should call the `supportsAsync()` method before trying to execute an asynchronous operation.

The EJB provider
The target service of the WSIF EJB provider must be a remote-home interface, it cannot be an EJB local-home interface. In addition, the EJB stub classes must be available on the client class path.

Running outside WebSphere Application Server
WSIF is not supported for use outside WebSphere Application Server.

Trace and logging for WSIF

The Web Services Invocation Framework (WSIF) offers trace points at the opening and closing of ports, the invocation of services, and the responses from services. WSIF also includes a `SimpleLog` utility that can run trace when you are using WSIF outside of WebSphere Application Server.

About this task

If you want to enable trace for the WSIF API within WebSphere Application Server, and have trace, stdout and stderr for the application server written to a well-known location, see Enabling tracing and logging.

To trace the WSIF API, you need to specify the following trace string:

```
wsif=all=enabled
```

To enable the WSIF `SimpleLog` utility, through which you can run trace when using WSIF outside of WebSphere Application Server, complete the following steps:

1. Create a file named `commons-logging.properties` with the following contents:

```
org.apache.commons.logging.LogFactory=org.apache.commons.logging.impl.LogFactoryImpl
org.apache.commons.logging.Log=org.apache.commons.logging.impl.SimpleLog
```

2. Create a file named `simplelog.properties` with the following contents:

```
org.apache.commons.logging.simplelog.defaultlog=trace
org.apache.commons.logging.simplelog.showShortLogname=true
org.apache.commons.logging.simplelog.showdatetime=true
```

3. Put both these files, and the `commons-logging.jar` file, on the class path.

Results

The `SimpleLog` utility writes trace to the `System.err` file.

Getting started with the UDDI registry

This section covers the basic knowledge you need to get started, either as an administrator of a UDDI registry, or as a user of a UDDI registry that is already set up.

- If you are an administrator of a UDDI registry, that is, you are need to install (set up and deploy), customize, or manage a UDDI registry, use the following topics to get started.
  - UDDI registry Terminology introduces some terms that you need to understand to administer a UDDI registry
  - Setting up and deploying a new UDDI registry explains how to install a UDDI registry node by setting up the resources that it will use, and deploying the UDDI registry application.
  - Migrating the UDDI registry explains how to use the scripts provided to migrate UDDI registries from the previous version of WebSphere Application Server.
  - Migrating to Version 3 of the UDDI registry explains how to migrate UDDI Version 2 registries to UDDI Version 3, introduced in WebSphere Application Server Version 6.0, by creating a migration datasource.
  - Configuring UDDI registry security explains how to configure different levels of security for the UDDI registry, and how other UDDI node settings can influence security.
  - Managing the UDDI registry explains how to use the UDDI pages in the administrative console, or the UDDI registry Administrative interface, to administer a UDDI registry node. It also covers how to back up and restore your UDDI registry data.
  - UDDI node settings explains how to view and set UDDI properties and policies, and how to manage UDDI publishers, tiers, and user entitlements.
  - UDDI registry Management Interfaces covers details of programmatic interfaces that you can use to administer a UDDI registry node (UDDI registry Administrative (JMX) Interface), to add custom value set data to a UDDI registry (User Defined Value Set Support), and to export and import UDDI version 2 entities (UDDI Utility Tools).
  - “Removing and reinstalling the UDDI registry” on page 978
- If you are a user of a UDDI registry, use the following topics to get started.
  - UDDI registry Terminology introduces some terms that you might need to understand to use a UDDI registry.
  - Using the UDDI registry user interface explains how to access the UDDI User Console, which is a user interface that allows you to find UDDI entities and carry out simple UDDI publish operations.
  - UDDI registry SOAP Service End Points contains details for accessing the UDDI Version 3 inquiry, publish, security, and custody transfer APIs, as well as the UDDI Version 1 and Version 2 APIs.
  - UDDI registry Client Programming explains how to write UDDI client application programs. The recommended client programming interface is the UDDI Version 3 Client for Java.
  - JAXR Provider for the UDDI registry is for users who want to use the Java API for XML Registries (JAXR) to access UDDI.
  - User Defined Value Set Support in the UDDI registry explains how to add custom value set data to a UDDI registry.
- For either role, UDDI registry troubleshooting might be useful if you encounter any problems or unexpected behavior while using the UDDI registry, and Messages links to messages that you might see.

Removing and reinstalling the UDDI registry

This task describes the points to consider when you remove a UDDI application, remove a UDDI registry node, or reinstall a UDDI registry node, and describes how to achieve this.

About this task

A UDDI registry node consists of an enterprise application, a store of data (using a relational database management system) referred to as the UDDI database, and a means to connect the application to the data (a data source and related elements). All the data relating to UDDI is stored within the UDDI database and therefore exists irrespective of the UDDI application.

With these facts in mind, consider the following options:

- To remove a UDDI registry node from a WebSphere Application Server, you do not need to delete the database. You just need to delete the UDDI application and any associated resources, such as the data source used (and J2EE Connector Architecture authentication data if used), because the data in the UDDI database is separate from the UDDI application.
- To start a new UDDI registry node, you do not need to remove the UDDI application. Instead, you can create a new replacement node by changing the data source that the UDDI application uses to access the new UDDI database.
- To remove a UDDI application or to remove a UDDI registry node, see Removing a UDDI Node. Remove the UDDI application if you no longer want a UDDI facility on a particular application server. You can subsequently move the UDDI registry node to a different application server.
- To reinstall a UDDI registry node, see Reinstalling the UDDI application. Reinstall the UDDI application if you wish to continue to provide the UDDI facility on a particular application server.

Removing a UDDI registry node

You can remove a UDDI registry node completely, or just remove the UDDI registry application, delete the UDDI registry database, or move a UDDI registry to another server or profile.

About this task

To remove a UDDI registry node completely, you need to remove the UDDI registry application and delete the UDDI registry database. However, there might be situations where you want to perform only one of these tasks:

Removing the UDDI registry application from an application server.
You might want to do this to reinstall the application, either because it has become corrupted, or to apply service. See also Reinstalling the UDDI registry application.

Deleting the UDDI registry database
You might want to do this to use a different database product as the persistence store for your UDDI data, to delete all your UDDI registry data to publish fresh data (for example, if you have completed a test cycle), or to re-initialize the UDDI registry node with new UDDI property settings (for example, to move from a default UDDI node to a customized UDDI node). Note that if you delete a UDDI registry database, all UDDI data for that UDDI registry is lost.

Moving a UDDI registry to another server or profile
You might want to do this after you create a new profile and you want to move the UDDI registry to the new profile.

Completely removing a UDDI registry node from an application server
You might want to do this to remove a UDDI registry that was used for testing.

Depending on what you wish to achieve, complete **one** of the following steps:

1. **Removing a UDDI registry application**

Start a Qshell session. To do this, enter the STRQSH command from the i5/OS command line.

To remove the UDDI application from an application server, run the wsadmin script uddiRemove.jacl, as shown, from the *app_server_root*/bin directory.

The syntax of the command is as follows:

```
wsadmin [-profileName profile_name] -f uddiRemove.jacl
               node_name
               server_name
               [default]
```

where

- '-profileName *profile_name*' is optional, and is the name of the profile in which the UDDI application is deployed. If you do not specify a profile, the default profile is used.
- *node_name* and *server_name* are the names of the WebSphere node and application server in which the UDDI application is deployed (these are the names that you specified when you ran uddiDeploy.jacl to install the UDDI application).
- 'default' is optional and is applicable only for Apache Derby, and then only if the default option was used when the uddiDeploy.jacl script was run to deploy the UDDI registry. Specifying default will remove the UDDI Apache Derby datasource but **not** the UDDI Apache Derby database.

By default, output appears on screen. To direct the output to a log file, add '> *removeuddi.log*' (where removeuddi.log can be any log name of your choice) to the end of the command.

For example, to remove the UDDI application from server 'server1' running in node 'MyNode' and send any messages to the file removeuddi.log:

```
wsadmin -profileName myProfile -f uddiRemove.jacl MyNode server1 > removeuddi.log
```

Note: You can also remove the UDDI registry application using the administrative console in the usual way, by selecting the application in the **Enterprise Applications** view and clicking **Uninstall**.

2. **Deleting a UDDI registry database**

   This action destroys all UDDI data in that UDDI registry.

   a. Stop the server that is hosting the UDDI registry application.
   b. Delete the database:
      - For DB2 for iSeries, use either iSeries Navigator or a 5250 Session to delete the schemas IBMUDI30 and IBMUDS30.
      - For Oracle, delete the schemas IBMUDDI, IBMUDI30 and IBMUDS30.
      - For Apache Derby, delete the directory tree containing the UDDI database. By default, this directory tree is located in *profile_root*/databases/com.ibm.uddi/UDDI30.

3. **Moving a UDDI registry to another server or profile**

   a. Make sure that the UDDI database will still be accessible. For example, if you are using a remote database, make sure that the new server can access it. If your database will not be accessible, or it will be deleted after the move, copy it to a new, accessible location. For example, if you want to move the UDDI registry to a new profile and then delete the old profile, any databases stored in the profile (such as an Apache Derby database created as part of the creation of a default UDDI node) will also be deleted.
   b. Remove the UDDI registry application by running the uddiRemove.jacl script as described above.
   c. If you ran the uddiRemove.jacl script using the default option, the datasource and related objects have already been deleted. If the default option was not valid for your configuration, delete the following objects:
      - the UDDI datasource that references the UDDI registry database (this was created when you set up the UDDI registry).
      - any UDDI JDBC provider that was created (if you did not reuse an existing JDBC provider).
      - any J2C Authentication Data Entry that was created.

d. In the new server create a J2C authentication data entry (if appropriate), JDBC provider and datasource, to reference the existing database (for more information see the relevant steps in Setting up a customized UDDI node).

e. Deploy the UDDI registry application as described in Deploying the UDDI registry application, noting that you should not specify the default option even if you previously used this option to set up a default UDDI node. If you use the default option, you might encounter an error during deployment, or in some circumstances your existing UDDI data might be overwritten.

Note: The UDDI node name will remain the same as before. If the UDDI node name included the node name and server name of the original server, there will be a mismatch between the UDDI node name and the node name and server name of the new server. However this name mismatch will not affect the functioning of the UDDI registry node.

f. Check that the UDDI data can be accessed. If you are using a copy of the original UDDI registry database, you can now delete the original as described above.

4. **Completely removing a UDDI registry node**

To completely remove a UDDI registry node from an application server, you need to remove the UDDI registry application and database, and also the resources that were used to reference the UDDI registry database.

a. Remove the UDDI registry application by running the uddiRemove.jacl script as described above.

b. Delete the UDDI registry database, as described above.

c. If you ran the uddiRemove.jacl script using the default option, the datasource and related objects have already been deleted so no further action is required. If the default option was not valid for your configuration, delete the following objects:

- the UDDI datasource that references the UDDI registry database (this was created when you set up the UDDI registry).
- any UDDI JDBC provider that was created (if you did not reuse an existing JDBC provider).
- any J2C Authentication Data Entry that was created.

Reinstalling the UDDI registry application

You can reinstall the UDDI registry application to remove the existing UDDI application and reinstall it with the existing UDDI database.

About this task

Perform this task if you wish to change the UDDI application code, but you want to continue to provide UDDI services with your existing UDDI database.

1. Make a note of any changes that you made to the installed UDDI application that you wish to keep, for example changes to security role mappings, changes to the deployment descriptor (web.xml) in v3soap.war, v3gui.war, v3soap.war, or soap.war, or customization of the UDDI user interface (GUI). All such changes are lost during the reinstallation process; if there are changes that you wish to keep, you must reapply them later.
2. Run the wsadmin script uddiDeploy.jacl from the *app_server_root*/bin directory, as shown. Note the following points:
   - Do not specify the default option, even if you used this option previously to set up a default UDDI node. If you use the default option, you might encounter an error during deployment, or in some circumstances your existing UDDI data might be overwritten.

   At a command prompt, enter:

```
wsadmin [-conntype none] [-profileName profile_name] –f uddiDeploy.jacl
               node_name
               server_name
```

   where

- '-profileName *profile_name*' is optional, and is the name of the profile in which the UDDI application is deployed. If you do not specify a profile, the default profile is used.
- '-conntype none' is optional, and is needed only if the application server is not running.
- *node_name* and *server_name* are the names of the WebSphere node and application server in which the UDDI application is deployed (these are the names that you specified when you ran uddiDeploy.jacl to install the UDDI application).

Optionally, you can redirect the output from this command to a log file. To do this, add '> *log_name*.log' at the end of the command, where *log_name*.log is the name of the log file to create.

The command removes the existing UDDI application and reinstalls it.

Note: This procedure does not change your existing JDBC provider, datasource and any J2C authdata entry. Your existing UDDI registry data, including UDDI entities as well as property and policy settings, are also unaffected.

3. If you noted any changes in step 1, reapply them now.
4. For the reapplied changes to take effect, start or restart the application server.

Creating a DB2 distributed database for the UDDI registry

Perform this task if you want to use DB2 on the Windows, Linux or UNIX operating systems, as the database store for your UDDI registry data.

Before you begin

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

<DataBaseName>
The name of the UDDI registry database. A recommended value is UDDI30, and this name is assumed throughout the UDDI information. If you use another name, substitute that name when UDDI30 is used in the information center.

<DB2UserID>
A DB2 userid with administrative privileges.

<DB2Password>
The password for the DB2 userid.

<BufferPoolName>
The name of a buffer pool to be used by the UDDI registry database. A suggested name is uddibp, but any name can be used, because the buffer pool is created as part of this task.

<TableSpaceName>
The name of a table space. A suggested value is uddits, but any name can be used.

<TempTableSpaceName>
The name of a temporary table space. A suggested value is udditstemp, but any name can be used, because the temporary table space is created as part of this task.

About this task

You need to perform this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

If you want to create a remote database, refer first to the database product documentation about the relevant capabilities of the product.

1. Change directory to *app_server_root*/UDDIReg/databaseScripts.
2. Start the DB2 Command Line Processor by entering `db2` at the command prompt.
3. Run the following command to setup the DB2 environment variables:

```
set DB2CODEPAGE=1208
```

4. Create the DB2 database by entering the following command:
   ```
   create database <DataBaseName> using codeset UTF-8 territory en
   ```
   where <DataBaseName> is the name of the database being created.
5. Configure the DB2 database by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `update db cfg for <DataBaseName> using applheapsz 2048`
   c. `update db cfg for <DataBaseName> using logfilsiz 8192`
   d. `connect reset`
   e. `terminate`
6. Create additional database structures by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `create bufferpool <BufferPoolName> size 250 pagesize 32K`
   c. `connect reset`
   d. `terminate`
   e. `force application all`
   f. `terminate`
   g. `stop`
   h. `start`
7. Create further database structures by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `create regular tablespace uddits pagesize 32K managed by system using ('<TableSpaceName>') extentsize 64 prefetchsize 32 bufferpool <BufferPoolName>`
   c. `create system temporary tablespace <TempTableSpacename> pagesize 32K managed by system using ('<TempTableSpacename>') extentsize 32 overhead 14.06 prefetchsize 32 transferrate 0.33 bufferpool <BufferPoolName>`
8. Exit the DB2 Command Line Processor and enter the following commands exactly as shown, noting that one step uses -vf rather than -tvf (on Windows platforms, run the commands from the db2cmd window). These commands define the database structures needed to store the UDDI data:
   a. `db2 -tvf uddi30crt_10_prereq_db2.sql`
   b. `db2 -tvf uddi30crt_20_tables_generic.sql`
   c. `db2 -tvf uddi30crt_25_tables_db2udb.sql`
   d. `db2 -tvf uddi30crt_30_constraints_generic.sql`
   e. `db2 -tvf uddi30crt_35_constraints_db2udb.sql`
   f. `db2 -tvf uddi30crt_40_views_generic.sql`
   g. `db2 -tvf uddi30crt_45_views_db2udb.sql`
   h. `db2 -vf uddi30crt_50_triggers_db2udb.sql`
   i. `db2 -tvf uddi30crt_60_insert_initial_static_data.sql`
9. [Optional] Enter the following command if you want the database to be used as a default UDDI node:
   ```
   db2 -tvf uddi30crt_70_insert_default_database_indicator.sql
   ```

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating a DB2 for iSeries database for the UDDI registry

Perform this task if you want to use DB2 for iSeries as the database store for your UDDI registry data.

Before you begin

IBMUDI30 and IBMUDS30 are the default names of the UDDI registry schema in the SQL scripts mentioned below. These default names are the recommended values and are assumed throughout the UDDI documentation. If you want to use different names, modify the SQL files listed below, then substitute your own names whenever you see 'IBMUDI30' or 'IBMUDS30' in other sections of the documentation.

About this task

You need to perform this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

1. Use iSeries Navigator to run SQL scripts.
   a. Open iSeries Navigator.
   b. Expand **My Connections** → **iSeriesName** → **Databases**.
   c. Select **iSeriesName**.
   d. Right-click **Run SQL Scripts...**.

   A **Run SQL Scripts** window opens.
2. Open the i5/OS DB2 SQL files.
   a. Map a network drive to the root directory of your i5/OS server's integrated file system.
   b. In Windows Explorer, expand the `WAS_HOME/UDDIReg/databaseScripts` directory.
   c. Open the following SQL files with a text editor (such as Notepad):
      - uddi30crt_10_prereq_db2_iSeries.sql
      - uddi30crt_20_tables_generic_iSeries.sql
      - uddi30crt_25_tables_db2udb_iSeries.sql
      - uddi30crt_30_constraints_generic_iSeries.sql
      - uddi30crt_35_constraints_db2udb_iSeries.sql
      - uddi30crt_40_views_generic_iSeries.sql
      - uddi30crt_45_views_db2udb_iSeries.sql
      - uddi30crt_50_triggers_db2udb_iSeries.sql
      - uddi30crt_60_insert_initial_static_data_iSeries.sql
3. Copy the text to the **Run SQL Scripts** window.
   a. In the text editor of the file `uddi30crt_10_prereq_db2_iSeries.sql`, click **Edit** → **Select All**.
   b. Click **Edit** → **Copy**.
   c. In the **Run SQL Scripts** window, click **Edit** → **Paste**.
   d. Click **Run** → **All**.
   e. After the script completes running, select all the SQL text and delete it from the **Run SQL Scripts** window.
   f. Repeat the above steps for all the SQL scripts listed in step 2.

   Note: iSeries Navigator for i5/OS V5R2 will encounter an error on the last line of the SQL script when running the `uddi30crt_25_tables_db2udb_iSeries.sql` script. This error can be ignored. i5/OS V5R2 does support running UDDI in a clustered high availability environment. For more information, see the WebSphere Application Server for i5/OS tech notes.
4. This step should only be run if you want your database to be used as a default UDDI node.
   a. Open `uddi30crt_70_insert_default_database_indicator.sql` as described in Step 2 above.
   b. Copy and run `uddi30crt_70_insert_default_database_indicator.sql` as described in Step 3 above.

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating an Apache Derby database for the UDDI registry

Perform this task to use Apache Derby (embedded or network) as the database store (either local or remote) for your UDDI registry.

Before you begin

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

arg1 The path of the SQL files. On a standard installation, this is *app_server_root*/UDDIReg/databasescripts

arg2 The path to the location where you want to install the Apache Derby database.

For example, *profile_root*/databases/com.ibm.uddi

arg3 The name of the Apache Derby database. A recommended value is UDDI30, and this name is assumed throughout the UDDI information. If you use another name, substitute that name when UDDI30 is used in the information center.

arg4 An optional argument, which must either be the string 'DEFAULT', or be omitted. Specify DEFAULT if you want the database to be used as a default UDDI node. This argument is case sensitive.

If you want to create a remote database, refer first to the database product documentation about the relevant capabilities of the product.

About this task

You need to perform this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

1. Start a Qshell session by entering the STRQSH command from the i5/OS command line.
2. Run the following Java -jar command from the *app_server_root*/UDDIReg/databaseScripts directory, to create a UDDI Apache Derby database using UDDIDerbyCreate.jar.

   ```
   java -Djava.ext.dirs=app_server_root/derby/lib:app_server_root/java/jre/lib/ext -jar UDDIDerbyCreate.jar
   arg1 arg2 arg3 arg4
   ```

   If the Apache Derby database already exists, you are asked if you want to recreate it. If you choose to recreate the database, your existing database is deleted and a new one is created in its place. If you choose not to recreate the database, the command exits and a new database is not created.

   Note: If the application server has already accessed the existing Apache Derby database, the uddiDeploy.jacl script cannot recreate the database. Use the uddiRemove.jacl script to remove the database, as described in "Removing a UDDI registry node" on page 978, restart the server, and run the uddiDeploy.jacl script again.
3. If you are using a remote database (which requires network Apache Derby), or you want to use network Apache Derby for other reasons, for example, if you want to use Apache Derby with a cluster, configure the Apache Derby Network Server framework. For details, see the section about managing the Derby Network Server in the Derby Server and Administration Guide.

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating an Oracle database for the UDDI registry

Perform this task if you want to use Oracle as the database store for your UDDI registry data. You need only do this once for each UDDI registry, as part of setting up and deploying a UDDI registry.

About this task

The supported versions of Oracle are Version 9i[7] and Version 10g[8]

You can create a remote database using Oracle, but not a local database. Because the database is remote, use the database product documentation to familiarize yourself with the relevant capabilities of the product before proceeding with this task.

Before you begin

This task creates three new schemas: ibmuddi, ibmudi30 and ibmuds30. You will be unable to complete this task if you already have existing schemas with these names.

The steps below use a number of variables for which you need to enter appropriate values. You should decide the values that you will use before you start. The variables used are:

<OracleUserID>
is the Oracle userid to be used to create the database.

<OraclePassword>
is the password for the Oracle userid.

1. Run the following commands:
   a. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_10_prereq_oracle.sql`
   b. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_20_tables_generic.sql`
   c. Complete one of the following actions depending on your level of Oracle:
      - For Oracle 9i:

```
sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_25_tables_oracle_pre10g.sql
```

      - For Version 10g and later:

```
sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_25_tables_oracle.sql
```

   d. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_30_constraints_generic.sql`
   e. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_35_constraints_oracle.sql`
   f. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_40_views_generic.sql`
   g. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_45_views_oracle.sql`
   h. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_50_triggers_oracle.sql`
   i. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_60_insert_initial_static_data.sql`

7.

Restrictions:
discoveryURL (Business) maximum 4000 bytes, UDDI specification 4096 characters; accessPoint (bindingTemplate) maximum 4000 bytes, UDDI Specification 4096 characters; instanceParms (tModelInstanceInfo) maximum 4000 bytes, UDDI specification 8192 characters; overviewURL (tModelInstanceInfo) maximum 4000 bytes, UDDI specification 4096 characters; Digital Signature maximum 4000 bytes.

8.

Restrictions:
discoveryURL (Business) maximum 4000 bytes, UDDI specification 4096 characters; accessPoint (bindingTemplate) maximum 4000 bytes, UDDI Specification 4096 characters.

2. This last command should only be run if you want the database to be used as a default UDDI node.

```
sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_70_insert_default_database_indicator.sql
```

What to do next

Continue with setting up and deploying your UDDI registry node.

Applying an upgrade to the UDDI registry

Use this task to apply an iFix, Fix Pack or Refresh Pack to the UDDI registry.

About this task

Note: Some upgrades may require additional steps. Before you complete this task, refer to the readme file for the upgrade.

1. Apply the WebSphere Application Server iFix, Fix Pack or Refresh Pack to your application server, or servers, using the WebSphere Application Server Update Installer. You must repeat this process for each server on which you want to incorporate the UDDI upgrade.
2. If you have not yet deployed a UDDI registry, no further action is required, because updates to the UDDI registry takes effect when you first deploy UDDI into any of your application server profiles.
3. If you have already deployed a UDDI registry to one or more application server profiles, to apply the upgrade, redeploy the UDDI application, as described in Reinstalling the UDDI registry application. The existing UDDI application is removed and the updated application is deployed.

Configuring SOAP API and GUI services for the UDDI registry

For SOAP application programming interface (API) and graphical user interface (GUI) UDDI services, you can configure whether or not the API is secure. For SOAP API services you can also configure the default pool size.

Before you begin

You must have installed the UDDI registry application.

About this task

For the Version 1 and Version 2 SOAP interface, you can configure the following properties:

- *defaultPoolSize*. This is the number of SOAP parsers with which to initialize the parser pool for the SOAP interface. You can set this independently for the Publish (uddipublish) and Inquiry (uddi) APIs. For example, if you expect more inquiries than publish requests through the SOAP interface, you can set a larger pool size for the Inquiry API. The default initial size for both APIs is 10.
- Whether the API is to be secure (accessed using HTTPS) or insecure (accessed using HTTP). The default for Publish is to use HTTPS and Inquiry to use HTTP.

For the Version 3 SOAP interface, you can specify whether Publish, Custody Transfer, Security and Inquiry APIs are to be secure (accessed using HTTPS) or insecure (accessed using HTTP).

For the Version 3 GUI interface, you can specify whether the Publish and Inquiry API services are to be secure (accessed using HTTPS) or insecure (accessed using HTTP).

- Optional: Configure Version 1 and Version 2 SOAP API services by performing the following steps.
  1. Edit the active deployment descriptor (web.xml) for the Version 1 and Version 2 SOAP module (soap.war).

     This file is located in the following directory:

profile_root/config/cells/*cell_name*/applications/
UDDIRegistry.*node_name*.*server_name*.ear/deployments/
UDDIRegistry.*node_name*.*server_name*/soap.war/WEB-INF

2. To modify defaultPoolSize for Version 1 or Version 2 Publish, modify the 'param-value' element in the servlet with 'servlet-name' = uddipublish
3. To modify defaultPoolSize for Version 1 or Version 2 Inquiry, modify the 'param-value' element in the servlet with 'servlet-name' = uddi
4. To modify the user data constraint transport guarantee for Version 1 or Version 2 publish, which determines whether the Publish service is to be confidential (accessed using HTTPS) or insecure (using HTTP), find the 'security-constraint' with id = 'UDDIPublishTransportConstraint' and set its 'user-data-constraint' 'transport-guarantee' to CONFIDENTIAL or NONE.
5. Stop and restart the application server for the changes to take effect.

- Optional: For the Version 3 SOAP interface, specify whether the Publish, Custody Transfer, Security and Inquiry API services are to be secure or insecure by performing the following steps. The defaults are for Publish, Custody Transfer and Security APIs to use HTTPS, and for the Inquiry API to use HTTP.
  1. Edit the active deployment descriptor (web.xml) for the Version 3 SOAP module (v3soap.war).

     This file is located in the following directory:

     profile_root/config/cells/*cell_name*/applications/
     UDDIRegistry.*node_name*.*server_name*.ear/deployments/
     UDDIRegistry.*node_name*.*server_name*/v3soap.war/WEB-INF
  2. Locate the <security-constraint> element for the service that you want to modify by searching the deployment descriptor (web.xml) file for the relevant <display-name> value (see the table below). When you have found the <security-constraint> element, set its <user-data-constraint> <transport-guarantee> to either CONFIDENTIAL (the service can only be accessed using HTTPS) or NONE (the service can be accessed using HTTP). The <security-constraint> element represents a type of service, and contains the <display-name> element, <user-data-constraint> <transport-guarantee> elements, and other elements.

Type of UDDI service	Value of <security-constraint> <display-name> element
Publish	AxisServlet Publish Resource Collection
Custody transfer	AxisServlet CustodyTransfer Resource Collection
Security	AxisServlet Security Resource Collection
Inquiry	AxisServlet Inquiry Resource Collection

  3. Stop and restart the application server for the changes to take effect.
- Optional: For the Version 3 GUI interface, specify whether the Publish and Inquiry API services are to be secure or insecure by performing the following steps. The defaults are for the Publish API to use HTTPS, and the Inquiry API to use HTTP.
  1. Edit the active deployment descriptor (web.xml) for the Version 3 GUI module (v3gui.war).

     This file is located in the following directory:

     profile_root/config/cells/*cell_name*/applications/
     UDDIRegistry.*node_name*.*server_name*.ear/deployments/
     UDDIRegistry.*node_name*.*server_name*/v3gui.war/WEB-INF
  2. Use the table below to find the id value for the <user-data-constraint> element that corresponds with the service that you want to change. Search for this value in the deployment descriptor (web.xml) file to find the <user-data-constraint> element, then set the <user-data-constraint> <transport-guarantee> to either CONFIDENTIAL (the service can only be accessed using HTTPS) or NONE (the service can be accessed using HTTP).

Type of UDDI service	Value of <user-data-constraint id>
Publish	UDDIPublishTransportConstraint
Inquiry	UDDIInquireTransportConstraint

3. Stop and restart the application server for the changes to take effect.

Managing the UDDI registry

You can use either the WebSphere Application Server administrative console or the Java Management Extensions (JMX) management interface to manage UDDI Registries.

About this task

In previous versions of WebSphere Application Server and the UDDI registry, a properties file was used, but from WebSphere Application Server Version 6, you manage all the policies and properties of the UDDI registry through either the JMX management interface or the administrative console.

JMX can be used to monitor and configure UDDI registries programmatically, and is explained in Using administrative programs (JMX). See UDDI registry Administrative (JMX) Interface for full details on using the UDDI administrative interface. To manage UDDI registries using the WebSphere Application Server administrative console, start from the UDDI link in the left navigation pane as described below.

Using the UDDI management functions available in the WebSphere Application Server administrative console, you can perform the following operations:

- view and manage the status of all UDDI nodes in a cell
- initialize UDDI nodes with required settings
- configure general properties that affect UDDI runtime behavior
- manage UDDI policy settings
- create, view and update UDDI publishers
- create, view and update publisher tiers which limit how many UDDI entries may be published
- view and manage the status of value sets

If WebSphere Application Server security is enabled, you will need to log in to the WebSphere Administrative Console, supplying a valid userid and password, in order to use the UDDI management functions.

UDDI node collection

Use this page to manage the UDDI nodes in this cell. Each UDDI node represents an individual UDDI registry application. A UDDI node will only appear in this list if its underlying UDDI application is started. The status of the UDDI node indicates whether the node is activated (available to accept API requests), deactivated (not allowing user requests), or not initialized. UDDI nodes that are not initialized require some properties to be set before they can be initialized and activated.

To view this administrative console page, click **UDDI** → **UDDI Nodes**.

Each UDDI node is represented by a UDDI Node ID, Description, UDDI Application Location and Status. To manage an individual UDDI node, click on its UDDI Node ID link. This takes you to the Configuration page where you can manage its general properties, initialize it if the status is set to *Initialization Pending*, and access pages for managing policies, UDDI publishers, tiers and value sets.

UDDI Node ID

Specifies the identifier for the UDDI node.

Description

Specifies the description of the UDDI node.

UDDI Application Location

Specifies the server in which the UDDI registry application is deployed and running.

Status
Specifies the status of the UDDI node.

The Status of the UDDI node can be *Not initialized*, *Initialization pending*, *Initialization in progress*, *Migration in progress*, *Migration pending*, *Value set creation in progress*, *Value set creation pending*, *Activated* or *Deactivated*. If a node is in the *Initialization pending* state, you must initialize it before you can activate it. If you attempt to initialize the node and it remains in a pending state, an error occurred during migration or initialization.

To activate UDDI nodes that are *Deactivated*, select them by checking the corresponding check boxes in the Select column and click **Activate**. Similarly to deactivate UDDI nodes, select them and click **Deactivate**.

Note: Restarting the UDDI application, or the application server, will always result in the reactivation of the UDDI node, even if the node was previously deactivated.

UDDI node settings
This topic contains details of the general properties that you can configure for a UDDI node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id*.

By clicking on a node in the UDDI node ID column the UDDI node detail page is displayed. The UDDI node detail page displays a set of General Properties for the UDDI node, some of which may be editable depending on the state of the node. There are also links to Additional Properties (Value sets, Tiers and UDDI Publishers) and links to Policy Groups where you can view and change UDDI node policy.

Unless you installed the UDDI node as a default UDDI node (as defined in UDDI registry terminology), there are some important general properties that you must set before you can initialize the UDDI node. These properties are marked as being required (indicated by the presence of a '*' next to the input field). You may set the values as many times as you wish before initialization. However, after you initialize the UDDI node, these properties will become read only for the lifetime of that UDDI node. It is very important to set these properties correctly. You can set other general properties of the UDDI node before, and after, initialization.

After you set the general properties to appropriate values, click **OK** to save your changes and exit the page, or **Apply** to save your changes and remain on the same page. At this point the changes are stored.

If the UDDI node is in the *Not Initialized* state, indicated on the UDDI node detail page by the presence of an **Initialize** button (above the General Properties section), you can initialize UDDI node by clicking **Initialize**. This operation can take a while to complete. It is important to save any changes you made to the general properties by clicking **Apply** or **OK**, before you click **Initialize**.

UDDI Node ID:

Specifies the unique identifier that is given to a UDDI node in a UDDI registry. The node ID must be a valid UDDI key. The value will also be the domain key for the UDDI node.

The value for the node ID will also be the domain key for this UDDI node.

Required	Yes
Data type	String
Default	uddi:*cell_name*:*node_name*:*server_name*:node_id

UDDI node description:

Specifies the description of this UDDI node.

Required	Yes
Data type	String
Default	WebSphere UDDI registry default node

Root key generator:

Specifies the root key space of the registry. Registries intending to become affiliate registries might want to specify a root key space in a partition below the root key generator of the parent root registry, for example, uddi:thisregistry.com:keygenerator.

Required	Yes
Data type	String
Default	uddi:*cell_name*:*node_name*:*server_name*:keyspace_id:keygenerator

Prefix for generated discoveryURLs:

Specifies the URL prefix that is applied to generated discoveryURLs in businessEntity elements, so they can be returned on HTTP GET requests. This property applies to UDDI version 2 API requests only. Set this prefix to a valid URL for your configuration, and do not change it unless absolutely necessary.

The format is `http://hostname:port/uddisoap/`, where `uddisoap` is the context root of the UDDI version 2 SOAP servlet.

Although this field is not required, you should set it so that the required and valid URL is generated in response to version 2 GET requests. After you have set the prefix you should not alter it unless a subsequent configuration change renders it invalid; if you change the prefix, discoveryURLs generated using the earlier prefix will no longer work.

Required	No
Data type	String
Default	http://localhost:9080/uddisoap

Host name for UDDI node services:

Specifies the host name root used by the UDDI node to model API services in its own node business entity. This value must be the fully qualified domain name, or IP address, of the network host.

The UDDI node provides Web services that implement each of the UDDI API sets that it supports. The host name is used to generate access point URLs in the bindingTemplate elements for each of the services. The access point URL is generated by prefixing the host name value with a protocol, such as http, and suffixing it with the corresponding host port number. The access point URL must resolve to a valid URL.

Data type	String
Default	localhost

Host HTTP port:

Specifies the port number used to access UDDI node services with HTTP. This port number must match the WebSphere Application Server port for HTTP requests.

Data type	Integer

Default 9080

Host HTTPS port:

Specifies the port number used to access UDDI node services with HTTPS. This port number must match the WebSphere Application Server port for HTTPS requests.

Data type Integer
Default 9443

Maximum inquiry result set size:

Specifies the maximum size of result set which the registry will process for an inquiry API request.

If the result set exceeds this value, an E_resultSetTooLarge error is returned to the user. If you set this value too low, and users use imprecise search criteria, the likelihood of receiving an E_resultSetTooLarge error is increased. Setting the value higher allows larger result sets but can cause increased response times.

Data type Integer
Default 500
Range 0 to 1024

Maximum inquiry response set size:

Specifies, for inquiry API requests, the maximum number of results returned in each response. Do not set this value higher than the value for **Maximum inquiry results**.

If the result set contains more results than this value, the response will include only a subset of those results. The user can retrieve the remaining results using the listDescription feature as described in the UDDI specification. If you set this value too low, the user has to make more requests to retrieve the remainder of the result set.

Data type Integer
Default 500
Range 0 to 1024

Maximum search names:

Specifies the maximum number of names that can be supplied in an inquiry API request. To avoid slowing UDDI node response times, set this value no higher than 8.

Higher values allow more complex requests to be processed by the UDDI node, however complex requests can significantly slow the response times of the UDDI node.

Data type Integer
Default 5
Range 1 to 64

Maximum search keys:

Specifies the maximum number of keys that can be supplied in an inquiry API request. To avoid slowing UDDI node response times, set this value no higher than 5.

This value limits the number of references that can be specified in categoryBag, identifierBag, tModelBag and discoveryURLs.

Higher values allow the UDDI node to process more complex requests, however complex requests can significantly slow the response times of the UDDI node. In exceptional cases, the UDDI node may reject complex requests with excessive numbers of keys even if the value of maxSearchKeys is not exceeded.

Data type	Integer
Default	5
Range	1 to 64

Key space requests require digital signature:

Specifies whether tModel:keyGenerator requests must be digitally signed.

Data type	Boolean (check box)
Default	False (cleared)

Use tier limits:

Specifies whether an approval manager is used to check publication tier limits. If you set this value to false, the number of UDDI entities that can be published is unlimited.

Data type	Boolean (check box)
Default	True (selected)

Use authInfo credentials if provided:

Specifies whether authInfo contents in UDDI API requests are used to validate users when WebSphere Application Server security is off. If you set this value to true, the UDDI node will use the authInfo element in the request, otherwise the default user name is used.

Data type	Boolean (check box)
Default	True (selected)

Authentication token expiry period:

Specifies the period, in minutes, after which an authentication token is invalidated and a new authentication token is required.

Set this value high enough to allow the registry to operate successfully, but be aware that high values can increase the risk of illegal use of authentication tokens.

Data type	Integer
Default	30
Range	1 to 10080 minutes (10080 minutes = 1 week)

Automatically register UDDI publishers:

Specifies whether UDDI publishers are automatically registered and assigned to the default tier. Automatically registered UDDI publishers are given default entitlements.

Data type	Boolean (check box)

Default	True (selected)

Default user name:

Specifies the user name used for publish operations when WebSphere Application Server security is disabled and **Use authInfo credentials if provided** is set to false.

Data type	String
Default	UNAUTHENTICATED

Default language code:

Specifies, for UDDI version 1 and version 2 requests, the default language code to be used for xml:lang, when not otherwise specified.

Data type	String
Default	en

Value set collection:

Use this page to view and configure the value sets that are installed in a UDDI node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* > **Value Sets**.

Value sets in a UDDI node are either supported or not supported by policy. By default, new value sets are *not* supported. After you publish a value set tModel and loaded value set data, you can control whether other UDDI entities can reference this value set tModel by setting the *Supported* policy.

To enable support for one or more value sets, select the value sets by selecting the appropriate check boxes in the **Select** column. Click **Enable Support**. The Supported field for all the selected value sets is updated, with a value of true, to reflect the new status.

To disable support for a value set, which might be necessary before you remove it from the UDDI node, select the value sets in the same manner as for enabling support. Click **Disable Support**. The Supported field for all the selected value sets is updated, with a value of false, to reflect the new status.

Clicking on a value set name in the list takes you to the general properties page for that value set as described in Value set settings.

Name:

Specifies the name of the tModel that represents this value set.

tModelkey:

Specifies the key for the tModel that represents this value set.

Supported:

Specifies whether this value set is supported by policy in this UDDI node.

Value set settings:

Use this page to view the attributes of a value set in a UDDI node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* > **Value Sets** > *value_set_name*.

This page shows the values of keyedReferences in the tModel that represents this value set. This page also shows the *Supported* status of the value set. All properties are read-only. To change the *Supported* status, use the Value sets collection page.

Unvalidatable:

Specifies whether this value set is unvalidatable. The value set tModel publisher sets this value, to indicate whether the value set is available for use by publish requests.

Checked:

Specifies whether this value set is checked. If you set this value to true, UDDI entities that reference this value set will be validated to ensure that their values are present in this value set.

Cached:

Specifies whether this value set is cached in this UDDI node.

Externally cacheable:

Specifies whether this value set is externally cacheable.

Externally validated:

Specifies whether this value set is externally validated.

Supported:

Specifies whether this value set is supported by policy in this UDDI node.

Last cached:

Specifies the date when this value set was last cached in the UDDI node.

Tier collection:

This page contains a list of the available tiers for the UDDI node. You can modify tiers, create new tiers and delete tiers from this page.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* > **Tiers**.

This page shows the available tiers for the UDDI node. Clicking a tier name will show the General Properties for the specific tier as detailed in Tier settings. To delete a Tier from the list, select the relevant name and click *Delete*. Clicking *New* will take you to the General Properties page with the same properties as described in Tier settings.

One of the tiers in the collection will be marked as the default tier, indicated by *(default)* appearing next to the tier's name. The default tier will be assigned to UDDI publishers that are registered automatically when automatic user registration is turned on. To set the default tier, select the appropriate tier in the collection and press the *Set default* button. Note that it is not possible to delete a tier if it is currently marked as the default tier, or it is currently assigned to a UDDI publisher.

Name:

Specifies the name of the tier.

Description:

Specifies the descriptive text about the tier.

UDDI Tier settings:

This topic contains details of the general properties that you can configure for a UDDI publisher tier.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* > **Tiers** > *tier_name*.

Name:

Specifies the name of the tier.

Required	Yes
Data type	String
Default	No default
Range	1 to 255

Description:

Specifies a description of the purpose or usage of this tier.

Data type	String
Default	No default
Range	0 to 255

Maximum properties:

For each of the maximum fields described below, the data is:

Required	Yes
Data type	Integer
Default	No default
Range	0 to 2147483647

Maximum businesses:

Specifies the maximum number of businesses that UDDI publishers in this tier are allowed to publish.

Maximum services per business:

Specifies the maximum number of services that UDDI publishers in this tier are allowed to publish for each business.

Maximum bindings per service:

Specifies the maximum number of bindings that UDDI publishers in this tier are allowed to publish for each service.

Maximum tModels:

Specifies the maximum number of tModels that UDDI publishers in this tier are allowed to publish.

Maximum publisher assertions:

Specifies the maximum number of publisher assertions that UDDI publishers in this tier are allowed to add.

UDDI Publisher collection:

This page shows the users that are currently registered as UDDI publishers.

To view this administrative console page, click **UDDI** → **UDDI Nodes >** *UDDI_node_id* **> [Additional Properties] UDDI Publishers**.

To create a UDDI publisher, click **New**. The "UDDI Publisher settings" on page 997 page, where you can enter details about the publisher, is displayed.

To register one or more existing WebSphere Application Server users as UDDI publishers, click **Create publishers**. The "Create UDDI Publishers" page, where you can select users and modify their entitlements, is displayed.

You can assign multiple publishers to a tier without editing each publisher individually, by completing the following steps:

1. Select the appropriate publishers in the collection table.
2. From the tier list at the top of the collection table, select one of the tiers that is available on the UDDI node.
3. Click **Assign tier** to update the selected publishers.

To delete publishers, select them in the collection table and then click **Delete**.

After you register the users as UDDI publishers, you can edit their entitlements as described in "UDDI Publisher settings" on page 997.

User name:

Specifies the name of the UDDI publisher.

Tier:

Specifies the tier to which the UDDI publisher is assigned.

Create UDDI Publishers:

Use this page to register one or more existing WebSphere Application Server users as UDDI publishers.

To view this administrative console page, click **UDDI** → **UDDI Nodes >** *UDDI_node_id* **> [Additional Properties] UDDI Publishers** → **Create publishers**.

To register as UDDI publishers one or more users that are known to the application server, complete the following steps:

1. Enter a string to search for the required users. To find all users, use the * character.
2. Optionally, enter a number in the limit field to restrict the number of returned results.
3. Click **Search** to display a list of users that match the string.
4. Select the users that you want to register from the **Available** list and use the arrows to move them into the **Selected** list.
5. Use the entitlements listed under **General Properties** to give the UDDI publishers permission to perform specific actions. Set the entitlements by selecting the check box next to each entitlement.

6. Select a tier for the users from the **Tier** list.
7. Click **OK** to register the users as UDDI publishers with the specified entitlements and tier.

Note: If you are using a Lightweight Directory Access Protocol (LDAP) user registry, the format of the name that is given to each UDDI Publisher is defined by the **User ID map** value in the LDAP advanced settings. To view the LDAP advanced settings, click **Security** → **Global security**, under **User account repository** select **Standalone LDAP registry** and click **Configure**, then under **Additional Properties** click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.

After a user has been registered as a UDDI publisher, you can edit their entitlements by clicking the user name.

Allowed to publish keyGenerator with derived key:

Specifies whether the UDDI publisher has permission to publish tModel: keyGenerator with a derived key.

The tModel:keyGenerator is a request for key space. An example of a legal derived key is uddi:tempuri.com:fish:buyingService where the key is based on the derivedKey ″uddi:tempuri.com:fish″. the string 'buyingService' is the key's key specific string (KSS).

Allowed to publish keyGenerator with domain keys:

Specifies whether the UDDI publisher has permission to publish tModel: keyGenerator with a domain key.

Allowed to publish keyGenerator:

Specifies whether the UDDI publisher has permission to publish tModel: keyGenerator.

If false, UDDI publishers cannot publish keyGenerators of any kind. In this situation all the entitlement settings are disregarded, regardless of how they are set.

Allowed to publish with UUID key:

Specifies whether the UDDI publisher has permission to publish elements with a UUID key.

Allowed to publish keyGenerator with UUID keys:

Specifies whether the UDDI publisher has permission to publish tModel: keyGenerator with a UUID key.

Tier:

Specifies the tier to which the UDDI publisher is assigned.

UDDI Publisher settings:

Use this page to view and edit the properties of a UDDI publisher, or to create a new UDDI publisher.

You can view this administrative console page in two ways:

- If you want to view and edit the properties of an existing UDDI publisher click **UDDI** → **UDDI Nodes** > *UDDI_node_id* > **UDDI Publishers** > *user_name*
- If you want to create a new UDDI publisher click **UDDI** → **UDDI Nodes** > *UDDI_node_id* > **UDDI Publishers** → **New**

This page shows the entitlements and publication limits tier for a particular UDDI publisher.

User name:

Specifies the name of the UDDI publisher.

If you are creating a new UDDI publisher, enter the name of a user known to the application server. If you are viewing or editing the properties of an existing publisher, the user name cannot be changed.

Allowed to publish keyGenerator with derived key:

Specifies whether the UDDI publisher has permission to publish tModel:keyGenerator with a derived key.

The tModel:keyGenerator is a request for key space. An example of a legal derived key is uddi:tempuri.com:fish:buyingService where the key is based on the derivedKey ″uddi:tempuri.com:fish″. the string 'buyingService' is the key's key specific string (KSS).

Data type	Boolean
Default	True (selected)

Allowed to publish keyGenerator with domain keys:

Specifies whether the UDDI publisher has permission to publish tModel:keyGenerator with a domain key.

Data type	Boolean
Default	True (selected)

Allowed to publish keyGenerator:

Specifies whether the UDDI publisher has permission to publish tModel:keyGenerator.

If you set this value to false, the UDDI publisher cannot publish keyGenerators of any kind. In this situation the following permissions will be disregarded irrespective of how they are set: **Allowed to publish keyGenerator with derived key**, **Allowed to publish keyGenerator with domain keys**, **Allowed to publish with UUID key** and **Allowed to publish keyGenerator with UUID keys**.

Data type	Boolean
Default	True (selected)

Allowed to publish with UUID key:

Specifies whether the UDDI publisher has permission to publish elements with a UUID key.

Data type	Boolean
Default	False (cleared)

Allowed to publish keyGenerator with UUID keys:

Specifies whether the UDDI publisher has permission to publish tModel:keyGenerator with a UUID key.

Data type	Boolean
Default	False (cleared)

Tier:

Specifies the tier to which the UDDI publisher is assigned.

Policy groups:

This topic contains links to the detailed settings information for every policy group that you can configure for a UDDI registry node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id*.

To the right of the page is a list of the Policy Groups that can be acted upon. Clicking on a specific group will open the page for the group required.

UDDI keying policy settings:

This topic contains details of the UDDI keying settings that you can configure for a UDDI registry.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* > **Keying policies**.

Registry key generation:

Specifies whether publishers are allowed to publish key generator tModels. You can manage how publishers are allowed to publish key generator tModels by configuring the entitlements in the UDDI Publishers page.

Data type	Boolean
Default	True (selected)

Registry support of UUID keys:

Specifies whether publisher supplied uuidKeys are allowed in publish requests. You can manage how publishers are allowed to use uuidKeys by configuring the entitlements in the UDDI Publishers page.

Data type	Boolean
Default	False (cleared)

UDDI node API policy settings:

This topic contains details of the API settings that you can configure for a UDDI registry node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** → ***UDDI_node_id*** → **API policies** .

Note: This information applies only to UDDI Version 3. You cannot change the settings for Versions 1 and 2; authentication tokens are required for publish requests, but not for inquiry requests (there are no custody transfer requests in Versions 1 or 2).

Authorization for inquiry:

Specifies whether authorization using the authInfo element is required for inquiry API requests. This setting is relevant only if the V3SOAP_Inquiry_User_Role is set to *Everyone* and WebSphere Application Server security is on.

If WebSphere Application Server security is off, this setting is ignored. If WebSphere Application Server security is on and the V3SOAP_Inquiry_User_role is not set to *Everyone*, this setting is ignored.

If this setting is true, an authorization token is required to complete the request. If this setting is false, an authorization token is not required; if one is supplied, it is ignored and the request is processed as if it the default user that is defined in the UDDI node settings made the request.

Typically, UDDI registries are configured to not require authorization for inquiry API requests.

Data type	Boolean
Default	False (cleared)

Authorization for publish:

Specifies whether authorization using the authInfo element is required for publish API requests. This setting is relevant only if the V3SOAP_Publish_User_Role is set to *Everyone* and WebSphere Application Server security is on.

If WebSphere Application Server security is off, this setting is ignored. If WebSphere Application Server security is on and the V3SOAP_Publish_User_role is not set to *Everyone*, this setting is ignored.

If this setting is true, an authorization token is required to complete the request. If this setting is false, an authorization token is not required; if one is supplied, it is ignored and the request is processed as if it the default user that is defined in the UDDI node settings made the request.

Typically, UDDI registries are configured to require authorization for publish API requests.

Data type	Boolean
Default	True (selected)

Authorization for custody transfer:

Specifies whether authorization using the authInfo element is required for custody transfer API requests. This setting is relevant only if the V3SOAP_CustodyTransfer_User_Role is set to *Everyone* and WebSphere Application Server security is on.

If WebSphere Application Server security is off, this setting is ignored. If WebSphere Application Server security is on and the V3SOAP_CustodyTransfer_User_role is not set to *Everyone*, this setting is ignored.

If this setting is true, an authorization token is required to complete the request. If this setting is false, an authorization token is not required; if one is supplied, it is ignored and the request is processed as if it the default user that is defined in the UDDI node settings made the request.

Typically, UDDI registries are configured to require authorization for custody transfer API requests.

Data type	Boolean
Default	True (selected)

UDDI user policy settings:

This topic contains details of the user policy settings that you can configure for a UDDI registry node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* > **User policies**.

Allow transfer of ownership:

When true, data ownership can be transferred between owners within the UDDI node.

Data type	Boolean
Default	True (selected)

UDDI data custody policy settings:

This topic contains details of the data custody settings that you can configure for a UDDI registry node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* > **Data custody policies**.

Transfer token expiration period:

Specifies the length of time from the issue of a transfer token, in minutes, after which that token expires.

If you set this value too high, you might expose the UDDI registry to a risk of misuse.

Data type	Integer
Default	1440
Range	1 to 2147483647 (for all intents and purposes, unlimited)

UDDI value set policy:

This topic contains details of the value set policy settings that you can configure for a UDDI registry node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**Value set policies**.

Enable checked value sets:

Specifies whether checked value sets are supported. If you set this value to false, publish requests of value set tModels that contain a 'checked' keyedReference will be rejected.

Data type	Boolean
Default	True (selected)

UDDI node miscellaneous:

This topic contains details of the miscellaneous settings that you can configure for a UDDI node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* > **Miscellaneous policies**.

Node generates discoveryURLs:

Specifies whether a UDDI node can establish a policy on whether it generates discoveryURLs.

Data type	Boolean
Default	False (cleared)

Node supports HTTP Get Service:

Specifies whether the UDDI node supports an HTTP GET service for access to the XML representations of UDDI data structures.

Data type	Boolean
Default	True (selected)

URL prefix for V3 GET servlet:

Specifies the prefix for the URL to the version 3 GET servlet that is used to retrieve the XML representation of a published entity. This property applies to UDDI version 3 API requests only.

The format of the prefix is http://hostname:port/uddiv3soap/, where uddisoap is the context root of the UDDI version 3 SOAP servlet.

When a businessEntity is published, if you have set **Node generates discovery URLs** to true, the discoveryURL value is generated based on this prefix value. Otherwise, the discoveryURL value will be empty.

The UDDI Version 3 specification recommends that you do **not** enable generation of discoveryURLs because they can affect the use of digital signatures. If you do enable generation of discoveryURLs, do not change the URL prefix afterward, otherwise discoveryURLs that were generated using the earlier URL prefix no longer work.

Data type	URL
Default	http://localhost:9080/uddiv3soap/

Backing up and restoring the UDDI registry database

If you want to protect the data in your UDDI registry database, you can back up and restore the database using the facilities of the database product that your UDDI node is on.

- To backup a Apache Derby UDDI registry database, first ensure that the UDDI application is stopped (and hence, not accessing the Apache Derby database), and ensure that no other application is using the Apache Derby UDDI30 database. Make a copy of the UDDI30 directory using the file system that the directory resides upon. To restore the database, replace the UDDI30 file structure with the back up. Note that any updates made since the back up was taken will be lost.
- To backup a non-Apache Derby UDDI registry database, use the appropriate backup and restore tools for the database. To use these tools, refer to the documentation for the database product.

Enabling Web services through the service integration bus

Web services can use the service integration bus to provide a single point of control, access, and validation of Web service requests and allow control of Web services that are available to different groups of Web service users.

About this task

With bus-enabled Web services you can achieve the following goals:

- Create an *inbound service*: Take an internally-hosted service that is available at a bus destination, and make it available as a Web service.
- Create an *outbound service*: Take an externally-hosted Web service, and make it available internally at a bus destination.

Bus-enabled Web services provide a choice of quality of service and message distribution options, along with intelligence in the form of mediations that allow for the rerouting of messages.

To enable Web services through service integration technologies, complete the following steps:

1. Optional: Learn about bus-enabled Web services. Explore the concepts that underly service integration bus-enabled Web services.
2. Plan your bus-enabled Web services installation. Determine the bus-enabled Web services roles that each server is to perform.
3. Ensure that every server that is to play a bus-enabled Web services role is a member of a service integration bus. For more information, see “Configuring the members of a bus” on page 1145.

4. For every server that is to play a bus-enabled Web services role, install and configure a Service Data Objects (SDO) repository on the server.

   Note: For WebSphere Application Server Version 6.0, you also had to manually install a selection of the following applications:
   - The service integration technologies resource adapter (used to invoke Web services at outbound ports).
   - The bus-enabled Web services application.
   - One or more endpoint listener applications.

   For later versions of WebSphere Application Server, these applications are installed automatically as and when needed. For example, the endpoint listener application is installed automatically when you configure an endpoint listener.
5. Create a new endpoint listener configuration for each endpoint listener application that you plan to use to receive inbound service requests.
6. Optional: Create an inbound service. An inbound service is a Web interface to a service that is provided internally (that is, a service provided by your own organization and hosted in a location that is directly available through a service integration bus destination). To configure a locally-hosted service as an inbound service, you associate it with a service destination, and with one or more endpoint listeners through which service requests and responses are passed to the service. You can also choose to have the local service made available through one or more UDDI registries.
7. Optional: Create an outbound service. An outbound service is a Web service that is hosted externally, and is made available through a service integration bus. To make an externally-hosted service available through a bus, you first associate it with a service destination, then you configure one or more port destinations (one for each type of binding, for example SOAP over HTTP or SOAP over JMS) through which service requests and responses are passed to the external service. You get the port definitions from the WSDL, but you can choose which ones you want to create.
8. Optional: Apply additional security to your bus-enabled Web services. By default, the bus-enabled Web services configuration works when WebSphere Application Server security is enabled and your service integration buses are secured. However this level of security does not impose any security restrictions on the users of your bus-enabled Web services configuration. To control how your bus-enabled Web services configuration is used by each group of your colleagues or customers, use the bus-enabled Web services additional security features to enable working with password-protected components and servers, with WS-Security and with HTTPS.

What to do next

For further information on specific aspects of bus-enabled Web services, see the following topics:
- Learning about bus-enabled Web services
- “Installing and configuring the SDO repository”
- “Configuring Web services for a service integration bus” on page 1008
- “Administering the bus-enabled Web services core resources” on page 1019
- Securing bus-enabled Web services
- “Passing SOAP messages with attachments through the service integration bus” on page 1052
- SIBWebServices command group for the AdminTask object
- Bus-enabled Web services troubleshooting tips
- Tuning bus-enabled Web services

Installing and configuring the SDO repository

Service Data Objects (SDO) is an open standard for enabling applications to handle data from different data sources in a uniform way, as DataGraphs. Service integration bus-enabled Web services use an SDO

repository for storing and serving WSDL definitions. Use this task to create and configure your preferred database to store SDO data, and to install and configure an SDO repository on each server that you plan to use for bus-enabled Web services.

Before you begin

Determine the servers on which to install and configure an SDO repository as described in Planning your bus-enabled Web services installation, then add each server as a member of a bus as described in "Configuring the members of a bus" on page 1145.

An SDO repository can work with most database products. For specific information about choosing and configuring your preferred database, consult your database administrator or database product documentation, as well as reading the notes on database usage given in this topic.

About this task

To install and configure an SDO repository, you complete the following broad steps:

- Install your preferred database product.
- Create a JDBC provider and a data source for your database.
- Run the `installSdoRepository.jacl` script one or more times, to install the SDO application on each server and to set the database type that the SDO repository is to use.

For detailed information about how to do this, first read the following notes on database usage and on the `installSdoRepository.jacl` script, then complete the steps for one of these configurations:

- "Configure the SDO repository for a single server, using the embedded Derby database" on page 1005.
- "Configure the SDO repository for a single server, using a database other than embedded Derby" on page 1005.

Note:

- For a single server configuration you can use either your preferred database or the embedded Apache Derby database that is supplied with WebSphere Application Server.
- The SDO repository dictates the schema and table names it uses, so different repositories must use different databases to ensure they do not access the same data.
- Create the database for your preferred database supplier using the `Table.ddl` file from the relevant *app_server_root*`/util/SdoRepository/`*database_type* directory. The `Table.ddl` file describes the database table that is needed by the SDO repository.
- The `-editBackendId` flag on the `installSdoRepository.jacl` script determines the database type that the repository is to use. The back end ID determines what database-specific rules the application follows when talking to the database. See the associated note on the `installSdoRepository.jacl` script.
- Some databases require that a user ID be created and granted permissions to access the SDO repository database. Create a user ID for user name `SDOREP` before you create the tables for Oracle, Sybase, and SQL Server databases. Because of the way these databases handle user names and table names, the user name must be `SDOREP` to enable the SDO repository to access its table with the fully qualified name `SDOREP.BYTESTORE`. Make sure you grant permission for the `SDOREP` user to read from, and write to, the database.
- If you use an Informix® database, do not disable logging.
- The SDO repository does not require *XA* support. In most cases you can use either an XA or a non-XA data source; however if your database is Oracle 8 or 9 then you must use the Oracle JDBC driver (non-XA) for the SDO repository data source.
- You might also choose to perform other steps such as creating an index of the primary key to improve database performance. Do not change the schema, table and column names.

Note:

- Use the wsadmin scripting client to run the script.
- Run the script from within QShell.
- The script is provided in the *app_server_root*/bin directory, where *app_server_root* is the root directory for the installation of WebSphere Application Server. If you choose to run the wsadmin scripting client from another directory, specify the full path to the script on the command option. For example to work with a profile other than the default profile, change to the *app_server_root*/profiles/*profile_name*/bin directory then specify the following path to the script:

  ```
  wsadmin -f app_server_root/bin/installSdoRepository.jacl
  ```
- The -editBackendId flag on the installSdoRepository.jacl script determines the database type that the repository is to use. The back end ID determines what database-specific rules the application follows when talking to the database. To see the full list of available back end ID values, use the -listBackendIds flag:

  ```
  wsadmin -f installSdoRepository.jacl -listBackendIds
  ```
- If the data source already exists, or there has been a previous broken or partial installation of the SDO repository application, the installSdoRepository.jacl script fails to complete and configuration changes are not saved. In these cases, run the SDO repository uninstall script, fix the problem, then rerun the installSdoRepository.jacl script.

Configure the SDO repository for a single server, using the embedded Derby database

About this task

If you are creating a single server configuration and you want to use embedded Derby, you run the installSdoRepository.jacl script with the -createDb switch. This action creates the Derby database and installs the SDO repository.

To configure the SDO repository for a single server using the embedded Derby database, complete the following steps:

1. Open a command prompt, then change to the *app_server_root*/bin directory.
2. Enter the following command:

```
wsadmin -f installSdoRepository.jacl -createDb
```

Note: The -createDb flag tells the command to create a default Derby database. If you omit this flag, the command still installs an SDO repository that is configured to use Derby, but the command does not also create the database.

Configure the SDO repository for a single server, using a database other than embedded Derby

About this task

If you are creating a single server configuration that uses a database other than embedded Derby, you install your preferred database product, then create a JDBC provider and a data source, then run the installSdoRepository.jacl script twice:

1. One time to install the SDO application on the application server.
2. One time to set the database type that the SDO repository is to use.

To configure the SDO repository for a single server using a database other than embedded Derby, complete the following steps:

1. Create the database for your preferred database supplier using the Table.ddl file from the relevant *app_server_root*/util/SdoRepository/*database_type* directory.

For an illustration of the process for creating tables in DB2, see Recreating database tables from the exported table data definition language. For more information, see Deploying data access applications.

2. Create a J2C authentication alias.

   This is for use with the data source that you create in the next step. Check that the authentication alias matches the login details for your database instance, otherwise a connection will not be made.

3. Create and configure a JDBC provider and data source.

   Set the following data source properties:

   - Set the **authentication** property to use the authentication alias you created in the previous step.
   - Select the **Use this Data Source in container managed persistence (CMP)** check box.
   - Set the **Name** property to a name of your own choosing. For example, `SDO Repository DataSource`.
   - Set the **JNDI name** property to the following exact value: `jdbc/com.ibm.ws.sdo.config/SdoRepository`.
   - Set any other properties that are required settings for your chosen database.

4. Optional: Test the data source connection:

   Note: This option does not work in all configurations. The availability of this option depends on the scope at which the data source is defined, and the scope of any WebSphere Application Server variables that are used in the JDBC provider and data source configurations. For more information about testing connections to data sources, see Test connection service.

   a. In the administrative console, navigate to **Resources** → **JDBC** → **Data sources**.

   b. Select the SDO repository data source.

   c. Click **Test connection**.

5. Configure the SDO repository:

   a. Open a command prompt, then change to the *app_server_root*`/bin` directory.

   b. Install the SDO repository application on the server:

```
wsadmin -f installSdoRepository.jacl
```

   c. Set the database type that the SDO repository is to use:

```
wsadmin -f installSdoRepository.jacl -editBackendId database_type
```

   for example:

```
wsadmin -f installSdoRepository.jacl -editBackendId DB2UDB_V82
```

The SDO repository uninstall script

Use this script to uninstall a Service Data Objects (SDO) repository that was previously installed, or failed to install correctly.

You install the SDO repository application on every server that you plan to use for one or more of the service integration bus-enabled Web services roles as described in “Installing and configuring the SDO repository” on page 1003.

If the data source already exists, or there has been a previous broken or partial installation of the SDO repository application, the `installSdoRepository.jacl` script fails to complete and configuration changes are not saved. In these cases, you need to run the `uninstallSdoRepository.jacl` script. This script continues when it finds unexpected results, so it can clean up a broken or partial installation.

Note: Run the script from within QShell.

The script is provided in the *app_server_root*`/bin` directory, where *app_server_root* is the root directory for the installation of WebSphere Application Server. If you choose to run the wsadmin scripting client from

another directory, specify the full path to the script on the command option. For example to work with a profile other than the default profile, change to the *app_server_root*/profiles/*profile_name*/bin directory then specify the following path to the script:

```
wsadmin -f app_server_root/bin/uninstallSdoRepository.jacl
```

The SDO repository script install and uninstall pairs

The following are the install and uninstall command pairs, where each uninstall command undoes the action of the related install command. If you attempt to uninstall with a different set of arguments to those previously used with the installSdoRepository.jacl script, you might find that the uninstall does not remove everything or that it displays warnings when it tries to remove non-existent settings.

For configuration of the SDO repository on a server, the -createDb flag tells the install command to create a default (Apache Derby) database and configure it for use with this application server. The -removeDb flag tells the uninstall command to remove the database configuration from the application server, but not to delete the Apache Derby database:

```
wsadmin -f installSdoRepository.jacl -createDb
wsadmin -f uninstallSdoRepository.jacl -removeDb
```

Note:

- If you did not use -createDb on the installer, because you had already configured an Apache Derby database for some other purpose, then you should not use the -removeDb flag on the uninstaller.
- To avoid deleting data that you might want to keep, the -removeDb flag does not delete the Apache Derby database. If you are certain that you want to delete the database, you can do so manually. An Apache Derby database is a directory on the file system. The one created by the installer with the -createDb flag is in the *profile_root*/databases/SdoRepDb directory, where *profile_root* is the directory in which profile-specific information is stored. If you do not delete the database and you try to install again with the -createDb flag, the install fails stating that the SdoRepDb directory already exists.

For installation or removal of the SDO repository application from a server:

```
wsadmin -f installSdoRepository.jacl
wsadmin -f uninstallSdoRepository.jacl
```

Bus-enabled Web services installation files and locations

When you install WebSphere Application Server, the files that are required for running service integration bus-enabled Web services are copied into your file system under *app_server_root*, where *app_server_root* is the root directory for the installation of WebSphere Application Server.

The following table lists the main bus-enabled Web services files that you might need to access, and the locations into which they are placed.

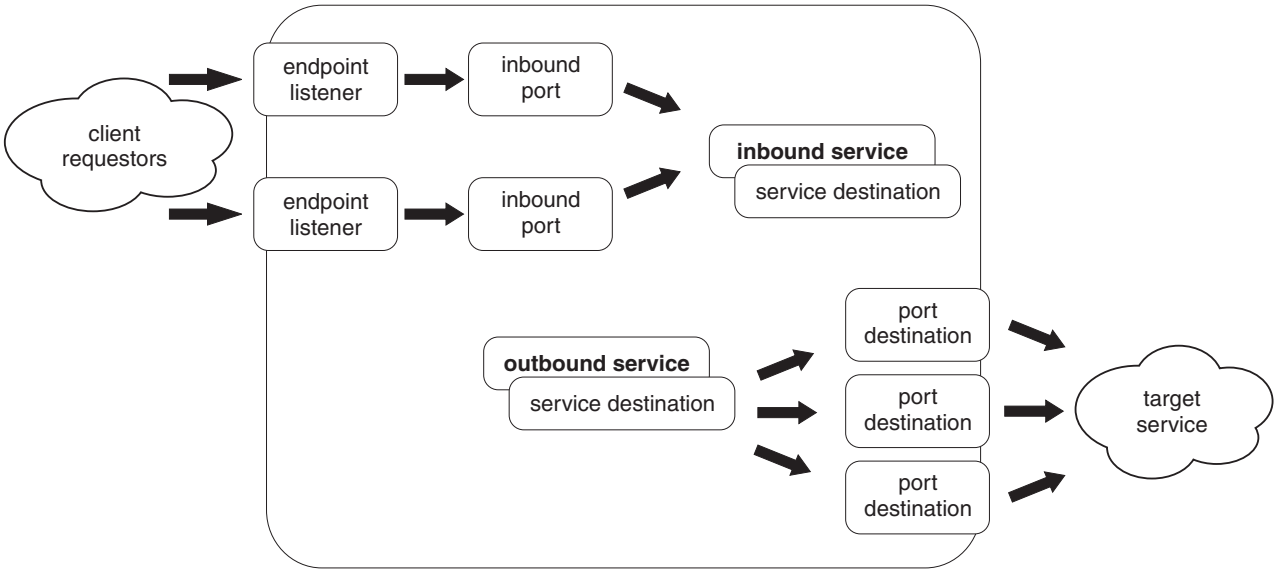
File name	Purpose	Location
installSdoRepository.jacl	The script used to configure the SDO repository. Bus-enabled Web services use an SDO repository for storing and serving their WSDL definitions.	*app_server_root*/bin
uninstallSdoRepository.jacl	The script used to uninstall the SDO repository.	*app_server_root*/bin
SDO repository resources	The resource files used to configure the SDO repository to work with a range of different databases.	*app_server_root*/util/SdoRepository

File name	Purpose	Location
sibwsauthbean.ear	The application for Password-protecting a Web service operation.	*app_server_root*/installableApps
sibwsAuthGen	The command file used to generate authorization beans for password-protecting a Web service operation.	*app_server_root*/util
soaphttpchannel1.ear	The SOAP over HTTP endpoint listener 1 application. This application is installed automatically when you create an associated endpoint listener configuration.	*app_server_root*/installableApps
soaphttpchannel2.ear	The SOAP over HTTP endpoint listener 2 application. This application is installed automatically when you create an associated endpoint listener configuration.	*app_server_root*/installableApps
soapjmschannel1.ear	The synchronous SOAP over Java Messaging Service (JMS) endpoint listener 1 application. This application is installed automatically when you create an associated endpoint listener configuration.	*app_server_root*/installableApps
soapjmschannel2.ear	The synchronous SOAP over JMS endpoint listener 2 application. This application is installed automatically when you create an associated endpoint listener configuration.	*app_server_root*/installableApps

Configuring Web services for a service integration bus

Take an internally-hosted service that is available at a bus destination, and make it available as a Web service; Take an externally-hosted Web service, and make it available internally at a bus destination; Use the Web services gateway to map an existing service - either an inbound or an outbound service - to a new Web service that appears to be provided by the gateway.

About this task



Through service integration bus-enabled Web services you can achieve the following goals:

- Create an *inbound service*: Take an internally-hosted service that is available at a bus destination, and make it available as a Web service.
- Create an *outbound service*: Take an externally-hosted Web service, and make it available internally at a bus destination.

Making an internally-hosted service available as a Web service

Create an inbound service. An inbound service is a Web interface to a service that is provided internally (that is, a service provided by your own organization and hosted in a location that is directly available through a service integration bus destination). To configure a locally-hosted service as an inbound service, you associate it with a service destination, and with one or more endpoint listeners through which service requests and responses are passed to the service. You can also choose to have the local service made available through one or more UDDI registries.

Before you begin

This topic assumes that:

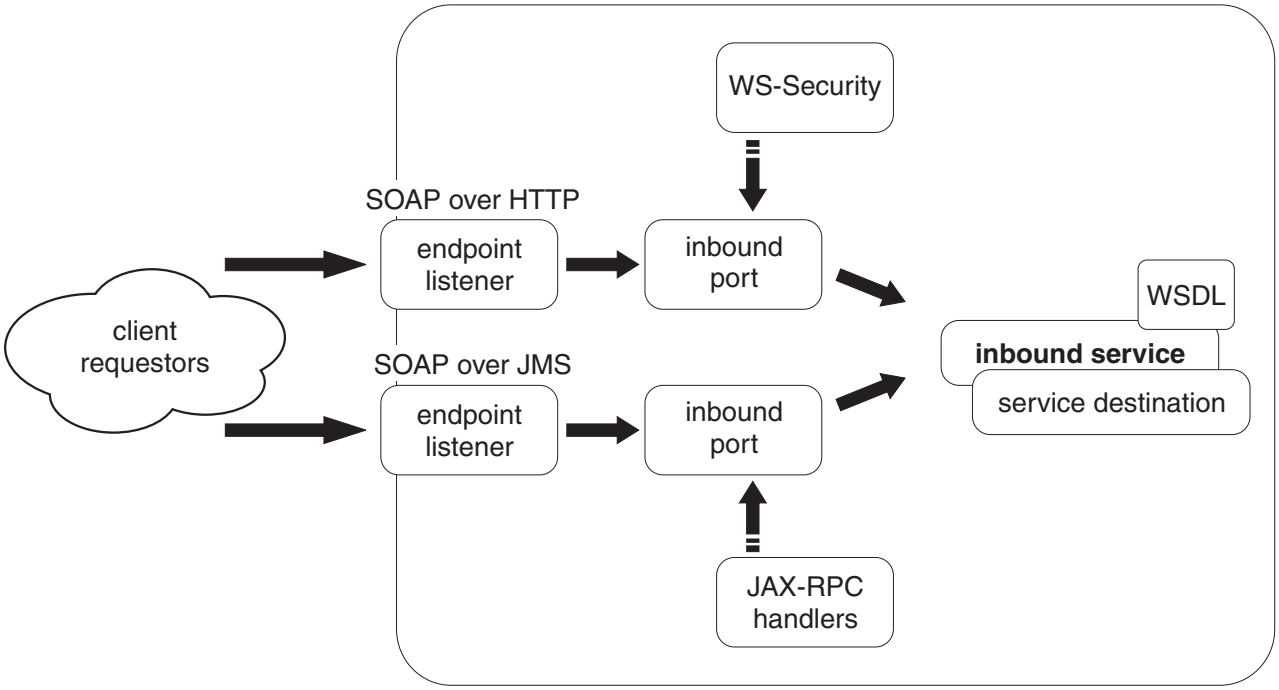
- You have created and installed a Service Data Objects (SDO) repository (used for storing and serving WSDL definitions) on every server that is to play a service integration bus-enabled Web services role.
- You have created a new endpoint listener configuration for each endpoint listener that you plan to use to receive inbound service requests.
- You already have an internally-hosted service that you want to configure as an inbound service, and you have made the service available at a service integration bus destination.
- You have created references to any UDDI registries in which you want to register this service.

You must also create a template WSDL file that describes the service, and make the WSDL available at a URL or through a UDDI registry. For information on how to create a WSDL file, see Developing a WSDL file.

You can create an inbound service by using the administrative console as described in this task, or by using the createSIBWSInboundService command.

Note: If the bus needs to pass messages through an authenticating proxy server to retrieve WSDL documents, then you cannot use the administrative console for this task and you must create your new inbound service by using the wsadmin tool. For more information see the corresponding troubleshooting tip.

About this task



service integration technologies

Web service requests and responses to an inbound service can be sent across any binding (for example SOAP over HTTP or SOAP over JMS) that is available to the bus. Each available binding type is represented by an inbound port, and each inbound port is associated with a binding-specific endpoint listener.

You can control and monitor access to your inbound services in the following ways:

- You can control which groups of users can access a particular inbound Web service by making the service available only through specific endpoint listeners.
- You can associate JAX-RPC handler lists with ports, so that the handlers can monitor activity at the port, and take appropriate action depending upon the sender and content of each message that passes through the port.
- You can set the level of security to be applied to messages (the WS-Security configuration and bindings). The security level can be set independently for request and response messages.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses** → ***bus_name*** → **[Services] Inbound Services**. The inbound services collection form is displayed.
3. Click **New**. The New inbound service wizard is displayed.
4. Use the wizard to create the new inbound service configuration by completing the following steps. For more information about the properties that you set with the wizard, see Inbound services settings.
   a. Select the service destination and template WSDL location.

      Note: The template WSDL is the service-specific WSDL file that you have created to describe this inbound service.

b. Select the service from the template WSDL.

Note:

- This option is needed in case there is more than one service in the template WSDL. The field is filled in for you by default. If there is only one service in the WSDL, accept the default.

c. Specify the name of the inbound service and select the endpoint listeners.

Note:

- You need not supply a name for the inbound service. If you choose not to supply a name, a default name is created. The default name is derived from the service destination name, with characters that are not valid for names filtered out.
- An inbound port is automatically created for each endpoint listener that you select. Each inbound port is created without a template port, JAX-RPC handler list or security settings and is given a default name that relates to the endpoint listener selected. For an overview of the relationship between endpoint listeners and inbound ports, see Endpoint listeners and inbound ports: Entry points to the service integration bus.

d. Define any UDDI publication properties.

Note: The wizard allows you to specify the UDDI publication properties that are used to publish this inbound service to an initial UDDI registry. After you create an inbound service through the wizard, you can use the modify an existing inbound service configuration option to publish the service to more UDDI registries. For information about the UDDI publication properties, see UDDI Publication settings and UDDI registries: Web service directories that can be referenced by bus-enabled Web services.

5. Click **Finish**.

Results

If the processing completes successfully, the list of inbound services for this service integration bus is updated to include the new inbound service. Otherwise, an error message is displayed.

What to do next

If you want to secure your new inbound service, or apply any JAX-RPC handler lists to the ports for the service, or publish the service to more UDDI registries, use the administrative console to modify your inbound service configuration.

Modifying an existing inbound service configuration:

Modify the configuration details for an existing inbound service. For example: secure the service; apply JAX-RPC handler lists to the ports for the service; publish the service to more than one UDDI registry.

About this task

An inbound service is a Web interface to a service that is provided internally (that is, a service provided by your own organization and hosted in a location that is directly available through a service integration bus destination).

When you first create an inbound service, you connect the service to one or more endpoint listeners and (optionally) specify the UDDI publication properties that are used to publish the inbound service to an initial UDDI registry. An inbound port is automatically created for each endpoint listener that you select, but each inbound port is created without a template port, JAX-RPC handler list or security settings. You need to modify your inbound service configuration if you want to control and monitor access to your inbound services in any of the following ways:

- Associate JAX-RPC handler lists with ports, so that the handlers can monitor activity at the port, and take appropriate action depending upon the sender and content of each message that passes through the port.
- Password-protect a Web service operation.
- Set the level of security to be applied to messages (the WS-Security configuration and bindings). The security level can be set independently for request and response messages.
- Publish the service to more than one UDDI registry.

To list the existing inbound services, and to view and modify their configuration details, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses** → ***bus_name*** → **[Services] Inbound Services**. A list of all the inbound services is displayed in an inbound services collection form.
3. Click the name of an inbound service in the list. The current settings for this inbound service are displayed.
4. Optional: Click **Reload template WSDL** to reload the template WSDL file for this inbound service.

   Note:

   - When you create a new inbound service, a copy of the template WSDL file for the service is loaded into a locally-maintained repository. If you change the template WSDL file, you must update the local copy.
   - When you click **Reload template WSDL**, you launch the command that is described in Refreshing the inbound service WSDL file by using the wsadmin tool. For the command to complete successfully, the conditions must be met that are described in that topic.
   - If the bus needs to pass messages through an authenticating proxy server to retrieve WSDL documents, then you cannot use the **Reload template WSDL** option and you must launch the refresh WSDL command by using the wsadmin tool. For more information, see the corresponding troubleshooting tip.
5. Modify the general properties. For information about each of these properties, see Inbound services settings.

   Note:

   - When you change an inbound service name, the system looks up all objects that refer to it and updates the name.
   - The template WSDL is the service-specific WSDL file that you create to describe this inbound service. For information on how to create a WSDL file, see Developing a WSDL file.
   - Although logically the template WSDL name and namespace are only required if there is more than one service in the WSDL, the fields that you use to set them are coded within the administrative console as compulsory fields. They are filled in for you by default, so if they are not logically required for your service you should leave the default values. If you remove the value from either field, the administrative console treats the empty field as an error.
   - If you select the option to **Enable operation-level security** then you must also complete, for this inbound service, the steps described in Password-protecting a Web service operation.
6. Modify the additional properties.
   a. Modify the inbound ports that are associated with this inbound service.

      An inbound port describes the Web service enablement of a service destination on a specific endpoint listener, with associated configuration. Each inbound port is associated with an endpoint listener, and you can control which groups of users can access a particular inbound service by making the service available only through specific endpoint listeners. For more information, see Endpoint listeners and inbound ports: Entry points to the service integration bus.

You can use a JAX-RPC handler list to monitor activity at the port, and take appropriate action (for example logging, or re-routing) depending upon the sender and content of each message that passes through the port. For more information, see Bus-enabled Web services and JAX-RPC handlers.

You can use WS-Security to set the levels of security to be applied to messages. The security level can be set independently for request and response messages. For more information, see Service integration technologies and WS-Security.

See also Inbound ports settings.

b. Modify the UDDI publication properties that are used to publish this inbound service to one or more UDDI registries. For information about the UDDI publication properties, see UDDI Publication settings and UDDI registries: Web service directories that can be referenced by bus-enabled Web services.

c. Modify the custom properties, if any, that you have set for this inbound service. These custom properties are name and value pairs that you can use to set internal system configuration properties. In each pair, the name is a property key and the value is a string value.

d. Use the publish WSDL files property to export the template WSDL for this inbound service to a ZIP file.

As a technology preview, the exported ZIP file includes a version of the WSDL file that has no ports (bindings) defined. This non-bound WSDL is intended for use by your colleagues preparing to deploy an inbound service. It gives you a convenient way of sharing information on the planned deployment details for the service among your team. When you finally deploy the inbound service, the associated WSDL must be complete (that is, it must include the binding information).

The non-bound WSDL file is always published in the exported ZIP file for the inbound service, along with the bound WSDL file if the inbound service has any ports defined. The ZIP file, named *inbound_service_name*.zip, therefore always contains the following files:

- *bus_name*.*inbound_service_name*NonBound.wsdl (this file contains the non-bound service, port and binding for the inbound service).
- *bus_name*.*inbound_service_name*PortTypes.wsdl (this file contains the port type definition for the inbound service).

If the inbound service has one or more ports, then the ZIP file additionally contains the following files:

- *bus_name*.*inbound_service_name*Service.wsdl (this file contains the service and port elements for the inbound service).
- *bus_name*.*inbound_service_name*Bindings.wsdl (this file contains the binding elements that correspond to the ports for the inbound service).

If there is an error generating the WSDL then an error page is returned.

7. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of inbound services for this service integration bus is redisplayed. Otherwise, an error message is displayed.

Deleting inbound services configurations:
Before you begin

Decide on which method you want to use to configure these resources. You can delete an inbound service by using the administrative console as described in this task, or by using the deleteSIBWSInboundService command.

About this task

To delete one or more inbound services by using the administrative console, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses** → ***bus_name*** → **[Services] Inbound Services**. A list of all the inbound services is displayed in an inbound services collection form.
3. Select the check box for every inbound service that you want to remove.
4. Click **Delete**.

Results

If the processing completes successfully, the list of inbound services for this service integration bus is updated. Otherwise, an error message is displayed.

Making an externally-hosted Web service available internally

Create an outbound service. An outbound service provides access, through one or more outbound ports, to a Web service that is hosted externally. An outbound service can be used by any of your internal systems that can access the service integration bus on which it is hosted. To make an externally-hosted service available through a bus, you first associate it with a service destination, then you configure one or more port destinations (one for each type of binding, for example SOAP over HTTP or SOAP over JMS) through which service requests and responses are passed to the external service. You get the port definitions from the WSDL, but you can choose which ones you want to create.

Before you begin

This topic assumes that you have created and installed a Service Data Objects (SDO) repository (used for storing and serving WSDL definitions) on every server that is to play a service integration bus Web services role.

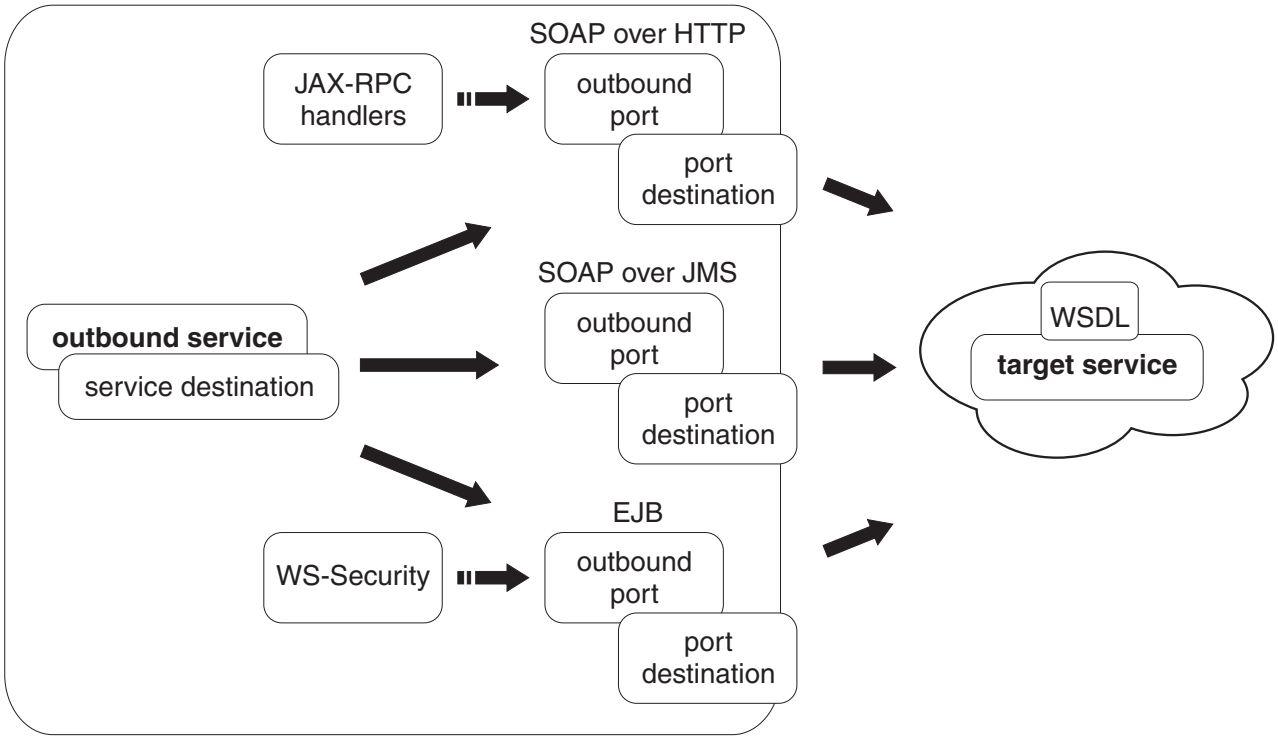
To create an outbound service, you need to know the location of the externally-published WSDL file that describes the service. This WSDL file is either available at a Web address or through a UDDI registry.

If the WSDL file for your outbound service is stored in a UDDI registry, you associate the outbound service with a UDDI reference to the registry. You choose the UDDI reference from a selection list, so you must configure the UDDI reference before you configure a new outbound service that uses it.

Decide on which method you want to use to configure these resources. You can create an outbound service by using the administrative console as described in this task, or by using the createSIBWSOutboundService command.

Note: If the bus needs to pass messages through an authenticating proxy server to retrieve WSDL documents, then you cannot use the administrative console for this task and you must create your new outbound service by using the wsadmin tool. For more information see the corresponding troubleshooting tip.

About this task



service integration technologies

Requests and responses to an outbound service are sent across any transport binding (for example SOAP over HTTP, SOAP over JMS, EJB binding) that is available to both the target service and the service integration bus. Each available binding type is represented by an outbound port configured at a port destination. For more information, see Outbound ports and port destinations.

You can control and monitor access to the target service in the following ways:

- You can associate JAX-RPC handler lists with ports, so that the handlers can monitor activity at the port, and take appropriate action depending upon the sender and content of each message that passes through the port.
- You can set the level of security to be applied to messages (the WS-Security binding). The security level can be set independently for request and response messages.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses** → ***bus_name*** → **[Services] Outbound Services**. The outbound services collection form is displayed.
3. Click **New**. The New outbound service wizard is displayed.
4. Use the wizard to create the new outbound service configuration by completing the following steps. For more information about the properties that you set with the wizard, see Outbound services settings and Outbound ports settings.
   a. Locate the target service WSDL.
   b. Select the service from the WSDL.

      Note:

      - This option is needed in case there is more than one service in the WSDL. The field is filled in for you by default. If there is only one service in the WSDL, accept the default.
      - There needs to be at least one port defined in the service you select.

c. Select the ports that are to be enabled for this service.

   Note: Select at least one port.

d. Name the outbound service, the service destination and all of the port destinations.

   Note:

   - Default names are generated, but you can rename them. The default names are unique within the current service integration bus. Any replacement names that you choose must be similarly unique. If you enter a name that is not unique, an error message is displayed.
   - If you have created a port selection mediation and deployed it to the service integration bus, then it is available for selection in the list of mediations. If you do not want to use a port selection mediation with this outbound service, select `none` from the selection list. This list contains all mediations, including port selection mediations, that are currently deployed to this service integration bus.
   - The list of available ports is a subset of the ports that are described in the WSDL file. You chose this subset in the previous step. If you selected more than one port in the previous step, you should also set the default port to be used unless otherwise specified by a port selection mediation.

e. Assign each port destination and (optionally) the port selection mediation to a bus member.

   Note:

   - Bus members are application servers or clusters that are added to this bus.
   - The option to assign a port selection mediation to a bus member is only displayed if you selected a mediation in the previous step.

5. Click **Finish**.

Results

If the processing completes successfully, the list of outbound services for this service integration bus is updated to include the new outbound service. Otherwise, an error message is displayed.

What to do next

Because the service is hosted externally, you might also need to enable proxy server authentication for each port to get permission to access the Internet.

If you want to secure your new outbound service, or apply any JAX-RPC handler lists to the ports, or enable proxy server authentication for any of the ports, use the administrative console to modify your outbound service configuration.

Modifying an existing outbound service configuration:

Modify the configuration details for an outbound service. For example: secure the service; apply JAX-RPC handler lists to the ports for the service; publish the service to more than one UDDI registry.

About this task

An outbound service provides access, through one or more outbound ports, to a Web service that is hosted externally. An outbound service can be used by any of your internal systems that can access the service integration bus on which it is hosted.

When you first create an outbound service you select the ports that are to be enabled for the service, but you do not associate the ports with JAX-RPC handler lists or security settings. You need to modify your outbound service configuration if you want to control and monitor access to the target service in any of the following ways:

- Associate JAX-RPC handler lists with ports, so that the handlers can monitor activity at the port, and take appropriate action depending upon the sender and content of each message that passes through the port.
- Password-protect a Web service operation.
- Set the level of security to be applied to messages (the WS-Security binding). The security level can be set independently for request and response messages.
- Enable proxy server authentication for any of the ports.

To list the existing outbound services, and to view and modify their configuration details, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses** → ***bus_name*** → **[Services] Outbound Services**. A list of outbound services is displayed in an outbound services collection form.
3. Click the name of an outbound service in the list. The current settings for this outbound service are displayed.
4. Optional: Click **Reload WSDL** to reload the external WSDL file for this outbound service.

   Note:

   - When you create a new outbound service, a copy of the external WSDL file for the service is loaded into a locally-maintained repository. If the external service provider changes the WSDL file, you must update the local copy.
   - When you click **Reload WSDL**, you launch the command that is described in Refreshing the outbound service WSDL file by using the wsadmin tool. For the command to complete successfully, the conditions must be met that are described in that topic.
   - If the bus needs to pass messages through an authenticating proxy server to retrieve WSDL documents, then you cannot use the **Reload WSDL** option and you must launch the refresh WSDL command by using the wsadmin tool. For more information see the corresponding troubleshooting tip.
5. Modify the general properties. For information about each of these properties, see Outbound services settings.

   Note:

   - When you change an outbound service name, the system looks up all objects that refer to it and updates the name. Any replacement name that you choose must be unique within the current service integration bus. If you enter a name that is not unique, an error message is displayed.
   - You cannot change the **Service destination name**. However, if you click **View** alongside the name, you can view and modify the configuration information for the service destination.
   - If you change the WSDL location information (that is the fields **WSDL location type**, **WSDL location** and **WSDL UDDI Registry**), then click **Apply**, the outbound service WSDL file is reloaded. Therefore you should click **Apply** after you make any changes to the WSDL location information and before you change any of the WSDL-derived fields (for example WSDL service name, and list of available ports).
   - Although logically the WSDL service name and namespace are only required if there is more than one service in the WSDL, the fields that you use to set them are coded within the administrative console as compulsory fields. They are filled in for you by default, so if they are not logically required for your service you should leave the default values. If you remove the value from either field, the administrative console treats the empty field as an error.

- The list of available ports from which you choose the **Default port name** is a subset of the ports that are described in the WSDL file. You chose this subset when you created or last modified this outbound service. To add or remove available ports, use the additional properties option **Outbound Ports**.
- If you have created a port selection mediation and deployed it to the service integration bus, then it is available for selection in the list of mediations. If you do not want to use a port selection mediation with this outbound service, select `none` from the selection list. This list contains all mediations, including port selection mediations, that are currently deployed to this service integration bus.
- Bus members are application servers or clusters that are added to this bus. The **Bus member** property defines the bus member to which the port selection mediation is assigned. If you change the **Port selection mediation** property value to `(none)`, you should also change the **Bus member** property value to `(none)`. If you want to use a port selection mediation, assign it to a bus member. If you do not do this, the administrative console displays an error message.
- If you select the option to **Enable operation-level security** then you must also complete, for this outbound service, the steps described in Password-protecting a Web service operation.
-

6. Modify the additional properties.
   a. Modify the ports that are associated with this outbound service. For information about the properties of outbound service ports, see Outbound ports settings.

      Note:

      - Requests and responses to an outbound service can be sent across any binding (for example SOAP over HTTP or SOAP over JMS) that is available to both the service integration bus and the external Web service. Each available binding is represented by a port.
      - You can use a JAX-RPC handler list to monitor activity at the port, and take appropriate action (for example logging or re-routing) depending upon the sender and content of each message that passes through the port. If the external Web service requires HTTP basic authentication, you can use a JAX-RPC handler list to provide an HTTP basic authentication header as described in Invoking a password-protected outbound service.
      - You can use WS-Security to set the levels of security to be applied to messages. The security level can be set independently for request and response messages. For more information, see Service integration technologies and WS-Security.
      - You can set the levels of security to be applied to messages. The security level can be set independently for request and response messages.
      - The service integration technologies require access to the Internet to invoke an outbound service or to retrieve a target service WSDL file. If you use a proxy server in support of Internet routing, and if your proxy server requires authentication before it grants access to the Internet, then you must enable proxy server authentication.

   b. Modify the custom properties, if any, that you have set for this outbound service. These custom properties are name and value pairs that you can use to set internal system configuration properties. In each pair, the name is a property key and the value is a string value.
7. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of outbound services for this service integration bus is redisplayed. Otherwise, an error message is displayed.

Deleting outbound service configurations:

Before you begin

Decide on which method you want to use to configure these resources. You can delete an outbound service by using the administrative console as described in this task, or by using the deleteSIBWSOutboundService command.

About this task

To delete one or more outbound services by using the administrative console, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses** → ***bus_name*** → **[Services] Outbound Services**. A list of outbound services is displayed in an outbound services collection form.
3. Select the check box for every outbound service that you want to remove.
4. Click **Delete**.

Results

If the processing completes successfully, the list of outbound services for this service integration bus is updated. Otherwise, an error message is displayed.

Administering the bus-enabled Web services core resources

Use the administrative console to configure the service integration bus-enabled Web services core resources: endpoint listeners; JAX-RPC handler lists; WS-Security bindings and configurations; references to UDDI registries.

About this task

When you configure a bus-enabled Web service you associate it with one or more of the following core resources:

- The endpoint listeners on which you want the service to be available.
- Any JAX-RPC handler lists that apply to the service.
- Any WS-Security bindings and configurations that apply to the service.
- Any references to UDDI registries in which entries for the service are created.

You choose each of these resources from a list of resources that you have previously configured.

Use the administrative console to administer the bus-enabled Web services core resources as described in the following topics:

1. “Creating a new endpoint listener configuration.”
2. “Working with JAX-RPC handlers and clients” on page 1029.
3. “Working with mediations” on page 1039.
4. “Creating a new UDDI reference” on page 1040.

Creating a new endpoint listener configuration

An endpoint listener is the point (address) at which messages for an inbound service are received. The endpoint listeners that are supplied with WebSphere Application Server support SOAP over HTTP and SOAP over JMS bindings.

Before you begin

For every server that is to host an endpoint listener, you must install and configure a Service Data Objects (SDO) repository on the server.

Note: For WebSphere Application Server Version 6.0.x, you also had to manually install the endpoint listener application before you configured an endpoint listener. For later versions of WebSphere Application Server the endpoint listener application is installed automatically.

If you want to change the default HTTP endpoint listener security role, do so before you configure the SOAP over HTTP endpoint listener.

Before you configure a SOAP over JMS endpoint listener, configure the associated JMS resources.

You can set up separate endpoint listeners for inbound and outbound requests. For more information, see Endpoint listeners and inbound ports: Entry points to the service integration bus.

Decide on which method you want to use to configure these resources. You can create a new endpoint listener configuration by using the administrative console as described in this task, or by using the createSIBWSEndpointListener command.

Note: If you want to create an endpoint listener configuration for your own endpoint listener application, rather than for one of the listeners that is supplied with WebSphere Application Server, you can only do so by using the wsadmin tool.

About this task

A request arrives at an endpoint listener. It is passed to an inbound port (at which point security and JAX-RPC handler lists can be applied) then sent on to the service destination. Responses follow the same path in reverse.

To configure a new endpoint listener for use with an inbound service is a three-stage process:

1. Configure the listener for a specific application server (this task).
2. Connect the listener to one or more service integration buses (the final part of task “Modifying an existing endpoint listener configuration” on page 1026).
3. Configure an inbound service on the same bus to use the listener (part of the task “Making an internally-hosted service available as a Web service” on page 1009).

To use the administrative console to configure an endpoint listener, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, click one of the following paths:
   - **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Endpoint listeners**
   - **Servers** → **Clusters** → **WebSphere application server clusters** → ***cluster_name*** → **Endpoint listeners**

   The endpoint listeners collection form is displayed.
3. Click **New**. The New endpoint listener wizard is displayed.
4. Use the wizard to create the new endpoint listener configuration by completing the following steps. For more information about the properties that you set with the wizard, see Endpoint listeners [Settings]. If you want to configure an endpoint listener with values that match those used for an endpoint listener supplied with WebSphere Application Server Version 6.0, see “Endpoint listener configuration details for Version 6.0.x compatibility” on page 1022.
   a. Select listener name and binding type.
      Endpoint listener name
      Type the name by which the endpoint listener is known.
      Binding type
      Select the type of binding that this endpoint listener supports. For example, for a SOAP over HTTP endpoint listener select `SOAP/HTTP`.
   b. Optional: Configure JMS settings.

This panel is only displayed if you selected a JMS binding in the previous panel.

By default, the wizard assumes that you are deploying your endpoint listener application to use a JMS activation specification with the default messaging provider. However, you can choose to deploy your endpoint listener application to use a listener port or another JMS provider (for example WebSphere MQ).

Select from the drop-down lists the **listener port**, or the **activation specification** and **queue connection factory** that you have previously configured as described in "Configuring JMS resources for the synchronous SOAP over JMS endpoint listener" on page 1025.

c. Configure required URLs. Configure Web addresses for the application root and the WSDL serving root. You can either select pre-configured addresses based on the known virtual hosts, or create new values.

URL root

Select or type the address at which external clients access the endpoint listener endpoint. The URL root is the context root of the endpoint listener application, and provides the root of the Web address that is used to build the endpoint addresses within WSDL files to direct requesters to this endpoint listener.

If external clients access the endpoint listener through an HTTP server or server cluster, using default port 80, then specify the HTTP server name and no port number. For example (for SOAP over HTTP endpoint listener 1):
`http://www.yourcompany.com/wsgwsoaphttp1`
However, if you allow external clients to connect direct to your application server (for example in a development or test environment) then specify the application server host name and port number. For example (for SOAP over HTTP endpoint listener 1):
`http://your.server.name:9080/wsgwsoaphttp1`

WSDL serving HTTP URL root

Type the root of the Web address for the WSDL files of the inbound services that are available at this endpoint listener. This address comprises the root of the HTTP address at which external clients access your endpoint listener application, followed by `/sibws`.

If external clients access the endpoint listener through an HTTP server or server cluster, typically using default port 80, then this URL root includes the HTTP server name and no port number. For example:

`http://www.yourcompany.com/sibws`

However, if you allow external clients to connect direct to your application server (for example in a development or test environment) then this URL root includes the application server host name and port number. For example:

`http://your.server.name:9080/sibws`

Note: The WSDL serving HTTP URL root is only used internally by other components of WebSphere Application Server (notably the IBM UDDI registry). For all other uses, you access the WSDL file through the endpoint listener endpoint for the inbound service. To get the location details for a given inbound service WSDL file, publish the WSDL file to a zip file as described in "Modifying an existing inbound service configuration" on page 1011, then look up the location within the exported WSDL file.

5. Click **Finish**.

Results

If the processing completes successfully, the list of endpoint listeners is updated to include the new endpoint listener. Otherwise, an error message is displayed.

What to do next

You are now ready to connect one or more service integration buses to this endpoint listener as described in “Modifying an existing endpoint listener configuration” on page 1026, then to select this endpoint listener for use with an inbound service as described in “Making an internally-hosted service available as a Web service” on page 1009.

Endpoint listener configuration details for Version 6.0.x compatibility:

In WebSphere Application Server Version 6.0.x, four endpoint listeners were supplied that are configured as described in this topic. In the current version of the product you can configure any number of endpoint listeners with values of your own choosing, including (if you wish) the values given in this topic.

When you create an endpoint listener configuration for a listener that is supplied with WebSphere Application Server Version 6.0.x, you provide the following configuration details:

Endpoint listener name
The name by which the endpoint listener is known. For example, for SOAP over HTTP endpoint listener 1 the endpoint listener name is `SOAPHTTPChannel1`.

URL root
The address at which external clients access the endpoint listener endpoint. The URL root is the context root of the endpoint listener application, and provides the root of the Web address that is used to build the endpoint addresses within WSDL files to direct requesters to this endpoint listener.

WSDL serving HTTP URL root
The root of the Web address for the WSDL files of the inbound services that are available at this endpoint listener. This address comprises the root of the HTTP address at which external clients access your endpoint listener application, followed by `/sibws`.

Note: The WSDL serving HTTP URL root is only used internally by other components of WebSphere Application Server (notably the IBM UDDI registry). For all other uses, you access the WSDL file through the endpoint listener endpoint for the inbound service. To get the location details for a given inbound service WSDL file, publish the WSDL file to a zip file as described in “Modifying an existing inbound service configuration” on page 1011, then look up the location within the exported WSDL file.

This topic specifies these configuration details (endpoint listener name, endpoint listener URL root and WSDL serving URL root) for the following endpoint listeners:

- “SOAP over HTTP endpoint listener 1”
- “SOAP over HTTP endpoint listener 2” on page 1023
- “Synchronous SOAP over Java Message Service (JMS) endpoint listener 1” on page 1023
- “Synchronous SOAP over JMS endpoint listener 2” on page 1024

SOAP over HTTP endpoint listener 1

Endpoint listener name
`SOAPHTTPChannel1`.

URL root
The address at which external clients access the endpoint listener endpoint. If external clients access the endpoint listener through an HTTP server or server cluster, using default port 80, then specify the HTTP server name and no port number. For example (for this endpoint listener):

`http://`*`www.yourcompany.com`*`/wsgwsoaphttp1`However, if you allow external clients to connect direct to your application server (for example in a development or test environment) then specify the application server host name and port number. For example (for this endpoint listener):

http://*your.server.name:9080*/wsgwsoaphttp1

WSDL serving HTTP URL root

The root of the HTTP address at which external clients access your endpoint listener application, followed by /sibws. For example:

http://*www.yourcompany.com*/sibws

or

http://*your.server.name:9080*/sibws

Note: The WSDL serving HTTP URL root is only used internally by other components of WebSphere Application Server (notably the IBM UDDI registry). For all other uses, you access the WSDL file through the endpoint listener endpoint for the inbound service.

SOAP over HTTP endpoint listener 2

Endpoint listener name

SOAPHTTPChannel2.

URL root

The address at which external clients access the endpoint listener endpoint. If external clients access the endpoint listener through an HTTP server or server cluster, using default port 80, then specify the HTTP server name and no port number. For example (for this endpoint listener):

http://*www.yourcompany.com*/wsgwsoaphttp2However, if you allow external clients to connect direct to your application server (for example in a development or test environment) then specify the application server host name and port number. For example (for this endpoint listener):

http://*your.server.name:9080*/wsgwsoaphttp2

WSDL serving HTTP URL root

The root of the HTTP address at which external clients access your endpoint listener application, followed by /sibws. For example:

http://*www.yourcompany.com*/sibws

or

http://*your.server.name:9080*/sibws

Note: The WSDL serving HTTP URL root is only used internally by other components of WebSphere Application Server (notably the IBM UDDI registry). For all other uses, you access the WSDL file through the endpoint listener endpoint for the inbound service.

Synchronous SOAP over Java Message Service (JMS) endpoint listener 1

Endpoint listener name

SOAPJMSChannel1.

URL root

You specify the properties of the synchronous SOAP over JMS endpoint listener 1 endpoint by using the following syntax:

jms:/*queue_or_topic_indicator*?*property_name=property_value* and so on, separating each property using the "&" character.

For example, if you use the default values for queue destination and queue connection factory when you install the synchronous SOAP over JMS endpoint listeners, then the first part of the end point address is:

jms:/queue?destination=jms/SOAPJMSQueue1&connectionFactory=jms/SOAPJMSFactory1

For each of the synchronous SOAP over JMS endpoint listeners, here is the full list of properties that you can specify in the endpoint address:

Property name	Property description
Destination-related Properties (required)	
connectionFactory	The JNDI name of the queue or topic connection factory.
destination	The JNDI name of the destination queue or topic.
JNDI-related Properties (optional)	
initialContextFactory	The name of the initial context factory to use (this is mapped to the java.naming.factory.initial property).
jndiProviderURL	The JNDI provider Web address (this is mapped to the java.naming.provider.url property).
JMS-related Properties (optional)	
deliveryMode	An indication as to whether or not the request message is persistent. The valid values are 1 (non persistent) and 2 (persistent). The default value is 1.
timeToLive	The lifetime (in milliseconds) of the request message. A value of 0 indicates an infinite lifetime.
priority	The JMS priority associated with the request message. Valid values are 0 - 9. The default value is 4.
userid	The User ID that is used to gain access to the connection factory.
password	The password that is used to gain access to the connection factory.

WSDL serving HTTP URL root

The root of the HTTP address at which external clients access your endpoint listener application, followed by /SIBWS.

If external clients access the endpoint listener through an HTTP server or server cluster, typically using default port 80, then this URL root includes the HTTP server name and no port number. For example:

http://*www.yourcompany.com*/sibws

However, if you allow external clients to connect direct to your application server (for example in a development or test environment) then this URL root includes the application server host name and port number. For example:

http://*your.server.name:9080*/sibws

Note: The WSDL serving HTTP URL root is only used internally by other components of WebSphere Application Server (notably the IBM UDDI registry). For all other uses, you access the WSDL file through the endpoint listener endpoint for the inbound service.

Synchronous SOAP over JMS endpoint listener 2

Endpoint listener name

SOAPJMSChannel2.

URL root

You specify the properties of the synchronous SOAP over JMS endpoint listener 2 endpoint by using the following syntax:

jms:/*queue_or_topic_indicator*?*property_name*=*property_value* and so on, separating each property using the "&" character.

For example, if you use the default values for queue destination and queue connection factory when you install the synchronous SOAP over JMS endpoint listeners, then the first part of the end point address is:

```
jms:/queue?destination=jms/SOAPJMSQueue2&connectionFactory=jms/SOAPJMSFactory2
```

For the full list of properties that can be specified in the endpoint address for synchronous SOAP over JMS endpoint listener 2, see the list of properties detailed above for Synchronous SOAP over JMS endpoint listener 1.

WSDL serving HTTP URL root

The root of the HTTP address at which external clients access your endpoint listener application, followed by `/SIBWS`.

If external clients access the endpoint listener through an HTTP server or server cluster, typically using default port 80, then this URL root includes the HTTP server name and no port number. For example:

```
http://www.yourcompany.com/sibws
```

However, if you allow external clients to connect direct to your application server (for example in a development or test environment) then this URL root includes the application server host name and port number. For example:

```
http://your.server.name:9080/sibws
```

Note: The WSDL serving HTTP URL root is only used internally by other components of WebSphere Application Server (notably the IBM UDDI registry). For all other uses, you access the WSDL file through the endpoint listener endpoint for the inbound service.

Configuring JMS resources for the synchronous SOAP over JMS endpoint listener:

Configure the synchronous SOAP over Java Message Service (JMS) endpoint listeners to use a JMS provider - either the default messaging provider, or another provider such as WebSphere MQ - to pass SOAP messages over JMS.

About this task

To install and configure the JMS provider for the synchronous SOAP over JMS endpoint listener, complete the following steps.

1. Optional: If you have not already done so, choose and configure a JMS messaging provider.
2. Use the administrative console to create and configure queue connection factories and queue destinations as described, for the most common JMS providers, in topics available from within Choosing a messaging provider. Create a connection factory and a queue for each endpoint listener that you plan to configure. For example if you plan to configure both of the SOAP over JMS endpoint listeners that are supplied with WebSphere Application Server, create two connection factories (one for each endpoint listener) and two queues. The JMS resources and JNDI names that the supplied SOAP over JMS endpoint listeners expect by default are provided in the following table. If you use different resources and names in this step, then change the defaults when you subsequently configure the endpoint listener.

JMS resource	default JNDI name (endpoint listener 1)	default JNDI name (endpoint listener 2)	queue name (endpoint listener 1)	queue name (endpoint listener 2)
JMS queue connection factory	jms/SOAPJMSFactory1	jms/SOAPJMSFactory2	Not required	Not required
JMS queue	jms/SOAPJMSQueue1	jms/SOAPJMSQueue2	User defined (for example: SOAPJMSDestQueue1)	User defined (for example: SOAPJMSDestQueue2)

3. Configure the underlying destination for each JMS queue.

If you are using the default messaging provider, use the administrative console to add the two new queue names specified in the previous table as destinations for your application server as described in Creating a queue for point-to-point messaging. The identifier for the destination should match that defined by the user as the queue name in the previous table.

Otherwise, configure these destinations as described in the documentation for your JMS provider.

4. Configure the deployment details for the application.

   If you are using activation specifications with the default messaging provider, use the administrative console to create and configure the activation specifications as described in “Configuring a JMS activation specification for the default messaging provider” on page 1591. Create two activation specifications, one for each endpoint listener. The default JMS resources and associated names that the synchronous SOAP over JMS endpoint listeners expect are provided in the following table. However, you can use any JNDI name for the activation specification, provided that the EAR file has the same JNDI reference in the administrative console “Binding enterprise beans to listener port names or activation specification JNDI names” panel. If you use different resources and names in this step, change the defaults when you subsequently configure the endpoint listener. You must also stop then restart the application server.

JMS resource	default JNDI name (endpoint listener 1)	default JNDI name (endpoint listener 2)	destination JNDI name (endpoint listener 1)	destination JNDI name (endpoint listener 2)
activation specification	eis/SOAPJMSChannel1	eis/SOAPJMSChannel2	jms/SOAPJMSQueue1	jms/SOAPJMSQueue2

   If you are using listener ports with any supported JMS provider (including the default messaging provider), use the administrative console to create and configure the listener ports in the message listener service as described in Adding a new listener port. Create two listener ports (one for each endpoint listener). The default JMS resources and associated names that the supplied SOAP over JMS endpoint listeners expect are provided in the following table. If you use different resources and names in this step, then change the defaults when you subsequently configure the endpoint listener.

JMS resource	default name (for use with SOAP over JMS endpoint listener 1)	default name (for use with SOAP over JMS endpoint listener 2)
listener port	SOAPJMSPort1	SOAPJMSPort2
connection factory	jms/SOAPJMSFactory1	jms/SOAPJMSFactory2
destination	jms/SOAPJMSQueue1	jms/SOAPJMSQueue2

5. Save your changes to the master configuration.
6. Bind the JMS resources by stopping then restarting the application server.

What to do next

You are now ready to create a new SOAP over JMS endpoint listener configuration.

Modifying an existing endpoint listener configuration:

Modify the additional properties for an endpoint listener that has been configured for use with inbound services.

Before you begin

You cannot use this task to modify the general properties of an existing endpoint listener. The reason for this is that, when you create a new endpoint listener, an associated endpoint listener application is automatically installed that uses the same general property values. Therefore if you subsequently change the general properties, you break the link between the configuration and the underlying application. If you need to change the general properties, you should delete and recreate the endpoint listener configuration.

About this task

To list the endpoint listeners, and to view and modify their configuration details, complete the following steps.

1. Start the administrative console.
2. In the navigation pane, click one of the following paths:
   - **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Endpoint listeners**
   - **Servers** → **Clusters** → **WebSphere application server clusters** → ***cluster_name*** → **Endpoint listeners**

   A list of endpoint listeners is displayed in an endpoint listener collection form.
3. Click the name of an endpoint listener in the list. The current endpoint listener settings for this endpoint listener are displayed.
4. View the following general properties. If you are configuring an endpoint listener that is supplied with WebSphere Application Server, the required values are given in Endpoint listener configuration details.

   Name View the name by which the endpoint listener is known. If this is your own endpoint listener, rather than one that is supplied with WebSphere Application Server, then this name must match the name given in the endpoint listener application that you have installed (that is, the *display name* of the endpoint module within the endpoint application EAR file).

   DescriptionDescription
   View the (optional) description of the endpoint listener.

   URL root
   View the address at which external clients access the endpoint listener endpoint. The URL root is the context root of the endpoint listener application, and provides the root of the Web address that is used to build the endpoint addresses within WSDL files to direct requesters to this endpoint listener.

   If external clients access the endpoint listener through an HTTP server or server cluster, using default port 80, then specify the HTTP server name and no port number. For example (for SOAP over HTTP endpoint listener 1):
   `http://www.yourcompany.com/wsgwsoaphttp1`
   However, if you allow external clients to connect direct to your application server (for example in a development or test environment) then specify the application server host name and port number. For example (for SOAP over HTTP endpoint listener 1):
   `http://your.server.name:9080/wsgwsoaphttp1`

   WSDL serving HTTP URL root
   View the root of the Web address for the WSDL files of the inbound services that are available at this endpoint listener. This address comprises the root of the HTTP address at which external clients access your endpoint listener application, followed by `/sibws`.

   If external clients access the endpoint listener through an HTTP server or server cluster, typically using default port 80, then this URL root includes the HTTP server name and no port number. For example:

`http://www.yourcompany.com/sibws`

   However, if you allow external clients to connect direct to your application server (for example in a development or test environment) then this URL root includes the application server host name and port number. For example:
   `http://your.server.name:9080/sibws`

   Note: The WSDL serving HTTP URL root is only used internally by other components of WebSphere Application Server (notably the IBM UDDI registry). For all other uses, you access the WSDL file through the endpoint listener endpoint for the inbound service. To get the location details for a given inbound service WSDL file, publish the WSDL file to a zip file as described in “Modifying an existing inbound service configuration” on page 1011, then look up the location within the exported WSDL file.

5. Under the additional properties heading, click **Connection properties**. A list of all the service integration buses that are currently connected to this endpoint listener is displayed in a service integration bus connection properties collection form. Add, amend or delete buses in the list of currently-connected buses. To add a new bus, complete the following steps:
   a. Click **New**. The service integration bus connection properties settings form is displayed.
   b. Under the general properties heading, choose an available service integration bus from the selection list. The bus is selected and the additional properties for the bus are displayed.

      Note: Under the connection properties for the bus there are **Custom properties**. These custom properties are name and value pairs that you can use to set internal system configuration properties. In each pair, the name is a property key and the value is a string value. You use custom properties to define the manner in which the endpoint listener connects to this bus. Included in this set is property name `com.ibm.ws.sib.webservices.replyDestination`, which defines the reply destination name used by the endpoint listener. Do not modify or remove this property, which is set automatically when the service integration bus is associated with the endpoint listener.
6. Under the additional properties heading, click **Associated application**. Details for the application that handles the requests for this endpoint listener are displayed in an enterprise application settings form.
7. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of service integration buses that are connected to this endpoint listener is updated, and the list of endpoint listeners is redisplayed. Otherwise, an error message is displayed.

What to do next

You are now ready to select this endpoint listener for use with an inbound service as described in “Making an internally-hosted service available as a Web service” on page 1009.

Deleting endpoint listener configurations:
Before you begin

You cannot delete an endpoint listener that has inbound ports associated with it. If you try to do this, an error is generated. Before you can delete an endpoint listener, you must either delete each associated inbound service or remove each associated port from the port list for the inbound service.

Decide on which method you want to use to configure these resources. You can delete an endpoint listener configuration by using the administrative console as described in this task, or by using the deleteSIBWSEndpointListener command.

About this task

To remove one or more endpoint listener configurations, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Endpoint listeners**. A list of endpoint listeners is displayed in an endpoint listener collection form.
3. Select the check box for every endpoint listener configuration that you want to remove.
4. Click **Delete**.

Results

If the processing completes successfully, the list of endpoint listeners is updated. Otherwise, an error message is displayed.

Working with JAX-RPC handlers and clients

The Java API for XML-based remote procedure calls (JAX-RPC) provides you with a standard way of developing interoperable and portable Web services. You can use JAX-RPC handlers, handler lists and client applications with your service integration bus-enabled Web services.

About this task

There are two main elements of JAX-RPC that you can use directly with the service integration bus:

- JAX-RPC handlers and handler lists.
- JAX-RPC client applications.

A JAX-RPC handler is a Java class that performs a range of handling tasks.For example: logging messages, or transforming their contents, or terminating an incoming request. To create a JAX-RPC handler, you can use a tool such as IBM Rational Application Developer. To enable handlers to perform more complex operations, you chain them together into handler lists. You associate each handler list with one or more ports, so that the handler list can monitor activity at the port, and take appropriate action depending upon the sender and content of each message that passes through the port.

JAX-RPC client applications send and receive Web service request and response messages. JAX-RPC client applications that use the IBM JAX-RPC run-time environment can do this in a number of different ways, depending on the bindings in the WSDL document that they are developed against, and the configuration data that is used at run time.

Detailed instructions on how to configure JAX-RPC handlers, handler lists and client applications for use with the service integration bus are provided in the following topics:

- “Creating a new JAX-RPC handler configuration.”
- “Creating a new JAX-RPC handler list” on page 1033.
- “Sending Web service messages directly over the bus from a JAX-RPC client” on page 1036.
- “Implementing JAX-RPC handlers to access SDO messages” on page 1038.

Creating a new JAX-RPC handler configuration:

Create a JAX-RPC handler configuration for use, as part of a handler list, with service integration bus-deployed Web services. Handlers monitor messages at ports, and take appropriate action depending upon the sender and content of each message.

Before you begin

This task assumes that you have already created your handler. You can do this using IBM Rational Application Developer or a similar tool. For more information, see the IBM developerWorks article Support for J2EE Web Services in WebSphere Studio Application Developer V5.1 -- Part 3: JAX-RPC Handlers.

You must also make the handler class available to the server that hosts the port for the service that you want to monitor, as detailed in “Loading JAX-RPC handler classes” on page 1030.

About this task

A Java API for XML-based remote procedure calls (JAX-RPC) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. To make WebSphere Application Server aware of your handler, and to make the handler

available for inclusion in one or more handler lists, you use the administrative console to create a new handler configuration.

1. In the navigation pane, click **Service integration** → **Web services** → **JAX-RPC Handlers**. The JAX-RPC handlers collection form is displayed.
2. Click **New**. The JAX-RPC handlers settings form is displayed.
3. Type the following general properties:
   Name Type the name by which the handler is known.

   This name must be unique, and it must obey the following syntax rules:
   - It must not start with "." (a period).
   - It must not start or end with a space.
   - It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

   For example `TestHandler`.

   Description
   Type the (optional) description of the handler.

   Class name
   Type the name of the class that is to be instantiated. For example `com.ibm.jaxrpc.handler.TestHandler`.

   Note: You can configure multiple instances of a handler by creating each instance with a different handler name, and pointing to the same handler class.
4. Click **OK**. The general properties for this item are saved, and the additional properties options are made available.
5. Type the following additional properties:
   SOAP roles
   Add SOAP actor definitions to the list of SOAP roles in which this handler acts. For more information, see the SOAP specification.

   JAX-RPC headers
   Add JAX-RPC header definitions (Namespace URI and Local part) to the list of JAX-RPC headers against which this handler operates. JAX-RPC headers are SOAP headers that are processed by a JAX-RPC handler.

   Custom properties
   Add custom properties (name/value pairs, where the name is a property key and the value is a string value that can be used to set internal system configuration properties).
6. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of handlers is updated to include the new handler. Otherwise, an error message is displayed.

What to do next

To use this handler, add it to a handler list as described in Creating a new JAX-RPC handler list or Modifying an existing JAX-RPC handler list.

Loading JAX-RPC handler classes:

A JAX-RPC handler interacts with messages as they pass into and out of the service integration bus, therefore you make the handler class available to the server or cluster that hosts the inbound or outbound port for the service that you want to monitor.

Before you begin

This task assumes that you have already created your handler. You can do this using IBM Rational Application Developer or a similar tool. For more information, see the IBM developerWorks article Support for J2EE Web Services in WebSphere Studio Application Developer V5.1 -- Part 3: JAX-RPC Handlers.

About this task

Before you can configure your JAX-RPC handler for use with service integration bus-deployed Web services, you must make the handler class available. If you want to monitor an inbound port, make the handler class available to the server on which the endpoint listener for that port is located. If you want to monitor an outbound port, make the handler class available to the server on which the outbound port destination is localized.

To make the handler class available to the server that hosts the port that you want to monitor, you create a shared library for the class then add the shared library to the class loader for the server.

1. Package the class file for your handler as a JAR file, then copy the JAR file into a convenient directory.

   Make the handler class available to the application server in one of the following ways:

   - Copy the individual class file into a directory structure under *app_server_root*/classes that matches the package name of the class, where *app_server_root* is the root directory for the installation of WebSphere Application Server. For example a handler class com.ibm.jaxrpc.handler.TestHandler is copied into the *app_server_root*/classes/com/ibm/jaxrpc/handler directory.
   - Package the class files for all your handlers as a JAR file, then copy it into the *app_server_root*/lib/app directory.

2. Start the administrative console.
3. Create a shared library for the JAR file.
   a. Navigate to **Environment** → **Shared libraries**.
   b. Set the scope at which you want the new library to be visible, then click **New**.
   c. Give the new library a name.
   d. Set the class path to the directory and file name for your handler JAR file.
   e. Save your changes to the master configuration.

   For more information, see Creating shared libraries.
4. Create a class loader for the server on which you want to make the JAR file available.
   a. Navigate to **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Server Infrastructure] Java and Process Management** → **Class loader**.
   b. Click **New**.
   c. Click **OK**.
   d. Save your changes to the master configuration.

   For more information, see Configuring class loaders of a server.
5. Add the shared library to the class loader for the server.
   a. Navigate to **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Server Infrastructure] Java and Process Management** → **Class loader** → ***class_loader_name*** → **[Additional Properties] Shared library references**.
   b. Click **Add**.
   c. Click on the name of your new library, then click **OK**.
   d. Save your changes to the master configuration.

   For more information, see Associating shared libraries with servers.

What to do next

You are now ready to configure your handler for use (as part of a handler list) with service integration bus-enabled Web services.

Modifying an existing JAX-RPC handler configuration:

A Java API for XML-based remote procedure calls (JAX-RPC) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. Handlers monitor messages at ports, and take appropriate action depending upon the sender and content of each message. Modify the configuration details for a JAX-RPC handler that has been configured for use, as part of a handler list, with service integration bus-deployed Web services.

Before you begin

If you modify a handler class but do not change the class name, you do not need to modify the handler configuration as described in this topic. You just need to stop then restart the servers that host the ports that this handler monitors.

About this task

To list the handlers, and to view and modify their configuration details, complete the following steps.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Web services** → **JAX-RPC Handlers**. A list of handlers is displayed in a JAX-RPC handlers collection form.
3. Click the name of a handler in the list. The current JAX-RPC handlers settings for this handler are displayed.
4. Modify the following general properties:
   Name Modify the name of the handler.

   This name must be unique, and it must obey the following syntax rules:
   - It must not start with "." (a period).
   - It must not start or end with a space.
   - It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

   Note: When you change a handler name, the system looks up all objects that refer to it and updates the name.

   Description
   Modify the (optional) description of the handler.

   Class name
   Change the name of the class that is to be instantiated. If you change the class name, you must also make the new class available to the servers that host the ports that this handler monitors, as detailed in "Loading JAX-RPC handler classes" on page 1030.
5. Modify the following additional properties:
   SOAP roles
   Add, modify or remove SOAP actor definitions from the list of SOAP roles in which this handler acts. For more information, see the SOAP specification.

   JAX-RPC headers
   Add, modify or remove JAX-RPC header definitions (Namespace URI and Local part) from the list of JAX-RPC headers against which this handler operates. JAX-RPC headers are SOAP headers that are processed by a JAX-RPC handler.

   Custom properties
   Add, modify or remove custom properties (name/value pairs, where the name is a property key and the value is a string value that can be used to set internal system configuration properties).

6. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of handlers is redisplayed. Otherwise, an error message is displayed.

Deleting JAX-RPC handler configurations:

A Java API for XML-based remote procedure calls (JAX-RPC) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. Delete JAX-RPC handlers that are configured for use (as part of a handler list) with service integration bus-deployed Web services.

About this task

When you remove a handler that is currently used by one or more Web services on a service integration bus, the system removes the handler from the handler lists for each associated Web service.

To remove one or more handlers that are currently configured for a service integration bus, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Web services** → **JAX-RPC Handlers**. A list of handlers is displayed in a JAX-RPC handlers collection form.
2. Select the check box for every handler that you want to remove.
3. Click **Delete**.

Results

If the processing completes successfully, the list of handlers is updated. Otherwise, an error message is displayed.

Creating a new JAX-RPC handler list:

A Java API for XML-based remote procedure calls (JAX-RPC) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. Create a JAX-RPC handler list for use with service integration bus-enabled Web services.

Before you begin

You can only add previously-configured handlers to a handler list. To configure a handler, see Creating a new JAX-RPC handler configuration.

About this task

Handlers monitor messages at ports, and take appropriate action depending upon the sender and content of each message. To enable handlers to perform more complex operations, you chain them together into handler lists. The approach taken in WebSphere Application Server is to apply handler lists (rather than individual handlers) at the ports, where each handler list contains one or more handlers.

To create a new JAX-RPC handler list, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Web services** → **JAX-RPC Handler Lists**. The JAX-RPC handler lists collection form is displayed.
2. Click **New**. The JAX-RPC handler lists settings form is displayed.
3. Type the following general properties:

Name Type the name by which the handler list is known.

This name must be unique, and it must obey the following syntax rules:
- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

For example `TestList`.

Description
Type the (optional) description of the handler list.

JAX-RPC handlers
In the JAX-RPC handlers pane, complete the following steps:
a. Select one or more handlers from the list of available JAX-RPC handlers, then click **Add** to move the selected handlers into the list of handlers for this JAX-RPC handler list.
b. Select a handler in the list of handlers for this JAX-RPC handler list, then click **Up** or **Down** to change the position of the handler within the list.

Handlers are applied in the sequence in which they appear in the handler list.

Note: If you click **Reset**, only the **Name** and **Description** fields are reset to their state when the form was first loaded. The two lists of available and assigned handlers are not reset.

4. Click **OK**. The general properties for this item are saved.
5. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of handler lists is updated to include the new handler list. Otherwise, an error message is displayed.

What to do next

To use this handler list, select it for use with a Web service as described in "Modifying an existing inbound service configuration" on page 1011 or "Modifying an existing outbound service configuration" on page 1016.

Modifying an existing JAX-RPC handler list:

A Java API for XML-based remote procedure calls (JAX-RPC) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. Modify the configuration details for a JAX-RPC handler list that has been configured for use with service integration bus-deployed Web services.

Before you begin

You can only add previously-configured handlers to a handler list. To configure a handler, see Creating a new JAX-RPC handler configuration.

About this task

Handlers monitor messages at ports, and take appropriate action depending upon the sender and content of each message. To enable handlers to perform more complex operations, you chain them together into handler lists. The approach taken in WebSphere Application Server is to apply handler lists (rather than individual handlers) at the ports, where each handler list contains one or more handlers.

To list the existing handler lists, and to view and modify their configuration details, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Web services** → **JAX-RPC Handler Lists**. A list of all the handler lists is displayed in a JAX-RPC handler lists collection form.
2. Click the name of a handler list in the list. The current JAX-RPC handler lists settings for this handler are displayed.
3. Modify the following general properties:
   Name Modify the name of the handler list.

   This name must be unique, and it must obey the following syntax rules:
   - It must not start with "." (a period).
   - It must not start or end with a space.
   - It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

   When you change a handler list name, the system looks up all objects that refer to it and updates the name.

   Description
   Modify the (optional) description of the handler list.

   JAX-RPC handlers
   In the JAX-RPC handlers pane, complete the following steps:
   a. Select one or more previously-configured handlers from either the list of available JAX-RPC handlers or the list of handlers for this JAX-RPC handler list, then click **Add** or **Remove** to modify the list of handlers for this JAX-RPC handler list.
   b. Select a handler in the list of handlers for this JAX-RPC handler list, then click **Up** or **Down** to change the position of the handler within the list.

   Handlers are applied in the sequence in which they appear in the handler list.

   Note: If you click **Reset**, only the **Name** and **Description** fields are reset to their state when the form was first loaded. The two lists of available and assigned handlers are not reset.
4. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of handler lists is redisplayed. Otherwise, an error message is displayed.

What to do next

To use this handler list, select it for use with a Web service as described in "Modifying an existing inbound service configuration" on page 1011 or "Modifying an existing outbound service configuration" on page 1016.

Deleting JAX-RPC handler lists:

A Java API for XML-based remote procedure calls (JAX-RPC) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. Delete JAX-RPC handler lists that are configured for use with service integration bus-deployed Web services.

About this task

When you remove a handler list that is currently used by one or more Web services on a service integration bus, the system removes the handler list for each associated Web service.

To remove one or more handler lists, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Web services** → **JAX-RPC Handler Lists**. A list of handler lists is displayed in a JAX-RPC handler lists collection form.

2. Select the check box for every handler list that you want to remove.
3. Click **Delete**.

Results

If the processing completes successfully, the list of handler lists is updated. Otherwise, an error message is displayed.

Sending Web service messages directly over the bus from a JAX-RPC client:
About this task

Java API for XML-based remote procedure calls (JAX-RPC) client applications send and receive Web service request and response messages. JAX-RPC client applications using the IBM JAX-RPC run-time environment can do this in a number of different ways, depending on the bindings in the WSDL document that they are developed against, and the configuration data that is used at run time.

For an introduction to basic JAX-RPC programming concepts, including the JAX-RPC client and server programming models, see Getting Started with JAX-RPC.

If you want to use a JAX-RPC client to send messages over the service integration bus, you have two choices:

- Use a SOAP binding (SOAP over HTTP or SOAP over JMS), and pass messages indirectly through an endpoint listener to an inbound service. You would do this if you had SOAP-specific JAX-RPC handlers that must run in the client application context.
- Pass messages directly into the service integration bus at a destination by “retargeting” the JAX-RPC client application as described in this topic.

  Note: There are currently limitations regarding the Java types used by services that are retargeted through a JAX-RPC client application.

Retargeting involves setting the following two values into the client application deployment descriptor, or specifying them dynamically at run time from within the client application:

- The *binding namespace* is set to indicate that the client uses the messaging bus directly.
- The *endpoint address* is set to include the particular destination and (optionally) the format of messages that the client uses.

The destination also needs to be configured so that it knows the port type of messages that the JAX-RPC client is using. There are two ways to achieve this:

- Create an outbound service. An outbound service represents an externally-provided Web service. In this case, requests from the JAX-RPC client pass through the service destination and are then sent on to the service provider defined by the outbound service configuration.
- Create an inbound service. An inbound service represents a service provided somewhere within or beyond the messaging bus. You can create an inbound service on any existing destination. The creation of an inbound service associates a WSDL port type with the destination. When retargeting to a destination with an inbound service, the client application needs to specify both the destination name and inbound service name, because it is possible to configure more than one inbound service against a single destination. In this case, requests from the JAX-RPC client pass through the destination and then onwards through the service integration bus depending on routing that is done at the initial destination.

To have Web service messages sent directly to a destination using a JAX-RPC client, complete the following steps:

1. Create the JAX-RPC client application.
2. Create the outbound service or inbound service with which you want the JAX-RPC client application to exchange messages.

3. Use the administrative console to access the port information for your JAX-RPC client application, as described in Configuring Web service client bindings and Web services client port information.
4. Override the default SOAP binding for your JAX-RPC client application. Change the binding namespace to `http://www.ibm.com/ns/2004/02/wsdl/mp/sib`
5. Override the endpoint that your JAX-RPC client application uses to send Web service requests. The new endpoint should use the sib: URL syntax and include either the outbound service destination name, or both the inbound service name and its corresponding destination name.

What to do next

After you change the *binding namespace*, any JAX-RPC handler lists that were configured for the retargeted port are ignored. For clients that are developed against WSDL with a SOAP binding, retargeting directly to the bus causes the handlers to be ignored. However if the client is developed against the non-bound WSDL for the service, retargeting to the bus is not considered to be changing the binding namespace, and so the handler information is retained. In this case the JAX-RPC handlers are called with the SDOMessageContext subclass.

Associated reference information:

- "sib: URL syntax"

sib: URL syntax:

The `sib:` URL has the following syntax:

`sib:/[destination|path]?property_1=value_1&property_2=value_2&...`

where:

- Square brackets ("[ ]") indicate that a parameter is optional.
- Transport type is `sib:`, followed by either `/destination` to specify destination type or `/path` to specify a forward routing path, followed by a "query string" that contains one or more properties. The permitted properties are described in the subsequent sections of this topic.

Required properties

The following properties are required. They are used to specify the destination for the request.

Note: All destination names must be fully-qualified. That is, they must include the name of the service integration bus as well as the destination name itself. Use the syntax *bus:destination*. If a bus or destination name contains a colon or comma, wrap the name in double quotation marks (""). If it contains a double quotation mark, repeat the quotation mark.

destinationName
The destination name.

path The forward routing path, in the form of a sequence of destination names separated by commas.

replyDestinationName
The name of the destination to be used for the reply.

inboundService
The name of the inbound service that identifies the specific attachment that the requester application uses. You can omit this value if the destination is a service destination with an associated outbound service configuration, because in that case the requester is attaching to the outbound service through the service destination.

timeout
The time the requester waits for a response. The default value is 60 seconds. A zero value indicates an unlimited wait.

Service integration technologies-related properties

The following properties are optional. If you do not specify a value for a property, then the default value is used. For more information regarding the permitted values for these properties, see the generated API information for the SIMessage interface.

reliability
The reliability of the request message.

timeToLive
The amount of time (in milliseconds) before the request times out. A zero value indicates that the request never times out.

Note: The **timeout** property (see the required properties) is the time delay after which the requester application blocks the application thread that is waiting for a response to a request and response operation. The **time to live** and **replyTimeToLive** optional properties indicate how long the request and reply messages should be processed by the messaging engines. This does not include the processing time at the service implementation. You would therefore usually set the timeout to be the sum of the request and response times to live, plus some amount for the service processing time.

priority
The priority of the request message.

user
The user ID required to access the request destination.

password
The password required to access the request destination.

replyReliability
The reliability of the reply message.

replyTimeToLive
The amount of time (in milliseconds) before the reply times out. A zero value indicates that the reply never times out.

replyPriority
The priority of the reply message.

Other properties

You can also include user-defined properties in the URL. These properties must be named with a `user.` prefix. For example:

```
sib:/destination?destinationName=myBus:myDestination & reliability=assured & user.customData=XYZ
```

After the request is sent, the URL itself is available within the message properties, named `inbound.url`.

Implementing JAX-RPC handlers to access SDO messages:

JAX-RPC handlers are invoked during processing of request and response messages. For messages that are exchanged using the SOAP protocol, each JAX-RPC handler is passed a SOAP-specific `MessageContext` object. For other protocols, the IBM Web services runtime environment passes a `MessageContext` object that provides a Service Data Objects view of the message. Service Data Objects (SDO) is an open standard for enabling applications to handle data from different data sources in a uniform way, as DataGraphs.

If the JAX-RPC handler only deals with message context properties, then it does not need to be aware of the particular subclass of `MessageContext` that it is given, because the context property methods are defined by the `MessageContext` interface itself. If the handler needs to process information contained within

the message, then it must be coded to work with the required subclasses. It is recommended that your JAX-RPC handlers test whether the `MessageContext` is an instance of the required subclass.

A JAX-RPC handler is given an SDO-specific `MessageContext` object (an instance of the `com.ibm.websphere.webservices.handler.sdo.SDOMessageContext` class) rather than the SOAP-specific `MessageContext` object in the following cases:

- A JAX-RPC client or outbound invocation from the service integration bus invokes a service using the EJB binding.
- A JAX-RPC client is developed against a non-bound WSDL and is retargeted to a destination in the service integration bus.

The `SDOMessageContext` class provides methods to get and set the `com.ibm.websphere.sdo.SDOMessage` instance that represents the actual message being processed. The `SDOMessage` in turn has a method to access the SDO DataGraph object that holds the message content as SDO DataObjects.

A JAX-RPC handler can modify the SDO DataGraph contents, but it cannot change the format or schema of the message.

Here is an example of the code that is used to access the SDO DataGraph from the `MessageContext` object in a JAX-RPC handler `handleRequest` method:

```
public boolean handleRequest(MessageContext messageContext) {

  // Convert the MessageContext into an SDOMessageContext
  if( messageContext instanceof SDOMessageContext) {
   SDOMessageContext smc = (SDOMessageContext)messageContext;

   // Retrieve the message
   SDOMessage message = smc.getSDOMessage();

   // Get the root object in the SDO DataGraph
   DataGraph graph = message.getDataGraph();
   DataObject content = graph.getRootObject();

   // Now do something with the message content.....
  }
  return true;
 }
```

Working with mediations

Use a mediation to change the content of a message, or the way in which a message is handled.

Before you begin

For an introduction to using mediations with the service integration bus, see Learning about mediations.

About this task

A mediation is an application that contains a mediation handler. You associate a mediation with a service integration bus destination, and the mediation acts on messages that pass through the destination. The action taken by a mediation depends upon the specific instructions you give in the mediation handler. For example, you can use a mediation to change the contents of a message, or to choose a particular forward route for a message.

To write a mediation application that contains a mediation handler, install it into WebSphere Application Server and associate it with a bus destination, complete the following steps:

1. Create the mediation application. For examples of how to do this, see:
   - Writing a routing mediation

- Writing a mediation that maps between attachment encoding styles

2. Install the mediation application into WebSphere Application Server.
3. Create the associated mediation object in the bus.

   Note: The **handler list name** is the name you gave to your handler when you defined the handler class as a mediation handler.
4. Mediate the destination. Use the administrative console to access the destination that you want to mediate, then select your mediation from the list of available mediations.

Creating a new UDDI reference

Create a reference (a pointer) to a UDDI registry for use with service integration bus-enabled Web services.

Before you begin

This topic assumes that you have already created a J2C authentication alias for each *Authorized Name* that you want to associate with this UDDI reference. For more information about *Authorized Names*, see UDDI registries: Web service directories that can be referenced by bus-enabled Web services.

About this task

A UDDI reference is a pointer to a UDDI registry. This registry can be a private UDDI registry such as the IBM WebSphere UDDI Registry, or a public UDDI registry. The service integration technologies interact with UDDI registries in two ways:

- When you configure an inbound service, you can create entries for the Web service in one or more UDDI registries.
- When you configure an outbound service, you specify the location of the target WSDL file that describes the Web service. This WSDL file can be located at a URL or through a UDDI registry.

In the UDDI model, Web services are owned by businesses, and businesses are owned by Authorized Names. Each UDDI reference gives access to the Web services that are owned by a single Authorized Name in a single UDDI registry. For more information about how the service integration technologies work with UDDI registries, see UDDI registries: Web service directories that can be referenced by bus-enabled Web services and Publishing a Web service to a UDDI registry. For more general information about UDDI and UDDI registries, see the UDDI community at uddi.org.

To create a new UDDI reference, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Web services** → **UDDI References**. The UDDI references collection form is displayed.
3. Click **New**. The UDDI references settings form is displayed.
4. Type the following general properties:

   Name Type the name by which the UDDI reference is known. This name must be unique, and it must follow the following syntax rules:
   - It must not start with "." (a period).
   - It must not start or end with a space.
   - It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

   You might need more than one UDDI reference for a given UDDI registry. For more information, see UDDI registries: Web service directories that can be referenced by bus-enabled Web services.

   Description
   Type the (optional) description of the UDDI reference.

   Inquiry URL
   Type the Web address that provides access to this registry for the SOAP inquiry API.

Publish URL

Type the Web address that provides access to this registry for the SOAP publish API.

Authentication alias

Type the J2C authentication alias for the User ID and password of an “Authorized Name” that has update access to this registry.

The alias you enter here must match the user ID of the owner of the corresponding business in the UDDI registry. You can see the owning user ID in UDDI by looking at the business details under the “Authorized Name” field. If the alias you enter here does not match the “Authorized Name” value for the business that owns the service, then the service is not published or found.

If the business has more than one “Authorized Name”, you might want to set up multiple UDDI references (each with a different authentication alias) to the same UDDI registry.

5. Click **OK**.

Results

If the processing completes successfully, the list of UDDI references is updated to include the new UDDI reference. Otherwise, an error message is displayed.

What to do next

To use this UDDI reference, select it when “Making an internally-hosted service available as a Web service” on page 1009 or “Making an externally-hosted Web service available internally” on page 1014.

Modifying an existing UDDI reference:

Modify the configuration details for a UDDI reference that has been configured for use with service integration bus-enabled Web services.

About this task

A UDDI reference is a pointer to a UDDI registry. This registry can be a private UDDI registry such as the IBM WebSphere UDDI Registry, or a public UDDI registry. The service integration technologies interact with UDDI registries in two ways:

- When you configure an inbound service, you can create entries for the Web service in one or more UDDI registries.
- When you configure an outbound service, you specify the location of the target WSDL file that describes the Web service. This WSDL file can be located at a URL or through a UDDI registry.

To list the UDDI references, and to view and modify their configuration details, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Web services** → **UDDI References**. A list of UDDI references is displayed in a UDDI references collection form.
3. Click the name of a UDDI reference in the list. The current UDDI reference settings for this UDDI reference are displayed.
4. Modify the following general properties:
   Name Modify the name of the UDDI reference.

   This name must be unique, and it must obey the following syntax rules:
   - It must not start with “.” (a period).
   - It must not start or end with a space.
   - It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

Note: When you change a UDDI reference name, the system looks up all objects that refer to it and updates the name.

Description

Modify the (optional) description of the UDDI reference.

Inquiry URL

Type the new Web address that provides access to this registry for the SOAP inquiry API.

Publish URL

Type the new Web address that provides access to this registry for the SOAP publish API.

Authentication alias

Type the new J2C authentication alias for the User ID and password of an "Authorized Name" that has update access to this registry.

The alias you enter here must match the user ID of the owner of the corresponding business in the UDDI registry. You can see the owning user ID in UDDI by looking at the business details under the "Authorized Name" field. If the alias you enter here does not match the "Authorized Name" value for the business that owns the service, then the service is not published or found.

If the business has more than one "Authorized Name", you might want to set up multiple UDDI references (each with a different authentication alias) to the same UDDI registry.

5. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of UDDI references is redisplayed. Otherwise, an error message is displayed.

What to do next

To use this UDDI reference, select it when "Making an internally-hosted service available as a Web service" on page 1009 or "Making an externally-hosted Web service available internally" on page 1014.

Deleting UDDI references:

delete UDDI references that are configured for use with service integration bus-deployed Web services.

About this task

When you remove a UDDI reference that is currently used by one or more Web services on a service integration bus, the system removes the UDDI reference for each associated Web service and makes any necessary updates in the associated UDDI registry.

To remove UDDI references, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Web services** → **UDDI References**. A list of UDDI references is displayed in a UDDI references collection form.
3. Select the check box for every UDDI reference that you want to remove.
4. Click **Delete**.

Results

If the processing completes successfully, the list of UDDI references is updated. Otherwise, an error message is displayed.

Publishing a Web service to a UDDI registry:

When you configure an inbound or outbound service, you enable UDDI interaction by associating the service with a UDDI reference, and (depending upon what you are trying to do) either or both of the following pieces of information: The *business key* that identifies the UDDI business category under which you want your service to appear in the UDDI registry, and the service-specific part of the *service key* that the UDDI registry assigns to your service. To help you understand what UDDI business keys and service keys are, and where you find them in a UDDI registry, here is a description of how to publish a Web service to a UDDI registry.

About this task

Service integration technologies interact with UDDI registries as described in UDDI registries: Web service directories that can be referenced by bus-enabled Web services. When you publish a Web service to a UDDI registry, you:

- Specify the type of business that your Web service supports. This usually means choosing an existing business type from a list, but you can also create a new business type. For each type of business there is an associated business key. Service integration bus-enabled Web services use this key, in combination with the service key, to find the Web service in the registry.
- Add a Technical model. Technical models are generic categories. Using these models, a UDDI registry user can search for a type of service, rather than needing to know the access details for a specific service. Bus-enabled Web services interact with UDDI registries at the level of individual Web services, and therefore do not use Technical models.
- Add the Web service. The UDDI registry assigns a service key to your service, and publishes the service. Bus-enabled Web services use this key, in combination with the business key, to find the Web service in the registry.

The following steps describe how you publish a Web service to the IBM WebSphere UDDI Registry. If you are working with a different UDDI registry, then the specific navigation is different but the underlying principles are the same.

1. Specify a business:
   a. To get a list of valid business keys, look up `businesses` in the UDDI registry. Here is an example of a UDDI business key:

      ```
      08A536DC-3482-4E18-BFEC-2E2A23630526
      ```

      .
   b. If you do not find an appropriate existing business in the UDDI registry, then use the **Add a business** option on the **Advanced Publish** section of the Publish pane to add a new one.
2. Add a technical model:
   a. Select **Add a technical model** on the **Advanced Publish** section of the Publish pane.
   b. Enter the name as specified for the target namespace of your binding (or interface) WSDL file, then add a description (if required).
   c. Add a category of Type `unspsc` and value `wsdlSpec` (the Key name field can be left blank).
   d. Add an overview URL specifying the Web address for your binding WSDL file, then add a description (if required).

      Note: The binding and the service definition for your Web service might be held in separate WSDL files, therefore be careful to type the Web address of the WSDL file that defines the *binding*.
   e. Click **Publish Technical Model**.
3. Add a service:
   a. Select **Show owned entities** on the **Advanced Publish** section of the Publish pane.
   b. Select **Add a Service** for your business.
   c. Enter the name as specified for the target service in your WSDL file, then add a description (if required).

d. For the **Access point** verify that the correct Web address type is selected (for example `http` for an HTTP access point), then enter the value of the `soap:address` location (or its equivalent) from your service definition WSDL file (for example `http://yourhost:80/SimpleTest/servlet/rpcrouter`).
e. For the **Technical model** select **Add**, then find the required Technical model by entering a suitable prefix and selecting **Find technical models**, then enable the check box for the required Technical model and click **Update**.
f. Click **Publish Service**.

Results

The UDDI registry assigns a service key to your service, and publishes the service.

What to do next

After the service has been published you can get the service key from the target UDDI registry.

Here is an example of a full UDDI service key:

```
uddi:blade108node01cell:blade108node01:server1:default:6e3d106e-5394-44e3-be17-aca728ac1791
```

The service-specific part of this key is the final part:

```
6e3d106e-5394-44e3-be17-aca728ac1791
```

Creating a new WS-Security binding

Create a new WS-Security binding for use with service integration bus-enabled Web services. You use WS-Security bindings to secure the SOAP messages that pass between service requesters (clients) and inbound services, and between outbound services and target Web services.

Before you begin

Use this option to create WS-Security bindings that comply with either the Web Services Security (WS-Security) 1.0 specification, or the previous WS-Security specification, WS-Security Draft 13 (also known as the Web Services Security Core Specification).

Note: Use of WS-Security Draft 13 was deprecated in WebSphere Application Server Version 6.x. You should only use Draft 13 bindings to enable inter-operation between applications running in WebSphere Application Server Version 5.1 and Version 7.0, or to allow continued use of an existing Web services client application that is written to the WS-Security Draft 13 specification.

This topic assumes that you have got, from the owning parties, the WS-Security bindings for the client (in the case of an inbound service) and the target Web service (in the case of an outbound service).

You can only use WS-Security with Web service applications that comply with the *Web services for Java Platform, Enterprise Edition (Java EE)* or *Java Specification Requirements (JSR) 109* specification. For more information, see Web services security and Java Platform, Enterprise Edition security relationship. For information about how to make your Web service applications JSR-109 compliant, see Developing and deploying JAX-RPC Web services clients or Developing and deploying JAX-WS Web services clients .

About this task

WS-Security bindings provide the information that the run-time environment needs to implement the WS-Security configuration (for example “To sign the body, use this key”), You receive this security binding information direct from the service requester or target service provider, in the form of an `ibm-webservicesclient-bnd.xmi` file for the client, and an `ibm-webservices-bnd.xmi` file for the target Web service. You extract the information from these `.xmi` files, then manually enter it into the WS-Security bindings forms.

Bindings are administered independently from any Web service that uses them, so you can create a binding then apply it to many Web services.

WebSphere Application Server also includes a set of default WS-Security binding objects, as described in Default bindings and runtime properties for Web services security. However, if you are using either of the single server products WebSphere Application Server or WebSphere Application Server Express, then these default bindings are configured within the application server, and are not available for use with bus-enabled Web services.

Unlike most other configuration objects, when you create a WS-Security binding you can only define its basic aspects. To define the binding details you need to save the new binding, then reopen it for modification as described in Modifying an existing WS-Security binding.

To create a new WS-Security binding, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Web services** → **WS-Security bindings**. The WS-Security bindings collection form is displayed.
3. Click **New**. The New WS-Security binding wizard is displayed.
4. Use the wizard to assign the following general properties:
   a. Select the version of the WS-Security specification. Set this option to either Draft 13 (for a binding that complies with the WS-Security Draft 13 specification) or 1.0 (for a binding that complies with the Web Services Security (WS-Security) 1.0 specification.

      Note: Use of WS-Security Draft 13 was deprecated in WebSphere Application Server Version 6.x. You should only use Draft 13 bindings to enable inter-operation between applications running in WebSphere Application Server Version 5.1 and Version 7.0, or to allow continued use of an existing Web services client application that is written to the WS-Security Draft 13 specification.

   b. Specify the binding type.

      Set this option to one of the following binding types:

      For WS-Security Version 1.0:

      - *request consumer*, for use when consuming requests from a client to an inbound service.
      - *request generator*, for use when generating requests from an outbound service to a target Web service.
      - *response consumer*, for use when consuming responses from a target Web service to an outbound service.
      - *response generator*, for use when generating responses from an inbound service to a client.

      For WS-Security Draft 13:

      - *request receiver*, for use when receiving requests from a client to an inbound service.
      - *request sender*, for use when sending requests from an outbound service to a target Web service.
      - *response receiver*, for use when receiving responses from a target Web service to an outbound service.
      - *response sender*, for use when sending responses from an inbound service to a client.

   c. Specify the WS-Security binding.

      Give a name to this binding. This name must be unique and it must follow the following syntax rules:

      - It must not start with “.” (a period).
      - It must not start or end with a space.
      - It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

(WS-Security 1.0 bindings only. Optional.) Select the **Use defaults** check box to create a convenient default binding for use in a development and test environment. If you select this option, the binding uses the WebSphere Application Server default set of binding information rather than any custom information that you might subsequently add. Note however that this default binding is by definition insecure, and is not for production use. You can also select or clear this check box when you modify an existing WS-Security binding.

Note: If you are creating a WS-Security 1.0 request generator binding, the Web address for the WS-Security 1.0 namespace is displayed in a selection list. This is the namespace used by WS-Security 1.0 to send a request, and you should not need to change this value. The other values included in the selection list refer to namespaces used by earlier versions of the WS-Security draft specification, and are included for backwards compatibility.

5. Click **Finish**. The general properties for this item are saved.

Results

If the processing completes successfully, the list of WS-Security bindings is updated to include the new binding. Otherwise, an error message is displayed.

What to do next

You are now ready to define the binding details as described in "Modifying an existing WS-Security binding."

Modifying an existing WS-Security binding

You can add or modify the configuration details for a WS-Security binding that is configured for use with service integration bus-enabled Web services. You use WS-Security bindings to secure the SOAP messages that pass between service requesters (clients) and inbound services, and between outbound services and target Web services.

About this task

WS-Security bindings provide the information that the run-time environment needs to implement the WS-Security configuration (for example "To sign the body, use this key"). You receive this security binding information direct from the service requester or target service provider, in the form of an `ibm-webservicesclient-bnd.xmi` file for the client, and an `ibm-webservices-bnd.xmi` file for the target Web service. You extract the information from these `.xmi` files, then manually enter it into the WS-Security bindings forms.

Bindings are administered independently from any Web service that uses them, so you can create a binding then apply it to many Web services.

To list the WS-Security bindings, and to view and modify their configuration details, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Web services** → **WS-Security bindings**. A list of WS-Security bindings is displayed in a WS-Security bindings collection form.

   Each available binding is flagged as one of the following binding types:

   For WS-Security Version 1.0:

   - *request consumer*, for use when consuming requests from a client to an inbound service.
   - *request generator*, for use when generating requests from an outbound service to a target Web service.
   - *response consumer*, for use when consuming responses from a target Web service to an outbound service.

- *response generator*, for use when generating responses from an inbound service to a client.

For WS-Security Draft 13:

- *request receiver*, for use when receiving requests from a client to an inbound service.
- *request sender*, for use when sending requests from an outbound service to a target Web service.
- *response receiver*, for use when receiving responses from a target Web service to an outbound service.
- *response sender*, for use when sending responses from an inbound service to a client.

Each available binding is also flagged as complying with either the Web Services Security (WS-Security) 1.0 specification or the WS-Security Draft 13 specification.

Note: Use of WS-Security Draft 13 was deprecated in WebSphere Application Server Version 6.x. You should only use Draft 13 bindings to enable inter-operation between applications running in WebSphere Application Server Version 5.1 and Version 7.0, or to allow continued use of an existing Web services client application that is written to the WS-Security Draft 13 specification.

3. Click the name of a WS-Security binding in the list. The current settings for this WS-Security binding are displayed.
4. Modify the configuration details for this WS-Security binding. For detailed reference information about each value that you can set, click on the associated link in the following tables:

WS-Security 1.0 request consumer	WS-Security 1.0 request generator
• Signing information • Encryption information • Token consumers • Key information • Key locators • Collection certificate store • Trust anchors • Properties	• Signing information • Encryption information • Token generators • Key information • Key locators • Collection certificate store • Properties

WS-Security 1.0 response generator	WS-Security 1.0 response consumer
• Signing information • Encryption information • Token generators • Key information • Key locators • Collection certificate store • Properties	• Signing information • Encryption information • Token consumers • Key information • Key locators • Collection certificate store • Trust anchors • Properties

WS-Security Draft 13 request receiver	WS-Security Draft 13 request sender
• Signing information • Encryption information • Trust anchors • Collection certificate store • Key locators • Trusted ID evaluators • Login mappings	• Signing information • Encryption information • Key locators • Login binding

WS-Security Draft 13 response sender	WS-Security Draft 13 response receiver
• Signing information • Encryption information • Key locators	• Signing information • Encryption information • Trust anchors • Collection certificate store • Key locators

5. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of WS-Security bindings is redisplayed. Otherwise, an error message is displayed.

Deleting WS-Security bindings

Delete WS-Security bindings that are configured for use with service integration bus-deployed Web services.

About this task

When you remove a WS-Security binding that is currently used by one or more Web services on a service integration bus, the system removes the WS-Security binding for each associated Web service. To remove WS-Security bindings, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Web services** → **WS-Security bindings**. A list of WS-Security bindings is displayed in a WS-Security bindings collection form.
3. Select the check box for every WS-Security binding that you want to remove.
4. Click **Delete**.

Results

If the processing completes successfully, the list of WS-Security bindings is updated. Otherwise, an error message is displayed.

Creating a new WS-Security configuration

Create a new WS-Security configuration for use with service integration bus-deployed Web services. You use WS-Security configurations to secure the SOAP messages that pass between service requesters (clients) and inbound services, and between outbound services and target Web services.

Before you begin

Use this option to work with WS-Security configurations that comply with either the Web Services Security (WS-Security) 1.0 specification, or the previous WS-Security specification, WS-Security Draft 13 (also known as the Web Services Security Core Specification).

Note: Use of WS-Security Draft 13 was deprecated in WebSphere Application Server Version 6.x. You should only use Draft 13 bindings to enable inter-operation between applications running in WebSphere Application Server Version 5.1 and Version 7.0, or to allow continued use of an existing Web services client application that is written to the WS-Security Draft 13 specification.

This topic assumes that you have got, from the owning parties, the WS-Security configurations for the client (in the case of an inbound service) and the target Web service (in the case of an outbound service).

You can only use WS-Security with Web service applications that comply with the *Web services for Java Platform, Enterprise Edition (Java EE)* or *Java Specification Requirements (JSR) 109* specification. For more information, see Web services security and Java Platform, Enterprise Edition security relationship. For information about how to make your Web service applications JSR-109 compliant, see Developing and deploying JAX-RPC Web services clients or Developing and deploying JAX-WS Web services clients .

About this task

WS-Security configurations specify the level of security that you require (for example “The body must be signed”). This level of security is then implemented through the run-time information contained in a WS-Security binding. You receive the security configuration information direct from the service requester or target service provider, in the form of an `ibm-webservicesclient-ext.xmi` file for the client, and an `ibm-webservices-ext.xmi` file for the target Web service, which contain the information on the levels of security (integrity, confidentiality and identification) that are required. You extract the information from these `.xmi` files, then manually enter it into the WS-Security configuration forms.

Configurations are administered independently from any Web service that uses them, so you can create a configuration then apply it to many Web services. However, the security requirements for an inbound service (which acts as a target Web service) are significantly different to those required for an outbound service (which acts as a client). Consequently, configurations are further divided by service type (inbound or outbound).

Unlike most other configuration objects, when you create a WS-Security configuration you can only define its basic aspects. To define the details you save the new WS-Security configuration, then reopen it for modification as described in “Modifying an existing WS-Security configuration” on page 1050.

To create a new WS-Security configuration, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Web services** → **WS-Security configurations**. The WS-Security service configurations collection form is displayed.
3. Click **New**. The New WS-Security Service Configuration wizard is displayed.
4. Use the wizard to assign the following general properties:
   a. Select the version of the WS-Security specification. Set this option to either Draft 13 (for a configuration that complies with the WS-Security Draft 13 specification) or 1.0 (for a configuration that complies with the Web Services Security (WS-Security) 1.0 specification.

      Note: Use of WS-Security Draft 13 was deprecated in WebSphere Application Server Version 6.x. You should only use Draft 13 bindings to enable inter-operation between applications running in WebSphere Application Server Version 5.1 and Version 7.0, or to allow continued use of an existing Web services client application that is written to the WS-Security Draft 13 specification.

   b. Specify the service type. If you are creating a configuration to secure the SOAP messages that pass between a service requester (client) and an inbound service (which acts as a target Web service), select Inbound Service. If you are creating a configuration to secure the SOAP messages that pass between an outbound service (which acts as a client) and a target Web service, select Outbound Service.
   c. Specify the WS-Security configuration type.

      Give a name to this configuration. This name must be unique across both WS-Security Version 1.0 and Draft 13 configurations, and it must follow the following syntax rules:

      - It must not start with “.” (a period).
      - It must not start or end with a space.
      - It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

(Optionally) Specify an Actor URI for this configuration. WS-Security headers within the consumed request message are only processed if they have the specified Actor URI.

5. Click **Finish**. The general properties for this item are saved.

Results

If the processing completes successfully, the list of WS-Security configurations is updated to include the new configuration. Otherwise, an error message is displayed.

What to do next

You are now ready to define the configuration details as described in "Modifying an existing WS-Security configuration."

Modifying an existing WS-Security configuration

You can add or modify the configuration details for a WS-Security configuration that is configured for use with service integration bus-enabled Web services. You use WS-Security configurations to secure the SOAP messages that pass between service requesters (clients) and inbound services, and between outbound services and target Web services.

About this task

WS-Security configurations specify the level of security that you require (for example "The body must be signed"). This level of security is then implemented through the run-time information contained in a WS-Security binding. You receive the security configuration information direct from the service requester or target service provider, in the form of an `ibm-webservicesclient-ext.xmi` file for the client, and an `ibm-webservices-ext.xmi` file for the target Web service, which contain the information on the levels of security (integrity, confidentiality and identification) that are required. You extract the information from these `.xmi` files, then manually enter it into the WS-Security configuration forms.

Configurations are administered independently from any Web service that uses them, so you can create a configuration then apply it to many Web services. However, the security requirements for an inbound service (which acts as a target Web service) are significantly different to those required for an outbound service (which acts as a client). Consequently, configurations are further divided by service type (inbound or outbound).

To list the WS-Security configurations, and to view and modify their configuration details, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Web services** → **WS-Security configurations**. A list of WS-Security configurations is displayed in a WS-Security service configurations collection form.

   Each available configuration is flagged as either `Inbound` or `Outbound`. You use an inbound configuration to secure the SOAP messages that pass between a service requester (client) and an inbound service (which acts as a target Web service). You use an outbound configuration to secure the SOAP messages that pass between an outbound service (which acts as a client) and a target Web service.

   Each available configuration is also flagged as complying with either the Web Services Security (WS-Security) 1.0 specification or the WS-Security Draft 13 specification.

   Note: Use of WS-Security Draft 13 was deprecated in WebSphere Application Server Version 6.x. You should only use Draft 13 bindings to enable inter-operation between applications running in WebSphere Application Server Version 5.1 and Version 7.0, or to allow continued use of an existing Web services client application that is written to the WS-Security Draft 13 specification.
3. Click the name of a WS-Security configuration in the list. The current settings for this WS-Security configuration are displayed.

4. Modify the configuration details for this WS-Security configuration. For detailed reference information about each value that you can set, click on the associated link in the following table:

WS-Security 1.0 inbound configuration	WS-Security 1.0 outbound configuration
Request consumer • Required integrity – Message parts – Nonce – Time stamp • Required confidentiality – Message parts – Nonce – Time stamp • Required security token • Caller – Trust method - Properties – Properties • Add time stamp – Properties • Properties **Response generator** • Actor • Integrity – Message parts – Nonce – Time stamp • Confidentiality – Message parts – Nonce – Time stamp • Security Token • Add time stamp – Properties • Properties	**Request generator** • Actor • Integrity – Message parts – Nonce – Time stamp • Confidentiality – Message parts – Nonce – Time stamp • Security Token • Add time stamp – Properties • Properties **Response consumer** • Required integrity – Message parts – Nonce – Time stamp • Required confidentiality – Message parts – Nonce – Time stamp • Required security token • Caller – Trust method - Properties – Properties • Add time stamp – Properties • Properties

WS-Security Draft 13 inbound configuration	WS-Security Draft 13 outbound configuration
Request receiver • Required integrity • Required confidentiality • Login configuration – Custom authentication methods • ID assertion • Add received time stamp • Properties	**Request sender** • Actor • Integrity • Confidentiality • Login configuration • ID assertion • Add created time stamp • Properties
Response sender • Actor • Integrity • Confidentiality • Add created time stamp • Properties	**Response receiver** • Required integrity • Required confidentiality • Add received time stamp • Properties

5. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of WS-Security configurations is redisplayed. Otherwise, an error message is displayed.

Deleting WS-Security configurations

Delete WS-Security configurations that are configured for use with service integration bus-enabled Web services.

About this task

When you remove a WS-Security configuration that is currently used by one or more Web services on a service integration bus, the system removes the WS-Security configuration for each associated Web service. To remove WS-Security configurations, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Web services** → **WS-Security configurations**. A list of WS-Security configurations is displayed in a WS-Security service configurations collection form.
3. Select the check box for every WS-Security configuration that you want to remove.
4. Click **Delete**.

Results

If the processing completes successfully, the list of WS-Security configurations is updated. Otherwise, an error message is displayed.

Passing SOAP messages with attachments through the service integration bus

The service integration technologies support Web services that use a SOAP binding to pass attachments in a MIME message.

Before you begin

See the restrictions detailed in Limitations in the support for SOAP with attachments.

About this task

The service integration bus supports SOAP messages that contain either old-style attachments (as described in the SOAP Messages with Attachments W3C Note) or attachments that use the Web Services-Interoperability (WS-I) Attachments Profile Version 1.0 (subject to the Limitations in the support for SOAP with attachments).

Attachments are carried through the service integration bus and passed to the inbound or outbound service. The content MIME type of each attachment is preserved. When the external target service for an outbound service is deployed to a Java API for XML-based Remote Procedure Call (JAX-RPC) compliant server, you can access the attachments on the target service using the `javax.activation.DataHandler` handler.

If the bus receives a message that contains attachments, and the bus subsequently rewrites the message, then the generated message uses the same attachment style as the received message. If you need to transform attachments from one style to another, you can use a mediation to modify the message.

For more information, see the following topics:

- "SOAP Messages with Attachments: WSDL examples" on page 1054
- "Supporting bound attachments: WSDL examples" on page 1054
- "Locating an attachment using swaref"
- Writing a mediation that maps between attachment encoding styles

Locating an attachment using swaref

About this task

When a Web Services-Interoperability (WS-I) Attachments Profile Version 1.0 message uses a SOAP with attachments reference (swaref) to refer to an attachment, the swaref might refer to either bound or non-bound attachments, and the swaref might refer to a single attachment several times. To enable you to locate the correct attachment, service integration technologies stores the value of the URI that is encoded in the message within the SDO data graph for the message body.

When storing the value of an element (or attribute) of type swaref in the data graph, service integration technologies stores the complete URI from the message instance. Therefore when you retrieve the URI you need to remove `cid:` from the beginning of the retrieved value to find the Content ID of the referenced attachment.

Example

The following example shows how to use the value of a swaref element to locate the correct attachment. This example uses the RPC/Literal WSDL and SOAP message from section 4.4 of Web Services-Interoperability (WS-I) Attachments Profile Version 1.0:

```
DataObject infoNode = graph.getRootObject().getDataObject("info");
String contentId = infoNode.getString("body/ClaimDetail/ClaimForm");

// Cut off the "cid:" part of the string
contentId = contentId.substring(4);

// Locate the value of the attachment
DataObject attachmentEntry =
    infoNode.getDataObject("attachments[contentId=" + contentId + "]");
byte[] data = attachmentEntry.getBytes("data");
```

SOAP Messages with Attachments: WSDL examples
Example

The following example WSDL illustrates a simple operation that has one attachment called `attch`:

```
<binding name="MyBinding" type="tns:abc" >
  <soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/http"/>
  <operation name="MyOperation">
    <soap:operation soapAction=""/>
    <input>
      <mime:multipartRelated>
        <mime:part>
          <soap:body parts="part1 part2 ..." use="encoded" namespace="http://mynamespace"
            encodingStyle="http://schemas.xmlsoap.org/soap/encoding"/>
        </mime:part>
        <mime:part>
          <mime:content part="attch" type="text/html"/>
        </mime:part>
      </mime:multipartRelated>
    </input>
  </operation>
</binding>
```

In this type of WSDL extension:

- There must be a `part` attribute (in this example `attch`) on the input message for the operation (in this example `MyOperation`). There can be other input parts to `MyOperation` that are not attachments.
- In the binding input there must either be a `<soap:body>` tag or a `<mime:multipartRelated>` tag, but not both.
- For MIME messages, the `<soap:body>` tag is inside a `<mime:part>` tag. There must only be one `<mime:part>` tag that contains a `<soap:body>` tag in the binding input and that must not contain a `<mime:content>` tag as well, because a content type of `text/xml` is assumed for the `<soap:body>` tag.
- There can be multiple attachments in a MIME message, each described by a `<mime:part>` tag.
- Each `<mime:part>` tag that does not contain a `<soap:body>` tag contains a `<mime:content>` tag that describes the attachment itself. The `type` attribute inside the `<mime:content>` tag is not checked or used by the service integration bus. It is there to suggest to the application using the service integration bus what the attachment contains. Multiple `<mime:content>` tags inside a single `<mime:part>` tag means that the back end service expects a single attachment with a type specified by one of the `<mime:content>` tags inside that `<mime:part>` tag.
- The `parts="..."` attribute inside the `<soap:body>` tag is assumed to contain the names of all the SOAP parts in the message, but not the attachment parts. If there are only attachment parts, specify `parts=""` (empty string). If you omit the `parts` attribute altogether, then the service integration bus assumes ALL parts including the attachments - which causes the attachments to appear twice.

In your WSDL you might have defined a schema for the attachment (for instance as a `binary[]`). The service integration technologies silently ignore this mapping and treat the attachment as a Data Handler.

You do not need to mention unreferenced attachments in the WSDL bindings.

Supporting bound attachments: WSDL examples
About this task

Web Services-Interoperability (WS-I) Attachments Profile Version 1.0 defines a convention for constructing the Content ID for a bound attachment. This convention encodes the message part name. Consequently, service integration technologies can recognize a bound attachment whether or not the SOAP body contains elements representing that message part. The convention for constructing a Content ID is as follows:

name=uuid@domain

where *name* is the name of the message part that is being encoded, *uuid* is a globally unique identifier, and *domain* is a domain identifier (for example `my.example.com`).

Note: This approach differs from the SOAP Messages with Attachments encoding scheme, which does not define a conventions for the Content ID but does use elements within the SOAP body to indicate that the message part is encoded as an attachment.

In order to distinguish between the cases, service integration technologies assumes that if a message attachment follows the Version 1.0 convention for constructing the Content ID, then it is a Version 1.0 message.

Example

The following WSDL fragment is for a bound attachment, with message instances that follow both styles:

```
<wsdl:binding name="BoundSoapBinding" type="intf:BoundPortType">
    <soap:binding style="rpc"
                  transport="http://schemas.xmlsoap.org/soap/http"/>
    <wsdl:operation name="bound">
      <soap:operation soapAction=""/>
      <wsdl:input>
        <mime:multipartRelated>
          <mime:part>
            <soap:body parts="stringIn" namespace="http://bound"
                       use="literal"/>
          </mime:part>
          <mime:part>
            <mime:content part="attachIn" type="text/xml"/>
          </mime:part>
        </mime:multipartRelated>
      </wsdl:input>
```

The following WSDL fragment is for a SOAP instance using Version 1.0 encoding. In this fragment, the message body contains no mention of the `attachIn` part, and the Content ID of the attachment identifies the part that is being encoded.

```
--myBoundary
Content-Type: text/xml
Content-Transfer-Encoding: 7bit
Content-Id: <myStartID>

<SOAP-ENV:Envelope
 xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">
  <SOAP-ENV:Body>
    <ns0:bound xmlns:ns0="http://bound">
      <stringIn>some string data</stringIn>
    </ns0:bound>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>

--myBoundary
Content-Type: text/xml
Content-Transfer-Encoding: 7bit
Content-Id: <attachIn=someUUID@some.domain.name>

<someOtherXMLElement/>
--myBoundary--
```

The following WSDL fragment is for a SOAP instance using SOAP Messages with Attachments encoding. In this fragment, the message body does contain a reference to the bound attachment, and the Content ID of the attachment is not constrained.

```
--myBoundary
Content-Type: text/xml
Content-Transfer-Encoding: 7bit
```

```
Content-Id: <myStartID>

<SOAP-ENV:Envelope
 xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">
  <SOAP-ENV:Body>
    <ns0:bound xmlns:ns0="http://bound">
      <stringIn>some string data</stringIn>
      <attachIn href="cid:notTheStart"/>
    </ns0:bound>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>

--myBoundary
Content-Type: text/xml
Content-Transfer-Encoding: 7bit
Content-Id: <notTheStart>

<someOtherXMLElement/>
--myBoundary--
```

In the previous two cases there is sufficient information in the message to identify the bound attachment, and in both cases service integration technologies places a bound attachment entry in the attachments list, and places the data from the attachment into the body section of the data graph.

Using WS-Notification for publish and subscribe messaging for Web services

WS-Notification enables Web services to use the “publish and subscribe” messaging pattern.

About this task

You use publish and subscribe messaging to publish one message to many subscribers. In this pattern a producing application inserts (publishes) a message (event notification) into the messaging system having marked it with a topic that indicates the subject area of the message. Consuming applications that have subscribed to the topic in question, and have appropriate authority, all receive an independent copy of the message that was published by the producing application.

Through the implementation of WS-Notification in WebSphere Application Server, you can achieve the following goals:

- Leverage existing service integration technologies and Web services components to deliver WS-Notification functionality.
- Interoperate with other publish and subscribe messaging clients (for example Java Message Service (JMS), WebSphere MQ) and with alternative message brokering products.

For more information about using WS-Notification, see the following topics:

- “Learning about WS-Notification” on page 1059
- “Accomplishing common WS-Notification tasks” on page 1057
- “Configuring WS-Notification resources” on page 1079
- “Securing WS-Notification” on page 1066
- Developing applications that use WS-Notification

What to do next

Note:

- For development use on a single server only, you can use a script to configure the necessary resources to get up and running quickly with WS-Notification.

- In WebSphere Application Server Version 6.1, support for WS-Notification is based on a pre-final approval public review draft of the WS-Notification standards. In Version 7.0, this support is extended to cover the final approved standards. The differences between the two versions of the standards are small, and your existing WS-Notification services and client applications will continue to work unchanged. However, you might choose to upgrade your existing applications as described in Enabling WebSphere Application Server Version 6.1 client applications to handle the additional error conditions introduced in the final Version 1.3 WS-Notification standards.

Accomplishing common WS-Notification tasks

The specific steps that you need to perform to implement the most common WS-Notification tasks. For some tasks the steps are subdivided by role, and each sub-task gives the steps that are completed by either the solution architect, the system administrator or the application developer.

About this task

In the following list the sub-tasks are grouped by role. For more information about the roles, see "WS-Notification roles and goals."

- "Solution architect" on page 1058 sub-tasks:
  - "Learning about WS-Notification" on page 1059.
  - Selecting a hardware and software product combination for the enterprise that supports the WS-Notification standards.
  - Designing a server topology to host the applications, in accordance with particular WS-Notification topologies.
- "System administrator" on page 1058 sub-tasks:
  - "Using a script to get up and running quickly with WS-Notification" on page 1059.
  - "Configuring a WS-Notification service for use only by WS-Notification applications" on page 1063.
  - "Providing access for WS-Notification applications to an existing bus topic space" on page 1065.
  - "Securing WS-Notification" on page 1066.
  - "Configuring JAX-WS handlers" on page 1068.
  - "Applying a JAX-WS handler list to a WS-Notification service" on page 1068.
  - "Configuring a Version 7.0 WS-Notification service with Web service QoS" on page 1070.
  - "Configuring WS-Notification for reliable notification" on page 1071.
  - "Migrating a Version 6.1 WS-Notification configuration from WebSphere Application Server Version 6.1 to Version 7.0" on page 1073.
  - "Preparing a migrated Version 6.1 WS-Notification configuration for reliable notification" on page 1073.
  - "Interacting at run time with WS-Notification" on page 1077.
  - "Publishing the WSDL files for a WS-Notification application to a ZIP file" on page 1079.
- "Application developer" on page 1059 sub-tasks:
  - Developing applications that use WS-Notification
  - Writing a WS-Notification application that exposes a Web service endpoint.
  - Writing a WS-Notification application that does not expose a Web service endpoint.
  - Filtering the message content of publications.

WS-Notification roles and goals

This topics lists a set of computing roles that members of your organization might perform, and explains how you can use WS-Notification to help meet the goals of each role.

For a general description of each of the following roles, see WebSphere Application Server roles and goals.

Enterprise architect

IT environments are currently evolving towards the following concepts:

- Service Oriented Architecture (SOA)
- Enterprise Service Bus (ESB)

The goal of the enterprise architect might be to guide their organization towards appropriate utilization of these concepts to maximize the efficiency and responsiveness of the business as a whole.

WS-Notification enables publish and subscribe communication patterns (such as a stock ticker) to be exposed using Web services in an SOA environment. This is done through open standards, enabling straightforward replacement of the service implementation. It promotes easy exchange of data between suppliers and customers through use of standard Web service operations and prevents vendor lock-in or adoption of proprietary standards.

WebSphere Application Server also allows WS-Notification to be used as an on- or off-ramp to an ESB, providing seamless interchange of data between different types of client connected to the bus.

Solution architect

The main goal of the solution architect is to design a solution that supports the specification set by the enterprise architect. This might include providing an environment in which Web service applications can participate in publish and subscribe messaging patterns. This participation might also include the requirement to be able to exchange event notifications between Web service clients and other clients of the enterprise service bus.

To create a design, the solution architect completes the following broad steps:

- Learn about the support provided for WS-Notification in WebSphere Application Server.
- Select a hardware and software product combination for the enterprise that supports the WS-Notification standards.
- Design a server topology to host the applications, in accordance with the particular WS-Notification topologies that are to be implemented.

System administrator

For the specific steps that the system administrator performs to help implement common WS-Notification tasks, see the following topics:

- “Using a script to get up and running quickly with WS-Notification” on page 1059.
- “Configuring a WS-Notification service for use only by WS-Notification applications” on page 1063.
- “Providing access for WS-Notification applications to an existing bus topic space” on page 1065.
- “Securing WS-Notification” on page 1066.
- “Configuring JAX-WS handlers” on page 1068.
- “Applying a JAX-WS handler list to a WS-Notification service” on page 1068.
- “Configuring a Version 7.0 WS-Notification service with Web service QoS” on page 1070.
- “Configuring WS-Notification for reliable notification” on page 1071.
- “Migrating a Version 6.1 WS-Notification configuration from WebSphere Application Server Version 6.1 to Version 7.0” on page 1073.
- “Preparing a migrated Version 6.1 WS-Notification configuration for reliable notification” on page 1073.
- “Interacting at run time with WS-Notification” on page 1077.
- “Publishing the WSDL files for a WS-Notification application to a ZIP file” on page 1079.

Application developer

If the solution architect specifies a requirement to insert event notifications into the system (that is publish messages) or receive event notifications from the system as a result of creating a subscription containing an interest profile, then the application developer can use WS-Notification to meet this requirement.

There are various patterns of producing and consuming application defined by WS-Notification that are available for use by the application developer, depending upon the exact requirements of the application in question. These options are explored in the following common WS-Notification tasks:

- Writing a WS-Notification application that exposes a Web service endpoint.
- Writing a WS-Notification application that does not expose a Web service endpoint.

See also Developing applications that use WS-Notification and Filtering the message content of publications.

Learning about WS-Notification

WS-Notification enables Web services to use the “publish and subscribe” messaging pattern. Use these topics to learn more about WS-Notification.

About this task

You use publish and subscribe messaging to publish one message to many subscribers. In this pattern a producing application inserts (publishes) a message (event notification) into the messaging system having marked it with a topic that indicates the subject area of the message. Consuming applications that have subscribed to the topic in question, and have appropriate authority, all receive an independent copy of the message that was published by the producing application.

To learn about the WS-Notification implementation in WebSphere Application Server, see the following topics:

- WS-Notification: Overview
- WS-Notification: Benefits
- WS-Notification and end-to-end reliability
- WS-Notification terminology
- WS-Notification: How client applications interact at runtime
- WS-Notification: Supported bindings
- WS-Notification and policy set configuration
- Reasons to create multiple WS-Notification services in a bus
- Reasons to create multiple WS-Notification service points
- Options for associating a permanent topic namespace with a bus topic space
- WS-Notification topologies

Using a script to get up and running quickly with WS-Notification

Use a jython script to configure the necessary resources to get up and running quickly with WS-Notification in WebSphere Application Server.

Before you begin

The example script provided in this topic is intended for development use on a single server only, and not for use in production or network deployment environments.

About this task

You can use the example script to configure a default set of resources that enable you to connect WS-Notification applications for development purposes. When executed, the script takes the following actions:

1. It searches in the configuration for an existing service integration bus, and creates one if necessary.
2. It searches for an existing bus member, and if one is not found it adds the (standalone) server to the bus, using the default data source.
3. It searches for an existing service integration bus topic space destination, and creates one if necessary.
4. It creates a Version 6.1 or Version 7.0 WS-Notification service.
5. It creates a Version 6.1 or Version 7.0 WS-Notification service point on the local server for a SOAP over HTTP binding.
6. It creates a WS-Notification permanent topic namespace to reference the service integration bus topic space that was found or created in step 3.
7. It saves the configuration, and describes where to find the WSDL for the new notification broker Web service that has been exposed.

To use the example script, complete the following steps:

1. Save the script to the file system using a name of your choice (for example `wsnQuickStart.py`).
2. Modify the *hostRoot* variable defined at the top of the script to point to the HTTP port of the local server (usually 9080).
3. Install and configure the SDO repository.
4. Start the server, then execute the following command. If you saved the script with a name other than `wsnQuickStart.py`, then use that name instead.

   ```
   wsadmin -f wsnQuickStart.py
   ```

Example

Here is the example script:

```
#############################################################################
# WS-Notification QuickStart script                                         #
#                                                                           #
# This Jython script will quickly create the basic resources required in order to     #
# start using WS-Notification in WebSphere Application Server Version 6.1 or later    #
#                                                                           #
# Before executing it you must modify the variables defined below to match your       #
# configuration settings.                                                   #
#                                                                           #
# Note:                                                                     #
#    - This script is not intended for production use, and is intended for use on     #
#      a standalone server (not network deployment) only.                   #
#    - The script will search the configuration for an existing bus, and if one is    #
#      not found then a new bus will be created                             #
#    - It will then look for an existing Bus Member on the chosen bus. If one is not  #
#      found then one will be created using the default File Store           #
#    - It will then look for an existing service integration bus topic space. If one  #
#      is not found then it will create one.                                #
#                                                                           #
# Execute the script by typing;                                             #
#   wsadmin -f wsnQuickStart.py                                             #
#                                                                           #
#############################################################################

#########################################################
# Configuration variables                               #
```

```
#                                                           #

Configuring a WS-Notification service for use only by WS-Notification applications

Define all the necessary objects to configure a WS-Notification service and associated service points.

Before you begin

This task assumes that you have already configured one or more application servers, and that there are no other messaging resources configured..

For Version 6.1 WS-Notification services, you must also create an endpoint listener configuration on each application server that you want to use to host a WS-Notification service.

About this task

You can configure one or more servers, each hosting a WS-Notification service to which Web services applications can connect, as described in the Simple Web services topology.

1. Use the information given in “Creating a bus” on page 1139 to create a service integration bus and add your existing server or servers as bus members. When you add a bus member, a messaging engine is created in the server. You choose the database that hosts the persistent storage required by the messaging engine. You can either use the default JDBC data source and Apache Derby JDBC provider, or you can configure a data source for use with your preferred database product.
2. Using the administrative console, navigate to **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services**. The WS-Notification services [Collection] form for this bus is displayed.
3. Click **New**. The “New WS-Notification service” wizard is displayed.
4. Complete steps 1 to 4 of the wizard, as described in “Creating a new Version 6.1 WS-Notification service” on page 1089 or “Creating a new Version 7.0 WS-Notification service” on page 1081. Pay particular attention to the following settings:
   - In wizard step 1: “Configure name, description, service integration bus and dynamic topic namespace settings”, you select the service integration bus to use to host the messaging resources. Choose the bus that you created at the beginning of this task.
   - In wizard step 4: “Create WS-Notification service points”, you select the bus member that is to host the new service. On a single server system there is only one option here. For Version 6.1 WS-Notification services, you also select the endpoint listener application to use to expose the service. Choose the endpoint listener application that you configured before you began this task.
5. Optional: In wizard step 5: “Create permanent topic namespaces”, configure the WS-Notification topic namespace to provide access to a service integration bus topic space:
   - Enter the topic namespace URI that you want WS-Notification applications to use when referring to the service integration bus topic space. This must be unique within the WS-Notification service, and is conventionally a URI related to your organization. For example `http://www.myorganization.com`.
   - Because there are no existing service integration bus topic spaces in your bus the “Use an existing service integration bus topic space” radio button and associated selection list are unavailable. To create a new bus topic space, enter your chosen name.
6. Complete wizard step 6: “Summary”.

   Check that the summary of the actions taken by the wizard is as you expected, then click **Finish**. If the processing completes successfully, the list of WS-Notification services is updated to include the new WS-Notification service. Otherwise, an error message is displayed.
7. Save your changes to the master configuration. You do not need to restart the server for these changes to take effect. However, you do need to start the endpoint listener or enterprise application associated with the service point that was created in step 4 of the wizard.

What to do next

For Version 7.0 WS-Notification services, you can view the URL to which WS-Notification applications connect by looking in the NotificationBroker.WSDL file for the NotificationBroker application. To view this file, see “Publishing the WSDL files for a WS-Notification application to a ZIP file” on page 1079.

For Version 6.1 WS-Notification services, you can view the URL to which WS-Notification applications connect by navigating to **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name*** → **NotificationBroker inbound port settings**.

To extend this configuration so that Web service applications can interact with non-Web service applications, see “Providing access for WS-Notification applications to an existing bus topic space.”

Providing access for WS-Notification applications to an existing bus topic space

Configure a solution such that Web services clients can share event notifications with other clients of a service integration bus.

Before you begin

This task assumes that you have an existing service integration bus, configured with at least one bus member and a bus topic space. For more information, see “Creating a bus” on page 1139.

About this task

This task focuses on the “Create permanent topic namespaces” step that is part of the “New WS-Notification service” wizard.

You can configure WS-Notification so that Web service applications receive event notifications generated by other clients of the service integration bus such as JMS clients. Similarly, Web service applications can generate notifications to be received by other client types. This configuration is described in the Topology for WS-Notification as an entry or exit point to the service integration bus. You achieve this configuration by creating a permanent topic namespace that allows messages to be shared between Web service and non-Web service clients of the bus. Specifically, you create a permanent topic namespace that links the service integration bus topic space used by messaging clients to a WS-Notification topic namespace URI.

For more information about programming the client applications, including example code for cross-streaming from a JMS client, see Sharing event notification messages with other bus client applications.

1. Start the administrative console.
2. Navigate to **Service integration** → **WS-Notification** → **Services** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services**. The WS-Notification services [Collection] form is displayed.
3. Click **New**. The “New WS-Notification service” wizard is displayed.
4. Complete steps 1 to 4 of the wizard, as described in “Creating a new Version 6.1 WS-Notification service” on page 1089 or “Creating a new Version 7.0 WS-Notification service” on page 1081.
5. In wizard step 5:“ Create permanent topic namespaces”, configure the WS-Notification topic namespace to provide access to the existing service integration bus topic space:
   - Enter the topic namespace URI that you want WS-Notification applications to use when referring to the service integration bus topic space. This must be unique within the WS-Notification service, and is conventionally a URI related to your organization. For example `http://www.myorganization.com`.
   - Enable the “Use an existing service integration bus topic space” radio button, then choose the name of your chosen service integration bus topic space from the selection list.
6. Complete wizard step 6: “Summary”.

   Check that the summary of the actions taken by the wizard is as you expected, then click **Finish**. If the processing completes successfully, the list of WS-Notification services is updated to include the new WS-Notification service. Otherwise, an error message is displayed.
7. Save your changes to the master configuration. You do not need to restart the server for these changes to take effect. However, you do need to start the endpoint listener or enterprise application associated with the service point that was created in step 4 of the wizard.

Results

WS-Notification applications can now connect to the WS-Notification service point and insert or receive event notifications from the service integration bus topic space.

What to do next

For Version 7.0 WS-Notification services, you can view the URL to which WS-Notification applications connect by looking in the NotificationBroker.WSDL file for the NotificationBroker application. To view this file, see “Publishing the WSDL files for a WS-Notification application to a ZIP file” on page 1079.

For Version 6.1 WS-Notification services, you can view the URL to which WS-Notification applications connect by navigating to **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name*** → **NotificationBroker inbound port settings**.

Securing WS-Notification

The WS-Notification security implementation requires that a user identity is flowed in requests for WS-Notification services. This identity is used to authenticate the client application and check that the client is authorized to invoke the requested operation, and to access the underlying service integration bus topic spaces and topic resources.

About this task

WS-Notification uses the same mechanisms as other Web services to provide an authenticated identity. For example WS-Security or HTTP Basic Authentication.

There are three parts to configuring secure access to WS-Notification:

- Securing the communication channel between the application and the server.
- Authorizing the application to invoke the NotificationBroker.
- Authorizing the application to access the resources of the service integration bus.

If messaging security is enabled, and the WS-Security or HTTP Basic Authentication components are not configured to flow a user identity in WS-Notification requests, then all such requests are treated as unauthenticated and can only access messaging resources that are accessible by the WebSphere Application Server “everyone” group.

1. Secure the communication between the application and the server:
   a. Provide security for inbound requests and associated responses by configuring the WS-Notification service point.
      - For Version 7.0 WS-Notification service points, attach security-enabled policy sets to the application associated with the service point. For Version 6.1 WS-Notification service points, configure security for the inbound ports associated with the service point.
      - If you are using SOAP over HTTP as the binding for your WS-Notification service point, modify it to use SOAP over HTTPS as described in Configuring secure access to WS-Notification service points using SOAP over HTTPS.
      - If you are using SOAP over JMS as the binding (for Version 6.1 WS-Notification services), configure the JMS connection factory used by the client application to use a secure communication protocol to communicate with the JMS provider. Exactly how you do this depends upon the JMS provider. If you are using the service integration bus as the JMS provider, configure the client to use SSL to communicate with the server by setting the **target inbound transport chain** to `InboundSecureMessaging` as described in How JMS applications connect to a messaging engine on a bus and its related tasks.
   b. Provide security for outbound requests (for example notifications from the server to subscribed consumers) by configuring the WS-Notification service.

- For Version 7.0 WS-Notification services, the steps involved are similar to those for applying security to JAX-WS Web service clients except that any binding or configuration created is applied to the WS-Notification service. For more information, see Securing JAX-WS Web services using message level security.
- For Version 6.1 WS-Notification services, the steps involved are similar to those for applying security to service integration bus-enabled Web services outbound ports except that any binding or configuration created is applied to the WS-Notification service. For more information, see Securing bus-enabled Web services and its sub-topics, notably Invoking outbound services over HTTPS.

c. You can also use WS-Security to sign or encrypt SOAP messages.
- For Version 7.0 WS-Notification services, see Signing and encrypting message parts using policy sets.
- For Version 6.1 WS-Notification services, see Configuring secure transmission of SOAP messages using WS-Security.

2. Authorize the application to invoke the NotificationBroker:

a. Configure the client application to provide an appropriate identity.

To authorize a Web service application to communicate with the server, the application must identify itself as running as a particular authenticated identity. The mechanism for doing this depends upon the type of Web service binding you are using:
- If you are using SOAP over HTTP Web service bindings, use either HTTP Basic Authentication or WS-Security to provide the authenticated identity.
- If you are using SOAP over JMS Web service bindings (for Version 6.1 WS-Notification services), use WS-Security to provide an authenticated identity.

b. Configure the server to authorize the client application identity to carry out the required operations.
- For Version 7.0 WS-Notification services, you can use Web services policy sets such as the “Username WS-I RSP default” or “Username WSSecurity default” policy sets to apply authorization to the Web services that are deployed in the enterprise application associated with a service point.
- For Version 6.1 WS-Notification services, you can apply authorization to the whole of an inbound service (for example the NotificationBroker endpoint of a WS-Notification service point) as described in Password-protecting inbound services, or configure authorization constraints independently for each Web service operation as described in Password-protecting a Web service operation.

3. Authorize the application to access the resources of the service integration bus.

Service integration bus security uses role-based authorization. When a user is assigned to a role, the user is granted all of the permissions that the role contains. By administering authorization permissions, you can control user access to a bus and to its resources when messaging security is enabled.

a. Authorize the application identity to be able to connect to the service integration bus, as described in “Administering the bus connector role” on page 1282.

b. When the application can connect to the bus, grant the application access to the appropriate destinations on the bus.

You can determine which service integration bus topic spaces are required, by checking which WS-Notification topic namespaces are used by the application then looking at the appropriate WS-Notification permanent topic namespace to find the service integration bus topic space to which it maps. You can then grant authorization (for example the Sender or Receiver roles) for the authenticated identity to access that topic space as described in “Administering destination roles” on page 1241.

c. After the client application has been authorized to access the appropriate topic space destination, you might also need to authorize the client application to access the individual topics within the topic space destination as described in “Administering topic roles” on page 1302.

For general information about configuring access to the service integration bus, see bus security.

Configuring JAX-WS handlers

A JAX-WS handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. You can create JAX-WS handlers, chain them together in the form of a handler list, then apply the handler list to a Version 7.0 WS-Notification service point (for inbound invocation handling) or WS-Notification service (for outbound invocation handling).

About this task

The Java API for XML-based Web services (JAX-WS) provides you with a standard way of developing interoperable and portable Web services. To create a JAX-WS handler, you can use a tool such as IBM Rational Application Developer. To enable handlers to perform more complex operations, you chain them together into handler lists. You associate each handler list with one or more Version 7.0 WS-Notification services or service points, so that the handler list can monitor WS-Notification activity and take appropriate action depending upon the sender and content of each inbound or outbound message.

Detailed instructions on how to configure JAX-WS handlers and handler lists for use with Version 7.0 WS-Notification services are provided in the following topics:

- Load JAX-WS handler classes.
- Create a new JAX-WS handler configuration.
- Modify an existing JAX-WS handler configuration.
- Delete JAX-WS handler configurations.
- Create a new JAX-WS handler list.
- Modify an existing JAX-WS handler list.
- Delete JAX-WS handler lists.

Applying a JAX-WS handler list to a WS-Notification service

To handle the messages that flow to and from an existing Version 7.0 WS-Notification service, you create JAX-WS handlers, chain them together in the form of a handler list, then apply the handler list to a NotificationBroker, PublisherRegistrationManager or SubscriptionManager endpoint at a Version 7.0 WS-Notification service point (for inbound invocation handling), or apply the handler list to a WS-Notification service (for outbound invocation handling).

Before you begin

This task assumes that you have already created a Version 7.0 WS-Notification service.

About this task

To create a JAX-WS handler, you can use a tool such as IBM Rational Application Developer. To enable handlers to perform more complex operations, you chain them together into handler lists. You associate each handler list with one or more Version 7.0 WS-Notification services or service points, so that the handler list can monitor WS-Notification activity and take appropriate action depending upon the sender and content of each inbound or outbound message. For example:

- You can use a handler list on the NotificationBroker Web service to log all notification messages received by this service point.
- You can use a handler list on a SubscriptionManager Web service to log all unsubscribe requests received by this service point.
- You can use a handler list on a PublisherRegistrationManager Web service to log all publisher deregistration requests received by this service point.

1. Create one or more JAX-WS handlers. You can do this using IBM Rational Application Developer or a similar tool.
2. Load JAX-WS handler classes. A JAX-WS handler interacts with messages through a Version 7.0 WS-Notification service point (for inbound invocation handling) or WS-Notification service (for outbound invocation handling), therefore you need to make the handler class available to the server or cluster that hosts the WS-Notification service point or service that you want to monitor.
3. Create a new JAX-WS handler configuration by using the administrative console or by using the createJAXWSHandler command. By creating a new handler configuration, you make WebSphere Application Server aware of your handler, and you make the handler available for inclusion in one or more handler lists.
4. Create a new JAX-WS handler list. The approach taken in WebSphere Application Server is to assign handler lists (rather than individual handlers) to WS-Notification service points (for inbound invocation handling) or WS-Notification services (for outbound invocation handling).
5. Optional: To apply a JAX-WS handler list to a service provider endpoint (NotificationBroker, PublisherRegistrationManager or SubscriptionManager) associated with a service point, use the administrative console to complete the following substeps:
   a. Navigate to **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional Properties] WS-Notification service points** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points**. The WS-Notification service points [Collection] form is displayed. This form shows all the service points configured for this Version 7.0 WS-Notification service.
   b. In the content pane, click the name of a Version 7.0 WS-Notification service point in the list. The current settings for this Version 7.0 WS-Notification service point are displayed in the WS-Notification service points [Settings] form.
   c. Apply the JAX-WS handler list by selecting it from the list box for one or more of the following general properties:

      NotificationBroker JAX-WS handler list

      The JAX-WS handler list that is applied to inbound requests from an application to the NotificationBroker endpoint of the WS-Notification service point.

      SubscriptionManager JAX-WS handler list

      The JAX-WS handler list that is applied to inbound requests from an application to the SubscriptionManager endpoint of the WS-Notification service point.

      PublisherRegistrationManager JAX-WS handler list

      The JAX-WS handler list that is applied to inbound requests from an application to the PublisherRegistrationManager endpoint of the WS-Notification service point.
6. Optional: To apply a JAX-WS handler list to a WS-Notification service, use the administrative console to complete the following substeps:
   a. Navigate to **Service integration** → **WS-Notification** → **Services** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services**. The WS-Notification services [Collection] form is displayed.
   b. In the content pane, click the name of a Version 7.0 WS-Notification service in the list. The current settings for this Version 7.0 WS-Notification service are displayed in the WS-Notification services [Settings] panel.
   c. Apply the JAX-WS handler list by selecting it from the list box for the following general property:

      JAX-WS handler list

      The JAX-WS handler list that is applied to outbound requests from the WS-Notification service.

Configuring a Version 7.0 WS-Notification service with Web service QoS

You use the administrative console to configure Web service qualities of service (QoS) such as reliability or security by applying policy sets to a Version 7.0 WS-Notification service. The configuration of policy sets for WS-Notification can be split into two types: service provider (for Version 7.0 WS-Notification service points) and service client (for Version 7.0 WS-Notification service clients). Policy set configuration for these two elements of a WS-Notification service is handled differently.

Before you begin

This task assumes that you have already created a Version 7.0 WS-Notification service. You must also have configured policy sets that meet your quality of service requirements. You can reuse existing policy sets within your organization, use the default policy sets provided by WebSphere Application Server, or create new policy sets. For more information, see Managing policy sets using the administrative console.

About this task

Version 7.0 WS-Notification service points (NotificationBrokers, PublisherRegistrationManagers and SubscriptionManagers) are implemented as JAX-WS applications that are deployed to servers or clusters, and the management of the policy sets for these WS-Notification service points is configured using the policy set administrative infrastructure for service providers (both panels and wsadmin commands). In the Service provider [settings] panel for a WS-Notification service provider, there is a link to the associated WS-Notification service point application. You can use the service provider settings panel to attach policy sets to each NotificationBroker, PublisherRegistrationManager and SubscriptionManager.

Version 7.0 WS-Notification services are implemented as two configurable service clients (OutboundNotificationService and OutboundRemotePublisherService) for each WS-Notification service. Events that need outgoing Web service invocations occur at the service integration bus level rather than the bus member level, even though notifications of the events occur within a particular bus member. The two service clients that a WS-Notification service implements are therefore configured using the policy set administrative infrastructure for service clients. In the Service client policy sets and bindings [collection] panel, the two service clients for a given WS-Notification service are listed in a tree structure, along with their endpoints and operations. You can use this panel to attach policy sets to each service client, or to both service clients for the WS-Notification service.

1. Start the administrative console.
2. Navigate to **Service integration** → **WS-Notification** → **Services** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services**. The WS-Notification services [Collection] form is displayed.
3. In the content pane, click the name of the Version 7.0 WS-Notification service to which to apply Web service qualities of service. The current settings for this Version 7.0 WS-Notification service are displayed in the WS-Notification services [Settings] panel.
4. Optional: To configure Web service QoS for inbound requests, apply policy sets to the service provider applications (NotificationBroker, PublisherRegistrationManager and SubscriptionManager) associated with a service point:

   Click **[Additional Properties] WS-Notification service points**. The WS-Notification service points [Collection] form is displayed. This form shows all the service points configured for this Version 7.0 WS-Notification service.

   Repeat the following steps, as required, to configure the policy set and binding information for one or more service provider applications for one or more service points:

   a. In the content pane, click the name of a Version 7.0 WS-Notification service point in the list. The current settings for this Version 7.0 WS-Notification service point are displayed in the WS-Notification service points [Settings] form.

   b. Click **[Additional Properties] Policy set configuration.** A link to each of the service provider applications (NotificationBroker, PublisherRegistrationManager and SubscriptionManager) for this service point is displayed in the Service provider [Collection] form.

c. Click the name of one of the applications. An indented list of endpoints and operations for this service is displayed in the Service provider [settings] form.
d. Select one or more items in the list (service, endpoint or operations), then perform one of the three available operations on the items you have selected:
   - Attach policy set
   - Detach policy set
   - Assign binding

   For more information, see Managing policy sets using the administrative console.
e. Restart the service provider application.

   Note: When you modify an existing policy set that has already been associated with a WS-Notification service point, there is no need to restart the service provider application; this is done automatically by the policy set infrastructure.

5. Optional: To configure Web service QoS for outbound requests, apply policy sets to one or both of the Web service clients associated with the WS-Notification service:
   a. If necessary, navigate back to the WS-Notification services [Settings] panel for this Version 7.0 WS-Notification service.
   b. Click **[Additional Properties] Outbound request policy sets and bindings**. The two service clients for this WS-Notification service are listed in a tree structure, along with their endpoints and operations, in the Service client policy set and bindings [collection] form.
   c. Select one or both service clients, then perform one of the three available operations on the items you have selected:
      - Attach client policy set
      - Detach client policy set
      - Assign binding

      For WS-Notification service clients, policy set attachments are not supported at the endpoint (port) or operation level. Therefore endpoints or operations are not selectable, and are shown as inheriting any policy set or binding that is attached to the service client. For more information, see Managing policy sets using the administrative console.

      Note: Using the Service client policy set and bindings [collection] form, you can configure the policy set and binding information for both service clients for the selected service. Alternatively, you can configure the policy set and binding information for a single Version 7.0 WS-Notification service client by clicking **Services** → **Service clients** → ***ws-notification_service_client_name*** and using the WS-Notification service client [settings] panel. This panel also provides links to the associated service integration bus and WS-Notification service.
   d. Restart the application server.

Results

The WS-Notification service has been successfully enabled with the required Web service QoS.

Configuring WS-Notification for reliable notification

To ensure that WS-Notification Web service interactions are performed in a reliable way, you configure a Version 7.0 WS-Notification service, JAX-WS client, and JAX-WS based WS-Notification consumer Web service (through policy set functionality) to use WS-ReliableMessaging.

Before you begin

This task assumes that you have created a Version 7.0 WS-Notification service and service point, and that you have created two JAX-WS applications:

- A JAX-WS client application, created from the WSDL of the new service point.
- A JAX-WS based WS-Notification consumer Web service.

For more information about how to create these applications, see “Using JAX-WS clients and Web services with new Version 7.0 WS-Notification service points” on page 1076.

About this task

Reliable notification refers to the reliable transmission of messages to and from the IBM WS-Notification implementation. You enable this reliability to mitigate the problems inherent in network transmission protocols such as HTTP.

Note: This reliability does not include the behavior of the application server itself. For more information, see WS-Notification and end-to-end reliability.

To enable reliable notification, you apply policy sets that include the WS-ReliableMessaging policy to the service point, service client, and service consumer applications.

You can configure policy sets for JAX-WS clients for both application server and client environments, including thin clients. For more information, see Managing policy sets using the administrative console.

1. Configure policy sets that meet your reliable messaging requirements.

   You can reuse existing policy sets within your organization, use the WS-ReliableMessaging default policy sets provided by WebSphere Application Server, or create new policy sets. For more information, see Configuring a WS-ReliableMessaging policy set using the administrative console.
2. Configure the Version 7.0 WS-Notification service and service points for reliable notification.

   Apply policy sets that include the WS-ReliableMessaging policy.
3. Configure the JAX-WS based WS-Notification client application so that it interacts reliably with its target Web service using WS-ReliableMessaging.

   Apply policy sets that include the WS-ReliableMessaging policy, as described in “Configuring a Version 7.0 WS-Notification service with Web service QoS” on page 1070 and Attaching and binding a WS-ReliableMessaging policy set to a Web service application.
4. Configure the JAX-WS based WS-Notification consumer Web service application so that it interacts reliably with clients that attempt to communicate with it.

   Apply policy sets that include the WS-ReliableMessaging policy, as described in Attaching and binding a WS-ReliableMessaging policy set to a Web service application.
5. Configure the WS-Notification client application (which has been configured to interact reliably) to communicate with the WS-Notification service point (which has similarly been configured to receive messages reliably).
6. Prompt the WS-Notification client application to subscribe on behalf on the (reliably configured) WS-Notification consumer Web service.

   Note: The WS-Notification consumer Web service might also act as a client to perform its own subscription. This client would require additional policy set configuration if reliable interactions were required.
7. Initiate notification message publications from the WS-Notification client application.

Results

The Version 7.0 WS-Notification service point receives the notification messages in a reliable way from the WS-Notification client, and publishes the notification messages in a reliable way to the WS-Notification consumer Web service.

Migrating a Version 6.1 WS-Notification configuration from WebSphere Application Server Version 6.1 to Version 7.0

You can migrate an existing Version 6.1 WS-Notification configuration to run in a WebSphere Application Server Version 7.0 environment.

Before you begin

This topic assumes that you have the following configuration:

- An existing server or cluster installation of WebSphere Application Server Version 6.1 that is ready for migration, including at least one WS-Notification service, service point, and underlying service integration bus.
- Existing subscriptions with associated messages pending notification.
- Existing operational WS-Notification client and Web service applications that are known to transmit and receive notifications through the existing Version 6.1 WS-Notification service.

About this task

When you migrate your system from WebSphere Application Server Version 6.1 to Version 7.0, any existing WS-Notification configuration (for example WS-Notification services, service points, administered subscribers), and the associated service integration bus resources (for example inbound services and endpoint listeners) are automatically migrated to valid configuration elements within the new installation. The services and service points are migrated to Version 6.1 WS-Notification services and service points, the endpoint URLs for the service points are unchanged, and the functionality supported is exactly the same as in WebSphere Application Server Version 6.1. For example, reliable notification is not possible with Version 6.1 WS-Notification services and service points.

Any messages pending notification are delivered following the update and server startup sequence.

1. Migrate your product configuration from WebSphere Application Server Version 6.1 to Version 7.0.
2. Check that notifications are being published and consumed correctly in your migrated system.

   Initiate the program, process, or application that includes the WS-Notification client (or clients), and that causes notifications to be requested and transmitted.

Results

The WS-Notification services and resources are migrated to Version 6.1 WS-Notification services and resources that run under WebSphere Application Server Version 7.0. Any messages pending notification are delivered.

What to do next

You are now ready (optionally) to prepare your migrated Version 6.1 WS-Notification configuration for reliable notification.

Preparing a migrated Version 6.1 WS-Notification configuration for reliable notification

You can gradually introduce JAX-WS based client and provider entities such that a migrated Version 6.1 WS-Notification configuration is ready to be configured for reliable notification.

Before you begin

This topic assumes that you have an existing server or cluster installation of WebSphere Application Server Version 7.0, including at least one WS-Notification service, service point, and underlying service integration bus that has been migrated to this version of the product as described in “Migrating a Version 6.1 WS-Notification configuration from WebSphere Application Server Version 6.1 to Version 7.0.”

About this task

For reliable notification, you apply policy sets that include WS-ReliableMessaging to your WS-Notification configuration. You can only use policy sets with Java API for XML-based Web services (JAX-WS) applications, and with Version 7.0 WS-Notification services and service points.

The WS-Notification implementation in WebSphere Application Server Version 6.1 uses service integration bus-enabled Web services to expose the WS-Notification service endpoint, so that it can be invoked by applications and configured with specific attributes such as WS-Security or JAX-RPC handlers. However, the Version 6.1 implementation is not compatible with JAX-WS handlers or applications, and it cannot compose with WS-ReliableMessaging.

To prepare a migrated Version 6.1 WS-Notification configuration for reliable notification, you need to recreate your Version 6.1 WS-Notification services and service points as Version 7.0 WS-Notification services and service points, and recreate each JAX-RPC client application to which you want to apply a policy set as a JAX-WS application. Note that you can continue to use JAX-RPC applications with Version 7.0 WS-Notification services and service points, and that you only need to recreate those applications that need to work with policy sets.

For information about coding JAX-RPC and JAX-WS client applications to perform specific WS-Notification tasks, see Developing applications that use WS-Notification. You might also find it useful to learn about JAX-WS and the JAX-WS client programming model. This should help you to determine the effort involved in porting client code from JAX-RPC to JAX-WS, or to validate JAX-WS client to JAX-RPC Web service interoperability.

To support a phased approach to preparing for reliable notification, and to describe the four main configurations that you might want to achieve, this task is divided into four subtasks:

- "Using JAX-WS clients and Web services with migrated service points."
- "Using JAX-RPC clients and Web services with new Version 7.0 WS-Notification service points" on page 1075.
- "Using JAX-WS clients and Web services with new Version 7.0 WS-Notification service points" on page 1076.
- "Sharing notifications between Version 6.1 and Version 7.0 WS-Notification service points" on page 1077.

What to do next

When you have completed these subtasks, you have a collection of WS-Notification client and server entities that are prepared for reliable notification, and you are ready to configure WS-Notification for reliable notification.

Using JAX-WS clients and Web services with migrated service points:

1. Publish notification messages through a migrated Version 6.1 WS-Notification service point, from a JAX-WS client application.
   a. Create a JAX-WS WS-Notification client application using the WSDL of the migrated service point.

      For more information, see Example: Publishing a WS-Notification message, Developing a JAX-WS client from a WSDL file and "Publishing the WSDL files for a WS-Notification application to a ZIP file" on page 1079.
   b. Run the application.
   c. Initiate one or more notification messages.

   The system accepts and publishes the notification messages from the JAX-WS client.
2. Receive notification messages in a new JAX-WS based WS-Notification consumer application, from a migrated Version 6.1 WS-Notification service point.

This validates that your Version 6.1 WS-Notification service point can deliver notifications to a JAX-WS consumer Web service.

a. Create a new JAX-WS based WS-Notification consumer Web service from the standard WS-Notification WSDL.

   For more information, see Example: Subscribing a WS-Notification consumer, Developing Web services applications from existing WSDL files with JAX-WS and "Publishing the WSDL files for a WS-Notification application to a ZIP file" on page 1079.

b. Create a subscription for the new consumer service through the Version 6.1 WS-Notification service point.

c. Prompt the WS-Notification service point to generate notifications (for example using a WS-Notification client application).

The system transmits the notifications to the new JAX-WS consumer application correctly.

Using JAX-RPC clients and Web services with new Version 7.0 WS-Notification service points:

1. Create a new Version 7.0 WS-Notification service.

   You can configure a Version 7.0 WS-Notification service and service points with policy sets to compose with WS-ReliableMessaging for reliable notification. The system creates and configures a new Version 7.0 WS-Notification service. This includes the creation of a Version 7.0 WS-Notification service point that exposes the service from a particular service integration bus member. Version 6.1 and Version 7.0 WS-Notification service points can coexist in WebSphere Application Server Version 7.0.

2. Publish notification messages through the new Version 7.0 WS-Notification service point, from a JAX-RPC client application.

   This validates the behavior of the Version 7.0 WS-Notification service point.

   a. Create the application using the WSDL of the new Version 7.0 WS-Notification service point.

      For more information, see Example: Publishing a WS-Notification message, Developing client bindings from a WSDL file for a JAX-RPC client and "Publishing the WSDL files for a WS-Notification application to a ZIP file" on page 1079.

      Note: Instead of creating a new JAX-RPC client application, you might choose to update an existing JAX-RPC client application from the WSDL of the new service point. The WSDL for a Version 7.0 WS-Notification service point contains a number of minor changes compared to a Version 6.1 service point, so you need to modify your existing JAX-WS client application to take account of these changes. Specifically, you need to regenerate the java proxy classes from the WSDL, and update any use of class names and methods that have changed. For example, there might be changes in the generated classes that include a port type or service from the WSDL.

   b. Run the application.

   c. Initiate one or more notification messages.

   The system accepts and publishes the notification messages from the JAX-RPC client.

3. Receive notification messages in a JAX-RPC based WS-Notification consumer application, from the new Version 7.0 WS-Notification service point.

   This validates that your Version 7.0 WS-Notification service point can deliver notifications to a JAX-RPC consumer Web service.

   a. Create a new JAX-RPC based WS-Notification consumer Web service from the standard WS-Notification WSDL.

      For more information, see Example: Subscribing a WS-Notification consumer, Developing Web services applications from existing WSDL files with JAX-WS and "Publishing the WSDL files for a WS-Notification application to a ZIP file" on page 1079.

Note: Instead of creating a new JAX-RPC consumer application, you can use an existing JAX-RPC consumer application from (for example) a Version 6.1 WS-Notification configuration.

b. Create a subscription for the new consumer service through the new Version 7.0 WS-Notification service point.

c. Prompt the WS-Notification service point to generate notifications (for example using a WS-Notification client application).

The system transmits the notifications to the new JAX-RPC consumer application correctly.

Using JAX-WS clients and Web services with new Version 7.0 WS-Notification service points:
Before you begin

Note that with this configuration you can compose with policy sets for reliable notification.

1. Publish notification messages through the new Version 7.0 WS-Notification service point, from a JAX-WS client application.

   a. Create a JAX-WS WS-Notification client application using the WSDL of the new Version 7.0 WS-Notification service point.

      For more information, see Example: Publishing a WS-Notification message, Developing a JAX-WS client from a WSDL file and "Publishing the WSDL files for a WS-Notification application to a ZIP file" on page 1079.

      Note: Instead of creating a new JAX-WS client application, you might choose to update the JAX-WS client application that you created in the subtask "Using JAX-WS clients and Web services with migrated service points" on page 1074. The WSDL for a Version 7.0 WS-Notification service point contains a number of minor changes compared to a Version 6.1 service point, so you need to modify your existing JAX-WS client application to take account of these changes. Specifically, you need to regenerate the java proxy classes from the WSDL, and update any use of class names and methods that have changed. For example, there might be changes in the generated classes that include a port type or service from the WSDL.

   b. Run the application.

   c. Initiate one or more notification messages.

   The system accepts and publishes the notification messages from the JAX-WS client.

2. Receive notification messages in a new JAX-WS based WS-Notification consumer application, from a new Version 7.0 WS-Notification service point.

   This validates that your Version 7.0 WS-Notification service point can deliver notifications to a JAX-WS consumer Web service.

   a. Create a new JAX-WS based WS-Notification consumer Web service from the standard WS-Notification WSDL.

      For more information, see Example: Subscribing a WS-Notification consumer, Developing Web services applications from existing WSDL files with JAX-WS and "Publishing the WSDL files for a WS-Notification application to a ZIP file" on page 1079.

      Note: Instead of creating a new JAX-WS consumer application, you might choose to update the JAX-WS consumer application that you created in the subtask "Using JAX-WS clients and Web services with migrated service points" on page 1074. The WSDL for a Version 7.0 WS-Notification service point contains a number of minor changes compared to a Version 6.1 service point, so you need to modify your existing JAX-WS client application to take account of these changes. Specifically, you need to regenerate the java proxy classes from the WSDL, and update any use of class names and methods that have changed. For example, there might be changes in the generated classes that include a port type or service from the WSDL.

b. Create a subscription for the new consumer service through the new Version 7.0 WS-Notification service point.
c. Prompt the WS-Notification service point to generate notifications (for example using a WS-Notification client application).

The system transmits the notifications to the new JAX-WS consumer application correctly.

Sharing notifications between Version 6.1 and Version 7.0 WS-Notification service points:
About this task

You can configure WS-Notification so that notifications received through migrated Version 6.1 WS-Notification service points are published through the new Version 7.0 service. You might want to do this so that (for example) you can receive notifications through existing, unreliable connections then publish them through new connections made reliable through WS-ReliableMessaging. To enable this configuration, the new Version 7.0 WS-Notification service needs to use the same service integration bus topic space as the migrated Version 6.1 WS-Notification service. You use a permanent topic namespace to statically define the association between a WS-Notification topic namespace URI and a service integration bus topic space destination. You configure a permanent topic namespace as a property of a WS-Notification service.

1. Discover which bus topic spaces the migrated Version 6.1 WS-Notification service is using. If none, create a new permanent topic namespace to connect to a bus topic space. For more information, see “Modifying a Version 6.1 WS-Notification service” on page 1092.
2. Create a new permanent topic namespace for the new Version 7.0 WS-Notification service, that connects to the same bus topic space. For more information, see “Modifying a Version 7.0 WS-Notification service” on page 1085.

Results

Notifications received by either the new or migrated service point are now published to subscriptions made on either WS-Notification service.

Interacting at run time with WS-Notification

View (and in some cases delete) at run time the active items associated with WS-Notification service points.

Before you begin

This task assumes that you have a fully configured and operational WS-Notification service point.

About this task

A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified Web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. The existence of a WS-Notification service point on a bus member implies that a WS-Notification Web service is exposed from that bus member, and causes Web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

You can use the administrative console to interact at run time with the following active items associated with WS-Notification service points:

Publisher registrations
A runtime list of existing publisher registrations is provided. This includes, for each publisher registration, the information that was used to create it and when it will terminate.

Pull points
A runtime list is provided of the pull points that have been created. This includes, for each pull point, its current termination time and a link to the associated subscription.

Subscriptions
A runtime view is provided for subscriptions that have been created by applications. This includes, for each subscription, the information that was used to create it and an indication of its current state.

Administered subscribers
A runtime list is provided of the administered subscribers for a given WS-Notification service point. This includes, for each administered subscriber, an indication of its current state; for example whether the subscription was successfully initialized at start time.

For each WS-Notification service point, runtime information is available for subscriptions, registrations, pull points and administered subscribers. **For each WS-Notification service**, runtime information is available - aggregated for all service points for the service - for subscriptions, registrations and pull points. There is no aggregated view for administered subscribers at the WS-Notification service level.

To access and use the runtime information for active items associated with WS-Notification service points, use the administrative console to complete the following steps:

1. Choose between information for a particular service point, or information aggregated for all service points for a particular service, by completing one of the following substeps:
   a. Optional: For runtime information for a particular service point, navigate to either **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name*** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name***, then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations, pull points and administered subscribers for this WS-Notification service point.
   b. Optional: For runtime information aggregated for all service points for a particular service, navigate to either **Service integration** → **WS-Notification** → **Services** → ***service_name*** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations and pull points for this WS-Notification service.
2. Click **Subscriptions** , **Publisher registrations**, **Pull points** or (for a particular service point) **Administered subscribers**.
   - If you click **Subscriptions**, a panel is displayed that lists the durable subscriptions that have been created by a WS-Notification service point in response to “Subscribe” requests from WS-Notification applications. You can view the subscription name (ID), topic and other information associated with the subscription, and you can view messages held on the durable subscription pending delivery. You can also delete subscriptions.

     Note: Both the WS-Notification subscription and publisher registration resources include the concept of scheduled termination, in which the application indicates a period of time after which the resource is destroyed. “Badly-behaved” in this case describes an application that requests an infinite lifetime for a resource and then does not explicitly delete the resource before it goes away (never to return).
   - If you click **Publisher registrations**, a panel is displayed that lists the publisher registrations that are currently in effect on this WS-Notification service or service point (that is, applications that have registered as publishers). You can view the basic properties of the registration record. You can also delete a publisher registration record.
   - If you click **Pull points**, a panel is displayed that lists the pull points that are currently active on this WS-Notification service or service point. You can view basic properties of the pull point such as the

subscription with which it is associated and the time at which it is currently set to expire, and you can navigate to the associated subscriptions where appropriate. You can also delete pull points.

- For a particular service point, if you click **Administered subscribers**, a panel is displayed that lists the administered subscribers that are currently in effect on this WS-Notification service point. You can use this information to see whether a given subscriber has been successfully initialized.

What to do next

For more detailed information about working with individual runtime panels, see the following topics:

- "Listing or deleting active WS-Notification subscriptions" on page 1119.
- "Listing or deleting active WS-Notification publisher registrations" on page 1121.
- "Listing or deleting active WS-Notification pull points" on page 1122.
- "Listing active WS-Notification administered subscribers" on page 1123.

Publishing the WSDL files for a WS-Notification application to a ZIP file

Use the administrative console to download a zip file that contains a WS-Notification application's published WSDL files.

About this task

The ability to publish these WSDL files to a ZIP file is particularly useful in the following circumstances:

- Writing a WS-Notification application that invokes Web service operations against the NotificationBroker application, as described in Writing a WS-Notification application that does not expose a Web service endpoint.
- Viewing the endpoint URLs to which WS-Notification applications connect, by looking in the WSDL file for the NotificationBroker application for Version 7.0 services, or the inbound service for Version 6.1 services.

1. Start the administrative console.
2. Navigate to the "Publish WSDL files to ZIP file [Settings]" form for the WS-Notification application.

   For Version 7.0 WS-Notification services, click one of the following paths:

   - **Service integration → WS-Notification → Services → *service_name* → [Additional Properties] WS-Notification service points → *point_name* → [Additional Properties] Publish WSDL files to zip**
   - **Service integration → Buses → *bus_name* → [Services] WS-Notification services → *service_name* → [Additional Properties] WS-Notification service points → *point_name* → [Additional Properties] Publish WSDL files to zip**

   For Version 6.1 WS-Notification services, click one of the following paths:

   - **Service integration → WS-Notification → Services → *service_name* → [Related Items] Notification broker inbound service settings → [Additional Properties] Publish WSDL files to ZIP file**
   - **Service integration → Buses → *bus_name* → [Services] WS-Notification services → *service_name* → [Related Items] Notification broker inbound service settings → [Additional Properties] Publish WSDL files to ZIP file**
3. Click on the file name to download a zip file that contains the application's published WSDL files.

Configuring WS-Notification resources

You can configure individual WS-Notification resources by using the administrative console or by using the wsadmin tool.

About this task

To complete the tasks described in "Accomplishing common WS-Notification tasks" on page 1057, you configure the following types of WS-Notification resource:

- WS-Notification service
- WS-Notification service point
- WS-Notification administered subscriber
- Permanent WS-Notification topic namespace
- WS-Notification topic namespace document

You can configure individual WS-Notification resources by using the administrative console or by using the wsadmin tool, as described in the following tasks:

- "Configuring WS-Notification resources by using the administrative console."
- WSNotificationCommands command group for the AdminTask object.
- "Interacting at run time with WS-Notification" on page 1077.

Configuring WS-Notification resources by using the administrative console

Use the administrative console to configure individual WS-Notification services, service points, administered subscribers, permanent topic namespaces, topic namespace documents and JAX-WS handlers.

Before you begin

Decide on which method you want to use to configure these resources. You can configure WS-Notification resources by using the administrative console as described in this task, or by using the commands in the WSNotificationCommands command group for the AdminTask object.

About this task

WS-Notification enables Web services to use the "publish and subscribe" messaging pattern. For more information, see WS-Notification: Overview and "Learning about WS-Notification" on page 1059.

For high-level configuration of WS-Notification, see "Accomplishing common WS-Notification tasks" on page 1057. Use the steps for this task to configure individual instances of each type of WS-Notification resource.

You access the WS-Notification panels through the **Service integration** section of the administrative console navigation pane:

- To see a list of all the WS-Notification services, click **Service integration** → **WS-Notification** → **Services**.
- To see a list of all the WS-Notification services for a particular service integration bus, click **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services**.

To support the Java API for XML-based Web services (JAX-WS) and composition with WS-ReliableMessaging, you create your WS-Notification services as JAX-WS applications. The implementation of WS-Notification in WebSphere Application Server Version 6.1 uses JAX-RPC applications, so there are now two different implementations of the WS-Notification service and service point:

- **Version 7.0**: You configure a Version 7.0 WS-Notification service and service points if you want to compose a JAX-WS WS-Notification service with WS-ReliableMessaging, or if you want to apply JAX-WS handlers to your WS-Notification service. This is the recommended type of service for new deployments.
- **Version 6.1**: You configure a Version 6.1 WS-Notification service and service points if you want to expose a JAX-RPC WS-Notification service using the same technology provided in WebSphere Application Server Version 6.1, including the ability to apply JAX-RPC handlers to the service.

To configure specific WS-Notification resources, use the administrative console to complete any of the following tasks:

- Configure a WS-Notification service.

  Complete any of the following tasks:
  - Create a new Version 7.0 WS-Notification service.
  - Modify a Version 7.0 WS-Notification service.
  - Create a new Version 6.1 WS-Notification service.
  - Modify a Version 6.1 WS-Notification service.
  - Delete WS-Notification services.
- Configure a WS-Notification service point.

  Complete any of the following tasks:
  - Create a new Version 7.0 WS-Notification service point.
  - Modify a Version 7.0 WS-Notification service point.
  - Create a new Version 6.1 WS-Notification service point.
  - Modify a Version 6.1 WS-Notification service point.
  - Delete WS-Notification service points.
- Configure a WS-Notification administered subscriber.

  Complete any of the following tasks:
  - Create a new WS-Notification administered subscriber.
  - Modify a WS-Notification administered subscriber.
  - Delete WS-Notification administered subscribers.
- Configure a permanent WS-Notification topic namespace.

  Complete any of the following tasks:
  - Create a new permanent WS-Notification topic namespace.
  - Show the properties of a permanent WS-Notification topic namespace.
  - Delete WS-Notification permanent topic namespaces.
- Configure a WS-Notification topic namespace document.

  Complete any of the following tasks:
  - Apply a WS-Notification topic namespace document.
  - Show the contents of a WS-Notification topic namespace document.
  - Delete WS-Notification topic namespace documents.
- Configure JAX-WS handlers and handler lists.

  Complete any of the following tasks:
  - Load JAX-WS handler classes.
  - Create a new JAX-WS handler configuration.
  - Modify an existing JAX-WS handler configuration.
  - Delete JAX-WS handler configurations.
  - Create a new JAX-WS handler list.
  - Modify an existing JAX-WS handler list.
  - Delete JAX-WS handler lists.

Creating a new Version 7.0 WS-Notification service:

Create a new WS-Notification service and the associated objects that form the infrastructure of the WS-Notification configuration. You configure a Version 7.0 WS-Notification service and service points if you

want to compose a JAX-WS WS-Notification service with WS-ReliableMessaging, or if you want to apply JAX-WS handlers to your WS-Notification service. This is the recommended type of service for new deployments.

Before you begin

Decide on which method you want to use to configure these resources. You can create a new Version 7.0 WS-Notification service by using the administrative console as described in this task, or by using the createWSNService command.

This task assumes that you have an existing service integration bus, configured with at least one bus member.

You usually configure one WS-Notification service for a service integration bus, but you can configure more than one. For more information, see Reasons to create multiple WS-Notification services in a bus.

Defining a Version 7.0 WS-Notification service is not the same as exposing a NotificationBroker (WSDL) port to which Web services applications can connect. To do this, create one or more Version 7.0 WS-Notification service points as described in this task.

About this task

A WS-Notification service provides the ability to expose some or all of the messaging resources defined on a service integration bus for use by WS-Notification applications.

To support the Java API for XML-based Web services (JAX-WS) and composition with WS-ReliableMessaging, you create your WS-Notification services as JAX-WS applications, then use this task to create a Version 7.0 WS-Notification service, one or more service points, and (optionally) a permanent topic namespace.

You can also apply JAX-WS handler lists to WS-Notification service points (for inbound invocation handling) and WS-Notification services (for outbound invocation handling).

When you create a Version 7.0 WS-Notification service, the wizard creates and deploys a JAX-WS based provider application. This application exposes the WS-Notification Web service interfaces for each of the three WS-Notification service roles:

- Notification broker
- Subscription manager
- Publisher registration manager

1. Start the administrative console.
2. Navigate to **Service integration** → **WS-Notification** → **Services** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services**. The WS-Notification services [Collection] form is displayed.
3. In the content pane, click **New**. The “New WS-Notification service” wizard is displayed. For more information about the properties that you set with the wizard, see WS-Notification services [Settings].
4. Step 1: Configure name, description, service integration bus and dynamic topic namespace settings.
   a. Enter your chosen name and an optional description.

      The name forms part of the endpoint on which the service is exposed (that is, the URL used to access the WS-Notification service points that are defined under the service). For Version 6.1 WS-Notification services, the service name is unique within a bus. For Version 7.0 WS-Notification services, the service name is unique within the cell - which matches the administration model used for policy sets, and therefore supports composition of Version 7.0 WS-Notification services with WS-ReliableMessaging.

b. Select or deselect the option **Enable dynamic topic namespaces?**.

Indicates whether dynamic topic namespaces can be used within the WS-Notification service. That is, whether this service allows dynamic topic namespaces to be created at run time. For more information, see Dynamic topic namespace.

Use this option to tightly control the topic namespaces that are used when connecting to a particular WS-Notification service (for example for security or auditing requirements). If you deselect this option, any applications that connect to the WS-Notification service and request topics from a dynamic topic namespace are stopped from publishing or receiving messages.

All messages published to a dynamic topic namespace are inserted with the default message reliability setting of `reliable persistent`. If this value is not acceptable, create a permanent topic namespace and manually configure the attribute to the appropriate value.

Note: The dynamic topic namespaces used on a particular WS-Notification service are backed by a service integration bus topic space that is created automatically when you create the topic namespace. The syntax of topics used within this topic space is internal to the WS-Notification service implementation.

c. Select or deselect the option **Requires registration**.

Indicates whether publisher applications are required to register with the broker before they can publish notifications.

d. Select a service integration bus from the selection list.

e. Click **Next**.

5. Step 2: Select WS-Notification service type.

Select **Version 7.0** as the type of service that you want to create.

6. Step 3: Configure handler and web service policy settings.

These settings are applied to the event notifications exchanged with WS-Notification client applications.

a. Optional: Choose a JAX-WS handler list.

The JAX-WS handler list that is applied to outbound requests from the WS-Notification service. A handler list defines the handlers that are applied when making outbound Web service invocations, for example monitoring outbound event notification (in response to a subscribe operation) and controlling demand-based publishers (subscribe, pause and resume). For more information about handler lists, see “Configuring JAX-WS handlers” on page 1068.

b. Enable or clear the **Query WSDL** option.

Indicates whether or not the Version 7.0 WS-Notification service queries the WSDL of other WS-Notification Web services when interacting with them. By default, this option is enabled. By clearing this option, you can improve performance by avoiding expensive WSDL queries. However, please note the following considerations when WSDL querying is not enabled:

- WS-Notification attempts to discover binding information (which is normally discovered through the WSDL) using other means. WS-Notification uses the SOAP version associated with the WS-Notification service point where subscriptions were made (by other Web services), or where administered subscriptions were created (by an administrator).
- There are some circumstances in which WS-Notification might be unable to determine binding information. This can happen when cleaning up subscriptions where the associated service point has been deleted and configuration information is no longer available. Under these circumstances WS-Notification makes a “best guess” at binding information to use to clean up the subscriptions.
- There is one scenario where incorrect binding information is used. That is, when a subscriber subscribes using a particular SOAP binding, on behalf of a NotificationConsumer that expects notifications using a different SOAP binding.

c. Enter a dynamic topic space name.

The name of the service integration bus topic space to be used as the dynamic topic space for this WS-Notification service. That is, the name of the bus topic space that is used to host the ad-hoc topic namespace, and to host dynamic topic namespaces if they are permitted. A default name of `WSN_dynamic_this_service_name` is offered.

d. Click **Next**.

7. Step 4: Create WS-Notification service points.

   A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified Web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. The existence of a WS-Notification service point on a bus member implies that a WS-Notification Web service is exposed from that bus member, and causes Web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service. For more information, see WS-Notification service point.

   a. Select **Yes** to create a new WS-Notification service point, then click **Next**.

      A WS-Notification service must have at least one service point.

   b. Supply a name and (optional) description for the WS-Notification service point, and from the selection list select the bus member on which the service point is to be configured, then click **Next**.

      The service point name forms part of the URL used to access the service point. On a single server system there is only one bus member in the list.

   c. Select the transport settings for the new service point.

      Service point accessed via HTTP proxy
      If the service point is accessed through a proxy, enable the check box, and type the root of the externally visible endpoint address URL for Web services accessed using this endpoint.

      The URL for the proxy is used to populate the WSDL endpoint address fields when publishing WSDL files to a zip file.

      SOAP Version
      Select the version of SOAP that is supported by the service point. This affects the WSDL definition that is exposed by the Web service.

   d. Optional: Select the JAX-WS handler list settings for the new service point.

      NotificationBroker JAX-WS handler list

      The JAX-WS handler list that is applied to inbound requests from an application to the NotificationBroker endpoint of the WS-Notification service point.

      SubscriptionManager JAX-WS handler list

      The JAX-WS handler list that is applied to inbound requests from an application to the SubscriptionManager endpoint of the WS-Notification service point.

      PublisherRegistrationManager JAX-WS handler list

      The JAX-WS handler list that is applied to inbound requests from an application to the PublisherRegistrationManager endpoint of the WS-Notification service point.

   e. Click **Next**. The new service point is added to the list of service points for this WS-Notification service.

   f. Optional: To create another service point, repeat the previous substeps.

   g. When you have finished creating service points for this WS-Notification service, select **No** for the option to create another service point, then click **Next**.

8. Optional: Step 5: Create permanent topic namespaces.

For more information, see Permanent topic namespace. When you create a new WS-Notification permanent topic namespace, you specify the namespace and associate it with one of the service integration bus topic spaces configured on the bus on which the parent WS-Notification service is defined. You cannot modify a permanent topic namespace after it has been created, other than to apply or remove topic namespace documents.

a. Select **Yes** to create a new permanent topic namespace, then click **Next**.
b. Enter a name for the permanent topic namespace.

   This is the URI by which WS-Notification applications refer to topics hosted by this namespace.
c. Associate this new permanent topic namespace with the service integration bus topic space that you want to use to publish and receive messages.

   From the service integration bus topic space selection list, complete one of the following actions:
   - Choose the name of an existing bus topic space.
   - Choose the option to `Create a new topic space`, then enter a name for the new topic space.
d. Select from the selection list the service integration bus reliability (quality of service) that is assigned to messages published using this topic namespace.

   You can choose one of five values, each representing one of the service integration bus message reliability levels. The default value is `reliable persistent`, which is the value used by default for JMS Persistent messages.
e. Click **Next**.

   The new permanent topic namespace is added to a list of permanent topic namespaces for this Version 7.0 WS-Notification service, and you are asked whether you want to create another permanent topic namespace (default is **Yes**).
f. Optional: To create another permanent topic namespace, repeat the previous substeps.
g. When you have finished creating permanent topic namespaces for this Version 7.0 WS-Notification service, select **No** for the option to create another permanent topic namespace, then click **Next**.

9. Step 6: Summary.

   Check that the summary of the actions taken by the wizard is as you expected, then click **Finish**. If the processing completes successfully, the list of Version 7.0 WS-Notification services is updated to include the new Version 7.0 WS-Notification service. Otherwise, an error message is displayed.
10. Save your changes to the master configuration.
11. Optional: Restart the server if either of the following conditions apply:
    - A new bus or new bus member has been created as part of this task.
    - **Configuration reload** is not enabled for the bus.

What to do next

To perform advanced configuration tasks for this WS-Notification service (for example, adding additional service points and applying topic namespace documents to permanent topic namespaces), see “Modifying a Version 7.0 WS-Notification service.”

To perform advanced configuration tasks for the WS-Notification service point that you created as part of this task (for example, adding administered subscribers, publishing WSDL files to zip, and configuring the enterprise application associated with this service point), see “Modifying a Version 7.0 WS-Notification service point” on page 1097.

To configure this WS-Notification service or service point with Web service qualities of service (QoS) such as reliability or security, see “Configuring a Version 7.0 WS-Notification service with Web service QoS” on page 1070.

Modifying a Version 7.0 WS-Notification service:

Modify the **description**, **Enabled dynamic topic namespaces?**, **Requires registration**, **JAX-WS handler list** and **Query WSDL** properties of a Version 7.0 WS-Notification service, and follow links to complete advanced configuration such as adding additional WS-Notification service points, applying topic namespace documents to permanent topic namespaces, and applying policy sets to enable WS-ReliableMessaging.

About this task

A WS-Notification service provides the ability to expose some or all of the messaging resources defined on a service integration bus for use by WS-Notification applications.

A handler list defines the handlers that are applied when making outbound Web service invocations, for example monitoring outbound event notification (in response to a subscribe operation) and controlling demand-based publishers (subscribe, pause and resume).

When you create a Version 7.0 WS-Notification service, the wizard creates and deploys a JAX-WS based provider application. This application exposes the WS-Notification Web service interfaces for each of the three WS-Notification service roles:

- Notification broker
- Subscription manager
- Publisher registration manager

You can also configure custom properties to specify a timeout time for outbound requests, and to determine the strictness of the syntax checking of topics used under this Version 7.0 WS-Notification service.

1. Start the administrative console.
2. Navigate to **Service integration** → **WS-Notification** → **Services** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services**. The WS-Notification services [Collection] form is displayed.
3. In the content pane, click the name of a Version 7.0 WS-Notification service in the list. The current settings for this Version 7.0 WS-Notification service are displayed in the WS-Notification services [Settings] panel.
4. Modify the following general properties:

   Description
   An optional description of the WS-Notification service.

   Enable dynamic topic namespaces?

   Indicates whether dynamic topic namespaces can be used within the WS-Notification service. That is, whether this service allows dynamic topic namespaces to be created at run time. For more information, see Dynamic topic namespace.

   Use this option to tightly control the topic namespaces that are used when connecting to a particular WS-Notification service (for example for security or auditing requirements). If you deselect this option, any applications that connect to the WS-Notification service and request topics from a dynamic topic namespace are stopped from publishing or receiving messages.

   All messages published to a dynamic topic namespace are inserted with the default message reliability setting of `reliable persistent`. If this value is not acceptable, create a permanent topic namespace and manually configure the attribute to the appropriate value.

   Note: The dynamic topic namespaces used on a particular WS-Notification service are backed by a service integration bus topic space that is created automatically when you create the topic namespace. The syntax of topics used within this topic space is internal to the WS-Notification service implementation.

Requires registration

Indicates whether publisher applications are required to register with the broker before they can publish notifications.

JAX-WS handler list

The JAX-WS handler list that is applied to outbound requests from the WS-Notification service.

A handler list defines the handlers that are applied when making outbound Web service invocations, for example monitoring outbound event notification (in response to a subscribe operation) and controlling demand-based publishers (subscribe, pause and resume). For more information about handler lists, see "Configuring JAX-WS handlers" on page 1068.

Query WSDL

Indicates whether or not the Version 7.0 WS-Notification service queries the WSDL of other WS-Notification Web services when interacting with them. By default, this option is enabled. By clearing this option, you can improve performance by avoiding expensive WSDL queries. However, please note the following considerations when WSDL querying is not enabled:

- WS-Notification attempts to discover binding information (which is normally discovered through the WSDL) using other means. WS-Notification uses the SOAP version associated with the WS-Notification service point where subscriptions were made (by other Web services), or where administered subscriptions were created (by an administrator).
- There are some circumstances in which WS-Notification might be unable to determine binding information. This can happen when cleaning up subscriptions where the associated service point has been deleted and configuration information is no longer available. Under these circumstances WS-Notification makes a "best guess" at binding information to use to clean up the subscriptions.
- There is one scenario where incorrect binding information is used. That is, when a subscriber subscribes using a particular SOAP binding, on behalf of a NotificationConsumer that expects notifications using a different SOAP binding.

5. Modify the additional properties:

WS-Notification service points

Select this link to configure the deployment of WS-Notification service points on one or more servers. For more information, see "Creating a new Version 7.0 WS-Notification service point" on page 1095 or "Modifying a Version 7.0 WS-Notification service point" on page 1097.

Permanent topic namespaces

Select this link to configure permanent topic namespaces for the WS-Notification service. For more information, see Permanent topic namespace. When you create a new WS-Notification permanent topic namespace, you specify the namespace and associate it with one of the service integration bus topic spaces configured on the bus on which the parent WS-Notification service is defined. You cannot modify a permanent topic namespace after it has been created, other than to apply or remove topic namespace documents.

Custom properties

Select this link to configure additional custom properties for this WS-Notification service. These custom properties are name and value pairs that you can use to set internal system configuration properties. In each pair, the name is a property key and the value is a string value.

To specify a timeout time for outbound requests sent from this WS-Notification service, set the following custom property:

```
outbound.timeout
```

The value of this property is the timeout time in milliseconds. If the property is not set, a default timeout of 2 minutes is used.

To determine the strictness of the syntax checking of topics used under this WS-Notification service, set the following custom property:

`com.ibm.ws.sib.wsn.strictTopicChecking`

Valid values for this property are TRUE and FALSE:

- If the property value is set to TRUE, the topic syntax rules defined in the WS-Topics standard are strictly enforced. Note that there is a performance overhead compared to the default setting, because each character of a topic is validated against a large list of permitted Unicode characters.
- If the property is omitted or set to FALSE, syntax checking only ensures that the basic topic structure is valid, and character checking is relaxed to allow any character exception "*" and "." as a topic name part.

Outbound request policy sets and bindings

The outbound request policy sets and bindings for the two WS-Notification service clients associated with this WS-Notification service. For reliable Web service transmission of notification messages, use this option to associate the WS-Notification service client with a policy set that enables WS-ReliableMessaging.

For more information, see "Configuring a Version 7.0 WS-Notification service with Web service QoS" on page 1070.

6. Apply any changes, then click **OK**. If the processing completes successfully, the list of WS-Notification services is redisplayed. Otherwise, an error message is displayed.
7. Save your changes to the master configuration. You need not restart the server for the changes to fully take effect if **configuration reload** is enabled for the service integration bus.

Deleting WS-Notification services:

Remove all configuration associated with one or more WS-Notification services. A WS-Notification service provides access to service integration bus resources for Web services publish and subscribe clients.

Before you begin

Decide on which method you want to use to configure these resources. You can delete a WS-Notification service by using the administrative console as described in this task, or by using the deleteWSNService command.

About this task

When you delete a Version 6.1 WS-Notification service, the associated inbound services and inbound ports are also deleted. The associated endpoint listeners are deleted if they were created in the process of creating a WS-Notification service point and are not used by any other configuration object. When you delete a Version 7.0 WS-Notification service, the associated service point provider applications and service points are also deleted. Do not delete these resources manually, because this might leave the associated configuration information in an inconsistent state.

For both types of WS-Notification service, you choose whether or not the associated service integration bus topic spaces are deleted.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **WS-Notification** → **Services** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services**. A list of all the WS-Notification services is displayed in a WS-Notification services [Collection] form.
3. Select the check box for every WS-Notification service that you want to remove.

4. Click **Delete**. A panel is displayed asking if the service integration bus topic spaces associated with the WS-Notification service (including those associated with all the WS-Notification topic namespaces) should also be deleted.
5. Optional: Select the check box if you want to delete the associated service integration bus topic spaces.

   Note: Deleting a service integration bus topic space causes exception messages to be generated for WS-Notification applications that reference the topic space, as described in Failures as a result of changes in topic space and topic namespace configurations.
6. Click **Delete**. If the processing completes successfully, the list of WS-Notification services is updated. Otherwise, an error message is displayed.
7. Save your changes to the master configuration.

Creating a new Version 6.1 WS-Notification service:

Create a new WS-Notification service and the associated objects that form the infrastructure of the WS-Notification configuration. You configure a Version 6.1 WS-Notification service and service points if you want to expose a JAX-RPC WS-Notification service using the same technology provided in WebSphere Application Server Version 6.1, including the ability to apply JAX-RPC handlers to the service.

Before you begin

Ensure that you have successfully configured an SDO repository, as described in “Installing and configuring the SDO repository” on page 1003. The SDO repository is used to store WSDL documents during the creation of the WS-Notification service. If you do not configure the repository, an error message appears when you create the service.

Decide on which method you want to use to configure these resources. You can create a new Version 6.1 WS-Notification service by using the administrative console as described in this task, or by using the createWSNService command.

This task assumes that you have an existing service integration bus, configured with at least one bus member.

You usually configure one WS-Notification service for a service integration bus, but you can configure more than one. For more information, see Reasons to create multiple WS-Notification services in a bus.

Defining a WS-Notification service on a bus is not the same as exposing a NotificationBroker (WSDL) port to which Web services applications can connect. To do this, create one or more WS-Notification service points as described in this task.

About this task

A WS-Notification service provides the ability to expose some or all of the messaging resources defined on a service integration bus for use by WS-Notification applications.

A JAX-RPC handler list and WS-Security bindings define the parameters and security policy that are used when making outbound Web service invocations, for example monitoring outbound event notification (in response to a subscribe operation) and controlling demand-based publishers (subscribe, pause and resume).

When you create a Version 6.1 WS-Notification service, the wizard configures three service integration bus inbound services for the WS-Notification service, one for each of the three WS-Notification service roles:

- Notification broker
- Subscription manager

- Publisher registration manager

These inbound services are defined on the same service integration bus as the Version 6.1 WS-Notification service, and each of these inbound services refers to the same bus destination.

1. Start the administrative console.
2. Navigate to **Service integration** → **WS-Notification** → **Services** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services**. The WS-Notification services [Collection] form is displayed.
3. In the content pane, click **New**. The "New WS-Notification service" wizard is displayed. For more information about the properties that you set with the wizard, see WS-Notification services [Settings].
4. Step 1: Configure name, description, service integration bus and dynamic topic namespace settings.
   a. Enter your chosen name and an optional description.

      The name forms part of the endpoint on which the service is exposed (that is, the URL used to access the WS-Notification service points that are defined under the service). For Version 6.1 WS-Notification services, the service name is unique within a bus. For Version 7.0 WS-Notification services, the service name is unique within the cell - which matches the administration model used for policy sets, and therefore supports composition of Version 7.0 WS-Notification services with WS-ReliableMessaging.
   b. Select or deselect the option **Enable dynamic topic namespaces?**.

      Indicates whether dynamic topic namespaces can be used within the WS-Notification service. That is, whether this service allows dynamic topic namespaces to be created at run time. For more information, see Dynamic topic namespace.

      Use this option to tightly control the topic namespaces that are used when connecting to a particular WS-Notification service (for example for security or auditing requirements). If you deselect this option, any applications that connect to the WS-Notification service and request topics from a dynamic topic namespace are stopped from publishing or receiving messages.

      All messages published to a dynamic topic namespace are inserted with the default message reliability setting of `reliable persistent`. If this value is not acceptable, create a permanent topic namespace and manually configure the attribute to the appropriate value.

      Note: The dynamic topic namespaces used on a particular WS-Notification service are backed by a service integration bus topic space that is created automatically when you create the topic namespace. The syntax of topics used within this topic space is internal to the WS-Notification service implementation.
   c. Select or deselect the option **Requires registration**.

      Indicates whether publisher applications are required to register with the broker before they can publish notifications.
   d. Select a service integration bus from the selection list.
   e. Click **Next**.
5. Step 2: Select WS-Notification service type.

   Select **Version 6.1** as the type of service that you want to create.
6. Step 3: Configure handler and web service policy settings.

   These settings are applied to the event notifications exchanged with WS-Notification client applications.
   a. Optional: Choose a JAX-RPC handler list.

      The JAX-RPC handler list that is applied to outbound requests from the WS-Notification service - for example the broker delivering notifications to a consumer. For more information about handler lists, see "Working with JAX-RPC handlers and clients" on page 1029.
   b. Optional: Choose a WS-Security configuration and bindings:

Outbound security request binding
The security binding to be used with consumer notifications and remote publisher requests sent by this WS-Notification service.

Outbound security response binding
The security binding to be used with remote publisher responses received by this WS-Notification service.

Outbound security configuration
Specifies the details of how security is applied to requests and responses.

For more information about Web services security resources, see Configuring secure transmission of SOAP messages using WS-Security.

c. Enter a dynamic topic space name.

The name of the service integration bus topic space to be used as the dynamic topic space for this WS-Notification service. That is, the name of the bus topic space that is used to host the ad-hoc topic namespace, and to host dynamic topic namespaces if they are permitted. A default name of `WSN_dynamic_this_service_name` is offered.

d. Click **Next**.

7. Step 4: Create WS-Notification service points.

A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified Web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. The existence of a WS-Notification service point on a bus member implies that a WS-Notification Web service is exposed from that bus member, and causes Web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service. For more information, see WS-Notification service point.

a. Select **Yes** to create a new WS-Notification service point, then click **Next**.

A WS-Notification service must have at least one service point.

b. Supply a name and (optional) description for the WS-Notification service point, and from the selection list select the bus member on which the service point is to be configured, then click **Next**.

The service point name forms part of the URL used to access the service point (that is, the address of the Web service that is exposed on the chosen server). On a single server system there is only one bus member in the list.

c. Select a listener application to use to expose the service. Either select an existing endpoint listener for this bus member, or **Create a new endpoint listener**.

For more information, see “Creating a new endpoint listener configuration” on page 1019.

d. Click **Next**. The new service point is added to the list of service points for this WS-Notification service.

e. Optional: To create another service point, repeat the previous substeps.

f. When you have finished creating service points for this WS-Notification service, select **No** for the option to create another service point, then click **Next**.

8. Optional: Step 5: Create permanent topic namespaces.

When you create a new WS-Notification permanent topic namespace, you specify the namespace and associate it with one of the service integration bus topic spaces configured on the bus on which the parent WS-Notification service is defined. You cannot modify a permanent topic namespace after it has been created, other than to apply or remove topic namespace documents. For more information, see Permanent topic namespace.

a. Select **Yes** to create a new permanent topic namespace, then click **Next**.

b. Enter a name for the permanent topic namespace.

   This is the URI by which WS-Notification applications refer to topics hosted by this namespace.

c. Associate this new permanent topic namespace with the service integration bus topic space that you want to use to publish and receive messages.

   From the service integration bus topic space selection list, complete one of the following actions:

   - Choose the name of an existing bus topic space.
   - Choose the option to `Create a new topic space`, then enter a name for the new topic space.

d. Select from the selection list the service integration bus reliability (quality of service) that is assigned to messages published using this topic namespace.

   You can choose one of five values, each representing one of the service integration bus message reliability levels. The default value is `reliable persistent`, which is the value used by default for JMS Persistent messages.

e. Click **Next**.

   The new permanent topic namespace is added to a list of permanent topic namespaces for this WS-Notification service, and you are asked whether you want to create another permanent topic namespace (default is **Yes**).

f. Optional: To create another permanent topic namespace, repeat the previous substeps.

g. When you have finished creating permanent topic namespaces for this WS-Notification service, select **No** for the option to create another permanent topic namespace, then click **Next**.

9. Step 6: Summary.

   Check that the summary of the actions taken by the wizard is as you expected, then click **Finish**. If the processing completes successfully, the list of WS-Notification services is updated to include the new Version 6.1 WS-Notification service. Otherwise, an error message is displayed.

10. Save your changes to the master configuration.

11. Optional: Restart the server if either of the following conditions apply:

    - A new bus or new bus member has been created as part of this task.
    - **Configuration reload** is not enabled for the bus.

What to do next

To perform advanced configuration tasks for this WS-Notification service (for example adding additional WS-Notification service points, or applying topic namespace documents to permanent topic namespaces), see “Modifying a Version 6.1 WS-Notification service.”

Modifying a Version 6.1 WS-Notification service:

Modify the **description**, **Enabled dynamic topic namespaces?** and **Requires registration** properties of a WS-Notification service, and follow links to complete advanced configuration of the WS-Notification service such as adding additional WS-Notification service points, or applying topic namespace documents to permanent topic namespaces.

About this task

A WS-Notification service provides the ability to expose some or all of the messaging resources defined on a service integration bus for use by WS-Notification applications.

A JAX-RPC handler list and WS-Security bindings define the parameters and security policy that are used when making outbound Web service invocations, for example monitoring outbound event notification (in response to a subscribe operation) and controlling demand-based publishers (subscribe, pause and resume).

When you create a Version 6.1 WS-Notification service, the wizard configures three service integration bus inbound services for the WS-Notification service, one for each of the three WS-Notification service roles:

- Notification broker
- Subscription manager
- Publisher registration manager

These inbound services are defined on the same service integration bus as the Version 6.1 WS-Notification service, and each of these inbound services refers to the same bus destination.

You can make Web services-specific modifications to the WS-Notification service behavior by modifying the three associated inbound services. You can also configure a custom property that determines the strictness of the syntax checking of topics used under this WS-Notification service.

To modify a WS-Notification service use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **WS-Notification** → **Services** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services**. The WS-Notification services [Collection] form is displayed.
2. In the content pane, click the name of a WS-Notification service in the list. The current settings for this WS-Notification service are displayed in the WS-Notification services [Settings] panel.
3. Modify the following general properties:

   Description
   An optional description of the WS-Notification service.

   Enable dynamic topic namespaces?

   Indicates whether dynamic topic namespaces can be used within the WS-Notification service. That is, whether this service allows dynamic topic namespaces to be created at run time. For more information, see Dynamic topic namespace.

   Use this option to tightly control the topic namespaces that are used when connecting to a particular WS-Notification service (for example for security or auditing requirements). If you deselect this option, any applications that connect to the WS-Notification service and request topics from a dynamic topic namespace are stopped from publishing or receiving messages.

   All messages published to a dynamic topic namespace are inserted with the default message reliability setting of `reliable persistent`. If this value is not acceptable, create a permanent topic namespace and manually configure the attribute to the appropriate value.

   Note: The dynamic topic namespaces used on a particular WS-Notification service are backed by a service integration bus topic space that is created automatically when you create the topic namespace. The syntax of topics used within this topic space is internal to the WS-Notification service implementation.

   Requires registration
   Indicates whether publisher applications are required to register with the broker before they can publish notifications.
4. Modify the JAX-RPC handler list and Web services security settings. These settings are applied to the event notifications exchanged with WS-Notification client applications. For more information about handler lists, see “Working with JAX-RPC handlers and clients” on page 1029. For more information about Web services security resources, see Configuring secure transmission of SOAP messages using WS-Security.

   JAX-RPC handler list
   The JAX-RPC handler list that is applied to outbound requests from the WS-Notification service - for example the broker delivering notifications to a consumer.

Outbound security request binding
The security binding to be used with consumer notifications and remote publisher requests sent by this WS-Notification service.

Outbound security response binding
The security binding to be used with remote publisher responses received by this WS-Notification service.

Outbound security configuration
Specifies the details of how security is applied to requests and responses.

5. Modify the additional properties:

WS-Notification service points
Select this link to configure the deployment of WS-Notification service points on one or more servers. For more information, see “Modifying a Version 6.1 WS-Notification service point” on page 1100.

Permanent topic namespaces
Select this link to configure permanent topic namespaces for the WS-Notification service. For more information, see Permanent topic namespace. When you create a new WS-Notification permanent topic namespace, you specify the namespace and associate it with one of the service integration bus topic spaces configured on the bus on which the parent WS-Notification service is defined. You cannot modify a permanent topic namespace after it has been created, other than to apply or remove topic namespace documents.

Custom properties
Select this link to configure additional custom properties for this WS-Notification service. These custom properties are name and value pairs that you can use to set internal system configuration properties. In each pair, the name is a property key and the value is a string value.

To specify a timeout time for outbound requests sent from this WS-Notification service, set the following custom property:

```
outbound.timeout
```

The value of this property is the timeout time in milliseconds. If the property is not set, a default timeout of 2 minutes is used.

To determine the strictness of the syntax checking of topics used under this WS-Notification service, set the following custom property:

```
com.ibm.ws.sib.wsn.strictTopicChecking
```

Valid values for this property are TRUE and FALSE:

- If the property value is set to TRUE, the topic syntax rules defined in the WS-Topics standard are strictly enforced. Note that there is a performance overhead compared to the default setting, because each character of a topic is validated against a large list of permitted Unicode characters.
- If the property is omitted or set to FALSE, syntax checking only ensures that the basic topic structure is valid, and character checking is relaxed to allow any character exception “*” and “.” as a topic name part.

6. Modify the inbound service settings for the notification broker, subscription manager or publisher registration manager. For more information, see “Modifying an existing inbound service configuration” on page 1011.
7. Apply any changes, then click **OK**. If the processing completes successfully, the list of WS-Notification services is redisplayed. Otherwise, an error message is displayed.
8. Save your changes to the master configuration. You need not restart the server for the changes to fully take effect if **configuration reload** is enabled for the service integration bus.

Deleting WS-Notification services:

Remove all configuration associated with one or more WS-Notification services. A WS-Notification service provides access to service integration bus resources for Web services publish and subscribe clients.

Before you begin

Decide on which method you want to use to configure these resources. You can delete a WS-Notification service by using the administrative console as described in this task, or by using the deleteWSNService command.

About this task

When you delete a Version 6.1 WS-Notification service, the associated inbound services and inbound ports are also deleted. The associated endpoint listeners are deleted if they were created in the process of creating a WS-Notification service point and are not used by any other configuration object. When you delete a Version 7.0 WS-Notification service, the associated service point provider applications and service points are also deleted. Do not delete these resources manually, because this might leave the associated configuration information in an inconsistent state.

For both types of WS-Notification service, you choose whether or not the associated service integration bus topic spaces are deleted.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **WS-Notification** → **Services** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services**. A list of all the WS-Notification services is displayed in a WS-Notification services [Collection] form.
3. Select the check box for every WS-Notification service that you want to remove.
4. Click **Delete**. A panel is displayed asking if the service integration bus topic spaces associated with the WS-Notification service (including those associated with all the WS-Notification topic namespaces) should also be deleted.
5. Optional: Select the check box if you want to delete the associated service integration bus topic spaces.

   Note: Deleting a service integration bus topic space causes exception messages to be generated for WS-Notification applications that reference the topic space, as described in Failures as a result of changes in topic space and topic namespace configurations.
6. Click **Delete**. If the processing completes successfully, the list of WS-Notification services is updated. Otherwise, an error message is displayed.
7. Save your changes to the master configuration.

Creating a new Version 7.0 WS-Notification service point:

You can add an additional Version 7.0 WS-Notification service point to an existing Version 7.0 WS-Notification service. A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified Web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. The existence of a WS-Notification service point on a bus member implies that a WS-Notification Web service is exposed from that bus member, and causes Web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

Before you begin

Decide on which method you want to use to configure these resources. You can create a new Version 7.0 WS-Notification service point by using the administrative console as described in this task, or by using the createWSNServicePoint command.

About this task

You can define any number of WS-Notification service points for a given WS-Notification service. Each service point defined for the same WS-Notification service represents an alternative entry point to the service. Event notifications published to a particular WS-Notification service point are received by all applications connected to any service point of the same WS-Notification service (subject to subscription on the correct topic) regardless of the particular service point to which they are connected. For more information, see Reasons to create multiple WS-Notification service points.

When you create a Version 7.0 WS-Notification service point you select a bus member on which the WS-Notification service point is configured. You also choose the SOAP version that is supported by the service point, and (optionally) apply JAX-WS handler lists to the NotificationBroker, SubscriptionManager or PublisherRegistrationManager that are exposed through this service point.

1. Start the administrative console.
2. Navigate to **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional Properties] WS-Notification service points** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points**. The WS-Notification service points [Collection] form is displayed. This form shows all the Version 7.0 WS-Notification service points configured for this Version 7.0 WS-Notification service.
3. In the content pane, click **New**. The “New WS-Notification service point” wizard is displayed. For more information about the properties that you set with the wizard, see WS-Notification service points [Settings].
4. Step 1: Configure name, description and select a bus member.
   a. Supply a name and (optional) description for the WS-Notification service point. The service point name forms part of the URL used to access the service point.
   b. From the selection list, select the bus member on which the service point is to be configured. On a single server system there is only one bus member in the list.
   c. Click **Next**.
5. Step 2: Define transport settings.
   a. Select the transport settings for the new service point.

      Service point accessed via HTTP proxy
      If the service point is accessed through a proxy, enable the check box, and type the root of the externally visible endpoint address URL for Web services accessed using this endpoint.

      The URL for the proxy is used to populate the WSDL endpoint address fields when publishing WSDL files to a zip file.

      SOAP Version
      Select the version of SOAP that is supported by the service point. This affects the WSDL definition that is exposed by the Web service.

   b. Optional: Select the JAX-WS handler list settings for the new service point.

      NotificationBroker JAX-WS handler list

      The JAX-WS handler list that is applied to inbound requests from an application to the NotificationBroker endpoint of the WS-Notification service point.

      SubscriptionManager JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the SubscriptionManager endpoint of the WS-Notification service point.

PublisherRegistrationManager JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the PublisherRegistrationManager endpoint of the WS-Notification service point.

6. Click **Finish**. If the processing completes successfully, the list of Version 7.0 WS-Notification service points for this Version 7.0 WS-Notification service is updated to include the new service point. Otherwise, an error message is displayed.
7. Save your changes to the master configuration.

What to do next

To perform advanced configuration tasks for this WS-Notification service point (for example, adding administered subscribers, publishing WSDL files to zip, and configuring the enterprise application associated with this service point), see "Modifying a Version 7.0 WS-Notification service point."

To configure this WS-Notification service point with Web service qualities of service (QoS) such as reliability or security, see "Configuring a Version 7.0 WS-Notification service with Web service QoS" on page 1070.

You can also use the administrative console to work with runtime information for service points. For more information, see "Interacting at run time with WS-Notification" on page 1077.

Modifying a Version 7.0 WS-Notification service point:

Modify the **description**, **SOAP Version**, and **JAX-WS handler list** properties of a Version 7.0 WS-Notification service point, and follow links to complete advanced configuration such as modifying the administered subscribers, applying policy sets to enable WS-ReliableMessaging, publishing the WSDL files to zip files, and configuring the enterprise application that is associated with this service point.

About this task

A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified Web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. The existence of a WS-Notification service point on a bus member implies that a WS-Notification Web service is exposed from that bus member, and causes Web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

1. Start the administrative console.
2. Navigate to **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional Properties] WS-Notification service points** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points**. The WS-Notification service points [Collection] form is displayed. This form shows all the service points configured for this Version 7.0 WS-Notification service.
3. In the content pane, click the name of a Version 7.0 WS-Notification service point in the list. The current settings for this Version 7.0 WS-Notification service point are displayed in the WS-Notification service points [Settings] form.
4. Modify the following general properties:

   Description
   An optional description of the WS-Notification service point.

Associated bus member
The name of the bus member on which this WS-Notification service point is deployed.

SOAP Version

Defines the version of SOAP supported by the service point. This affects the WSDL definition that will be exposed by the web service. Permitted values are “1.1” for SOAP 1.1 (the default), and “1.2” for SOAP 1.2.

NotificationBroker JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the NotificationBroker endpoint of the WS-Notification service point.

SubscriptionManager JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the SubscriptionManager endpoint of the WS-Notification service point.

PublisherRegistrationManager JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the PublisherRegistrationManager endpoint of the WS-Notification service point.

5. Modify the additional properties:

Administered subscribers
An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time. For more information, see “Modifying a WS-Notification administered subscriber” on page 1103.

Custom properties
Select this link to configure additional custom properties for this WS-Notification service point.

Policy set configuration
The policy set configuration associated with this WS-Notification service point. You can configure policy set and binding information for each port relating to this service point. For more information, see “Configuring a Version 7.0 WS-Notification service with Web service QoS” on page 1070.

Publish WSDL files to zip
Publish the WSDL files for this service point to a zip file. For more information, see “Publishing the WSDL files for a WS-Notification application to a ZIP file” on page 1079.

Service point application
The application associated with this WS-Notification service point. For Version 7.0 WS-Notification services, enterprise applications are used to expose the Web services associated with the WS-Notification service.

6. Apply any changes, then click **OK**. If the processing completes successfully, the list of WS-Notification service points for this Version 7.0 WS-Notification service is redisplayed. Otherwise, an error message is displayed.
7. Save your changes to the master configuration.

What to do next

You can also use the administrative console to work with runtime information for service points. For more information, see “Interacting at run time with WS-Notification” on page 1077.

Deleting WS-Notification service points:

Delete one or more WS-Notification service points and the associated resources (Version 7.0 service point provider applications, or Version 6.1 inbound services and endpoint listeners).

Before you begin

Decide on which method you want to use to configure these resources. You can delete a WS-Notification service point by using the administrative console as described in this task, or by using the deleteWSNServicePoint command.

Do not use this task to delete service points as part of the process of deleting a WS-Notification service. When you delete a WS-Notification service, the associated service points and resources are automatically deleted.

About this task

A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified Web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. When you delete a WS-Notification service point, the associated resources (Version 7.0 service point provider applications, or Version 6.1 inbound services and endpoint listeners) are automatically deleted. Do not delete these resources manually, because this might leave the associated configuration information in an inconsistent state.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional Properties] WS-Notification service points** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points**. A list of all the WS-Notification service points is displayed in a WS-Notification service points [Collection] form.
3. Select the check box for every WS-Notification service point that you want to remove.
4. Click **Delete**. If the processing completes successfully, the list of WS-Notification service points for this WS-Notification service is updated. Otherwise, an error message is displayed.
5. Save your changes to the master configuration.

Creating a new Version 6.1 WS-Notification service point:

You can add an additional Version 6.1 WS-Notification service point to an existing Version 6.1 WS-Notification service. A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified Web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. The existence of a WS-Notification service point on a bus member implies that a WS-Notification Web service is exposed from that bus member, and causes Web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

Before you begin

Decide on which method you want to use to configure these resources. You can create a new Version 6.1 WS-Notification service point by using the administrative console as described in this task, or by using the createWSNServicePoint command.

About this task

You can define any number of WS-Notification service points for a given WS-Notification service. Each service point defined for the same WS-Notification service represents an alternative entry point to the service. Event notifications published to a particular WS-Notification service point are received by all applications connected to any service point of the same WS-Notification service (subject to subscription on

the correct topic) regardless of the particular service point to which they are connected. For more information, see Reasons to create multiple WS-Notification service points.

When you create a Version 6.1 WS-Notification service point you select a bus member on which the WS-Notification service point is configured. You allocate a service point to a given bus member by specifying an endpoint listener that is configured for that bus member. You also choose the type of Web service binding (SOAP over HTTP or SOAP over JMS) that is used for the WS-Notification service point.

The existence of a WS-Notification service point on a bus member implies that a WS-Notification Web service is exposed from that bus member, and causes Web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

1. Start the administrative console
2. Navigate to **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional Properties] WS-Notification service points** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points**. The WS-Notification service points [Collection] form is displayed. This form shows all the Version 6.1 WS-Notification service points configured for this Version 6.1 WS-Notification service.
3. In the content pane, click **New**. The “New WS-Notification service point” wizard is displayed. For more information about the properties that you set with the wizard, see WS-Notification service points [Settings].
4. Use the wizard to create the new Version 6.1 WS-Notification service point configuration by completing the following steps.
   a. Supply a name and (optional) description for the WS-Notification service point, and from the selection list select the bus member on which the service point is to be configured, then click **Next**. The service point name forms part of the URL used to access the service point (that is, the address of the Web service that is exposed on the chosen server). On a single server system there is only one bus member in the list.
   b. Select a listener application to use to expose the service. Either select an existing endpoint listener for this bus member, or **Create a new endpoint listener**. For more information, see “Creating a new endpoint listener configuration” on page 1019.
5. Click **Finish**. If the processing completes successfully, the list of Version 6.1 WS-Notification service points for this Version 6.1 WS-Notification service is updated to include the new service point. Otherwise, an error message is displayed.
6. Save your changes to the master configuration.

What to do next

You can also use the administrative console to work with runtime information for service points. For more information, see “Interacting at run time with WS-Notification” on page 1077.

Modifying a Version 6.1 WS-Notification service point:

Modify an existing WS-Notification service point. A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified Web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service.

About this task

You can define any number of WS-Notification service points for a given WS-Notification service. Each service point defined for the same WS-Notification service represents an alternative entry point to the service. Event notifications published to a particular WS-Notification service point are received by all

applications connected to any service point of the same WS-Notification service (subject to subscription on the correct topic) regardless of the particular service point to which they are connected. For more information, see Reasons to create multiple WS-Notification service points.

The existence of a WS-Notification service point on a bus member implies that a WS-Notification Web service is exposed from that bus member, and causes Web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

To modify a WS-Notification service point use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional Properties] WS-Notification service points** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points**. The WS-Notification service points [Collection] form is displayed. This form shows all the WS-Notification service points configured for this WS-Notification service.
2. In the content pane, click the name of a WS-Notification service point in the list. The current settings for this WS-Notification service point are displayed in the WS-Notification service points [Settings] form.
3. Modify the general properties. The only general property that you can modify is the **description** property.
4. Modify the additional properties:
   a. Modify the administered subscribers that are associated with this WS-Notification service point. An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time. For more information, see “Modifying a WS-Notification administered subscriber” on page 1103.
   b. Modify the custom properties, if any, that you have set for this WS-Notification service point. These custom properties are name and value pairs that you can use to set internal system configuration properties. In each pair, the name is a property key and the value is a string value.
   a. Modify the inbound ports that are associated with this WS-Notification service point.

      An inbound port describes the Web service enablement of a service destination on a specific endpoint listener, with associated configuration. Each inbound port is associated with an endpoint listener, and you can control which groups of users can access a particular inbound service by making the service available only through specific endpoint listeners. For more information, see Endpoint listeners and inbound ports: Entry points to the service integration bus.

      You can use a JAX-RPC handler list to monitor activity at the port, and take appropriate action (for example logging, or re-routing) depending upon the sender and content of each message that passes through the port. For more information, see Bus-enabled Web services and JAX-RPC handlers.

      You can use WS-Security to set the levels of security to be applied to messages. The security level can be set independently for request and response messages. For more information, see Service integration technologies and WS-Security.

      See also Inbound ports settings.
5. Apply any changes, then click **OK**. If the processing completes successfully, the list of WS-Notification service points for this WS-Notification service is redisplayed. Otherwise, an error message is displayed.
6. Save your changes to the master configuration.

What to do next

You can also use the administrative console to work with runtime information for service points. For more information, see “Interacting at run time with WS-Notification” on page 1077.

Deleting WS-Notification service points:

Delete one or more WS-Notification service points and the associated resources (Version 7.0 service point provider applications, or Version 6.1 inbound services and endpoint listeners).

Before you begin

Decide on which method you want to use to configure these resources. You can delete a WS-Notification service point by using the administrative console as described in this task, or by using the deleteWSNServicePoint command.

Do not use this task to delete service points as part of the process of deleting a WS-Notification service. When you delete a WS-Notification service, the associated service points and resources are automatically deleted.

About this task

A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified Web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. When you delete a WS-Notification service point, the associated resources (Version 7.0 service point provider applications, or Version 6.1 inbound services and endpoint listeners) are automatically deleted. Do not delete these resources manually, because this might leave the associated configuration information in an inconsistent state.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional Properties] WS-Notification service points** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points**. A list of all the WS-Notification service points is displayed in a WS-Notification service points [Collection] form.
3. Select the check box for every WS-Notification service point that you want to remove.
4. Click **Delete**. If the processing completes successfully, the list of WS-Notification service points for this WS-Notification service is updated. Otherwise, an error message is displayed.
5. Save your changes to the master configuration.

Creating a new WS-Notification administered subscriber:

As part of the configuration of a WS-Notification service point you can configure any number of administered subscribers for that service point. An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time.

Before you begin

Decide on which method you want to use to configure these resources. You can create a new administered subscriber by using the administrative console as described in this task, or by using the createWSNAdministeredSubscriber command.

You should not define an administered subscriber for any of the endpoints exposed by the WS-Notification service on which it is being defined, because this would result in infinite looping of messages through the notification broker.

About this task

An administered subscriber contains the name of a NotificationProducer application or a (different) NotificationBroker endpoint and details of a subscription request (for example topic) that the WS-Notification service point should register as part of the server startup procedure. This allows you to

pre-configure links between the NotificationBroker and a NotificationProducer, which can be a remote NotificationBroker or a NotificationProducer application.

To create a new administered subscriber, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name*** → **Administered subscribers** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name*** → **Administered subscribers**. The Administered subscribers [Collection] form is displayed.
2. In the content pane, click **New**.
3. Specify the following properties for this administered subscriber.

   External web service endpoint
   The URL of the external Web service to which the service should subscribe. That is, the endpoint reference (Web address) of a notification producer or notification broker application. For example `http://remoteproducer.com`.

   Dialect
   The dialect in which the topic is expressed. The options are `Simple`, `Concrete`, or `Full`, as defined by the WS-Topics standard.

   Topic The topic on which the service should subscribe. This describes the class of notification messages that are delivered to the WS-Notification service point. For example `stock/IBM`. This property can include wildcards if they are supported by the topic dialect that you select.

   Topic namespace
   The URI that describes the topic namespace in which the specified topic is defined.

   Remote subscription timeout
   The length of time in hours after which the remote subscription will expire if not renewed by the server. This timeout minimizes the potential for orphaned subscriptions in the remote Web service if the local server is uninstalled. Note that this field does not indicate the actual time at which the remote subscription is due to expire. Set the timeout length to something larger than the maximum length of time that the server is expected to remain offline, otherwise the stream of messages from the remote Web service might be interrupted. While the server is running it occasionally renews the remote subscription termination time (with the specified timeout) to prevent it from expiring during normal operation. If not specified, this timeout defaults to 24 (hours).
4. Click **OK**. If the processing completes successfully, the list of administered subscribers associated with the WS-Notification service point is updated to include the new administered subscriber. Otherwise, an error message is displayed.
5. Save your changes to the master configuration.

What to do next

You can also use the administrative console to list runtime information for administered subscribers. For more information, see “Listing active WS-Notification administered subscribers” on page 1123.

Modifying a WS-Notification administered subscriber:

As part of the configuration of a WS-Notification service point you can configure any number of administered subscribers for that service point. An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time.

About this task

An administered subscriber contains the name of a NotificationProducer application or a (different) NotificationBroker endpoint and details of a subscription request (for example topic) that the WS-Notification service point should register as part of the server startup procedure. This allows you to pre-configure links between the NotificationBroker and a NotificationProducer, which can be a remote NotificationBroker or a NotificationProducer application.

To modify an administered subscriber, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name*** → **Administered subscribers** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name*** → **Administered subscribers**. The Administered subscribers [Collection] form is displayed. This form shows all the administered subscribers configured for this WS-Notification service point.
2. In the content pane, click the name of an administered subscriber in the list. The current settings for this administered subscriber are displayed in the **Configuration** panel.
3. Modify the properties for this administered subscriber.

   External web service endpoint
   The URL of the external Web service to which the service should subscribe. That is, the endpoint reference (Web address) of a notification producer or notification broker application. For example `http://remoteproducer.com`.

   Dialect
   The dialect in which the topic is expressed. The options are `Simple`, `Concrete`, or `Full`, as defined by the WS-Topics standard.

   Topic The topic on which the service should subscribe. This describes the class of notification messages that are delivered to the WS-Notification service point. For example `stock/IBM`. This property can include wildcards if they are supported by the topic dialect that you select.

   Topic namespace
   The URI that describes the topic namespace in which the specified topic is defined.

   Remote subscription timeout
   The length of time in hours after which the remote subscription will expire if not renewed by the server. This timeout minimizes the potential for orphaned subscriptions in the remote Web service if the local server is uninstalled. Note that this field does not indicate the actual time at which the remote subscription is due to expire. Set the timeout length to something larger than the maximum length of time that the server is expected to remain offline, otherwise the stream of messages from the remote Web service might be interrupted. While the server is running it occasionally renews the remote subscription termination time (with the specified timeout) to prevent it from expiring during normal operation. If not specified, this timeout defaults to 24 (hours).
4. Apply any changes, then click **OK**. If the processing completes successfully, the list of administered subscribers associated with the WS-Notification service point is redisplayed. Otherwise, an error message is displayed.
5. Save your changes to the master configuration.

What to do next

You can also use the administrative console to list runtime information for administered subscribers. For more information, see “Listing active WS-Notification administered subscribers” on page 1123.

Deleting WS-Notification administered subscribers:

Delete one or more WS-Notification administered subscribers. An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time.

Before you begin

Decide on which method you want to use to configure these resources. You can delete an administered subscriber by using the administrative console as described in this task, or by using the deleteWSNAdministeredSubscriber command.

About this task

To delete one or more administered subscribers, use the administrative console to complete the following steps :

1. In the navigation pane, click **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name*** → **Administered subscribers** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name*** → **Administered subscribers**. A list of all the administered subscribers is displayed in an Administered subscribers [Collection] form.
2. Select the check box for every administered subscriber that you want to remove.
3. Click **Delete**. If the processing completes successfully, the list of administered subscribers for this WS-Notification service is updated. Otherwise, an error message is displayed.
4. Save your changes to the master configuration.

Creating a new WS-Notification permanent topic namespace:

Create a new permanent topic namespace. A topic namespace is a grouping of topics that allows information to be shared between applications. You use a permanent topic namespace to statically define the association between a WS-Notification topic namespace URI and a service integration bus topic space destination.

Before you begin

Decide on which method you want to use to configure these resources. You can create a new WS-Notification permanent topic namespace by using the administrative console as described in this task, or by using the createWSNTopicNamespace command.

You can create many to many relationships between the set of permanent topic namespaces defined in a cell (that is for all WS-Notification services defined in that cell) and the service integration bus topic spaces with which they are associated. These relationships can become quite complex depending upon the topologies required by the applications that connect to the WS-Notification service. For guidance on when certain configurations might or might not be appropriate, see Options for associating a permanent topic namespace with a bus topic space.

About this task

A permanent topic namespace has the following characteristics:

- It enables you to expose an existing service integration bus topic space for use by WS-Notification clients, thus permitting interoperation between the WS-Notification applications and existing publish and subscribe applications connected to the bus such as JMS.
- It allows you to restrict the structure and content of the topic namespace by applying one or more topic namespace documents that describe the required structure.

- It allows the topic namespace to be used as part of a topic space mapping configured on a service integration bus link (between two service integration buses) or a topic mapping as part of a publish and subscribe bridge between a service integration bus and a WebSphere MQ network.

When you create a new WS-Notification permanent topic namespace, you specify the namespace and associate it with one of the service integration bus topic spaces configured on the bus on which the parent WS-Notification service is defined. You cannot modify a permanent topic namespace after it has been created, other than to apply or remove topic namespace documents.

You can also set a configuration attribute of a permanent topic namespace to control the reliability (persistence or non persistence) setting that is applied to any messages inserted using a given topic namespace.

To create a new WS-Notification permanent topic namespace, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **Permanent topic namespaces** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **Permanent topic namespaces**. The Permanent topic namespaces [Collection] form is displayed.
2. In the content pane, click **New**.
3. Specify the following properties for this permanent WS-Notification topic namespace:
   a. Enter a name for the permanent topic namespace. The URI string by which this topic namespace is known. That is, the namespace URI by which WS-Notification applications refer to topics hosted by this namespace. For example `http://widgetproducer.com/prices`.
   b. Associate this new permanent topic namespace with the service integration bus topic space that you want to use to publish and receive messages. From the service integration bus topic space selection list, complete one of the following actions:
      - Choose the name of an existing bus topic space.
      - Choose the offered default name of *this_service_name*`TopicSpace` for a new bus topic space.
      - Choose the option to `Create a new topic space`, then enter a name for the new topic space.
   c. Select from the selection list the service integration bus reliability (quality of service) that is assigned to messages published using this topic namespace. You can choose one of five values. Each value represents one of the service integration bus message reliability levels. The default value is `reliable persistent`, which is the value used by default for JMS Persistent messages.
4. Click **OK**. If the processing completes successfully, the list of permanent WS-Notification topic namespaces is updated to include the new topic namespace. Otherwise, an error message is displayed.
5. Save your changes to the master configuration.

What to do next

To view the configuration of the associated service integration bus topic space, see “Showing the properties of a permanent WS-Notification topic namespace.” To apply a topic namespace document, see “Applying a WS-Notification topic namespace document” on page 1108

Showing the properties of a permanent WS-Notification topic namespace:

A topic namespace is a grouping of topics that allows information to be shared between applications.You use a permanent topic namespace to statically define the association between a WS-Notification topic namespace URI and a service integration bus topic space destination.

Before you begin

Decide on which method you want to use to configure these resources. You can show the properties of a permanent WS-Notification topic namespace by using the administrative console as described in this task, or by using the showWSNTopicNamespace command.

About this task

A permanent topic namespace has the following characteristics:

- It enables you to expose an existing service integration bus topic space for use by WS-Notification clients, thus permitting interoperation between the WS-Notification applications and existing publish and subscribe applications connected to the bus such as JMS.
- It allows you to restrict the structure and content of the topic namespace by applying one or more topic namespace documents that describe the required structure.
- It allows the topic namespace to be used as part of a topic space mapping configured on a service integration bus link (between two service integration buses) or a topic mapping as part of a publish and subscribe bridge between a service integration bus and a WebSphere MQ network.

When you create a new WS-Notification permanent topic namespace, you specify the namespace and associate it with one of the service integration bus topic spaces configured on the bus on which the parent WS-Notification service is defined. You cannot modify a permanent topic namespace after it has been created, other than to apply or remove topic namespace documents.

To show the properties of a permanent WS-Notification topic namespace, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **Permanent topic namespaces** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **Permanent topic namespaces**. The Permanent topic namespaces [Collection] form is displayed. This form shows all the permanent topic namespaces configured for this WS-Notification service.
2. Optional: To view the configuration of the service integration bus topic space that is associated with a given permanent topic namespace, click the link in the **Service integration bus topic space** column. For more information, see Topic space [Settings]
3. Optional: To view the configuration of the namespace documents that are associated with a given permanent topic namespace, click the link in the **Namespace documents** column.

   Note: This link also shows the number of namespace documents (0 or more) that are currently applied.

   The Topic namespace document [Collection] form is displayed. Use this form to apply, show or delete topic namespace documents.

Deleting WS-Notification permanent topic namespaces:

Delete topic namespace definitions from a WS-Notification service. A topic namespace is a grouping of topics that allows information to be shared between applications.You use a permanent topic namespace to statically define the association between a WS-Notification topic namespace URI and a service integration bus topic space destination.

Before you begin

Decide on which method you want to use to configure these resources. You can delete a WS-Notification permanent topic namespace using the administrative console as described in this task, or you can delete a WS-Notification permanent topic namespace using the wsadmin tool.

About this task

Deleting the topic namespace mapping that was used to establish a (currently active) subscription has the same effect as deleting the underlying service integration bus topic space, and subscriptions that were created using this namespace mapping are deleted. For more information about the effect that deleting a topic namespace has upon new and existing WS-Notification applications, see Failures as a result of changes in topic space and topic namespace configurations.

To delete one or more permanent topic namespaces, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **Permanent topic namespaces** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **Permanent topic namespaces**. A list of all the permanent topic namespaces for this WS-Notification service is displayed in a Permanent topic namespaces [Collection] form.
2. Select the check box for every permanent topic namespace that you want to remove.
3. Click **Delete**.

   For each selected namespace, if the associated service integration bus topic space was created explicitly by the permanent topic namespace then you are asked whether or not to automatically delete the bus topic space. If the bus topic space was not created by the permanent topic namespace then you are not asked this question and the topic space is not deleted.

   Note: Deleting a service integration bus topic space causes exception messages to be generated for WS-Notification applications that reference the topic space, as described in Failures as a result of changes in topic space and topic namespace configurations.

   If the processing completes successfully, the list of permanent topic namespaces for this WS-Notification service is updated. Otherwise, an error message is displayed.
4. Save your changes to the master configuration.

Applying a WS-Notification topic namespace document:

A topic namespace can optionally have topic namespace documents applied to it that define the structure of the topics that are permitted within the namespace. Use the administrative console to apply a topic namespace document to an existing topic namespace.

Before you begin

This task assumes that you have already created the topic namespace document that you want to apply.

Decide on which method you want to use to configure these resources. You can apply a topic namespace document by using the administrative console as described in this task, or by using the createWSNTopicDocument command.

About this task

For more information about the relationship between a permanent topic namespace and a topic namespace document, see Chapter 5 of the WS-Topics standard.

To apply a topic namespace document to an existing topic namespace, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **Permanent topic namespaces** → ***namespace_name*** → **Topic namespace documents** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **Permanent topic namespaces** → ***namespace_name*** → **Topic namespace documents**. The Topic

namespace document [Collection] form is displayed. This form shows all the topic namespace documents configured for this permanent topic namespace.

2. In the content pane, click **New**. The Topic namespace document [Settings] form is displayed.
3. Specify the following properties for this topic namespace document:
   a. URL of topic namespace document The URL of the topic namespace document that should be loaded.
   b. Optional: Description An optional description of the topic namespace document.
4. Click **OK**. If the processing completes successfully, the list of topic namespace documents for this permanent topic namespace is updated to include the new document. Otherwise, an error message is displayed.
5. Save your changes to the master configuration.

Showing the contents of a WS-Notification topic namespace document:

A topic namespace can optionally have topic namespace documents applied to it that define the structure of the topics that are permitted within the namespace. Use the administrative console to show the contents of a topic namespace document.

Before you begin

Decide on which method you want to use to configure these resources. You can show the contents of a topic namespace document by using the administrative console as described in this task, or by using the showWSNTopicDocument command.

About this task

For more information about the relationship between a permanent topic namespace and a topic namespace document, see Chapter 5 of the WS-Topics standard.

To show the contents of a WS-Notification topic namespace document, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **Permanent topic namespaces** → ***namespace_name*** → **Topic namespace documents** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **Permanent topic namespaces** → ***namespace_name*** → **Topic namespace documents**. The Topic namespace document [Collection] form is displayed. This form shows all the topic namespace documents configured for this permanent topic namespace.
2. In the content pane, click the name of a topic namespace document in the list. The contents of this topic namespace document are displayed.

Deleting WS-Notification topic namespace documents:

A topic namespace can optionally have topic namespace documents applied to it that define the structure of the topics that are permitted within the namespace. Use the administrative console to delete one or more WS-Notification topic namespace documents.

Before you begin

Decide on which method you want to use to configure these resources. You can delete a WS-Notification topic namespace document by using the administrative console as described in this task, or by using the deleteWSNTopicDocument command.

About this task

To delete one or more WS-Notification topic namespace documents, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **Permanent topic namespaces** → ***namespace_name*** → **Topic namespace documents** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **Permanent topic namespaces** → ***namespace_name*** → **Topic namespace documents**. A list of all the WS-Notification topic namespace documents is displayed in a Topic namespace document [Collection] form.
2. Select the check box for every WS-Notification topic namespace document that you want to remove.
3. Click **Delete**. If the processing completes successfully, the list of WS-Notification topic namespace documents for this WS-Notification topic namespace is updated. Otherwise, an error message is displayed.
4. Save your changes to the master configuration.

Publishing the WSDL files for a WS-Notification application to a ZIP file:

Use the administrative console to download a zip file that contains a WS-Notification application's published WSDL files.

About this task

The ability to publish these WSDL files to a ZIP file is particularly useful in the following circumstances:

- Writing a WS-Notification application that invokes Web service operations against the NotificationBroker application, as described in Writing a WS-Notification application that does not expose a Web service endpoint.
- Viewing the endpoint URLs to which WS-Notification applications connect, by looking in the WSDL file for the NotificationBroker application for Version 7.0 services, or the inbound service for Version 6.1 services.

1. Start the administrative console.
2. Navigate to the "Publish WSDL files to ZIP file [Settings]" form for the WS-Notification application.

   For Version 7.0 WS-Notification services, click one of the following paths:

   - **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name*** → **[Additional Properties] Publish WSDL files to zip**
   - **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name*** → **[Additional Properties] Publish WSDL files to zip**

   For Version 6.1 WS-Notification services, click one of the following paths:

   - **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Related Items] Notification broker inbound service settings** → **[Additional Properties] Publish WSDL files to ZIP file**
   - **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Related Items] Notification broker inbound service settings** → **[Additional Properties] Publish WSDL files to ZIP file**
3. Click on the file name to download a zip file that contains the application's published WSDL files.

Configuring JAX-WS handlers:

A JAX-WS handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. You can create JAX-WS

handlers, chain them together in the form of a handler list, then apply the handler list to a Version 7.0 WS-Notification service point (for inbound invocation handling) or WS-Notification service (for outbound invocation handling).

About this task

The Java API for XML-based Web services (JAX-WS) provides you with a standard way of developing interoperable and portable Web services. To create a JAX-WS handler, you can use a tool such as IBM Rational Application Developer. To enable handlers to perform more complex operations, you chain them together into handler lists. You associate each handler list with one or more Version 7.0 WS-Notification services or service points, so that the handler list can monitor WS-Notification activity and take appropriate action depending upon the sender and content of each inbound or outbound message.

Detailed instructions on how to configure JAX-WS handlers and handler lists for use with Version 7.0 WS-Notification services are provided in the following topics:

- Load JAX-WS handler classes.
- Create a new JAX-WS handler configuration.
- Modify an existing JAX-WS handler configuration.
- Delete JAX-WS handler configurations.
- Create a new JAX-WS handler list.
- Modify an existing JAX-WS handler list.
- Delete JAX-WS handler lists.

Loading JAX-WS handler classes:

A JAX-WS handler interacts with messages through a Version 7.0 WS-Notification service point (for inbound invocation handling) or WS-Notification service (for outbound invocation handling), therefore you need to make the handler class available to the server or cluster that hosts the WS-Notification service point or service that you want to monitor.

Before you begin

This task assumes that you have already created your handler. You can do this using IBM Rational Application Developer or a similar tool.

About this task

Before you can configure a JAX-WS handler for use with WS-Notification, you must make the handler class available to the server or cluster that hosts the WS-Notification service point or service that you want to monitor. To do this, you create a shared library for the class then add the shared library to the class loader for the server.

1. Package the class file for your handler as a JAR file, then copy the JAR file into a convenient directory.

   Make the handler class available to the application server in one of the following ways:

   - Copy the individual class file into a directory structure under *app_server_root*/classes that matches the package name of the class, where *app_server_root* is the root directory for the installation of WebSphere Application Server. For example a handler class com.ibm.jaxws.handler.TestHandler is copied into the *app_server_root*/classes/com/ibm/jaxws/handler directory.
   - Package the class files for all your handlers as a JAR file, then copy it into the *app_server_root*/lib/app directory.
2. Start the administrative console.
3. Create a shared library for the JAR file.
   a. Navigate to **Environment** → **Shared libraries**.

b. Set the scope at which you want the new library to be visible, then click **New**.
c. Give the new library a name.
d. Set the class path to the directory and file name for your handler JAR file.
e. Save your changes to the master configuration.

For more information, see Creating shared libraries.

4. Create a class loader for the server on which you want to make the JAR file available.
   a. Navigate to **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Server Infrastructure] Java and Process Management** → **Class loader**.
   b. Click **New**.
   c. Click **OK**.
   d. Save your changes to the master configuration.

   For more information, see Configuring class loaders of a server.
5. Add the shared library to the class loader for the server.
   a. Navigate to **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Server Infrastructure] Java and Process Management** → **Class loader** → ***class_loader_name*** → **[Additional Properties] Shared library references**.
   b. Click **Add**.
   c. Click on the name of your new library, then click **OK**.
   d. Save your changes to the master configuration.

   For more information, see Associating shared libraries with servers.

What to do next

You are now ready to create a new JAX-WS handler configuration by using the administrative console or by using the createJAXWSHandler command.

Creating a new JAX-WS handler configuration:

Create a Java API for XML-based Web services (JAX-WS) handler configuration for use, as part of a handler list, with Version 7.0 WS-Notification services.

Before you begin

You can create a new JAX-WS handler configuration by using the administrative console as described in this topic, or by using the createJAXWSHandler command.

This task assumes that you have already created your handler. You can do this using IBM Rational Application Developer or a similar tool. You must also make the handler class available to the server or cluster that hosts the WS-Notification service points (for inbound invocation handling) or WS-Notification services (for outbound invocation handling) that you want to monitor, as detailed in “Loading JAX-WS handler classes” on page 1111.

About this task

A Java API for XML-based Web services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. To make WebSphere Application Server aware of your handler, and to make the handler available for inclusion in one or more handler lists, you use the administrative console to create a new handler configuration.

1. Start the administrative console.

2. Navigate to **Service integration** → **WS-Notification** → **JAX-WS Handlers**. The JAX-WS handlers collection form is displayed.
3. Click **New**. The JAX-WS handlers settings form is displayed.
4. Type the following general properties:
   Name Type the name by which the handler is known.

   This name must be unique at cell scope, and it must obey the following syntax rules:
   - It must not start with "." (a period).
   - It must not start or end with a space.
   - It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

   For example `TestHandler`.

   Description
   Type the (optional) description of the handler.

   Class name
   Type the name of the class that is to be instantiated. This name must be a fully qualified java class name. For example `com.ibm.jaxws.handler.TestHandler`.

   Note: You can configure multiple instances of a handler by creating each instance with a different handler name, and pointing to the same handler class.
5. Click **OK**. The general properties for this item are saved, and the additional properties options are made available.
6. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of handlers is updated to include the new handler. Otherwise, an error message is displayed.

What to do next

To use this handler, add it to a handler list as described in Creating a new JAX-WS handler list or Modifying an existing JAX-WS handler list.

Modifying an existing JAX-WS handler configuration:

Modify a Java API for XML-based Web services (JAX-WS) handler configuration for a handler that is used, as part of a handler list, with Version 7.0 WS-Notification services.

Before you begin

You can modify a JAX-WS handler configuration by using the administrative console as described in this topic, or by using the modifyJAXWSHandler command.

If you modify a handler class but do not change the class name, you do not need to modify the handler configuration as described in this topic. You just need to stop then restart the servers or clusters that host the services or service points that this handler monitors.

About this task

A Java API for XML-based Web services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. You can use the administrative console to list existing handler configurations, and to view and modify their configuration details.

1. Start the administrative console.

2. Navigate to **Service integration** → **WS-Notification** → **JAX-WS Handlers**. A list of handlers is displayed in a JAX-WS handlers collection form.
3. Click the name of a handler in the list. The current JAX-WS handlers settings for this handler are displayed.
4. Modify the following general properties:
   Name Modify the name of the handler.

   This name must be unique at cell scope, and it must obey the following syntax rules:
   - It must not start with "." (a period).
   - It must not start or end with a space.
   - It must not contain any of the following characters: \ / , # $ @ : ; " * ? < > | = + & % '

   Note: When you change a handler name, the system looks up all objects that refer to it and updates the name.

   Description
   Modify the (optional) description of the handler.

   Class name
   Change the name of the class that is to be instantiated.

   If you change the class name, you must also make the new handler class available to the server or cluster that hosts the WS-Notification service points (for inbound invocation handling) or WS-Notification services (for outbound invocation handling) that you want to monitor, as detailed in "Loading JAX-WS handler classes" on page 1111.

   Note: You can configure multiple instances of a handler by creating each instance with a different handler name, and pointing to the same handler class.
5. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of handlers is redisplayed. Otherwise, an error message is displayed.

Deleting JAX-WS handler configurations:

Delete the configuration for one or more Java API for XML-based Web services (JAX-WS) handlers that are configured for use, as part of a handler list, with Version 7.0 WS-Notification services.

Before you begin

You can delete a JAX-WS handler configuration by using the administrative console as described in this topic, or by using the deleteJAXWSHandler command.

About this task

A Java API for XML-based Web services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request.

When you remove a handler that is currently used by one or more Web services on a service integration bus, the system removes the handler from the handler lists for each associated Web service.

You can use the administrative console to remove one or more handler configurations.

1. Start the administrative console.
2. Navigate to **Service integration** → **WS-Notification** → **JAX-WS Handlers**. A list of handlers is displayed in a JAX-WS handlers collection form.

3. Select the check box for every handler that you want to remove.
4. Click **Delete**.

Results

If the processing completes successfully, the list of handlers is updated. Otherwise, an error message is displayed.

Creating a new JAX-WS handler list:

Create a Java API for XML-based Web services (JAX-WS) handler list for use with Version 7.0 WS-Notification services.

Before you begin

You can create a new JAX-WS handler list by using the administrative console as described in this topic, or by using the createJAXWSHandlerList command.

You can only add previously-configured handlers to a handler list. To configure a handler, see “Creating a new JAX-WS handler configuration” on page 1112.

About this task

A Java API for XML-based Web services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. To enable handlers to perform more complex operations, you chain them together into handler lists. The approach taken in WebSphere Application Server is to assign handler lists (rather than individual handlers) to WS-Notification service points (for inbound invocation handling) or WS-Notification services (for outbound invocation handling).

1. Start the administrative console.
2. Navigate to **Service integration** → **WS-Notification** → **JAX-WS Handler Lists**. The JAX-WS handler lists collection form is displayed.
3. Click **New**. The JAX-WS handler lists settings form is displayed.
4. Type the following general properties:
   Name Type the name by which the handler list is known.

   This name must be unique at cell scope, and it must obey the following syntax rules:
   - It must not start with “.” (a period).
   - It must not start or end with a space.
   - It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

   For example `TestList`.

   Description
   Type the (optional) description of the handler list.

   JAX-WS handlers
   In the JAX-WS handlers pane, complete the following steps:
   a. Select one or more handlers from the list of available JAX-WS handlers, then click **Add** to move the selected handlers into the list of handlers for this JAX-WS handler list.
   b. Select a handler in the list of handlers for this JAX-WS handler list, then click **Up** or **Down** to change the position of the handler within the list.

   Handlers are applied in the sequence in which they appear in the handler list.

   Note: If you click **Reset**, only the **Name** and **Description** fields are reset to their state when the form was first loaded. The two lists of available and assigned handlers are not reset.
5. Click **OK**. The general properties for this item are saved.

6. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of handler lists is updated to include the new handler list. Otherwise, an error message is displayed.

What to do next

To apply this handler list to inbound notification requests received at a Version 7.0 WS-Notification point, associate it with the service point as described in “Creating a new Version 7.0 WS-Notification service point” on page 1095 or “Modifying a Version 7.0 WS-Notification service point” on page 1097. To apply this handler list to outbound notification requests sent by your Version 7.0 WS-Notification service, associate the handler list with the service as described in “Creating a new Version 7.0 WS-Notification service” on page 1081 or “Modifying a Version 7.0 WS-Notification service” on page 1085.

For an overview of the end-to-end task of creating JAX-WS handlers, chaining them together in a handler list, then applying the handler list to a Version 7.0 WS-Notification service point or service, see “Applying a JAX-WS handler list to a WS-Notification service” on page 1068.

Modifying an existing JAX-WS handler list:

Modify the configuration details for a Java API for XML-based Web services (JAX-WS) handler list that is configured for use with Version 7.0 WS-Notification services.

Before you begin

You can modify a JAX-WS handler list by using the administrative console as described in this topic, or by using the modifyJAXWSHandlerList command.

You can only add previously-configured handlers to a handler list. To configure a handler, see “Creating a new JAX-WS handler configuration” on page 1112.

About this task

A Java API for XML-based Web services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. To enable handlers to perform more complex operations, you chain them together into handler lists. The approach taken in WebSphere Application Server is to assign handler lists (rather than individual handlers) to WS-Notification service points (for inbound invocation handling) or WS-Notification services (for outbound invocation handling).

You can use the administrative console to list existing handler lists, and to view and modify their configuration details.

1. Start the administrative console.
2. Navigate to **Service integration** → **WS-Notification** → **JAX-WS Handler Lists**. A list of all the handler lists is displayed in a JAX-WS handler lists collection form.
3. Click the name of a handler list in the list. The current JAX-WS handler lists settings for this handler are displayed.
4. Modify the following general properties:
   Name Modify the name of the handler list.

   This name must be unique at cell scope, and it must obey the following syntax rules:
   - It must not start with “.” (a period).
   - It must not start or end with a space.
   - It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

When you change a handler list name, the system looks up all objects that refer to it and updates the name.

Description

Modify the (optional) description of the handler list.

JAX-WS handlers

In the JAX-WS handlers pane, complete the following steps:

a. Select one or more previously-configured handlers from either the list of available JAX-WS handlers or the list of handlers for this JAX-WS handler list, then click **Add** or **Remove** to modify the list of handlers for this JAX-WS handler list.
b. Select a handler in the list of handlers for this JAX-WS handler list, then click **Up** or **Down** to change the position of the handler within the list.

Handlers are applied in the sequence in which they appear in the handler list.

Note: If you click **Reset**, only the **Name** and **Description** fields are reset to their state when the form was first loaded. The two lists of available and assigned handlers are not reset.

5. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of handler lists is redisplayed. Otherwise, an error message is displayed.

What to do next

To apply this handler list to inbound notification requests received at a Version 7.0 WS-Notification point, associate it with the service point as described in “Creating a new Version 7.0 WS-Notification service point” on page 1095 or “Modifying a Version 7.0 WS-Notification service point” on page 1097. To apply this handler list to outbound notification requests sent by your Version 7.0 WS-Notification service, associate the handler list with the service as described in “Creating a new Version 7.0 WS-Notification service” on page 1081 or “Modifying a Version 7.0 WS-Notification service” on page 1085.

For an overview of the end-to-end task of creating JAX-WS handlers, chaining them together in a handler list, then applying the handler list to a Version 7.0 WS-Notification service point or service, see “Applying a JAX-WS handler list to a WS-Notification service” on page 1068.

Deleting JAX-WS handler lists:

DeleteJava API for XML-based Web services (JAX-WS) handler lists that are configured for use with Version 7.0 WS-Notification services.

Before you begin

You can delete a JAX-WS handler list by using the administrative console as described in this topic, or by using the deleteJAXWSHandlerList command.

About this task

A Java API for XML-based Web services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request.

When you remove a handler list that is currently used by one or more Web services on a service integration bus, the system removes the handler list for each associated Web service.

You can use the administrative console to remove one or more handler list configurations.

1. Start the administrative console.
2. Navigate to **Service integration** → **WS-Notification** → **JAX-WS Handler Lists**. A list of handler lists is displayed in a JAX-WS handler lists collection form.
3. Select the check box for every handler list that you want to remove.
4. Click **Delete**.

Results

If the processing completes successfully, the list of handler lists is updated. Otherwise, an error message is displayed.

Interacting at run time with WS-Notification

View (and in some cases delete) at run time the active items associated with WS-Notification service points.

Before you begin

This task assumes that you have a fully configured and operational WS-Notification service point.

About this task

A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified Web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. The existence of a WS-Notification service point on a bus member implies that a WS-Notification Web service is exposed from that bus member, and causes Web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

You can use the administrative console to interact at run time with the following active items associated with WS-Notification service points:

Publisher registrations
: A runtime list of existing publisher registrations is provided. This includes, for each publisher registration, the information that was used to create it and when it will terminate.

Pull points
: A runtime list is provided of the pull points that have been created. This includes, for each pull point, its current termination time and a link to the associated subscription.

Subscriptions
: A runtime view is provided for subscriptions that have been created by applications. This includes, for each subscription, the information that was used to create it and an indication of its current state.

Administered subscribers
: A runtime list is provided of the administered subscribers for a given WS-Notification service point. This includes, for each administered subscriber, an indication of its current state; for example whether the subscription was successfully initialized at start time.

For each WS-Notification service point, runtime information is available for subscriptions, registrations, pull points and administered subscribers. **For each WS-Notification service**, runtime information is available - aggregated for all service points for the service - for subscriptions, registrations and pull points. There is no aggregated view for administered subscribers at the WS-Notification service level.

To access and use the runtime information for active items associated with WS-Notification service points, use the administrative console to complete the following steps:

1. Choose between information for a particular service point, or information aggregated for all service points for a particular service, by completing one of the following substeps:
   a. Optional: For runtime information for a particular service point, navigate to either **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name*** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name***, then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations, pull points and administered subscribers for this WS-Notification service point.
   b. Optional: For runtime information aggregated for all service points for a particular service, navigate to either **Service integration** → **WS-Notification** → **Services** → ***service_name*** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations and pull points for this WS-Notification service.
2. Click **Subscriptions** , **Publisher registrations**, **Pull points** or (for a particular service point) **Administered subscribers**.
   - If you click **Subscriptions**, a panel is displayed that lists the durable subscriptions that have been created by a WS-Notification service point in response to “Subscribe” requests from WS-Notification applications. You can view the subscription name (ID), topic and other information associated with the subscription, and you can view messages held on the durable subscription pending delivery. You can also delete subscriptions.

     Note: Both the WS-Notification subscription and publisher registration resources include the concept of scheduled termination, in which the application indicates a period of time after which the resource is destroyed. “Badly-behaved” in this case describes an application that requests an infinite lifetime for a resource and then does not explicitly delete the resource before it goes away (never to return).
   - If you click **Publisher registrations**, a panel is displayed that lists the publisher registrations that are currently in effect on this WS-Notification service or service point (that is, applications that have registered as publishers). You can view the basic properties of the registration record. You can also delete a publisher registration record.
   - If you click **Pull points**, a panel is displayed that lists the pull points that are currently active on this WS-Notification service or service point. You can view basic properties of the pull point such as the subscription with which it is associated and the time at which it is currently set to expire, and you can navigate to the associated subscriptions where appropriate. You can also delete pull points.
   - For a particular service point, if you click **Administered subscribers**, a panel is displayed that lists the administered subscribers that are currently in effect on this WS-Notification service point. You can use this information to see whether a given subscriber has been successfully initialized.

What to do next

For more detailed information about working with individual runtime panels, see the following topics:

- “Listing or deleting active WS-Notification subscriptions.”
- “Listing or deleting active WS-Notification publisher registrations” on page 1121.
- “Listing or deleting active WS-Notification pull points” on page 1122.
- “Listing active WS-Notification administered subscribers” on page 1123.

Listing or deleting active WS-Notification subscriptions:

List the subscriptions that exist at run time for a particular WS-Notification service point, or for all service points for a particular WS-Notification service.

About this task

The runtime panels for WS-Notification subscriptions list the durable subscriptions that have been created by a WS-Notification service point in response to “Subscribe” requests from WS-Notification applications. You can view the subscription name (ID), topic and other information associated with the subscription, and you can view messages held on the durable subscription pending delivery. You can also delete subscriptions. For example, to tidy up after a badly-behaved application.

Note: Both the WS-Notification subscription and publisher registration resources include the concept of scheduled termination, in which the application indicates a period of time after which the resource is destroyed. “Badly-behaved” in this case describes an application that requests an infinite lifetime for a resource and then does not explicitly delete the resource before it goes away (never to return).

A subscription created by a WS-Notification application can contain more than one topic expression, and each of these topic expressions can be in a different namespace, which can result in service integration bus subscriptions being created in multiple topic spaces.

To display a list of WS-Notification subscriptions that exist at run time, use the administrative console to complete the following steps:

1. Choose between information for a particular service point, or information aggregated for all service points for a particular service, by completing one of the following substeps:
   a. Optional: For runtime information for a particular service point, navigate to either **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name*** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name***, then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations, pull points and administered subscribers for this WS-Notification service point.
   b. Optional: For runtime information aggregated for all service points for a particular service, navigate to either **Service integration** → **WS-Notification** → **Services** → ***service_name*** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name***, then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations and pull points for this WS-Notification service.
2. Click **Subscriptions** The Subscriptions [Collection] form is displayed. This form shows all the currently active subscriptions for this WS-Notification service point or service. This collection form contains the following information about each list item:

   Subscription id
   The unique identifier of the subscription.

   Topics
   An array of topic names. Note that this will normally only contain one element.

   Delivery state
   The current runtime state of the subscription. In normal operation the subscription will show a state of **OK**. Other states are **PAUSED**, indicating that the application has paused the subscription as defined by the WS-Notification standards, or **ERROR**, indicating that the last attempt to deliver an event notification to the notification consumer was not successful. In the error case, further information on the cause of the failure can be found in the SystemOut log.

   Consumer EPR
   The endpoint reference to which event notifications matching the subscription are sent. That is, the endpoint reference to which notification messages are delivered as specified on the subscribe call.

   Creation time
   The time at which the subscription was created.

Termination time
The time at which the subscription will be deleted.

Pull type
Indicates whether the subscription is being used in pull mode. That is, whether this subscription is being accessed by a pull point. If the asynchronous (push) subscription model is being used, this field displays “No”. If a pull point is being used, this field displays “Yes”.

Service integration bus subscriptions
The service integration bus durable subscription or subscriptions that are associated with the WS-Notification subscription. This is a link to the service integration bus durable subscription detail panel for the subscriptions that contain data for this object.

3. Optional: To observe the runtime state of each of the service integration bus durable subscriptions that have been created, click the link in the **SIBus subscriptions** field.

   If only one durable subscription has been created, the bus durable subscription detail panel is displayed. For more information, see “Administering durable subscriptions” on page 1251.

   If multiple durable subscriptions have been created, for example if the WS-Notification subscription is spanned across multiple service integration bus topic spaces, a runtime collection form is displayed that shows the individual bus durable subscriptions. This form shows all the currently active publisher registrations for this WS-Notification service point or service.

   SIBus subscription
   The service integration bus durable subscription ID. This links to the associated bus durable subscription detail panel. For more information, see “Administering durable subscriptions” on page 1251.

   Topics
   The list of topics that are contained within a single service integration bus topic space (and thus durable subscription).

What to do next

To delete one or more WS-Notification subscriptions, and the associated service integration bus durable subscriptions, enable the check box next to each subscription name then click **Delete**.

Listing or deleting active WS-Notification publisher registrations:

List the publisher registrations that exist at run time for a particular WS-Notification service point, or for all service points for a particular WS-Notification service.

About this task

A WS-Notification application can register itself as a publisher in order to check that it is permitted to publish on the specified list of topics, or to initiate the demand based publisher pattern.

The runtime panels for WS-Notification publisher registrations list the publisher registrations that are currently in effect on this WS-Notification service or service point (that is, applications that have registered as publishers). You can view the basic properties of the registration record. You can also delete a publisher registration record. For example, to tidy up after a badly-behaved application.

Note: Both the WS-Notification subscription and publisher registration resources include the concept of scheduled termination, in which the application indicates a period of time after which the resource is destroyed. “Badly-behaved” in this case describes an application that requests an infinite lifetime for a resource and then does not explicitly delete the resource before it goes away (never to return).

To display a list of WS-Notification publisher registrations that exist at run time, use the administrative console to complete the following steps:

1. Choose between information for a particular service point, or information aggregated for all service points for a particular service, by completing one of the following substeps:
   a. Optional: For runtime information for a particular service point, navigate to either **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name*** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name***, then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations, pull points and administered subscribers for this WS-Notification service point.
   b. Optional: For runtime information aggregated for all service points for a particular service, navigate to either **Service integration** → **WS-Notification** → **Services** → ***service_name*** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name***, then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations and pull points for this WS-Notification service.
2. Click **Publisher registrations** The Publisher registrations [Collection] form is displayed. This form shows all the currently active publisher registrations for this WS-Notification service point or service. This collection form contains the following information about each list item:

   Publisher ID
   The unique identifier of this publisher registration.

   Topic The topic on which the publisher is registered to publish. That is, the list of topics that are contained within a single service integration bus topic space (and thus durable subscription).

   Creation time
   The time at which the registration was created.

   Termination time
   The time at which the registration will be deleted.

   Demand based
   Indicates whether this is a demand based publisher. This displays “Yes” or “No”.

   Producer EPR
   Additional publisher related data. The endpoint reference of the producer that created this registration.

What to do next

To delete one or more publisher registrations, enable the check box next to each registration ID then click **Delete**.

Listing or deleting active WS-Notification pull points:

List the pull points that exist at run time for a particular WS-Notification service point, or for all service points for a particular WS-Notification service.

About this task

To use the synchronous delivery mechanism described by the WS-Notification standards, a WS-Notification application creates a pull point against the notification broker.

The runtime panels for WS-Notification pull points list the pull points that are currently active on this WS-Notification service or service point. You can view basic properties of the pull point such as the subscription with which it is associated and the time at which it is currently set to expire, and you can navigate to the associated subscriptions where appropriate. You can also delete pull points.

To display a list of WS-Notification pull points that exist at run time, use the administrative console to complete the following steps:

1. Choose between information for a particular service point, or information aggregated for all service points for a particular service, by completing one of the following substeps:
   a. Optional: For runtime information for a particular service point, navigate to either **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name*** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name***, then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations, pull points and administered subscribers for this WS-Notification service point.
   b. Optional: For runtime information aggregated for all service points for a particular service, navigate to either **Service integration** → **WS-Notification** → **Services** → ***service_name*** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name***, then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations and pull points for this WS-Notification service.
2. Click **pull points** The Pull points [Collection] form is displayed. This form shows all the currently active pull points for this WS-Notification service point or service. This collection form contains the following information about each list item:

   Pull point id
   The unique identifier of the pull point.

   Creation time
   The time at which the pull point was created.

   Termination time
   The time at which the pull point will be deleted.

   Subscription id
   The unique identifier of the subscription associated with the pull point. If the pull point has not yet been supplied to a subscription, the text “Not Associated” is displayed.

What to do next

To delete one or more pull points, enable the check box next to each pull point ID then click **Delete**.

Listing active WS-Notification administered subscribers:

List the administered subscribers that exist at run time for a particular WS-Notification service point. An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time.

About this task

The runtime panels for WS-Notification administered subscribers list the administered subscribers that are currently in effect on this WS-Notification service point. You can use this information to see whether a given subscriber has been successfully initialized.

Administered Subscribers are defined on individual WS-Notification service points. There is no aggregated view for administered subscribers at the WS-Notification service level.

To display a list of WS-Notification administered subscribers that exist at run time, use the administrative console to complete the following steps:

1. For runtime information for a particular service point, navigate to either **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name*** or **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification**

services → ***service_name*** → **[Additional Properties] WS-Notification service points** → ***point_name***, then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations, pull points and administered subscribers for this WS-Notification service point.

2. Click **Administered subscribers** The Administered subscribers [Collection] form is displayed. This form shows all the currently active administered subscribers for this WS-Notification service point. This collection form contains the following information about each list item:

   Producer EPR
   The endpoint reference of the remote Web service application from which event notifications are received. That is, the endpoint reference (Web address) of a notification producer or notification broker application. For example `http://remoteproducer.com`. You provided this reference when you created the administered subscriber.

   Topic The topic for which event notifications have been requested.

   Subscription reference
   The string form of the endpoint reference that was returned by the remote service as a result of the subscribe, if successfully created.

   State The current runtime state of the administered subscriber. An icon indicator that displays either green or red to indicate whether the administered subscriber is OK or has failed. Hover over this icon to see a description of the current state. In the OK case, it describes the last successful operation - initially the time at which the subscription was contacted (for server startup) and subsequently the time the last message was received for this subscriber. In the failed case, it describes the details of the last failure.

   Subscription timeout
   The length of time in hours after which the remote subscription will expire if not renewed by the server. This timeout minimizes the potential for orphaned subscriptions in the remote Web service if the local server is uninstalled. Note that this field does not indicate the actual time at which the remote subscription is due to expire. Set the timeout length to something larger than the maximum length of time that the server is expected to remain offline, otherwise the stream of messages from the remote Web service might be interrupted. While the server is running it occasionally renews the remote subscription termination time (with the specified timeout) to prevent it from expiring during normal operation. If not specified, this timeout defaults to 24 (hours).

Chapter 6. Service integration

Service integration technologies

Service integration is a technology that provides asynchronous messaging services. This topic explains about the core technologies on which WebSphere Application Server service integration applications are developed and implemented.

About this task

WebSphere Application Server applications invoke asynchronous messaging services using the Java Messaging Service (JMS) application programming interface (API) to interface to a messaging provider. WebSphere Application Server supports a variety of messaging providers, including service integration which is the built-in messaging provider.

Service integration buses

Application servers or clusters of application servers in a WebSphere Application Server cell can cooperate to provide messaging services. A group of servers and/or clusters which cooperate in this way is called a service integration bus. Each of the cooperating servers or clusters is called a bus member. In the simplest case, a service integration bus consists of a single bus member which is one application server.

A WebSphere Application Server application does not need to be running on a service integration bus member to use its messaging services. If necessary, WebSphere Application Server automatically provides a connection to a suitable bus member.

Different service integration buses can, if required, be connected. This allows applications using one bus (the local bus) to send messages to destinations in another bus (a foreign bus). Note, though, that applications cannot receive messages from destinations in a foreign bus.

Messaging engines

Each service integration bus member contains a component called a messaging engine which processes messaging send and receive requests and which can host destinations. To host destinations, the messaging engine includes a message store where, if necessary, it can hold messages until consuming applications are ready to receive them. Each messaging engine also has a file store or a data store where it can hold messages so that they are not lost when the messaging engine fails.

A service integration bus member which is an application server cluster, can contain one or more messaging engines. These can be configured in a variety of ways which provide flexible availability and workload sharing options.

Why use a service integration bus?

- To connect any kind of application to any other kind of application. This is the traditional WebSphere MQ scenario, where different applications written in different languages are running on different operating systems and you want them all to be able to communicate with each other.
- To connect Java EE applications running in application servers. Service integration is a complete JMS v1.1 provider implementation (not just an API but a working messaging system). The JMS provider is a pure Java implementation that runs within the application server's JVM process. (For persistent messaging, WebSphere Application Server also requires a JDBC compliant database such as DB2.) As a result, JMS messaging is built into WebSphere Application Server and is easily available to any Java EE application deployed in WebSphere Application Server.

  For the situation where many WebSphere Application Server applications are communicating, and you also need to communicate with other non-WebSphere Application Server applications, you must still use WebSphere MQ as the messaging system.

Architectures you can use for interoperating WebSphere Application Server and WebSphere MQ are WebSphere MQ as an external JMS messaging provider, WebSphere MQ links, and WebSphere MQ servers.

What are the benefits of service integration bus?

- Secure externalizing of existing applications: You can use the bus to expose existing applications as Web services, for use by any Web service-enabled tool, regardless of the implementation details. This enables applications or Web services deployed on a server deep inside an enterprise to be made available as Web services on the Internet to customers, suppliers, and business partners. Security options mean that this access can be tightly controlled.
- Return on investment: Business partners can reuse an existing process that you make available as a Web service using the bus. This gives great scope for the reuse of existing assets.
- Protocol transformation: The bus provides support for exposing an existing service implemented in one protocol (for example, SOAP/jms), as something entirely different from clients (for example, SOAP/HTTP). This function is invaluable for ensuring smooth interoperability between businesses that may implement varying Web services protocols in their business applications.
- Messaging benefits: The fact that the bus is built on top of the Java Messaging Service (JMS) delivered in WebSphere Application Server means that it is able to expose messaging artifacts, such as queues and topics, as Web services. It also provides advanced options for asynchronous communication, prioritized message delivery, and quality of service (message persistence).

For more information about what is provided by service integration within WebSphere Application Server, see the following topics:

- “Service integration buses”
- “Messaging engines”
- “Managing data stores” on page 1127
- “Bus destinations” on page 1127
- “Mediations” on page 1127
- “Managing messaging with the default messaging provider” on page 1127
- “Using WebSphere MQ links to connect a bus to a WebSphere MQ network” on page 1614
- “Security” on page 1128
- High availability and workload sharing for service integration technologies
- “Enabling Web services through the service integration bus” on page 1002

Service integration buses

Service integration buses manage the messaging resources that are associated with a server using message-based and service-oriented architectures, including those using the Java Message Service (JMS) interfaces. They are not, however, associated with a specific bus or messaging engine.

- Learning about service integration buses
- “Planning a bus topology” on page 1135
- “Configuring buses” on page 1139
- “Operating buses” on page 1193

Messaging engines

These topics provide information about messaging engines, which provide the processing function on a service integration bus.

- Learning about messaging engines
- “Configuring messaging engines” on page 1152
- Operating messaging engines
- “Managing messaging engines with administrative commands” on page 1204
- SIBAdminCommands: Messaging engine administrative commands for the AdminTask object

- Messaging engine troubleshooting tips

Managing data stores

A data store is a message store that uses a relational database. A data store consists of a set of tables that are in the same database schema. It is used by a messaging engine to store operating information in the database, as well as to preserve essential objects that the messaging engine needs for recovery in the event of a failure.

About this task

A data store consists of the set of tables that a messaging engine uses to store persistent data in a database. Refer to “Data store tables” on page 1217 for a list of the tables that comprise a data store. All the tables in a data store are held in the same database schema. You can create multiple data stores in the same database only by using a different schema for each data store.

Bus destinations

This topic is the entry-point into a set of topics about bus destinations within a service integration bus, to which applications can attach as producers, consumers, or both to exchange messages.

- Learning about bus destinations
- “Configuring bus destinations” on page 1159
- “Configuring message points” on page 1248
- “Managing messages on message points” on page 1194
- “Administering durable subscriptions” on page 1251

Mediations

These topics provide information about mediations, which are used to change how messages are handled at destinations on a service integration bus.

- Learning about mediations
- Learning about programming mediations
- Programming mediations
- “Securing mediations” on page 1254

Managing messaging with the default messaging provider

This topic is the entry point into a set of topics about enabling WebSphere Application Server applications to use messaging resources provided by the default messaging provider.

Before you begin

For messaging between application servers, perhaps with some interaction with a WebSphere MQ system, you can use the default messaging provider as described in this topic. To integrate WebSphere Application Server messaging into a predominantly WebSphere MQ network, you can use the WebSphere MQ messaging provider. You can also use a third party messaging provider. To choose the provider that is best

suited to your needs, see Choosing a messaging provider.

About this task

The default messaging provider is installed and runs as part of WebSphere Application Server, and is based on service integration technologies.

The default messaging provider supports JMS 1.1 domain-independent interfaces (sometimes referred to as “unified” or “common” interfaces). This enables applications to use common interfaces for both point-to-point and publish/subscribe messaging. This also enables both point-to-point and publish/subscribe messaging within the same transaction. With JMS 1.1, this approach is recommended for new applications. The domain-specific interfaces are supported for backwards compatibility for applications developed to use domain-specific queue interfaces, as described in section 1.5 of the JMS 1.1 specification.

You can use the WebSphere Application Server administrative console to configure JMS resources for applications, and can manage messages and subscriptions associated with JMS destinations.

WebSphere Application Server Version 5.1 Java EE applications can use messaging resources of the default messaging provider in WebSphere Application Server Version 7.0. This JMS interoperation from WebSphere Application Server Version 5.1 to later versions is enabled and managed by a WebSphere MQ client link created on the WebSphere Application Server Version 7.0 node. This JMS interoperation is only intended as an aid to the migration from the embedded messaging in WebSphere Application Server Version 5.1 to the default messaging provider in WebSphere Application Server Version 7.0.

Note: Java EE applications running under WebSphere Application Server Version 7.0 can use messaging resources of Version 5 embedded messaging without any need for a WebSphere MQ client link.

For more information about using the default messaging provider of WebSphere Application Server, see the following topics:

- Learning about the default messaging provider
- “Configuring resources for the default messaging provider” on page 1584
- “Interoperating with a WebSphere MQ network” on page 1612
- Migrating from WebSphere Application Server Version 5 embedded messaging
- “Managing WebSphere Application Server Version 5.1 JMS use of messaging resources in later versions of the product” on page 1646
- “Configuring the messaging engine selection process for JMS applications” on page 1656
- “Managing messages and subscriptions for JMS destinations” on page 1657
- “Using JMS from standalone clients to interoperate with service integration resources” on page 1659
- “Using JMS from a third party application server” on page 1666

Security

This topic is an overview of the tasks for administering messaging security for a service integration bus.

Before you begin

Review the security requirements for the bus. For guidance, see Planning your security requirements.

About this task

Messaging security protects the bus from unauthorized access. By default, messaging security is enabled for the bus. Providing administrative security is also enabled, messaging security enforces a security policy that prevents unauthorized client applications from connecting to the bus, and accessing bus resources.

There may be circumstances when you do not require messaging security, for example on a development system. In this case, you can disable messaging security.

You can customize the security configuration for the bus using the administrative console, or wsadmin scripting commands. The security configuration controls the following aspects of bus security:

- Authorizing groups of users in the user registry to perform selected operations on bus destinations.
- The transport policies that maintain the integrity of messages in transit on the bus.
- The use of global, and multiple custom security domains.
- The integrity of links between messaging engines, foreign buses and databases.

Use the following tasks to administer messaging security:

- "Securing buses" on page 1272
- "Enabling client SSL authentication" on page 1279
- "Adding unique names to the bus authorization policy" on page 1281
- "Administering authorization permissions" on page 1281
- "Administering permitted transports for a bus" on page 1307
- "Securing messages between messaging buses" on page 1311
- "Securing access to a foreign bus" on page 1312
- "Securing links between messaging engines" on page 1313
- "Controlling which foreign buses can link to your bus" on page 1314
- "Securing database access" on page 1314
- "Securing mediations" on page 1254

Auditing the service integration security infrastructure

Security auditing is an important part of the security infrastructure. Security auditing provides a mechanism for auditable events to be tracked and archived while ensuring the integrity of the records.

Before you begin

Before enabling the security auditing subsystem for service integration, you must enable global security in your environment.

About this task

The primary responsibility of the security infrastructure is to prevent unauthorized usage of resources. Security auditing has two primary goals:

- Confirming the effectiveness and integrity of the existing security configuration.
- Identifying areas where improvement to the security configuration might be needed.

Security auditing achieves these goals by providing the infrastructure that allows you to implement your code to capture and store supported security auditable events. All code other than the Java enterprise application code is considered to be trusted. Each time an enterprise application accesses a resource, any internal application server process that has audit points that are added within their code can be recorded as an auditable event. The security auditing subsystem captures the following types of auditable events:

- Authentication
- Authorization
- Principal and Credential Mapping
- Key management
- System management
- Security policy management
- Audit policy management
- Administrative configuration management

- Administrative runtime management
- User registry and identity management
- Password changes
- Delegation

These types of events can be recorded into audit log files. The audit log flies can be signed and encrypted to ensure data integrity. These audit log files can be analyzed to discover breaches over the existing security mechanisms and to discover potential weaknesses in the current security infrastructure. Security event audit records are also useful for providing evidence, accountability, and vulnerability analysis. The security auditing configuration provides four default filters, a default audit service provider, and a default event factory. This following steps describe how to customize your security auditing subsystem. Additional information specific to messaging is included in the step description where appropriate.

1. Enabling the security auditing subsystem

   Security auditing is not performed unless the audit security subsystem has been enabled. Global security must be enabled for the security audit subsystem to function, as no security events occur if global security is not also enabled.

   To allow messaging security events to be audited, audit security must be enabled:

   a. For each bus to be audited, click **Service integration** → **Buses** → ***security_value***, and select the **Enable the auditing service for this bus** check box.

   b. For publish/subscribe messaging, also on each topic space on the bus being audited, click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations** → ***topic_space_name***, and select the **Enable the auditing service for this topic space** check box.

2. Auditor role

   A user with the auditor role is required to enable and configure the security auditing subsystem. It is important to require strict access control for security policy management. The auditor role provides granularity to support separation of the auditing role from the authority of the administrator.

3. Creating security auditing event type filters

   You can configure event type filters to only record a specific subset of auditable event types in your audit logs. Filtering the event types that are recorded makes for simpler analysis of your audit records by ensuring the records to only display what you selected as important for your an environment.

   The audit events that can be configured for messaging are:

   SECURITY_AUTHN
   This event is produced when the identity of a messaging client or messaging engine connecting to a messaging bus is authenticated.

   SECURITY_AUTHZ
   This event is produced when the identity of a messaging client is checked for access authority to a bus or a message queue when sending, directly or by publication, or receiving messages, directly or by subscription.

   SECURITY_AUTHN_TERMINATE
   This event is produced when the connection between a messaging client or messaging engine and a messaging bus is terminated.

   SECURITY_MGMT_CONFIG
   This event is produced when a messaging client changes the contents of a service data object (SDO) repository in an import or remove operation.

   You can create event filters for each permutation of an event and its possible outcomes such as SUCCESS, DENIED, or error conditions of different levels of severity.

   See messaging security events for more information on which messaging security audit events are produced and when they are produced.

4. Configuring audit service providers for security auditing

The audit service provider is used to format the audit data object that is passed to it before outputting the data to a repository.

5. Configuring audit event factories for security auditing

   The audit event factory gathers the data associated with the auditable events and creates an audit data object. The audit data object is then sent to the audit service provider to be formatted and recorded to the repository.

6. Protecting your security audit data It is important for the recorded audit data to be both secured and with the data integrity ensured. To ensure that access to the data is restricted and secure, you can encrypt and sign your audit data.

7. Configuring security audit subsystem failure notifications

   You can enable notifications to generate alerts when the security auditing subsystem experiences a failure. Notifications can be configured to record an alert in the audit logs or can be configured to send an alert through e-mail to a specified list of recipients.

Results

After successfully completing this task, you audit data is recorded for the selected auditable events that were specified in the configuration.

What to do next

After configuring security auditing, you can analyze your audit data for potential weaknesses in the current security infrastructure and to discover security breaches that might have occurred over the existing security mechanisms.

Enabling Web services through the service integration bus

Web services can use the service integration bus to provide a single point of control, access, and validation of Web service requests and allow control of Web services that are available to different groups of Web service users.

About this task

With bus-enabled Web services you can achieve the following goals:

- Create an *inbound service*: Take an internally-hosted service that is available at a bus destination, and make it available as a Web service.
- Create an *outbound service*: Take an externally-hosted Web service, and make it available internally at a bus destination.

Bus-enabled Web services provide a choice of quality of service and message distribution options, along with intelligence in the form of mediations that allow for the rerouting of messages.

To enable Web services through service integration technologies, complete the following steps:

1. Optional: Learn about bus-enabled Web services. Explore the concepts that underly service integration bus-enabled Web services.
2. Plan your bus-enabled Web services installation. Determine the bus-enabled Web services roles that each server is to perform.
3. Ensure that every server that is to play a bus-enabled Web services role is a member of a service integration bus. For more information, see “Configuring the members of a bus” on page 1145.
4. For every server that is to play a bus-enabled Web services role, install and configure a Service Data Objects (SDO) repository on the server.

   Note: For WebSphere Application Server Version 6.0, you also had to manually install a selection of the following applications:

- The service integration technologies resource adapter (used to invoke Web services at outbound ports).
- The bus-enabled Web services application.
- One or more endpoint listener applications.

For later versions of WebSphere Application Server, these applications are installed automatically as and when needed. For example, the endpoint listener application is installed automatically when you configure an endpoint listener.

5. Create a new endpoint listener configuration for each endpoint listener application that you plan to use to receive inbound service requests.
6. Optional: Create an inbound service. An inbound service is a Web interface to a service that is provided internally (that is, a service provided by your own organization and hosted in a location that is directly available through a service integration bus destination). To configure a locally-hosted service as an inbound service, you associate it with a service destination, and with one or more endpoint listeners through which service requests and responses are passed to the service. You can also choose to have the local service made available through one or more UDDI registries.
7. Optional: Create an outbound service. An outbound service is a Web service that is hosted externally, and is made available through a service integration bus. To make an externally-hosted service available through a bus, you first associate it with a service destination, then you configure one or more port destinations (one for each type of binding, for example SOAP over HTTP or SOAP over JMS) through which service requests and responses are passed to the external service. You get the port definitions from the WSDL, but you can choose which ones you want to create.
8. Optional: Apply additional security to your bus-enabled Web services. By default, the bus-enabled Web services configuration works when WebSphere Application Server security is enabled and your service integration buses are secured. However this level of security does not impose any security restrictions on the users of your bus-enabled Web services configuration. To control how your bus-enabled Web services configuration is used by each group of your colleagues or customers, use the bus-enabled Web services additional security features to enable working with password-protected components and servers, with WS-Security and with HTTPS.

What to do next

For further information on specific aspects of bus-enabled Web services, see the following topics:

- Learning about bus-enabled Web services

- Tuning bus-enabled Web services

Service integration topologies

This topic provides information about the service integration topologies that you can configure. A service integration topology can range from a single host running two connected applications to a globally-dispersed set of hundreds or thousands of communicating applications running over the bus.

A service integration topology is based on one or more service integration buses that provide a managed communication fabric that supports service integration through synchronous and asynchronous messaging.

A *service integration bus* supports applications using message-based and service-oriented architectures. A bus is a group of one or more interconnected servers that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

A service integration bus provides the following capabilities:

- Any application can exchange messages with any other application by using a *destination* to which one application sends, and from which the other application receives.
- A message-producing application, that is, a *producer*, can produce messages for a destination regardless of which messaging engine the producer uses to connect to the bus.
- A message-consuming application, that is, a *consumer*, can consume messages from a destination (whenever that destination is available) regardless of which messaging engine the consumer uses to connect to the bus.

The service integration bus is sometimes referred to as the *messaging bus* if it is used to provide the messaging system for JMS applications using the default messaging provider.

Many scenarios require a simple bus topology, for example, a single server. If you add multiple servers to a single bus, you increase the number of connection points for applications to use. Servers, however, do not have to be bus members to connect to a bus. In more complex bus topologies, multiple buses are configured, and can be interconnected to form complex networks. An enterprise might deploy multiple interconnected buses for organizational reasons. For example, an enterprise with several independent departments might want separately administered buses in each location.

With bus-enabled Web services you can achieve the following goals:

- Create an *inbound service*: Take an internally-hosted service that is available at a bus destination, and make it available as a Web service.
- Create an *outbound service*: Take an externally-hosted Web service, and make it available internally at a bus destination.

You can change the service integration topology to suit your needs; for example:

- You can add application servers as new bus members. Each new bus member is automatically assigned a messaging engine, with default data source, and a default exception destination. The messaging engines can communicate with, and use resources provided by, all other messaging engines on the bus.
- You can change the configuration of the data source for a messaging engine, for example to use a different JDBC provider.
- You can create new buses and add application servers as members of those buses. Each bus operates as a separate environment, unless connected by a gateway messaging engine.
- You can connect a message-driven bean to consume messages from a destination on a remote cell

Bus topologies

You can connect buses in different ways depending on your requirements. For example, you can link messaging engines to distribute message workload, and to provide availability in the event of system failure.

A topology that consists of a single messaging engine may be adequate for some applications. Deploying more than one messaging engine, and linking them together, provides the following advantages:

- Distributes the messaging workload across multiple servers.
- Positions message processing close to the applications that are using it, and reduces network traffic. For example, if both sending and receiving applications are running in the same server process, it is inefficient to route all the messages that flow between the two applications through a messaging engine running in a remote server.

- Improves availability in the event of system or link failure. For example, your bus topology can remove a single point of failure, and allow store and forward between two servers.
- Provides improved scalability.
- Accommodates firewalls, or other network restrictions that limit the ability of network hosts to connect to a single messaging engine.

Bus topologies that use multiple security domains have additional advantages provided by the presence of bootstrap members. Only servers that are nominated bootstrap members can access the bus. You can define a subset of servers and clusters that can access the bus, and use this information to isolate buses and the applications that use them, and enhance how you manage your bus topologies.

A bus topology can contain links to WebSphere MQ networks. This allows messages to flow between applications connected to a WebSphere MQ queue manager and applications attached to a service integration bus.

The service integration environment backup

It is advisable to back up your service integration system on a regular basis so that you can restore it in the event of an unrecoverable failure. Learn about the issues when taking backups and restoring from a backup.

For service integration, these are the main sections of the system that you can back up:

The configuration files for the system.
The configuration of the system is stored as XML files. To back up or restore these configuration files, use the relevant command as detailed in Backing up and restoring administrative configurations. Any backup or restore of a service integration environment must include a backup or restore of the configuration files.

The data stores that are accessed by the messaging engines.
Taking or restoring a backup of your data stores is optional. Messages are transient in nature, so you might not want to back up or restore the data stores.

- If you do not take a backup of the data stores, and you have modified your current configuration since it was last backed up, and you then restore the configuration backup, be aware that you may lose messages. For example, if you back up the configuration and then create a bus destination, when you restore the configuration backup the destination will no longer exist. Any messages for this destination will be deleted when the server that hosted that messaging engine is restarted.
- If you do take a backup of your data stores, you must also take a backup of the configuration files. You must take the configuration backup at the same time, and restore it at the same time, as the data store backups; taking the backup and restoring at the same time maintains the consistency of the system and reduce the possibility of loss of messages, or duplication of messages from the time of the backup.

To back up a data store, see “Backing up a data store” on page 1216.

The file stores that are accessed by the messaging engines.
Taking or restoring a backup of your file stores is optional. Messages are transient in nature, so you might not want to back up or restore the files. To back up a file store, see “Backing up a file store” on page 1208.

If your environment includes multiple servers, you should backup all the servers at the same time, otherwise messages from the time of the backup might be lost or duplicated. You should also minimize the amount of message traffic flowing through the system to reduce the possibility of lost or duplicate messages.

When you restart a messaging engine after restoring a backup, you should take steps to minimize loss of messages. See Restoring a data store and recovering its messaging engine .

Planning a bus topology

These topics contain information about planning a service integration bus topology. This information is intended primarily for use by solution architects and designers who are in the early stages of planning a bus topology.

About this task

To plan a bus topology, you must consider the following issues:

- How many buses will the topology comprise?
- How will messaging engines and bus destinations be distributed?
- What are the naming conventions for buses, messaging engines, and other service integration bus resources?

Note: Each bus name in a cell must be unique. It is advisable to use unique names for all buses, even when they are in different cells, because you cannot connect two buses with the same name.

You can find more in depth information about your chosen bus topology in the following topics.

Note: Your bus topology might be a combination of the topologies described in these topics.

Planning issues common to all bus topologies

Some planning issues apply to all types of service integration bus topology. This topic guides you through the common decisions you must make about your bus topology.

About this task

Service integration bus configuration

You need to consider the following:

- The volume of messages that the bus will handle. Depending on the volume of messages anticipated, you might need to adjust the **High message threshold** setting for a bus or messaging engine.
- The transport chain to be used for communication between messaging engines. For more information, see Selecting transport options
- Whether bus security is required. When bus security is enabled, access to the bus itself and to all destinations on the bus must be authorized. If you enable bus security, you may also want to define aliases for authenticating messaging engines and mediations accessing the bus. A single version bus (that is, all bus members are at WebSphere Application Server Version 7.0) does not require an authentication alias. If you create a mixed-version bus (that is, the bus contains a bus member at WebSphere Application Server Version 6.x and another bus member at WebSphere Application Server Version 7.0), you need to define an authentication alias for the WebSphere Application Server Version 6.x bus member, to enable it to establish trust with the other bus members.
- The bus name. It is advisable to choose bus names that are compatible with the WebSphere MQ queue manager naming restrictions. You cannot change a bus name after a bus is created, so if you need to interoperate with WebSphere MQ in the future, it will be much simpler if you use compatible names. See the topic about WebSphere MQ naming restrictions in the related links.

Bus member configuration

You need to decide which servers to use for bus members that host the messaging engines.

Messaging engine configuration

You might need to adjust the **High message threshold** setting for a messaging engine depending on the volume of messages anticipated.

Message store configuration

Each messaging engine has a single message store, which can be either a file store or a data store. See “Considerations when choosing between a file store and a data store” on page 1204.

You need to consider the sizes of messages. Larger messages will increase the space that a message store requires.

If you use a data store, the default database system for the data store is Apache Derby Version 10.3. However, you might need to use a different system, such as DB2.

You can select different data store topologies depending on your requirements; for more information see “Planning the configuration of a messaging engine to use a data store” on page 1209.

Bus destinations and their configuration

You need to decide on the number and type of destination, mediations, destination routing path, and quality of service for the destination.

For point-to-point messaging, you define bus destinations as queues and for publish/subscribe messaging, you define bus destinations as topic spaces. For point-to-point messaging only, you must select one bus member as the assigned bus member that is to hold messages for the queue. This action automatically defines a queue point for each messaging engine in the assigned bus member.

You can also define alias destinations to provide a level of abstraction between applications and the underlying target bus destinations. Applications interact with the alias destination, so you can change the target bus destination without changing the application

The reliability quality of service for messages on a destination has implications for performance and the amount of space required for a data store. Higher levels of reliability impact on performance and increase the space a data store requires because fewer messages are discarded.

You should decide how you want to use the bus destinations because you can configure a bus destination to prevent producers sending messages to the destination, or consumers receiving messages from the destination.

Application environment

An application attaches as a client to a messaging engine on the bus, either by an in-process call or across a network using a remote client. A remote client can run in either the Java EE application client environment or the Java EE application server environment. Various transport chains can be used. You might decide to provide samples for use with an application.

Application connections

The way that a messaging engine is selected, and the mechanism that an application uses to reach it is configured on a JMS connection factory. You need to decide which messaging engines the applications should connect to and on the transport chain to be used. For more information on connection factories, see “Configuring resources for the default messaging provider” on page 1584 and on transport options, see Selecting transport options.

WebSphere MQ client links

You might want to define WebSphere MQ client links to enable JMS clients developed for WebSphere Application Server Version 5.1 to use messaging resources on the bus. A WebSphere MQ client link is an optional component of a messaging engine that presents a messaging engine, and thereby the bus, as a WebSphere MQ queue manager to which these JMS clients can attach.

Transaction logs

You need to plan where transaction logs will be placed. See the topic about transactional high availability in the related links.

Planning a single-server bus topology

This topic outlines what you should consider when planning a basic bus topology that contains a single server. A single-server bus contains one messaging engine to which all destinations, for example queues and topic spaces, are assigned.

About this task

You need to decide if a single messaging engine is adequate for your needs. You should consider the following factors:

- Number of client connections
- Message throughput rates
- Size of messages

You should also review the planning issues that are common to all topologies.

Planning a multiple-bus topology

Use this task to plan a topology that contains multiple buses.

About this task

In addition to the planning that is common to all topologies, planning issues include:

- The naming of service integration buses; bus names must be unique.
- How buses are to be linked, that is, directly through a service integration bus link, or through an indirect link. For an indirect link, there can be one or more intermediate buses. For more information, see Direct and indirect routing between service integration buses. You also need to decide on the transport chain required, unless you want to use the default basic transport chain.
- Which messaging engines should contain service integration bus links.
- The distribution of destinations on different messaging engines in each bus. You might want to define alias destinations which make a destination available by a different name, on the same bus or a foreign bus. You might also want to define foreign destinations, which enable applications on one bus to directly access a destination on a foreign bus. If you do not define foreign destinations, you can configure destination defaults to be used. You can combine alias and foreign destinations for further flexibility in your topology. For example:

  Use destination defaults in the following scenarios:

  – you have a development environment and want things to work quickly.
  – you have an application in which destination names are received at run time in message body or headers.

  Use foreign destinations in the following scenarios:

  – you want an environment in which everything is statically defined.
  – you need to override destination defaults for a particular (foreign) destination, for example quality of service settings.

  Use an alias destination in the following scenarios:

  – you need to change the name of a destination, or move a destination to another bus, and want existing applications to carry on working regardless.
  – you need multiple names for the same destination.
- If necessary, the mapping between topic spaces on the local bus and topic spaces on foreign buses.

- The security configuration of the topology.
  - If security is enabled, you need to consider whether you have a single version or a mixed version bus. A mixed version bus has a bus member at WebSphere Application Server Version 6.x and another bus member at WebSphere Application Server Version 7.0. In this case, the bus members establish trust using an authentication alias. A single version bus (where bus members are at WebSphere Application Server Version 7.0) does not require you to define an authentication alias to ensure the secure operation of the bus.
  - If buses in different organizations are connected, you must decide whether to secure connections to a foreign bus with a user ID and password, and optionally with SSL authentication.

Planning a topology that includes WebSphere MQ

Use this task to plan a topology that includes WebSphere MQ.

About this task

In addition to the planning that is common to all topologies, planning issues include:

- The distribution of destinations on different messaging engines in each bus. You might want to define alias destinations because applications can use an alias destination to route messages to a target destination in the same bus or to a foreign bus (including across a WebSphere MQ link to a queue provided by WebSphere MQ). You can also use alias destinations to manage situations where the difference in the allowable name length of a bus destination in WebSphere Application Server and the allowable name length of a WebSphere MQ queue could cause a problem.
- You might want to define foreign destinations so that you can specify properties for those destinations. If you do not define either a foreign destination or an alias destination, the properties will have default settings.
- Which messaging engines should contain a WebSphere MQ link. You can have more than one messaging engine with a WebSphere MQ link in a service integration bus. Also, you can have more than one WebSphere MQ link on a single messaging engine. For example, you may decide to have:
  - One WebSphere MQ link engine with only a sender channel and another WebSphere MQ link engine with only a receiver channel.
  - One WebSphere MQ link to communicate with a WebSphere MQ queue manager or queue-sharing group (known as a “gateway queue manager”) in the WebSphere MQ network.

  Although you can have more than one WebSphere MQ link on a single messaging engine, each WebSphere MQ link must connect to a different gateway queue manager.
- The broker profile and associated topic mapping settings.
- The security configuration of the topology.

Enabling or disabling service integration notification events

You can monitor your service integration environment using notification events.

About this task

Service integration notification events allow you to monitor the activity of your service integration configuration using your own system management application. For more details see Service integration notification events.

You can enable or disable service integration notification events at either the bus or the messaging engine level. The following table illustrates the effect of the two setting levels on the enablement of notifications:

Bus-level notification setting	ME-level notification setting	Are notifications enabled
Not set	Not set	Disabled

Bus-level notification setting	ME-level notification setting	Are notifications enabled
Not set	Enabled	Enabled
Not set	Disabled	Disabled
Disabled	Not set	Disabled
Disabled	Enabled	Disabled
Disabled	Disabled	Disabled
Enabled	Not set	Enabled
Enabled	Enabled	Enabled
Enabled	Disabled	Disabled

1. By using the administrative console, open the **Custom properties** page for either the bus or the messaging engine for which you want to set notification events:
   - Click **Service integration** → **Buses** → ***bus_name*** → **[Additional Properties] Custom properties** to display the custom properties for a bus.
   - Click **Service integration** → **Buses** → ***bus_name*** → **[Topology] Messaging engines** → ***engine_name*** → **[Additional Properties] Custom properties** to display the custom properties for a messaging engine.
2. Click **New** to create a new custom property.
3. Enter sib.event.notification as the name of the custom property. Set the value of the custom property to either “enabled” or “disabled” as required.
4. Optional: Enter a description for the custom property.
5. Click **OK** and save your changes to the master configuration.

Service integration buses

Service integration buses manage the messaging resources that are associated with a server using message-based and service-oriented architectures, including those using the Java Message Service (JMS) interfaces. They are not, however, associated with a specific bus or messaging engine.

- Learning about service integration buses
- “Planning a bus topology” on page 1135
- “Configuring buses”
- “Operating buses” on page 1193

Configuring buses

You can configure service integration buses in a variety of ways; for example you can create and apply security to a bus and you can then add servers or server clusters to that bus.

Creating a bus

When you create a service integration bus, you add a new bus in the administrative console, and then add one or more servers or server clusters as bus members. Thereafter, you administer the bus, and its constituent bus members, as a single unit.

Before you begin

- Plan your bus topology. For more information, refer to “Planning a bus topology” on page 1135.
- Plan your security strategy. For more information, refer to Planning your security requirements.

About this task

You can create a bus by using the administrative console. Wizards are provided to help you add a secured bus, and add a member to the bus. A messaging engine is created for most types of bus member, and you are prompted to specify a data store. The exception is WebSphere MQ server: since a messaging engine is not created, a message store is not required. Use the administrative console to take the following steps:

1. Add a secured bus or an unsecured bus. For the steps, refer to “Adding buses.”
2. Add a member to the bus. See “Adding a server as a new bus member” on page 1145. This creates a messaging engine with default properties and that uses the default JDBC data source and Apache Derby Version 10.3 JDBC Provider for its data store.
3. Optional: Configure the messaging engine, if required. See “Configuring messaging engine properties” on page 1152.
4. Optional: Configure the data store for the messaging engine, if required. For a messaging engine in an application server, you can change the data store configuration. You could do this, for example, if you want to use DB2 rather than Apache Derby as the database system. For more information about changing the data store configuration, see “Configuring a JDBC data source for a messaging engine” on page 1213. You can also change the file store configuration. Refer to “Modifying file store configuration” on page 1206.
5. Restart the server. The messaging engine starts when the server starts.

Results

A new bus is created.

What to do next

You can now change the configuration of the bus; for example, by adding additional members, by creating bus destinations, and by creating links to WebSphere MQ networks. You can create other buses and, if required, connect them together.

Adding buses

You can add a new service integration bus by using the administrative console. If messaging security is enabled, security settings are configured for the bus by default. You can add a unsecured bus if you disable messaging security.

Adding a secured bus:

This task uses an administrative console wizard to add a new service integration bus that uses a security domain. A bus can use the global security settings, inherit the security settings that exist at cell level, or use a set of customized settings that are unique to the bus, or shared with another resource.

Before you begin

You must decide which type of security domain to use for the bus. For more information, refer to Planning your security requirements and Messaging security and multiple security domains.

About this task

By default, administrative security for the cell is enabled. If the wizard detects that administrative security is disabled, the wizard prompts you to enable it. You must specify the type of user repository, and the administrative security username and password.

Security settings are held in a security domain. If the bus might contain a WebSphere Application Server Version 6.x bus member, you must select the global domain. You can select any type of domain for a bus that contains only WebSphere Application Server Version 7.0 bus members.

1. Log into the administrative console.
2. Click **Service integration** → **Buses**. A list of buses is displayed.
3. In the content pane, click **New**.
4. Type a name for the new bus. It is advisable to choose bus names that are compatible with the WebSphere MQ queue manager naming restrictions. You cannot change a bus name after a bus is created, so if you need to interoperate with WebSphere MQ in the future, it will be much simpler if you use compatible names. See the topic about WebSphere MQ naming restrictions in the related links.
5. Ensure that the **Bus security** checkbox is checked.
6. Click **Next**. The Bus Security Configuration wizard is launched.
7. Read the Introduction panel, and click **Next**.
8. If administrative security is disabled, follow the instructions in the wizard to select, and configure the appropriate user repository.
9. Click **Next**. A summary of the administrative security settings for the bus is displayed.
10. Review the summary, and click **Finish**. Administrative security for the cell is now enabled.
11. By default, clients are required to use SSL protected transports to ensure data confidentiality and integrity. If you do not want clients to use SSL protected transports, clear the checkbox **Require clients use SSL protected transports** .
12. Select a security domain for the bus. The domain you specify depends on the versions of the bus members. If the bus may contain a Version 6.x bus member, you must select the global domain. If the bus will only contain Version 7.0 bus members, you can select the cell-level or a custom domain. If you select a custom security domain, you must also follow the instructions to specify a user realm.
13. Review the summary of your choices, and click **Finish**.
14. Save your changes to the master configuration.

Results

Administrative security is enabled, and a new bus is created with your chosen security settings.

What to do next

You can now add bus members to the bus.

Adding an unsecured bus:

This task adds a new unsecured service integration bus.

About this task

By default, bus security is enabled and you add buses with security configured. Use this task if you want to add a new service integration bus without any security settings. If you want to secure the bus at a later date, you can do so by configuring the security settings for the bus.

To add a bus, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Buses**. A list of buses is displayed.
2. In the content pane, click **New**.
3. Type a name for the new bus. It is advisable to choose bus names that are compatible with the WebSphere MQ queue manager naming restrictions. You cannot change a bus name after a bus is created, so if you need to interoperate with WebSphere MQ in the future, it will be much simpler if you use compatible names. See the topic about WebSphere MQ naming restrictions in the related links.
4. Clear the **Bus security** checkbox to disable bus security.
5. Click **Next**.

6. Review the summary of the settings for the new bus, then click **Finish**.
7. Save your changes to the master configuration.

Results

Bus security is disabled, and you have added a new unsecured service integration bus.

What to do next

You can now add servers to the bus.

Configuring bus properties

You can configure how many messages the bus can handle, when to discard messages, and which messaging engines the bus can communicate with. You can also specify changes that can be made to the bus that do not require a restart of the messaging engines.

About this task

You configure bus properties after you have created a bus. To configure the properties of a bus, use the administrative console to complete the following steps:

1. Click **Service integration** → **Buses** → ***bus_name***.
2. Specify the following properties for the bus:

   Description
   A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

   Inter-engine transport chain
   The transport chain used for communication between messaging engines in this bus.

   The transport chain must correspond to one of the transport chains defined in the *Messaging engine inbound transports* settings for the server. All servers automatically have a number of transport chains defined to them, and it is also possible to create new transport chains.

   When you specify the name of a transport chain, that chain must be defined to all servers hosting messaging engines in the bus. Otherwise, some messaging engines might not be able to communicate with their peers in the bus.

   When the use of permitted chains is enforced and a protocol is not specified for intra-bus communications then InboundSecureMessaging is assumed instead of InboundBasicMessaging. This can be overridden by setting the protocol attribute in the bus configuration. If InboundSecureMessaging is not a permitted chain then an error occurs.

   Discard messages
   Whether messages on a deleted message point should be retained at a system exception destination or can be discarded. Select this option to indicate that after a queue has been deleted, any messages left in the data store for that queue should be discarded.

   Configuration reload enabled
   Select this option to enable automatic update of configuration information on all the messaging engines on the bus.

   Changes to bus destinations or mediations are applied when destinations or mediations are added to or removed from the bus.

   Changes to the modifiable configuration information for any foreign bus connections are also updated automatically. The time when these changes take effect varies:

Foreign Bus Connection properties
Immediately

WebSphere MQ link properties
On channel restart, except Description (immediately), and Initial State (on messaging engine restart)

MQ sender channel properties
On channel restart, except Initial State (on messaging engine restart or sender channel creation)

MQ receiver channel properties
On channel restart, except Initial State (on messaging engine restart or receiver channel creation)

Publish/subscribe broker profile (0 to n) properties
Immediately

Service integration bus link properties
On link restart, except Description (immediately), and Initial State (on messaging engine restart or link creation)

To ensure that dynamic configuration updates are made on an application server, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Server messaging] SIB service** then select **Configuration reload enabled**.

To ensure that dynamic configuration updates are made to each node, click **System administration** → **Console Preferences** to display the Console Preferences window then select **Synchronize changes with nodes**.

Default messaging engine high message threshold
A threshold above which the messaging system will take action to limit the addition of more messages to a message point. When a messaging engine is created on the bus, the value of this property is used to set the default high message threshold for the messaging engine.

3. Specify topology, destination resources, Web services and additional properties for the bus, as required. To restrict the number of audit messages, add a custom property called `audit.bus.authentication` with one of the following values:
   - `all` (audit all attempts to authenticate to the bus)
   - `failure` (audit only failure to authenticate to the bus)
   - `none` (do not audit any attempts to authenticate to the bus)
4. Click **OK**.
5. Save your changes to the master configuration.

Listing the buses

You can view the list of the service integration buses that currently exist. You can decide which buses you want to change, for example, to add a server to a bus.

About this task

After you list the service integration buses, you can add or delete a bus. Also, you can select a bus to view its details and perform further actions, such as adding a member to a bus, creating a foreign bus connection, or applying security to a bus. To list the buses, use the administrative console to complete the following step.

In the navigation pane, click **Service integration** → **Buses**.

Results

A list of buses is displayed in the content pane.

What to do next

You can now add or delete buses, or click on a bus name to display or configure its properties.

Displaying the topology of a service integration bus

You can display a tree view of the members of a bus, and the messaging engines used by a selected bus, in the administrative console. You can also view the runtime status for each messaging engine.

About this task

Use this task to display a *local topology* view of the bus members and messaging engines in a service integration bus. You can use this view to add servers as members of the bus.

To display the local topology view of a service integration bus, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Buses**. A list of buses is displayed in the content pane.
2. In the content pane, click the name of the bus. For example, `SCA.SYSTEM.localhostCell01.Bus`
3. Click the tab **Local Topology**

Results

The topology of the bus is displayed as an expandable tree.

What to do next

You can expand nodes of the tree to display the bus members and their messaging engines.

You can add servers as members of the bus.

Deleting a bus

You can delete a service integration bus, for example if it is no longer in use.

Before you begin

Note: When you delete a bus, each messaging engine on the bus is also deleted and any associated messages are discarded. If you subsequently create a new bus with the same name as the deleted bus, the new bus will not have the same universal unique identifier (UUID) as the deleted bus.

About this task

To delete a bus, use the administrative console to complete the following steps.

1. In the navigation pane, click **Service integration** → **Buses**. A list of buses is displayed in the content pane.
2. In the content pane, select the bus that you want to delete.
3. Click **Delete**.
4. Click **OK**.
5. Save your changes to the master configuration.

What to do next

You must disable the SIB Service at server startup.

Configuring the members of a bus

Use the administrative console to add, remove, and list the members of a bus.

Adding a server as a new bus member:

The members of a service integration bus are the application servers within which messaging engines for that bus can run. When you add a new bus member, you configure its message store, which is either a file store or a data store.

About this task

If you add a server as a member of a bus, WebSphere Application Server creates a messaging engine for the server. By default, the messaging engine is configured to use a file store. If you choose a data store, you have the choice of using the default JDBC data source and Derby JDBC Provider for its data store. If you do not want to use the default data source configuration, you can choose to use a different data source or you can configure the data store to use a different JDBC provider. If you subsequently delete a bus member and then recreate it, you should make sure that you understand the life cycle of the file store or a data store. Refer to Data store life cycle and Learning about file stores for details.

You can optionally tune the initial and maximum Java virtual machine (JVM) heap sizes. Tuning the heap sizes helps to ensure that application servers hosting one or more messaging engines are provided with an appropriate amount of memory for the message throughput you require.

If security is enabled, and the bus has mixed version bus members; (that is, a bus member at WebSphere Application Server Version 6.x and another bus member at Version 7.0), the bus members establish trust using an authentication alias. If you add a server as a bus member at WebSphere Application Server Version 6.x, and it is the first bus member at this level, you need to select or create an authentication alias during this task.

To add an application server as a member of a bus, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Buses** → ***bus_name*** → **[Topology] Bus members**. A list of members in the bus is displayed.
2. Click **Add**.
3. Select scope of the new bus member: this is one of *Server*, *Cluster* or *WebSphere MQ server*. **Server** is selected by default. Only select the **Cluster** scope in WebSphere Application Server environments that support server clusters.
4. Make your selection and click **Next**.
5. Select the type of message store: it is either a file store or a data store. For more information, see File stores and Data stores. **File store** is selected by default.
6. Click **Next**.

   Note: If you use a file store and want to change the default values, you can change them here. For more information refer to “Modifying file store configuration” on page 1206.

   Note: If you use a data store and want the messaging engine in the bus member to use a non-default data source, select **Create new data source** and fill in **Data source JNDI name** field.
7. Click **Next**.

   Note: You can view the current settings of the initial and maximum Java Virtual Machine (JVM) heap sizes. If you want to tune performance by changing the current settings, select the **Change heap sizes** check box and enter the required changes in the **Proposed heap sizes** fields.
8. Click **Next**.

9. If security is enabled, and adding this server creates a mixed version bus, the wizard prompts for an authentication alias. Do one of the following:
   - Select an existing authentication alias.
   - Create a new authentication alias. You need to specify a unique alias name and password.
10. Click **Finish** to confirm the creation of the bus member.
11. Save your changes to the master configuration. You must restart the server for the changes to take effect.

Results

The member is added to the bus and a messaging engine is created for that member.

What to do next

Next, you can configure the messaging engine. For more information about configuring messaging engines and their message stores, see the related tasks.

Adding a WebSphere MQ server as a member of a bus:

A WebSphere MQ server provides a direct client connection between a service integration bus and queues on a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. A WebSphere MQ server bus member is used as a bus member for assigning queue points and mediation points to WebSphere MQ queues.

Before you begin

Get details of the client connection from your WebSphere MQ administrator.

Ensure that the WebSphere MQ server has been configured, that the bus has been defined and that the server is not already a member of the bus.

Decide on which method you want to use to configure these resources. You can add the WebSphere MQ server as a bus member by using the administrative console as described in this task, or by using the addSIBusMember command.

About this task

When you add a WebSphere MQ server to one or more buses, messaging engines on these buses can access queues on the target WebSphere MQ installation. When you make the server a bus member, you can override the server connection settings with settings that are specific to the new bus member. This can be useful in a multiple bus topology.

1. Start the administrative console.
2. Navigate to the list of bus members for the bus to which you are adding the WebSphere MQ server.
   Click **Service integration** → **Buses** → ***bus_name*** → **[Topology] Bus members**.
3. Click **Add**. The “Add a new bus member” wizard is displayed.
4. Select the WebSphere MQ server to add to the bus:
   a. Select the **WebSphere MQ server** radio button.
   b. From the drop-down list, select the server to add.
   c. Click **Next**.
5. Specify the virtual queue manager name.
   When sending messages to WebSphere MQ, the WebSphere MQ gateway queue manager sees the bus as a remote queue manager. The virtual queue manager name is the name that is passed to WebSphere MQ as the name of this remote queue manager. The default value is the name of the

bus. If this value is not a valid name for a WebSphere MQ queue manager, or if another WebSphere MQ queue manager already exists that has the same name, then replace the default value with another value that is a valid and unique name for a WebSphere MQ queue manager. To be valid, the name must meet the following criteria:

- It must contain between 1 and 48 characters.
- It must conform to the WebSphere MQ queue naming rules (see the WebSphere MQ topic Rules for naming WebSphere MQ objects).

6. Optional: To override the server connection settings, select the **Override WebSphere MQ server connection properties** check box.

   When you select this option, the connection properties for the server are made available so that you can change them to settings that are specific to this bus member. For more information about these connection properties, see WebSphere MQ server bus member [Settings].
7. Optional: If you have changed the server connection settings, you can click **Test connection** to test the connection to the associated WebSphere MQ network.
8. Click **Next**.
9. Click **Finish** to confirm.
10. Save your changes to the master configuration.

What to do next

You are now ready to create a WebSphere MQ queue-type destination for the new bus member.

Listing the members of a bus:

You can display a list of servers that have been added as members of a bus.

About this task

You can list the members of a bus, then you can add, remove, or edit the bus members. To list the members of a bus, use the administrative console to complete the following steps.

1. In the navigation pane, click **Service integration** → **Buses**. A list of buses is displayed in the content pane.
2. In the content pane, select the bus whose members you want to list.
3. In the content pane, under **Topology**, click **Bus members**. A list of members of the bus is displayed.

Removing a member from a bus:

You can remove an application server from a bus so that it is no longer used to process messages.

Before you begin

Note:

- When you remove a member from a bus, all messaging engines on that bus member are also deleted and their associated messages are discarded. If you add the same bus member again, first you must manually delete the old data source for the messaging engines to ensure that once the new messaging engines are created, they can restart.
- If you remove a member from a bus, and it is the only member for that server, you must also disable the SIB Service at server start up.

About this task

To remove a member from a bus, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Buses**. A list of buses is displayed in the content pane.
2. In the content pane, select the bus from which you want to remove the member.
3. In the content pane, under **Topology**, click **Bus members**. A list of members in the bus is displayed.
4. Select the bus member that you wish to remove.
5. Click **Remove**.
6. Save your changes to the master configuration.

Results

The member is removed from the bus. All the messaging engines on that bus member and the core group policies that are associated with those messaging engines are deleted.

What to do next

If you have removed the only bus member for a server, you must now disable the SIB Service at server start up.

Disabling the service integration service:

This task describes how to disable service integration bus functionality when the application server starts.

About this task

The SIB Service, which provides messaging capability, is enabled automatically when you add a server to a service integration bus. You can choose to disable the SIB service, for example if you have removed the only bus member for a server. You can use the administrative console to disable the SIB Service, or wsadmin scripting. The following example shows a Jython script for disabling the SIB Service:

```
server = AdminConfig.getid('/Server:server1/')
sibService = AdminConfig.list('SIBService', server)
AdminConfig.modify(sibService, [["enable", "false"]])
```

To use the administrative console, complete the following steps.

1. Click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Server messaging] SIB service** to display the SIB service settings pane.
2. Click the Configuration tab to display configuration properties for the service integration service.
3. Clear the Enable service at server startup check box.
4. Save your changes to the master configuration.

Results

You have disabled the SIB Service. Service integration bus functionality is not available when the application server starts up.

Administering bootstrap members for a bus

A service integration bus can have bootstrap members. These are bus members, cell members for which the Service Integration Bus Service is enabled, or nominated cell members that can service requests to bootstrap into the bus, depending on the bootstrap policy configured for the bus.

Before you begin

The bus must exist in a WebSphere Application Server Version 7.0 cell, or a mixed version cell with a Version 7.0 deployment manager.

About this task

You can configure the bootstrap member policy for a bus, nominate, list and delete bootstrap members for a selected bus as follows:

Configuring a bootstrap member policy for a bus:

By configuring a bootstrap member policy for a selected service integration bus, you control which servers respond to bootstrap requests from client applications.

Before you begin

You must ensure that the bus is in a WebSphere Application Server Version 7.0 cell, or in a mixed version cell with a Version 7.0 deployment manager.

About this task

A WebSphere Application Server Version 7.0 bus can use bootstrap members to service connection requests from client applications. In this task, you define a bootstrap member policy for a selected bus that defines which servers can bootstrap into the bus. The default bootstrap member policy is all cell members that have the Service Integration Bus Service enabled. You can restrict bootstrap membership to bus members only, or to bus members, and nominated bootstrap members. These are servers that are not bus members, but have been nominated as bootstrap members.

1. Log onto the administrative console.
2. Click **Service integration** → **Buses** → ***bus_name***. The configuration panel for the selected bus is displayed.
3. Choose one of the following bootstrap members policies for the bus:

   All members of the cell with the Service Integration Bus Service enabled
   This is the default option. All the servers in the cell that have the Service Integration Bus Service enabled are bootstrap members.

   Bus members and nominated bootstrap members
   Bootstrap membership is restricted to servers that are bus members, or have been nominated as bootstrap members.

   Bus members only
   Bootstrap membership is restricted to servers that are bus members.
4. Click **Apply**.
5. Save your changes to the master configuration.

Results

Requests from client applications to connect to the bus are serviced by the servers in the cell that meet the criteria set by the bootstrap member policy you have configured for the bus.

What to do next

Use the administrative console to list, nominate or delete bootstrap members for the selected bus.

Listing the bootstrap members for a bus:

Use this task to find out which servers in the cell are available to service requests from clients to connect to a particular service integration bus. The list of available servers is restricted by the bootstrap member policy configured for the bus.

Before you begin

You must ensure that the appropriate bootstrap member policy has been configured for the bus. For more information, refer to “Configuring a bootstrap member policy for a bus” on page 1149.

About this task

In this task, you use the administrative console to list the bootstrap members for a selected bus. The list of bootstrap members depends on which of the following bootstrap member policies is configured for the bus:

All members of the cell with the Service Integration Bus Service enabled
This is the default policy. The list includes all the WebSphere Application ServerVersion 7.0 servers in the cell that have the Service Integration Bus Service enabled.

Bus members and nominated bootstrap members
The list includes all the servers that are bus members, or have been nominated as bootstrap members.

Bus members only
The list includes only servers that are members of the bus.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***bus_name*** → **[Topology] Bootstrap members**.

Results

A list of the bootstrap members for the selected bus is displayed.

What to do next

You can use the administrative console to nominate or remove bootstrap members, or configure a different bootstrap member policy for the bus.

Nominating bootstrap members for a bus:

You can nominate one or more WebSphere Application Server Version 7.0 servers on Version 7.0 cell nodes as bootstrap members for a selected bus. When the Bus members and nominated bootstrap members policy is configured for the bus, the nominated bootstrap members can service requests from client applications to connect to the bus.

Before you begin

You must ensure that the following requirements are met:

- The bus is in a WebSphere Application Server Version 7.0 cell, or a mixed version cell with a Version 7.0 deployment manager.
- The servers that you want to nominate as bootstrap members must be on Version 7.0 cell nodes.

About this task

In this task, you use an administrative console wizard to configure the **Bus members and nominated bootstrap members** policy, and nominate bootstrap members for a selected bus.

1. Log onto the administrative console.
2. Click **Service integration** → **Buses** → ***bus_name*** → **[Topology] Bootstrap members**. The Bootstrap members panel displays all the bus members, servers in the cell that have the Service Integration Bus Service enabled.
3. Select the policy **Bus members and nominated bootstrap members**.
4. Click **Apply**. A list of current bus members, and nominated bootstrap members is displayed.

5. Click **New**. The Nominate a bootstrap server wizard is launched.
6. Type the name of the server that you want to add in the **Name** field. The first match in the list of available servers and clusters is highlighted. Click **Add** to add the named server to the list of servers to add.
7. When you have listed all the servers that you want to add, click **Next**.
8. Review the summary of the servers that you have chosen to add.
9. If you want to change your selections:
   a. Click **Previous** to return to the first step of the wizard.
   b. Make the changes you require, and click **Next**.
10. Click **Finish** to add the new bootstrap members to the local configuration.
11. Save your changes to the master configuration. An updated list of bus members and nominated bootstrap members is displayed.

Results

The nominated servers can service requests from client applications to bootstrap into the bus.

What to do next

You can use the administrative console to perform other bus configuration tasks.

Deleting nominated bootstrap members from a bus:

Deleting a nominated bootstrap member from a selected service integration bus prevents the server from servicing requests from client applications to bootstrap into the bus.

Before you begin

You must configure the **Bus members and nominated bootstrap members** policy for the selected bus. For more information, refer to “Configuring a bootstrap member policy for a bus” on page 1149.

About this task

In this task, you use the administrative console to list all the bootstrap members for a selected bus, and then delete the nominated bootstrap members that you no longer want to use to bootstrap into the bus. Note that you can delete only nominated bootstrap members.

1. Log onto the administrative console.
2. Click **Service integration** → **Buses** → ***bus_name*** → **[Topology] Bootstrap members**. All the nominated bootstrap members for the bus are listed.
3. Select the nominated bootstrap members that you no longer want to use to bootstrap into the bus, and click **Delete**. The Bootstrap members panel displays an updated list of bootstrap members.
4. Save your changes to the master configuration.

Results

You cannot use the deleted nominated bootstrap members to bootstrap into the selected bus.

What to do next

You can use the administrative console to perform other bus administrative tasks.

Configuring messaging engines

You can configure messaging engines in a variety of ways. For example, you can create and apply security to a messaging engine, then use this engine to send and receive messages. When you add a server cluster to a service integration bus, at least one messaging engine is created automatically. If you also use messaging engine policy assistance, some configuration properties are set automatically.

Configuring messaging engine properties:

You can configure the properties of a messaging engine in the administrative console. For example you can select whether the messaging engine is started automatically when its associated application server is started, how many messages it can process, and target groups that the engine can join.

About this task

In most cases, you can configure the properties of a messaging engine without interrupting the processing of messages by the messaging engine.

1. Start the administrative console.
2. Navigate to **Service integration** → **Buses** → ***bus_name*** → **[Topology] Messaging engines** → ***engine_name***.
3. Configure the messaging engine properties. For information about the properties that you can configure, see the property descriptions in Messaging engines [Settings]
4. Click **OK**.
5. Save your changes to the master configuration.

Listing the messaging engines in a bus:

You can view the list of existing messaging engines in a bus by using the administrative console. You can decide which messaging engines you want to change, for example which buses they are associated with.

About this task

To list the messaging engines in a bus, use the administrative console to complete the following steps.

1. In the navigation pane, click **Service integration** → **Buses**.
2. In the content pane, click the name of the bus that your messaging engine belongs to.
3. In the content pane, under **Topology**, click **Messaging engines**. The list of messaging engines in the bus is displayed.

Removing a messaging engine from a bus:

You can remove a messaging engine from a service integration bus if you no longer require it to send and receive messages on the bus.

Before you begin

You should be wary of deleting and re-creating messaging engines on bus members for which WS-Notification-administered subscribers have been configured, because in some cases this can leave the remote Web service subscription active (and passing notification messages to the local server) even though there is no longer any record of it. For more information, see the WS-Notification troubleshooting tip Deleting administered subscribers and messaging engines.

1. Stop the messaging engine. You can stop either in **Immediate** or **Force** mode, as described in “Stopping a messaging engine” on page 1202.
2. Use the wsadmin command deleteSIBEngine to delete the messaging engine. All service integration bus links, MQ links, and custom properties that are owned by the engine are deleted.

Note: When you remove a messaging engine, WebSphere Application Server does not delete the data store tables automatically. You must remove them manually, or delete all the rows in all the tables. If you do this, a new messaging engine might fail to start if it attempts to use an orphaned data store. Refer to the documentation for your chosen relational database management system for information about deleting tables.

Alternatively, for Apache Derby, you can delete the database's directory, which is located in *profile_root*/databases/com.ibm.ws.sib, where *profile_root* is the directory in which profile-specific information is stored. However, do this only if the messaging engine is the sole user of the database.

For more information, see Data store life cycle.

Similarly, the file store files are not automatically deleted when you delete the messaging engine. You might want to delete the file store files to reclaim disk space.

Listing the messaging engines defined for a server bus member:

You can display a list of messaging engines defined for a server bus member by using the administrative console. You can decide which messaging engines you want to change, for example, which buses they are associated with.

About this task

To display the list of messaging engines, use the administrative console to complete the following steps:

1. In the navigation pane, click either **Service integration** → **Buses** → ***bus_name*** → **[Topology] Messaging engines** or **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Server messaging] Messaging engines**. A list of messaging engines is displayed in the content pane.
2. Optional: Select one or more messaging engines to work with, for example to change the properties of the messaging engine.

Setting up the data store for a messaging engine:

To set up a data store for a messaging engine, the database administrator must first create the database. You must then configure the data source and configure the messaging engine to use it.

Before you begin

Before you use this task, review the information in "Planning the configuration of a messaging engine to use a data store" on page 1209, and ensure that your database administrator has taken any appropriate action.

About this task

This task summarizes the steps that you must perform to set up the data store for a messaging engine. You need to work with your database administrator to complete step 1 of this task.

1. Ask your database administrator to perform the following steps:
   a. Create the database. Refer to "Creating the database" on page 1210
   b. Create users and schemas. Refer to "Creating users and schemas in the database" on page 1211
   c. Create the data store tables. Refer to "Creating the tables" on page 1212
   d. Ensure that the user has sufficient privilege to allow the messaging engine to operate. For more information about the privileges that required for the selected database, refer to "Database privileges" on page 1218.

2. When the database administrator has completed step 1, perform the following steps:
   a. Obtain a user ID from your database administrator.
   b. Configure a data source. Refer to “Configuring a JDBC data source for a messaging engine” on page 1213.
   c. Configure the messaging engine to use the data source. Refer to “Configuring a messaging engine data store to use a data source.”

Configuring a messaging engine data store to use a data source:

After configuring a data source, you can configure a messaging engine data store to use the data source.

Before you begin

This topic assumes that you have chosen or created a bus and a messaging engine, and that the messaging engine specifies “data store” as its message store type.

You must also have configured a data source, as described in “Setting up the data store for a messaging engine” on page 1153.

About this task

A messaging engine uses an instance of a JDBC data source to interact with the database that contains the data store for that messaging engine.

Use the WebSphere Application Server administrative console to set the data store configuration parameters.

To configure the messaging engine to use a data source, use the administrative console to complete the following steps:

Service integration → Buses → *bus_name* → [Topology] Messaging engines → *engine_name* → [Additional Properties] Message store

1. In the navigation pane, click **Service integration → Buses → *bus_name* → [Topology] Messaging engines → *engine_name***.
2. Check that the **Message store type** is *Data store*.
3. Click **[Additional Properties] Message store**. The data store configuration detail panel is displayed.
4. Specify the following data store configuration details:

   Data source JMDI name
   Type the JNDI name of the data source that provides access to database that holds the data store.

   Schema name
   Type the name of the database schema that contains the tables used by the data store.

   Note: The schema name is usually the same as the user ID that is declared in the authentication alias. With some databases, for example DB2, you can provide an alternative schema name. For more information about the relationship between users and schema, refer to the documentation for your chosen RDBMS.

   Note: When you configure your messaging engine to use an Informix database, you must specify the schema name in lowercase letters.

   When starting, a messaging engine that uses a data store checks to see if its data store exists. If the user has selected the **Create tables** option in the configuration, whose tick-box is ticked by default, the messaging engine creates the tables in its chosen schema.

The **Schema name** field is optional, and:

- The default schema name is *IBMWSSIB*.
- If you delete the text so that field is blank, the messaging engine takes the user id defined in the authentication alias to be the schema name.
- If you define a schema name explicitly, that schema name is used by the messaging engine.

Authentication alias
Select the authentication alias that enables access to the data source.

Note: When you create a new Network Attached Apache Derby data store, by default you get a blank authentication alias.

Create tables
Select the check box if you want WebSphere Application Server to create the database tables automatically. For more information, refer to “Creating the tables” on page 1212.

Note: The user ID that the data store uses to connect to the data source must have sufficient authority to create the database tables and indexes.

Note: The option for WebSphere Application Server to create the tables is not available with DB2 for z/OS. Refer to “Enabling your database administrator to create the data store tables” on page 1212 if you use DB2 for z/OS.

Number of permanent tables
Permanent table contains persistent objects for the data store.

Note: You can only increase the number of permanent tables or temporary tables, not decrease them.
See related links for more information.

Number of temporary tables
Temporary tables nonpersistent objects that have been saved to the data store to reduce the messaging engine memory requirement.

Note: You can only increase the number of permanent tables or temporary tables, not decrease them.
See related links for more information.

Configuring service integration bus links:

You can configure service integration bus links on messaging engines in a variety of ways. For example, you can start, stop, or remove links.

About this task

When you create a foreign bus connection to connect two service integration buses, a service integration bus link is created automatically. The foreign bus connection contains a routing definition, which is a virtual link, and the service integration bus link is the corresponding physical link on the messaging engine.

Configuring foreign bus connections:

You can configure a bus to connect to, and exchange messages with, other messaging networks. To do this, you must configure a foreign bus connection. A foreign bus connection encapsulates information related to the remote messaging network, such as the type of the foreign bus and whether messaging applications are allowed to send messages to the foreign bus.

About this task

A foreign bus connection is associated with a service integration bus. The bus with which the foreign bus connection is associated is known as the local bus. The foreign bus connection represents another service integration bus, either in the same cell as the local bus or in a different cell, or it represents a WebSphere MQ queue manager. From the local bus, every other bus is regarded as a foreign bus, even if it is a bus in the same cell.

Messages route to a foreign bus either directly through a link between the local bus and the foreign bus, or indirectly through one or more intermediate buses.

If, when you configure the local bus, you select **Configuration reload enabled**, future changes to the configuration information for any foreign bus connections are updated automatically. The time when these changes take effect varies:

Foreign Bus Connection properties
Immediately

WebSphere MQ link properties
On channel restart, except Description (immediately), and Initial State (on messaging engine restart)

MQ sender channel properties
On channel restart, except Initial State (on messaging engine restart or sender channel creation)

MQ receiver channel properties
On channel restart, except Initial State (on messaging engine restart or receiver channel creation)

Publish/subscribe broker profile (0 to n) properties
Immediately

Service integration bus link properties
On link restart, except Description (immediately), and Initial State (on messaging engine restart or link creation)

To ensure that dynamic configuration updates are made to each node, click **System administration** → **Console Preferences** to display the Console Preferences window, then select **Synchronize changes with nodes**.

Configuring the properties of a service integration bus link:

After establishing a service integration bus link you might want to configure the properties of a service integration bus link such as the name of the service integration bus link, or authentication alias used by foreign bus that the link connects to.

About this task

To configure the properties of a service integration bus link, use the administrative console to complete the following steps:

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine for which you want to configure the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to configure.
5. Specify the following properties for the service integration bus link:

Name The name of the service integration bus link. In order to work, the name must be the same as the name of the corresponding service integration bus link configured on the target foreign bus.

Description
An optional description for the service integration bus link, for administrative purposes.

UUID The universal unique identifier assigned by the system to the service integration bus link for administrative purposes.

Foreign messaging engine
The messaging engine on the foreign bus to which this link connects.

Note: This foreign bus name must not be altered after it has been configured. If you alter it, any messaging engines that already hold state information about the link will not be able to use the link unless the foreign bus name is reset to its original value.

Target inbound transport chain
The type of transport chain used for communication with the foreign bus. The transport chain name must be the name of the transport chain as defined on the server on which the target messaging engine is hosted.

Bootstrap endpoints
The comma-separated list of endpoints used to connect to a bootstrap server. This property is set in the same way as the **Provider endpoint** property in the JMS connection factory settings. For more information, see steps 1 and 2 of "Configuring a connection to a non-default bootstrap server" on page 1598. Although this task primarily describes how to configure a JMS connection factory, it is also applicable to setting several bootstrap endpoint values if the remote messaging engine is in a cluster.

Note: Service integration bus links over BootstrapTunneledMessaging and BootstrapTunneledSecureMessaging transport chains only work directly between application server instances. Bus links over TunneledMessaging transport chains do not work if an HTTP server is placed in front of either application server instance.

Authentication alias
The name of the authentication alias, used to authenticate access to the foreign bus. The alias must be known to the foreign bus.

Initial state
Whether the link is started automatically when the messaging engine is started. Until started, the gateway link is unavailable. If this property is set to **Started** the service integration bus link is started when the messaging engine is started.

6. Click **OK**.
7. Save your changes to the master configuration.

Listing the service integration bus links:

You can list all the service integration bus links that are linked to a messaging engine.

About this task

To list the service integration bus links for a messaging engine, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Buses**.
2. In the content pane, click the name of the bus that your messaging engine belongs to.
3. In the content pane, under **Additional properties**, click **Messaging engines**. The list of messaging engines in the bus is displayed.

4. In the content pane, select the messaging engine for which you want to list the service integration bus links.
5. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.

Example

The following combinations of **Status** and **Activity** values are possible:

Status	Activity	Meaning
started	inactive	The service integration bus link is started on the local messaging engine but has no connection to the foreign bus. The service integration bus link is attempting to activate a connection to the foreign bus. The service integration bus link on the foreign bus must also be started to successfully activate of a connection between the buses.
started	active	The service integration bus link is started on the local messaging engine and has an active connection to the foreign bus.
stopped	inactive	The service integration bus link is stopped on the local messaging engine and there is no connection to the foreign bus.
unknown	inactive	An error might have occurred in setting up the link, such that the object that is used to report the current state is not available.

What to do next

You can now add or remove a service integration bus link or select a service integration bus link to start, stop, or configure.

Starting a service integration bus link:

When a service integration bus link has been started, it can be used for communicating with its associated messaging engines.

About this task

To start a service integration bus link, use the administrative console to complete the following steps:

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine for which you want to start the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you wish to start.
5. Click **Start**.

Stopping a service integration bus link:

When a service integration bus link has been stopped, it cannot be used for communication until it is restarted.

About this task

To stop a service integration bus link, use the administrative console to complete the following steps:

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine to which the service integration bus link that you wish to stop belongs.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you wish to stop.
5. Click **Stop**.

Removing a service integration bus link:

When a service integration bus link to a messaging engine has been removed, it cannot be used for communication until it is recreated.

Before you begin

Before you remove the service integration bus link you must stop the link.

When you remove a service integration bus link, all traffic using the link needs to be dealt with in a similar way to when you remove a destination. For further details, see “Deleting a non-topic space bus destination” on page 1246. Note that express Quality of Service (QoS) messages are discarded.

About this task

To remove a service integration bus link from a messaging engine, use the administrative console to complete the following steps:

1. Display the list of messaging engines.
2. In the content pane, select which the messaging engine has own association with the service integration bus link that you wish to remove.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you wish to remove.
5. Click **Delete**.
6. Save your changes to the master configuration.

What to do next

When you remove a service integration bus link, all traffic using the link must be diverted by alternative routes or held pending further administrative action. Express QoS messages are discarded.

Configuring bus destinations

Use the following tasks to configure permanent bus destinations on service integration buses.

About this task

The steps involved in configuring a bus destination depend on the intended usage of the destination.

For example, the following figure shows a basic scenario based on an application using a JMS queue for point-to-point messaging.

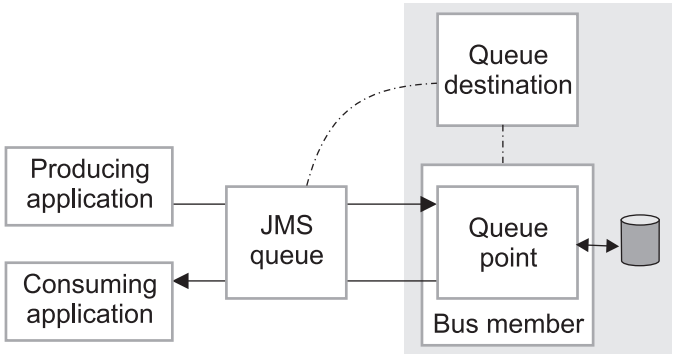

Figure 14. Application use of destinations - basic case

To enable the JMS applications to use a queue destination, you configure the following administrative destination objects:

1. A queue destination on a service integration bus. This configures the properties of the queue, such as the name, and associates the queue with one bus member (an application server). This also automatically configures, on the bus member, a queue point where messages for the queue are held and processed.
2. A JMS queue, which configures the name that applications can use to look up the queue in JNDI. The JMS queue encapsulates the name of the queue destination, as defined in the queue destination above, together with other properties to be used by applications.

After you have created a queue destination, you can optionally configure the queue point to override some properties configured on the queue destination. You can also perform other configuration tasks on the destination and its queue point, and can act on the runtime view.

Each messaging engine has a default exception destination, named `_SYSTEM.Exception.Destinaton.`*`me_name`*. This exception destination can be used to handle messages that cannot be delivered for all bus destination that are localized to the messaging engine. Each bus destination can be configured with a non-default exception destination.

For more information about configuring bus destinations, see the following topics:
- Listing bus destinations
- Creating a bus destination
- Configuring qualities of service for a destination
- Deleting a non-topicspace bus destination
- Deleting a topicspace

Connecting buses

You can connect several service integration buses in a network directly, or indirectly, by creating and configuring foreign bus connections. You can connect a service integration bus and a WebSphere MQ queue manager or queue-sharing group in a similar way. You can enable point-to-point or publish-subscribe messaging across multiple buses.

About this task

For a conceptual overview of connecting different service integration buses, including security issues, refer to Multiple bus topology. You can configure a bus to connect to, and exchange messages with, other messaging networks. To do this, you must configure a foreign bus connection. A foreign bus connection encapsulates information related to the remote messaging network, such as the type of the foreign bus and whether messaging applications are allowed to send messages to the foreign bus. Messages route to

a foreign bus either directly through a link between the local bus and the foreign bus, or indirectly through one or more intermediate buses.

Configuring foreign bus connections:

You can configure a bus to connect to, and exchange messages with, other messaging networks. To do this, you must configure a foreign bus connection. A foreign bus connection encapsulates information related to the remote messaging network, such as the type of the foreign bus and whether messaging applications are allowed to send messages to the foreign bus.

About this task

A foreign bus connection is associated with a service integration bus. The bus with which the foreign bus connection is associated is known as the local bus. The foreign bus connection represents another service integration bus, either in the same cell as the local bus or in a different cell, or it represents a WebSphere MQ queue manager. From the local bus, every other bus is regarded as a foreign bus, even if it is a bus in the same cell.

Messages route to a foreign bus either directly through a link between the local bus and the foreign bus, or indirectly through one or more intermediate buses.

If, when you configure the local bus, you select **Configuration reload enabled**, future changes to the configuration information for any foreign bus connections are updated automatically. The time when these changes take effect varies:

Foreign Bus Connection properties
: Immediately

WebSphere MQ link properties
: On channel restart, except Description (immediately), and Initial State (on messaging engine restart)

MQ sender channel properties
: On channel restart, except Initial State (on messaging engine restart or sender channel creation)

MQ receiver channel properties
: On channel restart, except Initial State (on messaging engine restart or receiver channel creation)

Publish/subscribe broker profile (0 to n) properties
: Immediately

Service integration bus link properties
: On link restart, except Description (immediately), and Initial State (on messaging engine restart or link creation)

To ensure that dynamic configuration updates are made to each node, click **System administration** → **Console Preferences** to display the Console Preferences window, then select **Synchronize changes with nodes**.

Connecting a bus and a WebSphere MQ gateway queue manager to use point-to-point messaging:

You can connect a service integration bus to a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue sharing group to send or receive messages using point-to-point messaging. One way to do this is to create a foreign bus connection, where the WebSphere MQ queue manager or queue-sharing group is configured as a foreign bus.

Before you begin

To connect a service integration bus and a WebSphere MQ queue manager or queue-sharing group to use point-to-point messaging, the following resources must be defined in WebSphere Application Server:

- A service integration bus that you want to connect from, known as the local bus. The bus must have at least one bus member.

The following resources must be defined in WebSphere MQ:

- A queue manager or queue-sharing group, which acts as the gateway to the WebSphere MQ network.
- A listener that is configured and running.
- A sender channel (to receive messages on the local bus), a receiver channel (to send messages from the local bus), or both.

About this task

In point-to-point messaging, the sending application specifies the target destination for the message. To receive the message, the receiving application specifies the same destination when it communicates with the messaging provider. Therefore, there is a one-to-one mapping between the sender and receiver of a message.

This task describes one way to achieve point-to-point messaging between WebSphere MQ queue manager or queue-sharing group. For further information about interoperation with a WebSphere MQ network, see the related tasks.

1. In the navigation pane, click **Service integration** → **Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that you want to connect from, that is, the local bus.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**.
4. In the Foreign bus connections pane, click **New** to start the Foreign bus connection wizard.
5. In the Bus connection type pane, ensure that **Direct connection** is selected.
6. In the Foreign bus type pane, select **WebSphere MQ**.
7. In the Local bus details pane, select the messaging engine that you want to use and enter the name of the virtual queue manager, that is, the name by which the virtual queue manager of the service integration bus is known to the WebSphere MQ network.
8. In the WebSphere MQ details pane, enter a name for the foreign bus, that is, the bus that represents the WebSphere MQ queue manager. Enter a name for the WebSphere MQ link that connects to the foreign bus. Ensure that these two names are not the same.
9. Ensure that the **Configure publish-subscribe messaging for this connection** check box is clear.
10. To send messages from the local bus to the WebSphere MQ queue manager, complete the following details:
    a. Ensure that **Enable Service integration bus to WebSphere MQ message flow** is selected.
    b. Enter the WebSphere MQ receiver channel name, host name and communication port.
    c. If the WebSphere MQ queue manager requires a secure connection, select the **Is the WebSphere MQ receiver channel secure?** check box. When this option is selected, the WebSphere MQ receiver channel accepts only connections that have secure sockets layer (SSL) based encryption. The connection is successful only if a set of suitably compatible SSL credentials are associated with the service integration bus outbound channel and the WebSphere MQ receiver channel that it connects to.
11. To receive messages on the local bus from the WebSphere MQ queue manager, complete the following details:
    a. Ensure that **Enable WebSphere MQ to Service integration bus message flow** is selected.

b. Enter the WebSphere MQ sender channel name.

c. Optionally, enter the service integration bus inbound user ID. When the local bus is secure, the inbound user ID replaces the user ID in messages from the foreign bus that arrive at the local bus and is used to authorize whether those messages can access their destinations. Specify an inbound user ID for the local service integration bus under the following circumstances:

   - The foreign bus is in a different security domain, so user IDs in the foreign bus are not recognized in the local bus.
   - You want local control of access to inbound messages to the local bus.

   If the local bus is not secure, the inbound user ID has no effect on messages. If the local bus is secure, the foreign bus is not secure, and an inbound user ID is not set, an inbound message from the foreign bus is only authorized to destinations that allow unauthenticated users access.

12. When the Foreign bus connection wizard is finished, save your changes to the master configuration.

Results

You have created a connection between a service integration bus and a WebSphere MQ queue manager to use point-to-point messaging. You have created a direct foreign bus connection, which contains a routing definition, or virtual link. The physical link, a WebSphere MQ link on the messaging engine for the local bus, is created automatically.

What to do next

You can test the connection.

Connecting a bus and a WebSphere MQ network to use publish-subscribe messaging:

You can connect a service integration bus and a WebSphere MQ network to send and receive messages using publish-subscribe messaging. To do this, you create a foreign bus connection, where the WebSphere MQ network is viewed as a foreign bus.

Before you begin

To connect a service integration bus and a WebSphere MQ network to use publish-subscribe messaging, the following resources must be defined in WebSphere Application Server:

- A service integration bus that you want to connect from, known as the local bus. The bus must have at least one bus member.

The following resources must be defined in WebSphere MQ:

- A queue manager or (for WebSphere MQ for z/OS) queue-sharing group, which acts as the gateway to the WebSphere MQ network.
- A listener that is configured and running.
- A topic and input queue for broker publish-subscribe flow configured in WebSphere MQ.
- A sender channel (to receive messages on the local bus), a receiver channel (to send messages from the local bus), or both.

About this task

In publish-subscribe messaging, the sending application publishes messages to an intermediate broker destination. Multiple receiving applications can subscribe to this destination to receive a copy of any messages that are published. When a message arrives at a destination, the messaging provider distributes a copy of the message to all the receiving applications that subscribe to the destination. There can be a one-to-many relationship between the sender and receiver of a message, depending on how many receiving applications are subscribed to a destination when a message arrives.

1. In the navigation pane, click **Service integration** → **Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that you want to connect from, that is, the local bus.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**.
4. In the Foreign bus connections pane, click **New** to start the Foreign bus connection wizard.
5. In the Bus connection type pane, ensure that **Direct connection** is selected.
6. In the Foreign bus type pane, select **WebSphere MQ**.
7. In the Local bus details pane, select the messaging engine that you want to use and enter the name of the virtual queue manager, that is, the name by which the virtual queue manager of the service integration bus is known to the WebSphere MQ network.
8. In the WebSphere MQ details pane, complete the following details:
   a. Enter a name for the foreign bus, that is, the bus that represents the WebSphere MQ network.
   b. Enter a name for the WebSphere MQ link that connects to the foreign bus. Ensure that the Foreign bus name and MQ link name are different.
   c. Select the **Configure publish-subscribe messaging for this connection** check box.
9. To send messages from the local bus to the WebSphere MQ network, complete the following details:
   a. Ensure that **Enable Service integration bus to WebSphere MQ message flow** is selected.
   b. Enter the WebSphere MQ receiver channel name, host name and communication port.
   c. If the WebSphere MQ gateway queue manager or queue-sharing group requires a secure connection, select the **Is the WebSphere MQ receiver channel secure?** check box. When this option is selected, the WebSphere MQ receiver channel accepts only connections that have secure sockets layer (SSL) based encryption. The connection is successful only if a set of suitably compatible SSL credentials are associated with the service integration bus outbound channel and the WebSphere MQ receiver channel that it connects to.
10. To receive messages on the local bus from the WebSphere MQ network, complete the following details:
    a. Ensure that **Enable WebSphere MQ to Service integration bus message flow** is selected.
    b. Enter the WebSphere MQ sender channel name.
    c. Optionally, enter the service integration bus inbound user ID. When the local bus is secure, the inbound user ID replaces the user ID in messages from the foreign bus that arrive at the local bus and is used to authorize whether those messages can access their destinations. Specify an inbound user ID for the local service integration bus under the following circumstances:
       - The foreign bus is in a different security domain, so user IDs in the foreign bus are not recognized in the local bus.
       - You want local control of access to inbound messages to the local bus.

       If the local bus is not secure, the inbound user ID has no effect on messages. If the local bus is secure, the foreign bus is not secure, and an inbound user ID is not set, an inbound message from the foreign bus is only authorized to destinations that allow unauthenticated users access.
11. From the Publish-subscribe details pane, repeat the following steps for each topic mapping you want to create:
    a. Enter the name of the topic on the local bus.
    b. Select the name of the topic space on the local bus that will map to the topic space on the foreign bus.
    c. Enter the name of the gateway queue manager or queue sharing group for the WebSphere MQ broker configured for broker publish-subscribe flow.
    d. To send messages from the local bus to the WebSphere MQ gateway queue manager or queue-sharing group, enter the name of the queue for the WebSphere MQ broker destination.

e. To receive messages on the local bus from the WebSphere MQ gateway queue manager or queue-sharing group, enter the name of the subscription point that will receive messages.
f. Select the direction of message flow for the publish-subscribe topic mapping. The options available depend on whether you completed details on the WebSphere MQ details pane to send messages, receive messages, or both, on the local bus.
g. Click **Add**.

12. When the Foreign bus connection wizard is finished, save your changes to the master configuration.

Results

You have created a connection between a service integration bus and a WebSphere MQ network to use publish-subscribe messaging. You have created a direct foreign bus connection, which contains a routing definition, or virtual link. The physical link, a WebSphere MQ link on the messaging engine for the local bus, is created automatically.

What to do next

You can test the connection.

Connecting service integration buses to use point-to-point messaging:

You can connect a service integration bus to another service integration bus to send and receive messages using point-to-point messaging. To do this, you create a foreign bus connection.

Before you begin

To connect a service integration bus to another service integration bus to use point-to-point messaging, the following resources must be defined:

- A service integration bus that you want to connect from, known as the local bus. The bus must have at least one bus member.
- A service integration bus that you want to connect to, known as the foreign bus. The bus must have at least one bus member.
- Optionally, to configure a secure connection, an authentication alias.

The buses that you connect must have unique names, because the connection will fail if the buses have the same name.

About this task

In point-to-point messaging, the sending application specifies the target destination for the message. To receive the message, the receiving application specifies the same destination when it communicates with the messaging provider. Therefore, there is a one-to-one mapping between the sender and receiver of a message.

1. In the navigation pane, click **Service integration** → **Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that you want to connect from, that is, the local bus.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**.
4. In the Foreign bus connections pane, click **New** to start the Foreign bus connection wizard.
5. In the Bus connection type pane, ensure that **Direct connection** is selected.
6. In the Foreign bus type pane, ensure that **Service integration bus** is selected.
7. In the Local bus details pane, select the messaging engine that you want to use from the drop-down list.

8. Optionally, enter a name for the inbound user ID. When the local bus is secure, the inbound user ID replaces the user ID in messages from the foreign bus that arrive at the local bus and is used to authorize whether those messages can access their destinations. Specify an inbound user ID for the local service integration bus under the following circumstances:
   - The foreign bus is in a different security domain, so user IDs in the foreign bus are not recognized in the local bus.
   - You want local control of access to inbound messages to the local bus.

   If the local bus is not secure, the inbound user ID has no effect on messages. If the local bus is secure, the foreign bus is not secure, and an inbound user ID is not set, an inbound message from the foreign bus is only authorized to destinations that allow unauthenticated users access.
9. In the Foreign bus details pane, complete the details as appropriate:
   - If the service integration bus you want to connect to is in a different cell from the local bus, complete the following details:
     a. Ensure that **Configure a foreign bus in a remote cell** is selected.
     b. Enter the name of the service integration bus to connect to, that is, the foreign bus. Enter the exact name of the existing service integration bus.
     c. Enter the name of the gateway messaging engine in the foreign bus, that is, the messaging engine to connect to in the foreign bus.
     d. Ensure that the **Configure publish-subscribe messaging for this connection** check box is clear.
     e. Enter the name of the service integration bus link.
     f. Enter one or more bootstrap endpoints, that is, the host, port location, and transport chain for the messaging engine on the foreign bus that the local service integration bus connects to. The port is the SIB_ENDPOINT_ADDRESS (or SIB_ENDPOINT_SECURE_ADDRESS if security is enabled) of the messaging engine. Use the format *hostName*:*portNumber*:*chainName*, separating each bootstrap endpoint by a comma. For more information, see steps 1 and 2 of “Configuring a connection to a non-default bootstrap server” on page 1598. Although this task primarily describes how to configure a JMS connection factory, it is also applicable to setting several bootstrap endpoint values if the remote messaging engine is in a cluster.
   - If the service integration bus you want to connect to is in the same cell as the local bus, complete the following details:
     a. Ensure that **Configure a foreign bus in a local cell** is selected.
     b. Select the name of the service integration bus to connect to, that is, the foreign bus.
     c. Select the name of the gateway messaging engine in the foreign bus, that is, the messaging engine to connect to in the foreign bus.
     d. Ensure that the **Configure publish-subscribe messaging for this connection** check box is clear.
     e. Enter the name of the service integration bus link.
10. Optionally, to secure the connection, in the Foreign bus details pane, complete the following details:
    a. Select the **Secure connection** check box.
    b. Select the type of transport chain to use to communicate with the messaging engine in the foreign bus. Select one of the following:
       - InboundBasicMessaging. InboundBasicMessaging is a predefined transport chain where communication uses the TCP protocol.
       - InboundSecureMessaging. InboundSecureMessaging is a predefined transport chain where communication is secured by using the secure sockets layer (SSL) based encryption protocol over a TCP network. For successful connection, a set of suitably compatible SSL credentials must be associated with the local bus inbound channel and the foreign bus outbound channel.
       - Other, please specify. Select this option to specify your own transport chain and enter the details in the field that appears.

c. Select the name of the authentication alias to use to authenticate access to the foreign bus. The alias must be known to the foreign bus.

11. When the Foreign bus connection wizard is finished, save your changes to the master configuration.

Results

You have created a connection from a local service integration bus to a foreign service integration bus to use point-to-point messaging. You have created a direct foreign bus connection, which contains a routing definition, or virtual link. The physical link, a service integration bus link on the messaging engine for the local bus, is created automatically.

What to do next

You need to create a connection in the opposite direction between the two buses. To do this, repeat the procedure, using the bus you have just connected to as the local bus, and the bus you have just connected from as the foreign bus. Ensure that you use exactly the same name for the service integration bus link. After you create a foreign bus connection for each service integration bus, you can test the connection.

Connecting service integration buses to use publish-subscribe messaging:

You can connect a service integration bus to another service integration bus to send and receive messages using publish-subscribe messaging. To do this, you create a foreign bus connection.

Before you begin

To connect a service integration bus to another service integration bus to use publish-subscribe messaging, the following resources must be defined:

- A service integration bus that you want to connect from, known as the local bus. The bus must have at least one bus member.
- A service integration bus that you want to connect to, known as the foreign bus. The bus must have at least one bus member.
- A topic space on both service integration buses. If the foreign bus is in a remote cell, you need to know the topic space name.
- Optionally, to configure a secure connection, an authentication alias.

The buses that you connect must have unique names, because the connection will fail if the buses have the same name.

About this task

In publish-subscribe messaging, the sending application publishes messages to an intermediate broker destination. Multiple receiving applications can subscribe to this destination to receive a copy of any messages that are published. When a message arrives at a destination, the messaging provider distributes a copy of the message to all the receiving applications that subscribe to the destination. There can be a one-to-many relationship between the sender and receiver of a message, depending on how many receiving applications are subscribed to a destination when a message arrives.

1. In the navigation pane, click **Service integration** → **Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that you want to connect from, that is, the local bus.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**.
4. In the Foreign bus connections pane, click **New** to start the Foreign bus connection wizard.
5. In the Bus connection type pane, ensure that **Direct connection** is selected.

6. In the Foreign bus type pane, ensure that **Service integration bus** is selected.
7. In the Local bus details pane, select the messaging engine that you want to use from the drop-down list.
8. Optionally, enter a name for the inbound user ID. When the local bus is secure, the inbound user ID replaces the user ID in messages from the foreign bus that arrive at the local bus and is used to authorize whether those messages can access their destinations. Specify an inbound user ID for the local service integration bus under the following circumstances:
   - The foreign bus is in a different security domain, so user IDs in the foreign bus are not recognized in the local bus.
   - You want local control of access to inbound messages to the local bus.

   If the local bus is not secure, the inbound user ID has no effect on messages. If the local bus is secure, the foreign bus is not secure, and an inbound user ID is not set, an inbound message from the foreign bus is only authorized to destinations that allow unauthenticated users access.
9. In the Foreign bus details pane, complete the details as appropriate:
   - If the service integration bus you want to connect to is in a different cell from the local bus, complete the following details:
     a. Ensure that **Configure a foreign bus in a remote cell** is selected.
     b. Enter the name of the service integration bus to connect to, that is, the foreign bus. Enter the exact name of the existing service integration bus.
     c. Enter the name of the gateway messaging engine in the foreign bus, that is, the messaging engine to connect to in the foreign bus.
     d. Select the **Configure publish-subscribe messaging for this connection** check box.
     e. Enter the name of the service integration bus link.
     f. Enter one or more bootstrap endpoints, that is, the host, port location, and transport chain for the messaging engine on the foreign bus that the local service integration bus connects to. The port is the SIB_ENDPOINT_ADDRESS (or SIB_ENDPOINT_SECURE_ADDRESS if security is enabled) of the messaging engine. Use the format *hostName*:*portNumber*:*chainName*, separating each bootstrap endpoint by a comma. For more information, see steps 1 and 2 of "Configuring a connection to a non-default bootstrap server" on page 1598. Although this task primarily describes how to configure a JMS connection factory, it is also applicable to setting several bootstrap endpoint values if the remote messaging engine is in a cluster.
   - If the service integration bus you want to connect to is in the same cell as the local bus, complete the following details:
     a. Ensure that **Configure a foreign bus in a local cell** is selected.
     b. Select the name of the service integration bus to connect to, that is, the foreign bus.
     c. Select the name of the gateway messaging engine in the foreign bus, that is, the messaging engine to connect to in the foreign bus.
     d. Select the **Configure publish-subscribe messaging for this connection** check box.
     e. Enter the name of the service integration bus link.
10. Optionally, to secure the connection, in the Foreign bus details pane, complete the following details:
    a. Select the **Secure connection** check box.
    b. Select the type of transport chain to use to communicate with the messaging engine in the foreign bus. Select one of the following:
       - InboundBasicMessaging. InboundBasicMessaging is a predefined transport chain where communication uses the TCP protocol.
       - InboundSecureMessaging. InboundSecureMessaging is a predefined transport chain where communication is secured by using the secure sockets layer (SSL) based encryption protocol over a TCP network. For successful connection, a set of suitably compatible SSL credentials must be associated with the local bus inbound channel and the foreign bus outbound channel.

- Other, please specify. Select this option to specify your own transport chain and enter the details in the field that appears.

c. Select the name of the authentication alias to use to authenticate access to the foreign bus. The alias must be known to the foreign bus.

11. In the Publish-subscribe details pane, repeat the following steps for each topic mapping you want to create:
    a. Select the name of the topic space on the local bus that will map to the topic space on the foreign bus.
    b. Enter the name of the topic space on the foreign bus. If the foreign bus is in the same cell as the local bus, you can select this name from a drop-down list.
    c. Click **Add**.
12. When the Foreign bus connection wizard is finished, save your changes to the master configuration.

Results

You have created a connection from a local service integration bus to a foreign service integration bus to use publish-subscribe messaging. You have created a direct foreign bus connection, which contains a routing definition, or virtual link. The physical link, a service integration bus link on the messaging engine for the local bus, is created automatically.

What to do next

You need to create a connection in the opposite direction between the two buses. To do this, repeat the procedure, using the bus you have just connected to as the local bus, and the bus you have just connected from as the foreign bus. Ensure that you use exactly the same name for the service integration bus link. After you create a foreign bus connection for each service integration bus, you can test the connection.

Connecting buses using an indirect connection:

You can connect a service integration bus to another service integration bus or a WebSphere MQ queue manager or queue-sharing group (known as the “gateway queue manager”) through one or more intermediate foreign buses. To do this, you create an indirect foreign bus connection.

Before you begin

To create an indirect foreign bus connection, the following resources must be defined:

- A service integration bus that you want to connect from, known as the local bus.
- A direct foreign bus connection from the local bus to the bus you want to use as the intermediate bus.
- A service integration bus or a gateway queue manager that you want to connect to indirectly, known as the target foreign bus.

About this task

To connect two buses indirectly, you create a indirect foreign bus connection on the local bus that specifies a suitable intermediate bus and the required target bus. There must be a connection, either direct or indirect, between the intermediate bus and the target foreign bus, that is, the service integration bus or a gateway queue manager that you want to connect to.

To connect one bus to another bus through an intermediate bus or a chain of buses, if the connection between the intermediate bus or the chain of buses and the target bus already exists, you do not require any new physical links. Instead, each foreign bus connection identifies a neighboring bus on the route to the final target bus as the ″next hop″ in the chain. Each bus in the chain must know about the next hop in the chain to reach the target bus. The local bus uses a foreign bus connection to identify the next bus in

the chain to the target bus, and uses its direct physical link to flow messages to that bus. Then, each intermediate bus uses its locally defined foreign bus connection to identify the next bus in the chain until the target bus is reached.

1. In the navigation pane, click **Service integration** → **Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that you want to connect from, that is, the local bus.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**.
4. In the Foreign bus connections pane, click **New** to start the Foreign bus connection wizard.
5. In the Bus connection type pane, select **Indirect, using another bus**.
6. In the Indirect connection details pane, complete the following details:
   a. Enter the name of the target foreign bus that you want to connect to indirectly.
   b. Select the name of the existing, directly connected foreign bus that will be the intermediate bus to the target bus.
7. When the Foreign bus connection wizard is finished, save your changes to the master configuration.

Results

You have created a connection from the local bus to the target bus via the intermediate bus. You have created an indirect foreign bus connection, which contains a routing definition, or virtual link.

What to do next

Check whether there are connections between the intermediate bus you specified and the target bus. If necessary, repeat the procedure to create the ″next hop″ in the chain.

Testing foreign bus connections:

After you define a direct foreign bus connection between a service integration bus and either another service integration bus or a WebSphere MQ queue manager, you can test the connection to check that it can be used to exchange messages.

Before you begin

To test a foreign bus connection, the following resource must be defined:

- A service integration bus, known as the local bus, with a direct foreign bus connection to a service integration bus or a WebSphere MQ queue manager.

About this task

You might want to test a foreign bus connection before you send messages that use that connection, or if you have difficulty sending and receiving messages that use that connection. You can test only direct foreign bus connections. You cannot test indirect foreign bus connections, because it might not be possible to reach the target destination bus.

1. In the navigation pane, click **Service integration** → **Buses**.
2. In the Buses pane, click the bus that has the connection you want to test.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**. A list of foreign bus connections is displayed.
4. Select the check box for the connection you want to test.
5. Click **Test Connection**. A message is displayed at the top of the pane that shows the result of the test.

Results

You have tested a bus connection.

Listing the foreign bus connections:

You can list the foreign bus connections that are associated with a local bus to see which buses are currently configured.

Before you begin

To list foreign bus connections, the following resources must be defined:

- A service integration bus with one or more foreign bus connections between it and another service integration bus or a WebSphere MQ queue manager.

About this task

You can list foreign bus connections by using the administrative console, as described in this topic, or by using the wsadmin tool and the listSIBForeignBuses command.

To list the foreign bus connections that are associated with the local bus, complete the following steps.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses**.
3. In the service integration buses pane, select the bus for which you want to list the connections.
4. In the configuration tab, under **Topology**, click **Foreign bus connections**. A list of buses that have a foreign bus connection from the local bus is displayed.

Results

You have listed the foreign bus connections that are associated with the local bus.

Removing a foreign bus connection from a bus:

You can remove a foreign bus connection from a bus so that the connection can no longer be used for sending and receiving messages.

Before you begin

When a foreign bus connection is deleted from the configuration, the next time the hosting messaging engine for a link transmitter is started, it moves the messages to the exception destination. To avoid this situation, drain the messages from the link transmitter as far as is possible and then, before deleting the link configuration, either move any remaining messages from the transmission queues to an exception destination or delete them. For more details refer to the sub-topics below.

About this task

Removing a foreign bus connection from a bus removes the resources associated with the connection. The bus will no longer service the deleted link.

To remove a foreign bus connection:

1. In the navigation pane, click **Service integration** → **Buses**.
2. In the Buses pane, select the bus from which you want to remove the foreign connection.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**. to display a list of connections for this bus.

4. Select the check box that corresponds to the connection that you want to remove.
5. Click **Delete**.
6. Save your changes to the master configuration.

Results

You have now deleted the foreign bus connection from a bus. This connection can no longer be used for communication.

Preparing to remove a foreign bus connection between two service integration buses:

Perform this task before you remove a foreign bus connection.

Before you begin

Before you start you must know which foreign bus connection is being prepared for deletion.

About this task

When a foreign bus connection and its service integration bus link is deleted from the configuration, the next time the hosting messaging engine for a link transmitter is started, it deletes all its messages or moves them to the exception destination. To avoid messages being unintentionally deleted or moved to the exception destination, drain the messages from the link transmitter as much as possible and then, before deleting the link configuration, either move any remaining messages to an exception destination or delete them.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses** to display a list of local buses.
3. Select the bus from which you want to remove the foreign bus connection.
4. In the **Configuration** tab, under **Topology**, click **Foreign bus connections**. A list of connections for this bus is displayed.
5. From the list of foreign buses, click the name of the foreign bus to display its details.
6. Under **General properties**, clear the **Send Allowed** check box to prevent new messages from being produced for this service integration bus link.
7. Click **Apply** to save the configuration.
8. To determine when there are no more messages queued on this link, under **Related Items** click **Service integration bus links** to display the details of the service integration bus links.
9. Click the **Refresh** icon of **Status** to refresh the view of the **Current outbound messages**.
10. When there are no **Current outbound messages**, select the check box next to the appropriate link and then click **Stop** to stop the link to the foreign bus.
11. When the **Status** of the link turns to red, the link to the foreign bus has no remaining messages and is stopped.
12. Repeat steps 2 to 11 on the foreign bus side because the foreign bus can continue to produce messages after the local bus connection has been deleted.
13. Save your changes to the master configuration.

Results

You have drained the messages from the link transmitter as much as possible, and either moved any remaining messages from the transmission queues to an exception destination or deleted them. You are now ready to remove the foreign bus connection.

Preparing to remove a foreign bus connection between a service integration bus and a WebSphere MQ network:

Perform this task before you remove a foreign bus connection.

Before you begin

Before you start you must know which foreign bus connection is being prepared for deletion. You should also inform the WebSphere MQ administrator that the foreign bus link is about to be deleted and therefore no longer paired with its WebSphere MQ gateway queue manager or message broker in the WebSphere MQ network.

About this task

When a foreign bus link is deleted from the configuration, the next time the hosting messaging engine for a link transmitter is started it deletes all its messages or moves them to the exception destination. To avoid messages being unintentionally deleted or moved to the exception destination, drain the messages from the link transmitter as much as possible and then, before deleting the link configuration, either move any remaining messages to an exception destination or delete them.

If there are publish/subscribe broker profiles defined, you should remove the subscriptions.

1. Start the administrative console.
2. Optional: If there are publish/subscribe broker profiles defined on any of the links for this foreign bus connection, remove the subscriptions.

   Complete the following substeps for each broker profile:

   a. Navigate to **Service integration** → **Buses** → ***bus_name*** → **[Topology] Foreign bus connections** → ***foreign_bus_name*** → **[Related Items] WebSphere MQ links** → ***link_name*** → **[Additional Properties] Publish/subscribe broker profiles** → ***profile_name***
   b. Click the **Runtime** tab.
   c. Click **Subscriptions**.
   d. Click **Unsubscribe** to remove all the subscriptions listed.

   When an unsubscribe command is sent to the message broker in the WebSphere MQ network, the relevant topic mapping is put into an ″in doubt″ state until the unsubscribe is confirmed when the topic mapping is deleted. After the unsubscribe is confirmed the topic mapping is no longer shown in the runtime view. You might need to refresh the runtime view for all subscriptions to be shown as removed.
3. Prevent new messages from being produced for this foreign bus connection.
   a. Navigate to **Service integration** → **Buses** → ***bus_name*** → **[Topology] Foreign bus connections** → ***foreign_bus_name***
   b. Under **General properties**, clear the **Send Allowed** check box.
   c. Click **Apply** to save the configuration.
4. Determine when there are no more messages queued, then stop the link to the foreign bus in a controlled manner.
   a. Under **Related Items**, click **WebSphere MQ links** to display the list of links for this bus.
   b. Click the **Refresh** icon of **Status** to refresh the view of the **Current outbound messages**.
   c. When there are no **Current outbound messages**, select the check box next to the appropriate link and then select a **Stop mode** of **Quiesce**.
   d. Select a **Target state** of **Stopped** so that the link can only be started again by administrator action.
   e. When the **Status** of the link turns to red, the link to the foreign bus has no remaining messages and is stopped.

5. The foreign bus can continue to produce messages after the local bus connection has been deleted. Because the foreign bus is a WebSphere MQ network, refer to the WebSphere MQ Intercommunication guide for details about the safe deletion of channels at Managing WebSphere MQ channels.
6. Save your changes to the master configuration.

Results

You have removed the subscriptions from any publish/subscribe brokers on the link. You have drained the messages from the link transmitter as much as possible, and either moved any remaining messages from the transmission queues to an exception destination or deleted them.

What to do next

You are now ready to remove the foreign bus connection.

Configuring destination defaults for a foreign bus connection:

You can use destination defaults to configure the destination for messages handled by a foreign bus connection. A foreign bus connection can be either a service integration bus or a WebSphere MQ queue manager or queue-sharing group (known as a “gateway queue manager”).

Before you begin

To configure destination defaults for a foreign bus connection, the following resource must be defined:

- At least one foreign bus connection, configured

About this task

Destination defaults are used where an application is producing messages destined for a destination on a foreign bus connection, but where that application has not explicitly set certain attributes on the message, or where a foreign destination has not been explicitly defined.

1. In the navigation pane, click **Service integration** → **Buses**.
2. In the service integration buses pane, select the bus that you want to configure.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**. A list of foreign bus connections is displayed.
4. Select the foreign bus connection that you want to configure.
5. In the content pane, under **Additional properties**, click **Destination defaults**.
6. Specify the following properties for the destination defaults:

   Default priority
   The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

   Default reliability
   The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

   Maximum reliability
   The maximum reliability of messages accepted by this destination.

   Send allowed
   Clear this option (setting it to false) to stop producers from being able to send messages to destinations on this foreign bus.

Enable producers to override default reliability
Select this option to enable producers to override the default reliability that is set on the destination.

7. Click **OK**.
8. Save your changes to the master configuration.

Results

You have now configured destination defaults for a foreign bus connection.

Managing messages on foreign buses:

This task describes how to manage messages on a foreign bus.

Before you begin

The steps required depend on whether the foreign bus connection connects a service integration bus to:

- another service integration bus
- a WebSphere MQ network

About this task

If the foreign bus connection connects a service integration bus to another service integration bus, you can manage messages on:

- link transmitters
- link receivers

If the foreign bus connection connects a service integration bus to a WebSphere MQ network, you can manage messages on:

- link transmitters
- known link transmitters
- sender channel transmitter

There is one link transmitter for each message engine, one known link for each link transmitter, and one sender channel transmitter on the WebSphere MQ link sending messages to a gateway queue manager on the WebSphere MQ network acting as the foreign bus.

Perform this task when you want to view, delete, or move messages on a transmitter.

Refer to the list of sub-topics below and select the appropriate task.

Results

You have managed the messages on a foreign bus.

Configuring an exception destination for messages on a foreign bus connection:

You can configure an exception destination for messages handled by a foreign bus connection. A foreign bus connection can be either a connection between two service integration buses or a connection between a service integration bus and a WebSphere MQ network.

Before you begin

To configure an exception destination default for a foreign bus connection, you must know the name of the foreign bus connection.

About this task

If specified, the link exception destination is used as the target for messages being exceptioned for that link. The exception destination can be specific to that link, the system default local messaging engine exception destination or, if the exception destination is specified as **None**, the messages are discarded.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses** to display a list of local buses.
3. Select the bus from which you want to remove the foreign bus connection.
4. In the **Configuration** tab, under **Topology**, click **Foreign bus connections** to display a list of connections for this bus.
5. From the list of foreign buses, click the name of the foreign bus to display its details.
6. Under **Related Items** click **Service integration bus links** (if the foreign bus is another service integration bus) or **WebSphere MQ links** (if the foreign bus is WebSphere MQ network).
7. From the list of links, click the name of a link to display its details.
8. In the **Configuration** tab, under **General properties**, use the radio buttons to configure the **Exception destination** to which error messages are sent for this link. Select **None** to discard error messages. Select **System** to send error messages to the system default local messaging engine exception destination. Select **Specify** and enter an exception destination to send error messages to the specified exception destination.
9. Save your changes to the master configuration.

Results

You have now configured an exception destination for messages on a foreign bus connection.

Managing messages in a link transmission queue connection between two service integration buses:

This task describes how to manage messages in a link transmission queue connected to a foreign bus connection between two service integration buses.

Before you begin

You must know the link transmitter from which messages are to be removed.

About this task

There is one link transmitter for each message engine.

Perform this task when you want to view, delete or move messages on a link transmitter.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses**. A list of buses is displayed in the content pane.
3. Select the bus whose link transmission queue you want to manage.
4. In the **Configuration** tab, under **Topology**, click **Foreign bus connections**. A list of connections for this bus is displayed.
5. Select the **Name** of the foreign bus from the list of foreign buses. The details of the selected foreign bus are displayed in the content pane.

6. In the **Configuration** tab, under **Related Items**, click **Service integration bus links**, then select the name of the link.
7. In the **Runtime** tab, click **Link transmitters** to display the list of link transmitters for messaging engines that are sending messages to the foreign bus.
8. Optional: To manage all messages on the link transmitter, select the **Link transmitter** and perform your required task:
   - Click **Delete all messages** to delete all the available messages on the selected link transmitter.
   - Click **Move all messages** to move all the available messages on the selected link transmitter to the configured exception destination. If the exception destination is configured as **None** the messages are discarded. If it is configured as **System default** the messages are sent to the system default exception destination. If a **Specified destination** is configured, the messages are sent to the exception destination specified for this link.
9. Optional: To manage selected messages on the link transmitter, click the name of the **Messaging engine** from the list of **Link transmitters** and then click **View messages** to view the messages on an outbound stream from this link transmitter to the foreign bus.
10. Select one or more messages and :
    - Click **Delete** to delete the selected messages.
    - Click **Move** to move the selected messages to the local exception destination.
    - Click **Refresh** to view the current messages on the selected link transmitter.

      Note: Only messages up to the specified **Maximum displayed messages** are displayed.

Results

You have managed the messages on a specified link transmitter connected to a foreign bus.

Managing messages in a link receiver queue connected to a foreign bus:

This topic describes how to manage messages in a link receiver queue connection between two service integration buses.

Before you begin

There is one link receiver for each message producing foreign messaging engine on the service integration bus link.

About this task

Perform this task when you want to view messages on a link receiver.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses** to display a list of buses.
3. Click the bus whose link receiver queue you want to view.
4. In the **Configuration** tab, under **Topology**, click **Foreign bus connections**.
5. Click the name of the foreign bus connection to display its details.
6. Under **Related links** click **Service integration bus links** and click the name of the link.
7. In the **Runtime** tab, click **Link receivers** to display the list of link receivers for messaging engines that are sending messages to this bus.
8. To view the messages on the link receiver, click the name of the **Messaging engine** from the list of link receivers and then click **View messages** to view the messages on an inbound stream from the messaging engine on the foreign bus. Click **Refresh** to view the current messages on the selected link receiver.

Results

You have viewed the messages on a specified link receiver connected to a foreign bus.

Managing messages in a link transmission queue connection between a bus and a WebSphere MQ network:

This task describes how to manage messages in a link transmission queue connected to a foreign bus connection between a service integration bus and a WebSphere MQ network.

Before you begin

You must know the foreign bus whose messages are to be removed.

About this task

There is one link transmitter for each message engine producing messages on the foreign bus link.

Perform this task when you want to view, delete or move messages on a link transmitter.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses**. A list of buses is displayed in the content pane.
3. Select the bus whose link transmission queue you want to manage.
4. In the **Configuration** tab, under **Topology**, click **Foreign bus connections**. A list of connections for this bus is displayed.
5. Select the **Name** of the foreign bus from the list of foreign buses. The details of the selected foreign bus are displayed in the content pane.
6. In the **Configuration** tab, under **Related Items**, click **WebSphere MQ links**, then select the **Name** of the link.
7. In the **Runtime** tab, click **Sender channel** to display the sender channels that are sending messages to the foreign bus.
8. Optional: To manage all messages on the link transmitter, select the **Link transmitter** and perform your required task:
   - Click **Delete all messages** to delete all the available messages on the selected link transmitter.
   - Click **Move all messages** to move all the available messages on the selected link transmitter to the configured exception destination. If the exception destination is configured as **None** the messages are discarded. If it is configured as **System default** the messages are sent to the system default exception destination. If a **Specified destination** is configured, the messages are sent to the exception destination specified for this link.
9. Optional: To manage selected messages on the link transmitter, click the name of the **Messaging engine** from the list of **Link transmitters** and then click **View messages** to view the messages on an outbound stream from this link transmitter to the foreign bus.
10. Select one or more messages and :
    - Click **Delete** to delete the selected messages.
    - Click **Move** to move the selected messages to the local exception destination.
    - Click **Refresh** to view the current messages on the selected link transmitter.

      Note: Only messages up to the specified **Maximum displayed messages** are displayed.

Results

You have managed the messages on a link transmitter connected to a foreign bus.

Managing messages in a known link transmission queue connected to a foreign bus:

How to manage messages in a known link transmission queue connection between a service integration bus and a WebSphere MQ network.

Before you begin

There is one known link transmitter for each message producing messaging engine on the foreign bus link.

About this task

Perform this task when you want to manage messages on a known link transmitter.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses** to display a list of buses.
3. Click the bus whose known link transmission queue you want to view.
4. In the **Configuration** tab, under **Topology**, click **Foreign bus connections**. to display a list of connections for this bus.
5. From the list of foreign buses, click the name of the foreign bus to display its details.
6. Under **Related Items** click **WebSphere MQ links** and click the **Name** of the link.
7. In the **Configuration** tab, under **Additional Properties** click **Sender channel** to display the sender channels for all messaging engines that are sending messages to this bus. The sender channel sends messages to the gateway queue manager.
8. From the list of sender channels, select the check box of a **Sender MQ channel name** and click **View known link transmitters** to display a list the remote messaging engines producing messages for this WebSphere MQ link.
9. Click **Refresh** to view the current messages on the message engines.
10. Select the check box of the known link transmitter and:
    - Click **Delete all messages** to remove them from the known link transmission queue.
    - Click **Move all messages** to move all the available messages on the known link transmitter to the configured exception destination. If the exception destination is configured as **None** the messages are discarded. If it is configured as **System default** the messages are sent to the system default exception destination. If a **Specified destination** is configured, the messages are sent to the exception destination specified for this link.

Results

You have managed the messages on known link transmitters producing messages to a sender channel transmitter connected to a foreign bus.

Managing messages in a sender channel transmission queue connected to a foreign bus:

How to manage messages in a sender channel transmission queue connection between a service integration bus and a WebSphere MQ network.

Before you begin

There is one sender channel transmitter on the foreign bus link sending messages to a gateway queue manager on the WebSphere MQ network acting as the foreign bus.

About this task

Perform this task when you want to manage messages on the sender channel transmitter.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses** to display a list of buses.
3. Click the bus whose sender channel transmission queue you want to view.
4. In the **Configuration** tab, under **Topology**, click **Foreign bus connections**. to display a list of connections for this bus.
5. From the list of foreign buses, click the name of the foreign bus to display its details.
6. In the **Configuration** tab, under **Related Items** click **WebSphere MQ links** and select the check box for a link.
7. Click **Sender channel transmitter** under **Current outbound messages** or click **Sender channel transmitter** under **Messages sent** to see the relevant message details for this sender channel transmitter.
8. Select the check box of the sender channel transmitter and:
   - Click **Delete all messages** to remove them from the sender channel transmission queue.
   - Click **Move all messages** to move all the available messages on the sender channel transmitter to the configured exception destination. If the exception destination is configured as **None** the messages are discarded. If it is configured as **System default** the messages are sent to the system default exception destination. If a **Specified destination** is configured, the messages are sent to the exception destination specified for this link.

Results

You have managed the messages on a sender channel transmitter sending messages to a gateway queue manager on the WebSphere MQ network acting as the foreign bus.

Managing pending acknowledgement messages on a deleted WebSphere MQ link:

This topic describes how to manage pending acknowledgement messages on a WebSphere MQ link that has been deleted from a foreign bus connecting to a service integration bus.

Before you begin

Before you start you need to know the name of the WebSphere MQ link that has been deleted.

About this task

If a foreign bus link to a WebSphere MQ network is deleted from the WebSphere Application Server configuration before being drained of messages, a batch of messages pending acknowledgement remains persisted in the WebSphere MQ link sender channel transmitter.

To resolve pending acknowledgement messages on a deleted WebSphere MQ link, use the administrative console to complete the following steps.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses**. to display a list of buses.
3. Click the bus whose link transmission queue you want to manage.
4. In the **Configuration** tab, under **Topology**, click **Foreign Bus Connections** to display a list of connections for this bus.
5. From the list of foreign buses, click the name of the foreign bus to display its details.
6. Under **Related Items** click **Service integration bus links** to display the details of the service integration bus links.

7. Click the MQ network foreign bus that has a connection that is active, but a configuration status that is **Deleted**. If clicking **Link transmitters** displays an empty list, no messaging engines are producing messages to this link and all the link transmitters have been deleted because they were drained of messages. The **Sender channel transmitter** link displays the **Status** of the sender channel as stopped but **Current outbound messages** shows remaining messages on the sender channel transmitter.
8. Click a WebSphere MQ link **sender channel** link to display the messages that are queued on the WebSphere MQ link sender channel transmitter for transmission to the WebSphere MQ network.
9. If the **Status** of a batch of messages is **Commit pending batch**, the batch has arrived safely at the MQ network. Select the batch and click **Commit pending batch** to remove the messages from the transmission queue.
10. If the **Status** of a batch of messages is **Pending batch acknowledgement**, the batch did not arrive at the MQ network. Select the batch and click **Rollback pending acknowledge batch** to rollback the transaction and restore the messages to the channel in an available state. These messages are either automatically deleted or moved to the exception destination. When the channel transmitter is empty, the link is automatically deleted from the runtime environment.

Results

You have resolved any pending acknowledgement messages on a WebSphere MQ link that has been deleted from a foreign bus connecting to a service integration bus.

Modifying a routing definition:

You can view or change the routing definition of an existing foreign bus connection between a local bus and a foreign bus. The routing definition defines the virtual link between two buses that enables them to exchange messages. The routing definition can define properties for a virtual service integration bus link, a virtual WebSphere MQ link, or an indirect foreign bus connection.

About this task

You create a routing definition when you create a foreign bus connection. For a direct foreign bus connection, the routing definition, or virtual link, has a corresponding physical link on a messaging engine.

To change the properties of the routing definition, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that is connected to another bus, that is, the local bus you require.
3. In the content pane, under **Topology**, click **Foreign bus connections**. A list of buses that have a foreign bus connection from the local bus is displayed.
4. Select the required foreign bus.
5. In the content pane, under **Additional properties**, click the routing properties option. The routing properties option depends on the type of routing definition and is one of the following:
   - **Service integration bus link routing properties**
   - **WebSphere MQ link routing properties**
   - **Indirect routing properties**
6. Specify the new routing properties:
   - For a virtual service integration bus link or a virtual WebSphere MQ link, specify properties as follows:

Inbound user ID

The user name used to authenticate inbound message flows from the foreign bus.

When the local bus is secure, the inbound user ID replaces the user ID in messages from the foreign bus that arrive at the local bus and is used to authorize whether those messages can access their destinations. Specify an inbound user ID for the local service integration bus under the following circumstances:

– The foreign bus is in a different security domain, so user IDs in the foreign bus are not recognized in the local bus.

– You want local control of access to inbound messages to the local bus.

If the local bus is not secure, the inbound user ID has no effect on messages. If the local bus is secure, the foreign bus is not secure, and an inbound user ID is not set, an inbound message from the foreign bus is only authorized to destinations that allow unauthenticated users access.

Outbound user ID

The user name used to authenticate outbound message flows to the foreign bus.

The outbound user ID replaces the user ID that identifies the message source in every message sent to the foreign bus. Where it is defined, the outbound user ID replaces the user ID in messages sent by the local bus to the foreign bus. If the local bus and the foreign bus are both secure, and the foreign bus has not overridden the user ID with its own inbound user ID, the foreign bus also uses the outbound user ID to authorize the message to its destination.

- For an indirect foreign bus connection, select the name of the next foreign bus you require in the chain of intermediate buses. For a bus to be available for selection, it must already have a direct foreign bus connection from the local bus.

7. Click **OK**.
8. Save your changes to the master configuration.

Configuring service integration bus links:

You can configure service integration bus links on messaging engines in a variety of ways. For example, you can start, stop, or remove links.

About this task

When you create a foreign bus connection to connect two service integration buses, a service integration bus link is created automatically. The foreign bus connection contains a routing definition, which is a virtual link, and the service integration bus link is the corresponding physical link on the messaging engine.

Configuring the properties of a service integration bus link:

After establishing a service integration bus link you might want to configure the properties of a service integration bus link such as the name of the service integration bus link, or authentication alias used by foreign bus that the link connects to.

About this task

To configure the properties of a service integration bus link, use the administrative console to complete the following steps:

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine for which you want to configure the service integration bus link.

3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to configure.
5. Specify the following properties for the service integration bus link:

   Name The name of the service integration bus link. In order to work, the name must be the same as the name of the corresponding service integration bus link configured on the target foreign bus.

   Description
   An optional description for the service integration bus link, for administrative purposes.

   UUID The universal unique identifier assigned by the system to the service integration bus link for administrative purposes.

   Foreign messaging engine
   The messaging engine on the foreign bus to which this link connects.

   Note: This foreign bus name must not be altered after it has been configured. If you alter it, any messaging engines that already hold state information about the link will not be able to use the link unless the foreign bus name is reset to its original value.

   Target inbound transport chain
   The type of transport chain used for communication with the foreign bus. The transport chain name must be the name of the transport chain as defined on the server on which the target messaging engine is hosted.

   Bootstrap endpoints
   The comma-separated list of endpoints used to connect to a bootstrap server. This property is set in the same way as the **Provider endpoint** property in the JMS connection factory settings. For more information, see steps 1 and 2 of “Configuring a connection to a non-default bootstrap server” on page 1598. Although this task primarily describes how to configure a JMS connection factory, it is also applicable to setting several bootstrap endpoint values if the remote messaging engine is in a cluster.

   Note: Service integration bus links over BootstrapTunneledMessaging and BootstrapTunneledSecureMessaging transport chains only work directly between application server instances. Bus links over TunneledMessaging transport chains do not work if an HTTP server is placed in front of either application server instance.

   Authentication alias
   The name of the authentication alias, used to authenticate access to the foreign bus. The alias must be known to the foreign bus.

   Initial state
   Whether the link is started automatically when the messaging engine is started. Until started, the gateway link is unavailable. If this property is set to **Started** the service integration bus link is started when the messaging engine is started.
6. Click **OK**.
7. Save your changes to the master configuration.

Listing the service integration bus links:

You can list all the service integration bus links that are linked to a messaging engine.

About this task

To list the service integration bus links for a messaging engine, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Buses**.

2. In the content pane, click the name of the bus that your messaging engine belongs to.
3. In the content pane, under **Additional properties**, click **Messaging engines**. The list of messaging engines in the bus is displayed.
4. In the content pane, select the messaging engine for which you want to list the service integration bus links.
5. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.

Example

The following combinations of **Status** and **Activity** values are possible:

Status	Activity	Meaning
started	inactive	The service integration bus link is started on the local messaging engine but has no connection to the foreign bus. The service integration bus link is attempting to activate a connection to the foreign bus. The service integration bus link on the foreign bus must also be started to successfully activate of a connection between the buses.
started	active	The service integration bus link is started on the local messaging engine and has an active connection to the foreign bus.
stopped	inactive	The service integration bus link is stopped on the local messaging engine and there is no connection to the foreign bus.
unknown	inactive	An error might have occurred in setting up the link, such that the object that is used to report the current state is not available.

What to do next

You can now add or remove a service integration bus link or select a service integration bus link to start, stop, or configure.

Starting a service integration bus link:

When a service integration bus link has been started, it can be used for communicating with its associated messaging engines.

About this task

To start a service integration bus link, use the administrative console to complete the following steps:

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine for which you want to start the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you wish to start.
5. Click **Start**.

Stopping a service integration bus link:

When a service integration bus link has been stopped, it cannot be used for communication until it is restarted.

About this task

To stop a service integration bus link, use the administrative console to complete the following steps:

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine to which the service integration bus link that you wish to stop belongs.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you wish to stop.
5. Click **Stop**.

Removing a service integration bus link:

When a service integration bus link to a messaging engine has been removed, it cannot be used for communication until it is recreated.

Before you begin

Before you remove the service integration bus link you must stop the link.

When you remove a service integration bus link, all traffic using the link needs to be dealt with in a similar way to when you remove a destination. For further details, see “Deleting a non-topic space bus destination” on page 1246. Note that express Quality of Service (QoS) messages are discarded.

About this task

To remove a service integration bus link from a messaging engine, use the administrative console to complete the following steps:

1. Display the list of messaging engines.
2. In the content pane, select which the messaging engine has own association with the service integration bus link that you wish to remove.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you wish to remove.
5. Click **Delete**.
6. Save your changes to the master configuration.

What to do next

When you remove a service integration bus link, all traffic using the link must be diverted by alternative routes or held pending further administrative action. Express QoS messages are discarded.

Configuring topic space mappings between service integration buses:

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. You can configure topic space mappings between a local service integration bus and a foreign service integration bus.

About this task

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. For publications to flow from the local topic space into the foreign bus, an equivalent topic space mapping is required by the foreign bus.

If you want to publish messages from a local bus to a foreign bus that is linked indirectly through a third bus, you must configure topic space mappings between the local bus and the intermediate bus, and between the intermediate bus and the foreign bus. The messages can be for publication to the foreign bus only, or to all three buses. If you want to publish messages only to the local and foreign buses, these two buses must be connected directly.

If you want to publish messages from a local service integration bus to a foreign bus that represents a WebSphere MQ network, you must define topic mappings on the broker profile associated with the WebSphere MQ link.

For more details about the foreign bus and publish/subscribe messaging between buses, see Foreign buses.

Creating topic space mappings:

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. You can create topic space mappings between two service integration buses.

About this task

You can create topic space mappings as part of the procedure to create a foreign bus connection, or you can create them separately, as described in this topic.

Note that for publishing and subscribing between a service integration bus and a foreign bus that represents a WebSphere MQ network, you must define topic mappings on the broker profile associated with the WebSphere MQ link.

To map a topic space on a local service integration bus to a topic space on a foreign service integration bus, use the administrative console to complete the following steps.

1. In the navigation pane, click **Service integration** → **Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that is connected to another bus, that is, the local bus you require.
3. In the content pane, under **Topology**, click **Foreign bus connections**. A list of buses that have a foreign bus connection from the local bus is displayed.
4. Select the required foreign bus.
5. In the content pane, under **Additional properties**, click **Service integration bus link routing properties**.
6. In the content pane, under **Additional properties**, click **Topic space map entries**.
7. Click **New**.
8. Specify the mappings as follows:

   Local topic space
   The name of the topic space on this (local) bus that is mapped to the remote topic space on the foreign bus.

   Remote topic space
   The name of the topic space on the foreign bus that is mapped to the local topic space.

   Note: The names of the local and foreign topic space do not have to match, but the names of the topics must match in both local and foreign buses.
9. Click **OK**.
10. Save your changes to the master configuration.

Results

The remote topic space is mapped to the local topic space.

Deleting topic space mappings:

You can delete topic space mappings so that subscribers on the local topic space cannot receive messages that are published in the foreign topic space.

About this task

To delete topic space mappings, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that is connected to another bus, that is, the local bus you require.
3. In the content pane, under **Topology**, click **Foreign bus connections**. A list of buses that have a foreign bus connection from the local bus is displayed.
4. Select the required foreign bus.
5. In the content pane, under **Additional properties**, click **Service integration bus link routing properties**.
6. In the content pane, under **Additional properties**, click **Topic space map entries**. A list of topic space map entries is displayed.
7. Select the topic space map entry that you wish to remove.
8. Click **Delete**.
9. Save your changes to the master configuration.

Listing topic space map entries:

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. You can list topic space map entries to view existing map entries.

Before you begin

There must be a service integration bus link between a local service integration bus and a foreign service integration bus.

About this task

To list the topic space map entries, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that is connected to another bus, that is, the local bus you require.
3. In the content pane, under **Topology**, click **Foreign bus connections**. A list of buses that have a foreign bus connection from the local bus is displayed.
4. Select the required foreign bus.
5. In the content pane, under **Additional properties**, click **Service integration bus link routing properties**.
6. In the content pane, under **Additional properties**, click **Topic space map entries**. The list of mappings between topic spaces in the local bus and topic spaces in the foreign bus is shown.

Topic names and use of wildcard characters in topic expressions:

This topic describes the use of wildcard characters in topic expressions to retrieve topics provided by the default messaging provider and service integration technologies.

Each subscribe request includes a topic expression that identifies one or more topics that the subscription is to be associated with, and which the request uses to match against incoming messages.

Subscription topic expressions for the default messaging provider and service integration technologies are based on a subset of the XPath location path syntax.

Identifying individual topics

Every topic in a topic space has a *topic name* consisting of one or more name parts, separated by / (forward slash) characters:

```
Topic name = name_part | (name_part '/' topic_name)
```

Using wildcards to identify multiple topics

To select one or more topics in a topic space, you can use a *topic path*, a location path that contains wildcard characters. Topic spaces are evaluated using a subset of the XPath location path syntax with the <topicspace> element as the initial context node, so that non-wildcarded topic paths look exactly like topic names.

The syntax for topic paths can be summarized as follows:

- A topic path that contains no * (asterisk), // (double forward slash), or . (dot) symbols is asking for an exact match with the topic name specified.
- A * (asterisk) can be used as a wild card and matches one level (regardless of the value of the name part at that level)

  A * can be used anywhere in a topic path expression, but if it isn't at the start it must be preceded by a /, and if it is isn't at the end it must be followed by a /
- // can be used as a wild card and matches 0 or more levels

  A // can be used anywhere in the expression except at the end. To match 0 or more levels at the end of the expression you end the expression with the syntax //. (double-slash dot). To match one or more levels at the end use //* (double-slash asterisk)

  A topic path must not contain more than two consecutive / symbols.

The following table lists some example topic paths using the XPath syntax and the equivalent WBI Message Broker selectors:

Topic path	Topics selected	WBI Message Broker equivalent
A/B	Selects the B child of A	A/B
A/*	Selects all children of A	A/+
A//*	Selects all descendents of A	A/#/+
A//.	Selects A and all descendents of A	A/#
//*	Selects everything	# (or #/+)
A/./B	Equivalent to A/B	A/B
A/*/B	Selects all B grandchildren of A	A/+/B
A//B	Selects all B descendents of A	A/#/B
//A	Selects all A elements at any level	#/A

*	Selects all first level elements	+

Interoperation with Version 5.1 clients

Existing WebSphere Application Server Version 5.1 client applications using Version 5.1 connection factory and destination definitions use the WBI Message Broker wildcard convention. Such applications can connect to the default messaging provider and service integration bus, and automatically have their wildcard syntax mapped to the XPath convention when subscriptions are created. Any display of these subscriptions through an administrative interface to the bus shows the XPath syntax.

Defining outbound chains for bootstrapping

You can define new outbound chains using the wsadmin utility. These chains can be used for bootstrapping connections to messaging engines.

About this task

To create outbound chains for bootstrapping, there are involves several main steps:

1. Locate the appropriate TransportChannelService configuration object. This object is the parent object of all the objects created.
2. Create the individual channels that comprise the transport channel service. Some of these channels might require references to other configuration objects.
3. Assemble the channels that you have created into an outbound channel chain.

The channels used to build an outbound bootstrap chain determine the protocol with which the outbound chain can be used to bootstrap. The following table shows all valid bootstrap chains with their bootstrap protocols.

Bootstrap protocol	TCP channel	SSL channel	HTTP channel	HTTP tunneling channel	JFAP channel
TCP	X				X
SSL	X	X			X
HTTP	X		X	X	X
HTTPS	X	X	X	X	X

For example, a chain for bootstrapping using the SSL protocol would consist of a TCP channel, SSL channel, and JFAP channel. When you create chains, the order of channels in the chain is important. You must specify channels in the order (left to right) in which they appear in the preceding table.

The example in this topic describes how to create a bootstrap chain that is capable of bootstrapping using the HTTPS protocol. This requires a chain containing all the channel types described. Thus, it is easy to see how to create chains for other protocols by omitting channels during the chain creation step.

Note: You open a wsadmin command session from within Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

1. Locate the TransportChannelService object for the server in which you wish to create the new chain. For example, in a WebSphere Application Server Network Deployment configuration, you can list the available TransportChannelService objects and select the appropriate service as follows.

   Using Jython:

```
wsadmin>AdminConfig.list("TransportChannelService" )
(cells/BadgerCell01/nodes/BadgerCellManager01/servers/dmgr|server.xml
#TransportChannelService_1)
(cells/BadgerCell01/nodes/BadgerNode01/servers/nodeagent|server.xml
#TransportChannelService_1095
711814579)
```

```
(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml
#TransportChannelService_109571
2023139)
(cells/BadgerCell01/nodes/BadgerNode01/servers/server2|server.xml
#TransportChannelService_109571
2039302)
wsadmin>tcs = AdminConfig.list("TransportChannelService" ).split("\r\n")[2]
```

Using Jacl:

```
wsadmin> $AdminConfig list TransportChannelService
(cells/BadgerCell01/nodes/BadgerCellManager01/servers/dmgr|server.xml
#TransportChannelService_1)
(cells/BadgerCell01/nodes/BadgerNode01/servers/nodeagent|server.xml
#TransportChannelService_1095
711814579)
(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml
#TransportChannelService_109571
2023139)
(cells/BadgerCell01/nodes/BadgerNode01/servers/server2|server.xml
#TransportChannelService_109571
2039302)
wsadmin> set tcs [lindex [$AdminConfig list TransportChannelService] 2]
(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
TransportChannelService_1095712023139)
```

2. Define an outbound TCP channel called testTCPChannel.

   Using Jython:

```
wsadmin>tcpChannel = AdminConfig.create("TCPOutboundChannel", tcs,
[["name", "testTCPChannel"]] )
```

   Using Jacl:

```
wsadmin>set tcpChannel [$AdminConfig create TCPOutboundChannel $tcs
"{name testTCPChannel}"]
testTCPChannel(cells/BadgerCell01/nodes/BadgerNode01/servers/
server1|server.xml#TCPOutboundChannel_1095969213949)
```

3. Define an outbound SSL channel called testSSLChannel. There are two steps required to define such a channel.

   a. Identify the SSL alias to be used by the channel.

      Using Jython:

```
wsadmin>for obj in AdminConfig.list("SSLConfig" ).split("\r\n"):
print obj+AdminConfig.show(obj, "alias")
(cells/BadgerCell01|security.xml#SSLConfig_1)
[alias BadgerCellManager01/DefaultSSLSettings]
(cells/BadgerCell01|security.xml#SSLConfig_1095711819776)
[alias BadgerNode01/DefaultSSLSettings]
```

      Using Jacl:

```
wsadmin>foreach obj [$AdminConfig list SSLConfig] { puts "$obj
[$AdminConfig show $obj alias]]" }
(cells/BadgerCell01|security.xml#SSLConfig_1) {alias BadgerCellManager01/
DefaultSSLSettings}]
(cells/BadgerCell01|security.xml#SSLConfig_1095711819776) {alias BadgerNode01/
DefaultSSLSettings}]
```

   b. Create an SSL channel as in the following example, in which the BadgerNode01/DefaultSSLSettings alias is used.

      Using Jython:

```
wsadmin>sslChannel =
AdminConfig.create("SSLOutboundChannel", tcs, [["name", "testSSLChannel"],
["sslConfigAlias", "BadgerNode01/DefaultSSLSettings"]] )
```

      Using Jacl:

```
wsadmin>set sslChannel [$AdminConfig create SSLOutboundChannel $tcs
"{name testSSLChannel}
{sslConfigAlias BadgerNode01/DefaultSSLSettings}"]
testSSLChannel(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
SSLOutboundChannel_1095971760671)
```

4. Define an outbound HTTP channel called testHTTPChannel.

   Using Jython:

```
wsadmin>httpChannel = AdminConfig.create("HTTPOutboundChannel", tcs,
[["name", "testHTTPChannel"]] )
```

Using Jacl:

```
wsadmin>set httpChannel [$AdminConfig create HTTPOutboundChannel $tcs
"{name testHTTPChannel}"]
testHTTPChannel(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
HTTPOutboundChannel_1095971896556)
```

5. Define an outbound HTTP tunneling channel called testHTCChannel.

   Using Jython:

```
wsadmin>htcChannel = AdminConfig.create("HTTPTunnelOutboundChannel", tcs,
[["name", "testHTCChannel"]] )
```

   Using Jacl:

```
wsadmin>set htcChannel [$AdminConfig create HTTPTunnelOutboundChannel $tcs
"{name testHTCChannel}"]
testHTCChannel(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
HTTPTunnelOutboundChannel_1095972164201)
```

6. Define an outbound JFAP channel called testJFAPChannel.

   Using Jython:

```
wsadmin>jfapChannel = AdminConfig.create("JFAPOutboundChannel", tcs,
[["name", "testJFAPChannel"]] )
```

   Using Jacl:

```
wsadmin>set jfapChannel [$AdminConfig create JFAPOutboundChannel $tcs
"{name testJFAPChannel}"]
testJFAPChannel(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
JFAPOutboundChannel_1095972226631)
```

7. Finally, create the channel chain by combining the channels defined so far. For example, to create a chain called testChain:

   Using Jython:

```
wsadmin>AdminConfig.create("Chain", tcs, [["name", "testChain"], ["enable", "true"],
["transportChannels", [tcpChannel, httpChannel, htcChannel, jfapChannel]]] )
testChain(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
Chain_1095972662147)
```

   Using Jacl:

```
wsadmin>$AdminConfig create Chain $tcs "{name testChain} {enable true}
{transportChannels {$tcpChannel $httpChannel $htcChannel $jfapChannel}}"
testChain(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
Chain_1095972662147)
```

Defining outbound chains for WebSphere MQ interoperation

You can define new outbound chains using the wsadmin utility. These chains can be used for interoperating with WebSphere MQ.

About this task

The channels used to build an outbound chain determine with which configurations of the WebSphere MQ queue manager sender channel a network connection can be successfully established. The following table shows all the valid chain configurations and describes the configuration of WebSphere MQ queue manager sender channel with which they can be used to establish a connection.

WebSphere MQ channel	TCP channel	SSL channel	MQFAP channel
Unsecured WebSphere MQ channel	X		X
WebSphere MQ channel secured using SSL	X	X	X

For example, an SSL-based chain would consist of a TCP channel, SSL channel and MQFAP channel. When creating chains, the order of channels in the chain is important. You must specify channels in the order (left to right) in which they appear in the above table.

The example in this topic describes how to create an outbound chain capable of being used to contact WebSphere MQ queue manager receiver channels using SSL-based encryption.

Note: You open a wsadmin command session from within Qshell. For more information, see the topic "Configure Qshell to run WebSphere Application Server scripts".

1. Locate the TransportChannelService object for the server in which you wish to create the new chain. For example, in a WebSphere Application Server Network Deployment configuration, you can list the available TransportChannelService objects and select the appropriate service.

   Using Jython:

```
wsadmin>AdminConfig.list("TransportChannelService" )
(cells/BadgerCell01/nodes/BadgerCellManager01/servers/dmgr|server.xml
#TransportChannelService_1)
(cells/BadgerCell01/nodes/BadgerNode01/servers/nodeagent|server.xml
#TransportChannelService_1095
711814579)
(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml
#TransportChannelService_109571
2023139)
(cells/BadgerCell01/nodes/BadgerNode01/servers/server2|server.xml
#TransportChannelService_109571
2039302)
wsadmin>tcs = AdminConfig.list("TransportChannelService" ).split("\r\n")[2]
```

   Using Jacl:

```
wsadmin> $AdminConfig list TransportChannelService
(cells/BadgerCell01/nodes/BadgerCellManager01/servers/dmgr|server.xml
#TransportChannelService_1)
(cells/BadgerCell01/nodes/BadgerNode01/servers/nodeagent|server.xml
#TransportChannelService_1095711
814579)
(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml
#TransportChannelService_109571202
3139)
(cells/BadgerCell01/nodes/BadgerNode01/servers/server2|server.xml
#TransportChannelService_109571203
9302)
wsadmin> set tcs [lindex [$AdminConfig list TransportChannelService] 2]
(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml
#TransportChannelService_109571202
3139)
```

2. Define an outbound TCP channel called testTCPChannel.

   Using Jython:

```
wsadmin>tcpChannel = AdminConfig.create("TCPOutboundChannel", tcs,
[["name", "testTCPChannel"]] )
```

   Using Jacl:

```
wsadmin>set tcpChannel [$AdminConfig create TCPOutboundChannel $tcs
"{name testTCPChannel}"]
testTCPChannel(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
TCPOutboundChannel_1095969213949)
```

3. Define an outbound SSL channel called testSSLChannel. There are two steps required to define such a channel.

   a. Identify the SSL alias to be used by the channel.

      Using Jython:

```
wsadmin>for obj in AdminConfig.list("SSLConfig" ).split("\r\n"):
print obj+AdminConfig.show(obj, "alias")
```

      Using Jacl:

```
wsadmin>foreach obj [$AdminConfig list SSLConfig] { puts "$obj
[$AdminConfig show $obj alias]]" }
(cells/BadgerCell01|security.xml#SSLConfig_1) {alias BadgerCellManager01/
DefaultSSLSettings}]
(cells/BadgerCell01|security.xml#SSLConfig_1095711819776) {alias BadgerNode01/
DefaultSSLSettings}]
```

   b. Create an SSL channel as in the following example, in which the BadgerNode01/ DefaultSSLSettings alias is used.

Using Jython:

```
wsadmin>sslChannel = AdminConfig.create("SSLOutboundChannel", tcs, [["name",
"testSSLChannel"], ["sslConfigAlias","BadgerNode01/DefaultSSLSettings"]])
```

Using Jacl:

```
wsadmin>set sslChannel [$AdminConfig create SSLOutboundChannel $tcs
"{name testSSLChannel}
{sslConfigAlias BadgerNode01/DefaultSSLSettings}"]
testSSLChannel(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
SSLOutboundChannel_1095971760671)
```

4. Define an outbound MQFAP channel called testMQFAPChannel.

   Using Jython:

```
wsadmin>mqfapChannel = AdminConfig.create("MQFAPOutboundChannel", tcs,
[["name", "testMQFAPChannel"]] )
```

   Using Jacl:

```
wsadmin>set mqfapChannel [$AdminConfig create MQFAPOutboundChannel $tcs
"{name testMQFAPChannel}"]
testMQFAPChannel(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
MQFAPOutboundChannel_1095977512682)
```

5. Finally, create the channel chain by combining the channels defined so far. For example, to create a chain called testChain:

   Using Jython:

```
wsadmin>AdminConfig.create("Chain", tcs, [["name", "testChain"], ["enable",
"true"], ["transportChannels", [tcpChannel, sslChannel, mqfapChannel]]] )
```

   Using Jacl:

```
wsadmin>$AdminConfig create Chain $tcs "{name testChain} {enable true}
{transportChannels {$tcpChannel $sslChannel $mqfapChannel}}"
testChain(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#Chain_109
5977640896)
```

Operating buses

Use these tasks to operate service integration buses.

About this task

The topics in this section describe how to display the runtime properties of messaging engines and their associated service integration bus links. The properties are influenced by the following operations:

- Starting and stopping messaging engines.
- Starting and stopping service integration bus links.

Displaying the runtime properties of a messaging engine

Display the runtime properties of a messaging engine using the administrative console.

Before you begin

To be able to retrieve the status of messaging engines, you must be logged into the administrative console with at least monitor authority. If you do not have this authority, the messaging engine status is displayed as ″Unavailable″, even if the messaging engine has started. Also, if you are not logged in with the authority needed to retrieve the status of messaging engines, a SECJ0305I error message is logged in the server's systemOut log file.

About this task

To display the runtime properties of a messaging engine, use the administrative console to complete the following steps.

1. In the navigation pane, click **Service integration** → **Buses**.
2. In the content pane, click the name of the bus to which your messaging engine belongs.

3. In the content pane, under **Topology**, click **Messaging engines**. A list of messaging engines is displayed.
4. Click the messaging engine name.
5. Click the **Runtime** tab. The status of the messaging engine, that is, whether it is currently started or stopped is displayed.

Displaying the runtime properties of a service integration bus link

Display the runtime properties of a service integration bus link using the administrative console.

About this task

To display the runtime properties of a service integration bus link, use the administrative console to complete the following steps:

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine that contains the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link whose properties you want to display.
5. Click the **Runtime** tab. The following properties are displayed:

   Status
   The runtime status of the service integration bus link.

   Activity
   Whether the service integration bus link is currently inactive, active, or its activity is unknown.

Managing messages on message points

Use these tasks to list and act on runtime messages that exist on message points in a service integration bus.

About this task

You can list the message points for bus destinations and messaging engines, and list the messages on a selected message point. You can use the list of messages as part of a troubleshooting task to find messages that need to be deleted.

- “Listing messages on a message point” on page 1250
- “Deleting messages on a message point” on page 1251

Managing service integration buses with administrative commands

You can use these commands to manage service integration buses.

About this task

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and Jython.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

1. Open a wsadmin command session in local mode For example:

   ```
   wsadmin -conntype none -lang jython
   ```

2. Type `AdminTask.`*`command`*, where *command* is the command format as indicated in the related reference topics.

   For example:

```
wsadmin>AdminTask.listSIBusMembers('[-bus bus1 ]')
[cells/cell01/buses/bus1|sib-bus.xml#SIBusMember_1092155259869]
[cells/cell01/buses/bus1|sib-bus.xml#SIBusMember_1092159844593]
[cells/cell01/buses/bus1|sib-bus.xml#SIBusMember_1092160253751]

wsadmin>AdminTask.listSIBEngines('[-bus bus1 ]')
'node01.server1-bus1(cells/cell01/nodes/node01/servers/server1|sib-engines.xml#
SIBMessagingEngine_1212163145962)\r\n
node02.server2-bus2(cells/cell01/nodes/node02/servers/server2|sib-engines.xml#
SIBMessagingEngine_1212163146273)'
```

Messaging engines

These topics provide information about messaging engines, which provide the processing function on a service integration bus.

- Learning about messaging engines
- “Configuring messaging engines” on page 1152
- Operating messaging engines
- “Managing messaging engines with administrative commands” on page 1204
- SIBAdminCommands: Messaging engine administrative commands for the AdminTask object
- Messaging engine troubleshooting tips

Configuring messaging engines

You can configure messaging engines in a variety of ways. For example, you can create and apply security to a messaging engine, then use this engine to send and receive messages. When you add a server cluster to a service integration bus, at least one messaging engine is created automatically. If you also use messaging engine policy assistance, some configuration properties are set automatically.

Configuring messaging engine properties

You can configure the properties of a messaging engine in the administrative console. For example you can select whether the messaging engine is started automatically when its associated application server is started, how many messages it can process, and target groups that the engine can join.

About this task

In most cases, you can configure the properties of a messaging engine without interrupting the processing of messages by the messaging engine.

1. Start the administrative console.
2. Navigate to **Service integration** → **Buses** → ***bus_name*** → **[Topology] Messaging engines** → ***engine_name***.
3. Configure the messaging engine properties. For information about the properties that you can configure, see the property descriptions in Messaging engines [Settings]
4. Click **OK**.
5. Save your changes to the master configuration.

Listing the messaging engines in a bus

You can view the list of existing messaging engines in a bus by using the administrative console. You can decide which messaging engines you want to change, for example which buses they are associated with.

About this task

To list the messaging engines in a bus, use the administrative console to complete the following steps.

1. In the navigation pane, click **Service integration** → **Buses**.
2. In the content pane, click the name of the bus that your messaging engine belongs to.

3. In the content pane, under **Topology**, click **Messaging engines**. The list of messaging engines in the bus is displayed.

Removing a messaging engine from a bus

You can remove a messaging engine from a service integration bus if you no longer require it to send and receive messages on the bus.

Before you begin

You should be wary of deleting and re-creating messaging engines on bus members for which WS-Notification-administered subscribers have been configured, because in some cases this can leave the remote Web service subscription active (and passing notification messages to the local server) even though there is no longer any record of it. For more information, see the WS-Notification troubleshooting tip Deleting administered subscribers and messaging engines.

1. Stop the messaging engine. You can stop either in **Immediate** or **Force** mode, as described in "Stopping a messaging engine" on page 1202.
2. Use the wsadmin command deleteSIBEngine to delete the messaging engine. All service integration bus links, MQ links, and custom properties that are owned by the engine are deleted.

   Note: When you remove a messaging engine, WebSphere Application Server does not delete the data store tables automatically. You must remove them manually, or delete all the rows in all the tables. If you do this, a new messaging engine might fail to start if it attempts to use an orphaned data store. Refer to the documentation for your chosen relational database management system for information about deleting tables.

   Alternatively, for Apache Derby, you can delete the database's directory, which is located in *profile_root*/databases/com.ibm.ws.sib, where *profile_root* is the directory in which profile-specific information is stored. However, do this only if the messaging engine is the sole user of the database.

   For more information, see Data store life cycle.

   Similarly, the file store files are not automatically deleted when you delete the messaging engine. You might want to delete the file store files to reclaim disk space.

Listing the messaging engines defined for a server bus member

You can display a list of messaging engines defined for a server bus member by using the administrative console. You can decide which messaging engines you want to change, for example, which buses they are associated with.

About this task

To display the list of messaging engines, use the administrative console to complete the following steps:

1. In the navigation pane, click either **Service integration** → **Buses** → ***bus_name*** → **[Topology] Messaging engines** or **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Server messaging] Messaging engines**. A list of messaging engines is displayed in the content pane.
2. Optional: Select one or more messaging engines to work with, for example to change the properties of the messaging engine.

Setting up the data store for a messaging engine

To set up a data store for a messaging engine, the database administrator must first create the database. You must then configure the data source and configure the messaging engine to use it.

Before you begin

Before you use this task, review the information in “Planning the configuration of a messaging engine to use a data store” on page 1209, and ensure that your database administrator has taken any appropriate action.

About this task

This task summarizes the steps that you must perform to set up the data store for a messaging engine. You need to work with your database administrator to complete step 1 of this task.

1. Ask your database administrator to perform the following steps:
   a. Create the database. Refer to “Creating the database” on page 1210
   b. Create users and schemas. Refer to “Creating users and schemas in the database” on page 1211
   c. Create the data store tables. Refer to “Creating the tables” on page 1212
   d. Ensure that the user has sufficient privilege to allow the messaging engine to operate. For more information about the privileges that required for the selected database, refer to “Database privileges” on page 1218.
2. When the database administrator has completed step 1, perform the following steps:
   a. Obtain a user ID from your database administrator.
   b. Configure a data source. Refer to “Configuring a JDBC data source for a messaging engine” on page 1213.
   c. Configure the messaging engine to use the data source. Refer to “Configuring a messaging engine data store to use a data source” on page 1154.

Configuring a messaging engine data store to use a data source:

After configuring a data source, you can configure a messaging engine data store to use the data source.

Before you begin

This topic assumes that you have chosen or created a bus and a messaging engine, and that the messaging engine specifies “data store” as its message store type.

You must also have configured a data source, as described in “Setting up the data store for a messaging engine” on page 1153.

About this task

A messaging engine uses an instance of a JDBC data source to interact with the database that contains the data store for that messaging engine.

Use the WebSphere Application Server administrative console to set the data store configuration parameters.

To configure the messaging engine to use a data source, use the administrative console to complete the following steps:

Service integration → **Buses** → ***bus_name*** → **[Topology] Messaging engines** → ***engine_name*** → **[Additional Properties] Message store**

1. In the navigation pane, click **Service integration** → **Buses** → ***bus_name*** → **[Topology] Messaging engines** → ***engine_name***.
2. Check that the **Message store type** is *Data store*.
3. Click **[Additional Properties] Message store**. The data store configuration detail panel is displayed.

4. Specify the following data store configuration details:

Data source JMDI name
Type the JNDI name of the data source that provides access to database that holds the data store.

Schema name
Type the name of the database schema that contains the tables used by the data store.

Note: The schema name is usually the same as the user ID that is declared in the authentication alias. With some databases, for example DB2, you can provide an alternative schema name. For more information about the relationship between users and schema, refer to the documentation for your chosen RDBMS.

Note: When you configure your messaging engine to use an Informix database, you must specify the schema name in lowercase letters.

When starting, a messaging engine that uses a data store checks to see if its data store exists. If the user has selected the **Create tables** option in the configuration, whose tick-box is ticked by default, the messaging engine creates the tables in its chosen schema.

The **Schema name** field is optional, and:

- The default schema name is *IBMWSSIB*.
- If you delete the text so that field is blank, the messaging engine takes the user id defined in the authentication alias to be the schema name.
- If you define a schema name explicitly, that schema name is used by the messaging engine.

Authentication alias
Select the authentication alias that enables access to the data source.

Note: When you create a new Network Attached Apache Derby data store, by default you get a blank authentication alias.

Create tables
Select the check box if you want WebSphere Application Server to create the database tables automatically. For more information, refer to “Creating the tables” on page 1212.

Note: The user ID that the data store uses to connect to the data source must have sufficient authority to create the database tables and indexes.

Note: The option for WebSphere Application Server to create the tables is not available with DB2 for z/OS. Refer to “Enabling your database administrator to create the data store tables” on page 1212 if you use DB2 for z/OS.

Number of permanent tables
Permanent table contains persistent objects for the data store.

Note: You can only increase the number of permanent tables or temporary tables, not decrease them.
See related links for more information.

Number of temporary tables
Temporary tables nonpersistent objects that have been saved to the data store to reduce the messaging engine memory requirement.

Note: You can only increase the number of permanent tables or temporary tables, not decrease them.
See related links for more information.

Configuring service integration bus links

You can configure service integration bus links on messaging engines in a variety of ways. For example, you can start, stop, or remove links.

About this task

When you create a foreign bus connection to connect two service integration buses, a service integration bus link is created automatically. The foreign bus connection contains a routing definition, which is a virtual link, and the service integration bus link is the corresponding physical link on the messaging engine.

Configuring the properties of a service integration bus link:

After establishing a service integration bus link you might want to configure the properties of a service integration bus link such as the name of the service integration bus link, or authentication alias used by foreign bus that the link connects to.

About this task

To configure the properties of a service integration bus link, use the administrative console to complete the following steps:

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine for which you want to configure the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to configure.
5. Specify the following properties for the service integration bus link:

   Name The name of the service integration bus link. In order to work, the name must be the same as the name of the corresponding service integration bus link configured on the target foreign bus.

   Description
   An optional description for the service integration bus link, for administrative purposes.

   UUID The universal unique identifier assigned by the system to the service integration bus link for administrative purposes.

   Foreign messaging engine
   The messaging engine on the foreign bus to which this link connects.

   Note: This foreign bus name must not be altered after it has been configured. If you alter it, any messaging engines that already hold state information about the link will not be able to use the link unless the foreign bus name is reset to its original value.

   Target inbound transport chain
   The type of transport chain used for communication with the foreign bus. The transport chain name must be the name of the transport chain as defined on the server on which the target messaging engine is hosted.

   Bootstrap endpoints
   The comma-separated list of endpoints used to connect to a bootstrap server. This property is set in the same way as the **Provider endpoint** property in the JMS connection factory settings. For more information, see steps 1 and 2 of “Configuring a connection to a non-default bootstrap server” on page 1598. Although this task primarily describes how to configure a JMS connection factory, it is also applicable to setting several bootstrap endpoint values if the remote messaging engine is in a cluster.

Note: Service integration bus links over BootstrapTunneledMessaging and BootstrapTunneledSecureMessaging transport chains only work directly between application server instances. Bus links over TunneledMessaging transport chains do not work if an HTTP server is placed in front of either application server instance.

Authentication alias
The name of the authentication alias, used to authenticate access to the foreign bus. The alias must be known to the foreign bus.

Initial state
Whether the link is started automatically when the messaging engine is started. Until started, the gateway link is unavailable. If this property is set to **Started** the service integration bus link is started when the messaging engine is started.

6. Click **OK**.
7. Save your changes to the master configuration.

Listing the service integration bus links:

You can list all the service integration bus links that are linked to a messaging engine.

About this task

To list the service integration bus links for a messaging engine, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Buses**.
2. In the content pane, click the name of the bus that your messaging engine belongs to.
3. In the content pane, under **Additional properties**, click **Messaging engines**. The list of messaging engines in the bus is displayed.
4. In the content pane, select the messaging engine for which you want to list the service integration bus links.
5. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.

Example

The following combinations of **Status** and **Activity** values are possible:

Status	Activity	Meaning
started	inactive	The service integration bus link is started on the local messaging engine but has no connection to the foreign bus. The service integration bus link is attempting to activate a connection to the foreign bus. The service integration bus link on the foreign bus must also be started to successfully activate of a connection between the buses.
started	active	The service integration bus link is started on the local messaging engine and has an active connection to the foreign bus.
stopped	inactive	The service integration bus link is stopped on the local messaging engine and there is no connection to the foreign bus.
unknown	inactive	An error might have occurred in setting up the link, such that the object that is used to report the current state is not available.

What to do next

You can now add or remove a service integration bus link or select a service integration bus link to start, stop, or configure.

Starting a service integration bus link:

When a service integration bus link has been started, it can be used for communicating with its associated messaging engines.

About this task

To start a service integration bus link, use the administrative console to complete the following steps:

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine for which you want to start the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you wish to start.
5. Click **Start**.

Stopping a service integration bus link:

When a service integration bus link has been stopped, it cannot be used for communication until it is restarted.

About this task

To stop a service integration bus link, use the administrative console to complete the following steps:

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine to which the service integration bus link that you wish to stop belongs.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you wish to stop.
5. Click **Stop**.

Removing a service integration bus link:

When a service integration bus link to a messaging engine has been removed, it cannot be used for communication until it is recreated.

Before you begin

Before you remove the service integration bus link you must stop the link.

When you remove a service integration bus link, all traffic using the link needs to be dealt with in a similar way to when you remove a destination. For further details, see “Deleting a non-topic space bus destination” on page 1246. Note that express Quality of Service (QoS) messages are discarded.

About this task

To remove a service integration bus link from a messaging engine, use the administrative console to complete the following steps:

1. Display the list of messaging engines.
2. In the content pane, select which the messaging engine has own association with the service integration bus link that you wish to remove.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you wish to remove.
5. Click **Delete**.
6. Save your changes to the master configuration.

What to do next

When you remove a service integration bus link, all traffic using the link must be diverted by alternative routes or held pending further administrative action. Express QoS messages are discarded.

Starting a messaging engine

You can either start a messaging engine directly by using the administrative console or by starting the server that hosts the messaging engine.

About this task

To start a messaging engine, use the administrative console to complete the following steps.

1. In the navigation pane, click **Service integration** → **Buses**.
2. In the content pane, click the name of the bus that your messaging engine belongs to.
3. Do one of the following to display a list of messaging engines:
   - For a list of messaging engines in the bus, in the content pane, under **Topology**, click **Messaging engines**.
   - For a list of messaging engines for a server, in the content pane, under **Topology**, click **Bus Members**. Click the name of the required server.
   - For a list of messaging engines for a cluster, in the content pane, under **Topology**, click **Bus Members**. Click the name of the required cluster.
4. Select the messaging engine that you wish to start.
5. Click **Start**.

Stopping a messaging engine

You can either stop a messaging engine directly or stop it by stopping the server that hosts the messaging engine.

About this task

A messaging engine can stop in two ways:

Immediate
The messaging engine is stopped on completion of all messaging operations that are being carried out at the time of the stop request.

Force The messaging engine is stopped without allowing messaging operations to complete and applications are forcefully disconnected.

To stop a messaging engine, use the administrative console to complete the following steps.

1. In the navigation pane, click **Service integration** → **Buses**.
2. In the content pane, click the name of the bus that the messaging engine belongs to.
3. Do one of the following to display a list of messaging engines:

- For a list of messaging engines in the bus, in the content pane, under **Topology**, click **Messaging engines**.
- For a list of messaging engines for a server, in the content pane, under **Topology**, click **Bus Members**. Click the name of the required server.
- For a list of messaging engines for a cluster, in the content pane, under **Topology**, click **Bus Members**. Click the name of the required cluster.

4. Select the messaging engine that you wish to stop.
5. Select **Immediate** or **Force** from the **Stop mode** drop-down list.
6. Click **Stop**.

What to do next

Note: If an immediate stop is taking too long, you can escalate it to a force stop by selecting the **Force** option. This overrides your previous selection of the **Immediate** option.

Displaying the runtime properties of a messaging engine

Display the runtime properties of a messaging engine using the administrative console.

Before you begin

To be able to retrieve the status of messaging engines, you must be logged into the administrative console with at least monitor authority. If you do not have this authority, the messaging engine status is displayed as ″Unavailable″, even if the messaging engine has started. Also, if you are not logged in with the authority needed to retrieve the status of messaging engines, a SECJ0305I error message is logged in the server's systemOut log file.

About this task

To display the runtime properties of a messaging engine, use the administrative console to complete the following steps.

1. In the navigation pane, click **Service integration** → **Buses**.
2. In the content pane, click the name of the bus to which your messaging engine belongs.
3. In the content pane, under **Topology**, click **Messaging engines**. A list of messaging engines is displayed.
4. Click the messaging engine name.
5. Click the **Runtime** tab. The status of the messaging engine, that is, whether it is currently started or stopped is displayed.

Displaying the runtime properties of a service integration bus link

Display the runtime properties of a service integration bus link using the administrative console.

About this task

To display the runtime properties of a service integration bus link, use the administrative console to complete the following steps:

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine that contains the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link whose properties you want to display.
5. Click the **Runtime** tab. The following properties are displayed:

Status
The runtime status of the service integration bus link.

Activity
Whether the service integration bus link is currently inactive, active, or its activity is unknown.

Managing messaging engines with administrative commands

You can use these commands to manage messaging engines.

About this task

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and Jython.

1. Open a wsadmin command session in local mode. For example:

```
wsadmin -conntype none -lang jython
```

   The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

2. Type `AdminTask.`*`command`*, where *command* is the command format as indicated in the related reference topics.

   For example:

```
wsadmin>AdminTask.listSIBusMembers('[-bus bus1 ]')
[cells/cell01/buses/bus1|sib-bus.xml#SIBusMember_1092155259869]
[cells/cell01/buses/bus1|sib-bus.xml#SIBusMember_1092159844593]
[cells/cell01/buses/bus1|sib-bus.xml#SIBusMember_1092160253751]

wsadmin>AdminTask.listSIBEngines('[-bus bus1 ]')
'node01.server1-bus1(cells/cell01/nodes/node01/servers/server1|sib-engines.xml#
SIBMessagingEngine_1212163145962)\r\n
node02.server2-bus2(cells/cell01/nodes/node02/servers/server2|sib-engines.xml#
SIBMessagingEngine_1212163146273)'
```

Message stores

Message stores play an essential part in the operation of messaging engines. Each messaging engine has one and only one message store. This can either be a file store or a data store.

About this task

A message store enables a messaging engine to preserve operating information and to retain those objects that messaging engines need for recovery in the event of a failure.

A messaging engine preserves both volatile and durable data in its message store. Volatile data is lost when a messaging engine stops, in either a controlled or an uncontrolled manner. Durable data is available after the server restarts. For more information, refer to Message reliability levels. A messaging engine stores various types of data, including messages, transaction states, and communication channel states.

When started, a messaging engine obtains configuration information from the WCCM (WebSphere Application Server Common Configuration Model) repository. A messaging engine retrieves all other data from its own file store or data store.

Note: There are currently no facilities available for migrating from a data store to a file store.

Considerations when choosing between a file store and a data store

Choosing to use a file store for your messaging engine can have several advantages over using a data store.

1. Better performance

To achieve best performance using a data store, you often need to use a separate remote database server. File store can exceed the performance of a data store using a remote database server without needing a separate server.

2. Low administration requirements

   The file store combines high throughput with little or no administration. This makes it suitable for those who do not want to worry about where the messaging engine is storing its recoverable data. File store improves on the throughput, scalability, and resilience of Apache Derby.

3. Lower deployment costs

   Use of data store might require database administration to configure and manage your messaging engines. File store can be used in environments without a database server.

As a managerial decision, some organizations prefer to use data store because it utilizes their existing resources more effectively. For example, this might be the case for a company with a strong team of database specialists, or a stable database infrastructure.

One technical advantage of using data store is that some Java EE applications can share JDBC connections to benefit from one-phase commit optimization. For more information refer to Sharing connections to benefit from one-phase commit optimization. File store does not support this optimization.

Data stored in both data store and file store benefit from security features provided by WebSphere Application Server when accessed using the WebSphere Application Server APIs, that is JMS messaging. Further security features can be taken advantage of depending on the type of message store you use. For more details see File stores and Data stores.

- Data store: access to your chosen database will be through a userid/password that will be administered using the supplied tools for your specified DBMS. Logical and physical separation of your database server can also be used to improve the overall security of your data.
- File store: additional security can be provided when using a file store by careful consideration of your file store files. For example making use of a secure network attached drive to store your file store files will improve the physical security of your data. Another example would be using an operating system encrypted file system to store your files on.

Both file store and data store offer high availability capabilities, for more details refer to “Message store high availability considerations.”

Message store high availability considerations

High availability refers to the capability of failing over messaging engines between servers. Both file stores and data stores can be deployed to be used in a highly available environment.

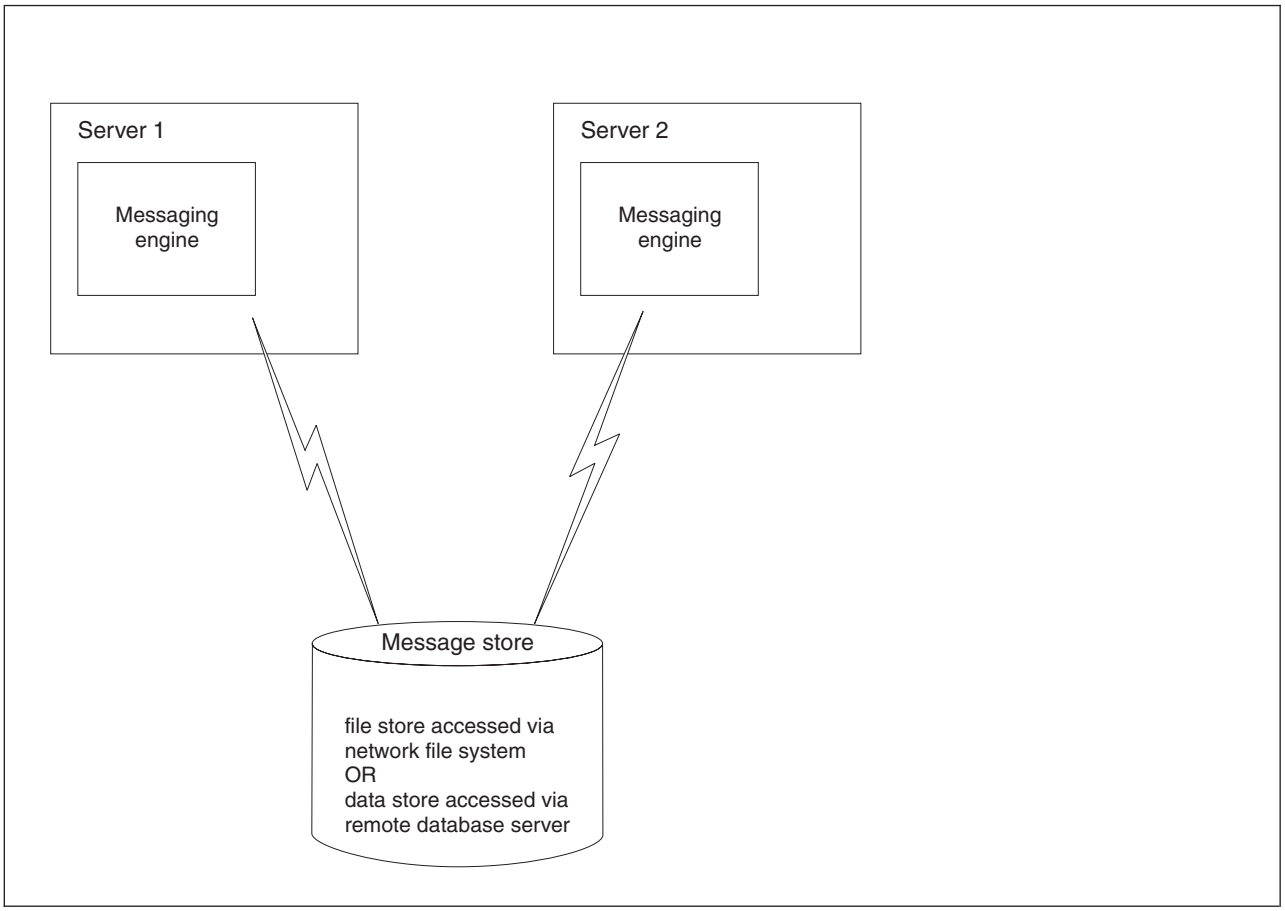

Figure 15. Failover of a messaging engine between servers.

For more information see related links.

Managing file stores

A file store is a message store which directly uses files in the file system via the operating system. Each messaging engine has one and only one file store.

Configuring a messaging engine to use a file store

When a messaging engine is created, it uses a file store by default. You can configure the file store attributes to suit system needs.

About this task

You set up a messaging engine to use a file store by accepting the default choice of message store when you are creating a bus and adding a new bus member. You can choose either to accept the default settings that the administrative console displays or to make changes to these settings. After the file store has been created, you can, if required, subsequently make changes to the current file store settings.

Modifying file store configuration:

After a file store has been created, you can, if required, modify file store attributes to suit your system needs.

About this task

When you add a new bus member that uses a file store, you can choose either to accept the default settings for the file store or make changes to these settings, depending on your requirements.

After the file store has been created, you can, if required, subsequently modify the log size, permanent store size or temporary store size settings directly through the administrative console. The new values take effect the next time that the messaging engine is started.

The directory paths for the file store are fixed when the file store is created, and cannot subsequently be modified. You can create a new file store in a new location. To do this you remove the server or cluster as a bus member and then add it again choosing a new location for the file store. Any messages remaining in the original file store would be lost during this process.

Note: The default configuration for a file store is intended to be sufficient when used in typical messaging workloads. To improve the performance or resilience of the log file, the permanent store file or the temporary store file, you can modify the file store attributes to control where these files are placed. For example, you can achieve better performance if you place these three file store files in a faster disk. Similarly, you can control the sizes of the log file, the permanent store file and the temporary store file to handle workloads with a large number of active transactions, large messages or a large volume of message data resident in the messaging engine.

- To make changes to the log size, permanent store size or temporary store size, complete the following steps:
  1. Open the Administrative console.
  2. Click **Service integration** → **Buses** → ***bus_name*** → **[Topology] Messaging engines** → ***engine_name*** → **[Additional Properties] Message store**.
  3. Make the changes that you require to the existing log size, permanent store size or temporary store settings, then click **OK**. For more information about configuring the properties, see File store [Settings]
  4. Save your changes to the master configuration.
- To choose a new location for a file store, complete the following steps:
  1. To avoid losing messages on destinations that are localized on the file store, first ensure that no messages are left on the queues.
  2. Remove the server or cluster as a member of the bus.
  3. Add the server and cluster as a bus member again, choosing a new location for the file store.

Deleting files following removal of a messaging engine:

Removing a messaging engine from the configuration does not automatically delete the file store's files. You need to also find and delete the log file, the permanent store file and the temporary store file from the disk in order to reclaim disk space.

About this task

Note: Files comprising a file store still remain when the messaging engine is deleted. If you are using the default values for the file store directory names, it is possible to delete and then recreate a messaging engine with the same name without manually removing the files. This is due to the presence of the messaging engine's Universal Unique IDentifier (UUID) in the default log and store directory names of a file store.

Example: If the deleted messaging engine is called *messagingengine0*, and the new one *messagingengine1* then the log files in the old and new file stores are

```
C:\{USER_INSTALL_ROOT}\filestores\..\messagingengine0\..\logfile
```

and

```
C:\{USER_INSTALL_ROOT}\filestores\..\messagingengine1\..\logfile
```

The two log files coexist in the same file stores directory. You do not have to delete the old files if you choose.

1. Locate the directory in which your old file store log files and store files are stored.
2. Delete the redundant files using the facilities of the operating systems.

Results

After deleting the files left by the redundant file store, free disk space becomes available to your file system.

Administering messaging engine file stores

A file store is a type of message store that directly uses files in a file system through the operating system. Therefore, administration of the file store depends on the type of operating system.

About this task

- “Backing up a file store”
- “Restoring a file store”

Backing up a file store:

Backing up the files in a file store should be done according to your operating system or by using a backup tool.

About this task

A file store is a type of message store that directly uses files in a file system through the operating system. Use the facilities of your operating system or a backup tool to take a backup copy of the log file, the permanent store file and the temporary store file, which comprise a file store. For more information about these files, see File store configuration attributes.

Note: You must not start backing up files while the messaging engine is still running or data might be corrupted.

Note: You must treat the log file, the temporary store file and the permanent store file as one unit, that is, any operations must be performed on all three files.

Restoring a file store:

Restoring the files in a file store should be done according to your operating system or by using a backup tool to restore the backup copies of your files.

Before you begin

Before you start this task, make sure that the messaging engine is not running.

Note: You must not restore a file store while the messaging engine is still running or data might be corrupted.

About this task

When performing this task, you must treat the log file, the temporary store file and the permanent store file which comprise a file store as one unit, that is, any operations must be performed on all three files. For more information about these files, see File store configuration attributes.

Use the facilities of your operating system or a backup tool to restore the backup copy of the log file, the permanent store file and the temporary store file.

Managing data stores

A data store is a message store that uses a relational database. A data store consists of a set of tables that are in the same database schema. It is used by a messaging engine to store operating information in the database, as well as to preserve essential objects that the messaging engine needs for recovery in the event of a failure.

About this task

A data store consists of the set of tables that a messaging engine uses to store persistent data in a database. Refer to “Data store tables” on page 1217 for a list of the tables that comprise a data store. All the tables in a data store are held in the same database schema. You can create multiple data stores in the same database only by using a different schema for each data store.

Configuring a messaging engine to use a data store

Although the default message store for a typical messaging engine is file store you can also configure a messaging engine to use a data store.

About this task

Each messaging engine has its own file store or data store. If the data store is chosen the messaging engine uses an instance of a JDBC data source to interact with the database that contains the data store for that messaging engine.

When a new messaging engine that uses a data store is created on a single server, it is configured to use an Apache Derby data source by default. This enables the messaging engine to run without needing any additional configuration.

If you want to configure a new messaging engine to use your chosen data source when you create that messaging engine on a single server, refer to “Adding a server as a new bus member” on page 1145.

If you do not want to use the default data source configuration, you can use the WebSphere Application Server administrative console to change the configuration parameters. For example, you can change the data source or you can configure the data store to use a different JDBC provider.

Planning the configuration of a messaging engine to use a data store:

There are a number of choices that you need to consider before you configure a messaging engine to use a data store.

1. Choose the relational database management system (RDBMS) for the data store. You might want to choose the RDBMS that you use for other applications, particularly if you are already familiar with the tools you use for managing that RDBMS. You might also want to consider the following criteria:
   - Performance
   - Scalability
   - Availability, especially if you are running messaging engines in a high availability environment

   When a new messaging engine that uses a data store is created on a single server, it is configured to use an Apache Derby data source by default. This enables the messaging engine to run without needing any additional configuration. The default embedded Derby data source is sufficient for many purposes. Other relational database management systems offer more comprehensive tooling and improved performance, particularly scalability on larger machines with more than two processors.

2. Choose your database topology. In some cases, running the data store on a remote node can improve performance. In other cases, a local database provides performance equivalent to a remote database. You might want to conduct your own performance analysis, because the performance characteristics can be very sensitive to the hardware specification.
3. Consider whether you want WebSphere Application Server to create the data store tables automatically or whether you want your database administrator to create the tables beforehand. For more information, refer to “Creating the tables” on page 1212.
4. Message data is stored in a database table column of datatype BLOB. Before you create a datastore, you must consider the size of your expected workload to ensure that your database administrator creates a sufficiently large enough BLOB space to hold your message data.

Selecting the data store topology:

You have several options to consider when selecting the relative location of a data store and its messaging engine.

- Decide whether the data store will run on the same node as its messaging engine or on a remote node.
- Decide whether the data store will have a dedicated database or share a database with other data stores.

Setting up the data store for a messaging engine:

To set up a data store for a messaging engine, the database administrator must first create the database. You must then configure the data source and configure the messaging engine to use it.

Before you begin

Before you use this task, review the information in “Planning the configuration of a messaging engine to use a data store” on page 1209, and ensure that your database administrator has taken any appropriate action.

About this task

This task summarizes the steps that you must perform to set up the data store for a messaging engine. You need to work with your database administrator to complete step 1 of this task.

1. Ask your database administrator to perform the following steps:
   a. Create the database. Refer to “Creating the database”
   b. Create users and schemas. Refer to “Creating users and schemas in the database” on page 1211
   c. Create the data store tables. Refer to “Creating the tables” on page 1212
   d. Ensure that the user has sufficient privilege to allow the messaging engine to operate. For more information about the privileges that required for the selected database, refer to “Database privileges” on page 1218.
2. When the database administrator has completed step 1, perform the following steps:
   a. Obtain a user ID from your database administrator.
   b. Configure a data source. Refer to “Configuring a JDBC data source for a messaging engine” on page 1213.
   c. Configure the messaging engine to use the data source. Refer to “Configuring a messaging engine data store to use a data source” on page 1154.

Creating the database:

When creating the database for your messaging engine using a data store you must do it according to your Relational Database Management System (RDBMS).

Before you begin

Choose which Relational Database Management System (RDBMS) you want to use for the data store. Unless you are using the embedded Apache Derby provider, create the database before you create a messaging engine. Make a note of the database parameters that you need for configuring the data source. Refer to “Configuring a JDBC data source for a messaging engine” on page 1213 for more information.

Refer to the documentation for your chosen RDBMS for information about how to create a database. The default database for a data store is an embedded Apache Derby database. If you have chosen to configure the bus member to use a data store with default settings, it can only be a server. Unless the data store database exists already, the messaging engine creates the database automatically when the messaging engine makes its initial connection.

Note:

- Ensure that you create the database server with a page size of at least 4k.
- Ensure that you set the **lock scheme** property on your server to the value *datarows*. This avoids the possibility of a deadlock on the data store tables.
- Ensure that you set the **enable housekeeper GC** property on your server to the value *5*. This improves the ability of the server to reclaim redundant space within your database when it is under heavy load.
- Ensure that you select the **allow nulls by default** option for your database instance. This is required for the correct operation of the messaging engine.

Note: The one-to-one relationship between a messaging engine and a data store means that every messaging engine must have its own database tables. If you are using the Informix RDBMS, configure a separate database instance for each messaging engine. Problems have been observed in this environment when the data stores for multiple messaging engines were configured to use separate schemas in the same database.

Creating users and schemas in the database:

After you have created a database, you need to create the schema in which all tables in the data store are held.

Before you begin

Before you begin this task, create the database for your messaging engine.

About this task

All the tables in the data store must be stored in the same schema. If the schema names are different, a database can hold more than one data store. Although every messaging engine uses the same table names, its relationship with the schema gives each messaging engine exclusive use of its own tables.

To connect to WebSphere Application Server, the database administrator must create at least one user. The number of user IDs you need depends on the database you use:

- If you are using Derby, DB2 or Oracle, then the messaging engine can be configured to create any additional schemas that may be required for other data stores. That is, if you only create one user, it can have one to many relationships with the schemas in the database. Refer to “Configuring a messaging engine data store to use a data source” on page 1154 for details.
- For all other types of databases, the schema must be created prior to starting the messaging engines that depend on them.

If the user ID can be configured to use multiple schemas, then only that user ID is needed for all messaging engines. Otherwise the user is restricted to using tables in its own schema. In this case there can only be one user ID per schema.

1. Refer to the documentation for your chosen relational database management system (RDBMS) for more information about how to create users and schema. With DB2 databases, you create users and schema in separate steps. With the other databases, there is a one-to-one relationship between a schema and a user.
2. Refer to “Database privileges” on page 1218 for information about the authorities that you require to access the data store.

Creating the tables:

When creating the data store tables, you have two options. You can either choose that the database administrator does it manually, or that WebSphere Application Server does it automatically.

Before you begin

Decide whether you want your database administrator to create the tables, or WebSphere Application Server to create the tables automatically.

- If you want your database administrator to create the database tables, refer to “Enabling your database administrator to create the data store tables.”
- If you want WebSphere Application Server to create the tables, refer to “Enabling WebSphere Application Server to create the data store tables”

Enabling WebSphere Application Server to create the data store tables:

WebSphere Application Server can create the tables for the messaging engine data store automatically.

Before you begin

Before you use this task, decide whether you want WebSphere Application Server to create the tables.

Note: The option for WebSphere Application Server to create the tables is not available with DB2 for z/OS. Refer to “Enabling your database administrator to create the data store tables” if you use DB2 for z/OS.

1. Ensure that WebSphere Application Server has sufficient authority to create tables and indexes. For more information about the privileges that you require for your chosen database, refer to “Database privileges” on page 1218.
2. When you configure your messaging engine data store, ensure that **Create tables** is selected. For more information, refer to “Configuring a messaging engine data store to use a data source” on page 1154.

   Note: Do not select **Create tables**, otherwise an exception will be thrown when WebSphere Application Server attempts to create the tables.

Enabling your database administrator to create the data store tables:

Before you begin

Before you use this task, review the information in “Planning the configuration of a messaging engine to use a data store” on page 1209, and ensure that your database administrator has taken any appropriate action.

About this task

Use the sibDDLGenerator command to generate the DDL statements that the database administrator will need to create the tables for the messaging engine data store:

1. At a command prompt, issue the sibDDLGenerator command and redirect the output to a file. Refer to sibDDLGenerator command for a description of the sibDDLGenerator command.

   Note: If you want to process the DDL statements with a command line processor that requires the statements to conform to a specific format, use the optional parameters that control the format of the DDL statements. For example, if each statement must be terminated with a semicolon, use **-statementend** *;*

   To access the i5/OS command line, or run an i5/OS command line program, use the STRQSH command to launch a Qshell session. For more information, see Configuring Qshell to run WebSphere Application Server scripts .
2. Send the output file to your database administrator to process the DDL statements that are generated. The DDL statements can be ported across operating systems, for example you can generate the DDL statements on a machine running the Windows operating system and then run them on a machine running the z/OS operating system.

   Note:

   - Your database administrator can modify the DDL statements, but *must not* modify the table names or the column names in any way. Doing so might cause the messaging engine to fail to start.
   - If the DDL statements are to be run on the z/OS operating system, your database administrator must change the VCAT name in the first line of the DDL statements (the create storage group statement) to a valid high level qualifier for their system.

Configuring a JDBC data source for a messaging engine:

Learn about how to use the WebSphere Application Server administrative console to configure a data source for a messaging engine.

Before you begin

Note:

When configuring a service integration bus member to use a data store, be aware that using a type 2 JDBC driver for the data store is not supported for configurations where WebSphere MQ server definitions are also used. If your configuration includes WebSphere MQ server definitions and you are using a data store you must use type 4 JDBC drivers.

Note: When you create a new Network Attached Apache Derby data store, by default you get a blank authentication alias.

Note: Use the Oracle 10g thin driver for the service integration data store. This driver is compatible with earlier versions of Oracle.

About this task

Each messaging engine has its own file store or data store. If the data store is chosen the messaging engine uses an instance of a JDBC data source to interact with the database that contains the data store for that messaging engine.

Use the WebSphere Application Server administrative console to set the data source configuration parameters. Note that your choice of relational database management system (RDBMS) determines the parameters you set.

Perform the following steps to configure the data source:

1. Create a JDBC provider. Refer to Creating and configuring a JDBC provider using the administrative console. Under **General Properties**, in the **Select the implementation type** field, ensure that you select *Connection pool data source*.

   For information about the settings for your chosen RDBMS, refer to Vendor-specific data sources minimum required settings.
2. Create a data source for the JDBC provider. Refer to Creating and configuring a data source by using the administrative console.
   a. Under **Additional Properties**, ensure that you select *Data sources*.
   b. Configure the connection pool for the JDBC data source. Set the **Maximum connections** to the number of connections you require, for example, at least 50. The default number of connections is 10. For more information, refer to Tuning the JDBC data source of a messaging engine.
3. Test the connection. Refer to Test connection.

Configuring a messaging engine data store to use a data source:

After configuring a data source, you can configure a messaging engine data store to use the data source.

Before you begin

This topic assumes that you have chosen or created a bus and a messaging engine, and that the messaging engine specifies “data store” as its message store type.

You must also have configured a data source, as described in “Setting up the data store for a messaging engine” on page 1153.

About this task

A messaging engine uses an instance of a JDBC data source to interact with the database that contains the data store for that messaging engine.

Use the WebSphere Application Server administrative console to set the data store configuration parameters.

To configure the messaging engine to use a data source, use the administrative console to complete the following steps:

Service integration → Buses → *bus_name* → [Topology] Messaging engines → *engine_name* → [Additional Properties] Message store

1. In the navigation pane, click **Service integration → Buses → *bus_name* → [Topology] Messaging engines → *engine_name***.
2. Check that the **Message store type** is *Data store*.
3. Click **[Additional Properties] Message store**. The data store configuration detail panel is displayed.
4. Specify the following data store configuration details:

   Data source JMDI name
   Type the JNDI name of the data source that provides access to database that holds the data store.

   Schema name
   Type the name of the database schema that contains the tables used by the data store.

Note: The schema name is usually the same as the user ID that is declared in the authentication alias. With some databases, for example DB2, you can provide an alternative schema name. For more information about the relationship between users and schema, refer to the documentation for your chosen RDBMS.

Note: When you configure your messaging engine to use an Informix database, you must specify the schema name in lowercase letters.

When starting, a messaging engine that uses a data store checks to see if its data store exists. If the user has selected the **Create tables** option in the configuration, whose tick-box is ticked by default, the messaging engine creates the tables in its chosen schema.

The **Schema name** field is optional, and:

- The default schema name is *IBMWSSIB*.
- If you delete the text so that field is blank, the messaging engine takes the user id defined in the authentication alias to be the schema name.
- If you define a schema name explicitly, that schema name is used by the messaging engine.

Authentication alias
Select the authentication alias that enables access to the data source.

Note: When you create a new Network Attached Apache Derby data store, by default you get a blank authentication alias.

Create tables
Select the check box if you want WebSphere Application Server to create the database tables automatically. For more information, refer to “Creating the tables” on page 1212.

Note: The user ID that the data store uses to connect to the data source must have sufficient authority to create the database tables and indexes.

Note: The option for WebSphere Application Server to create the tables is not available with DB2 for z/OS. Refer to “Enabling your database administrator to create the data store tables” on page 1212 if you use DB2 for z/OS.

Number of permanent tables
Permanent table contains persistent objects for the data store.

Note: You can only increase the number of permanent tables or temporary tables, not decrease them.
See related links for more information.

Number of temporary tables
Temporary tables nonpersistent objects that have been saved to the data store to reduce the messaging engine memory requirement.

Note: You can only increase the number of permanent tables or temporary tables, not decrease them.
See related links for more information.

Administering messaging engine data store
Administering the data store for a messaging engine involves restoration and back up of the data store.

About this task

For more information about administering messaging engine data store, see the following topics:
- “Backing up a data store” on page 1216
- “Restoring a data store” on page 1216

Backing up a data store:

Learn to back up a data store

About this task

A data store consists of the set of tables that a messaging engine uses to store persistent data in a database. Refer to “Data store tables” on page 1217 for a list of the tables that comprise a data store. All the tables in a data store are held in the same database schema. You can create multiple data stores in the same database only by using a different schema for each data store.

To back up this data, refer to the documentation for your chosen database.

Backup can make use of the suspended I/O feature of DB2 if that RDBMS is used as the persistent store. With other databases that do not possess this capability, the backup could present a longer interruption to service, or require that the messaging engine is stopped while the backup is made. If you attempt to back up the data store for a messaging engine that is still running, you might lose or corrupt important data.

Include the tables that the topic “Data store tables” on page 1217 describes.

Restoring a data store:

Learn to restore a data store

About this task

A data store consists of the set of tables that a messaging engine uses to store persistent data in a database. Refer to “Data store tables” on page 1217 for a list of the tables that comprise a data store. All the tables in a data store are held in the same database schema. You can create multiple data stores in the same database only by using a different schema for each data store.

To restore this data, refer to the documentation for your chosen database.

Note: You must stop the messaging engine before restoring the data store. If you attempt to restore the data store for a messaging engine that is still running, you might lose or corrupt important data.

Include the tables that the topic “Data store tables” on page 1217 describes.

Increasing the number of item tables for a messaging engine when tables are not automatically created

If a concurrency bottleneck had occurred on the item tables, increasing the number of them will in turn increase the throughput of the messaging engine.

Before you begin

Before performing this task you must ensure that the messaging engine is using a data store, and its *Create tables automatically* option is set to *False*. The purpose of this task is to relieve concurrency bottleneck, which is documented in Increasing the number of data store tables to relieve concurrency bottleneck. For more information on the creation of tables consult “Creating the tables” on page 1212.

1. Relevant performance monitoring tools show that the throughput of a messaging engine is inefficient.
2. Use your database performance monitoring tools to examine lock statistics for the item tables for evidence of a bottleneck. Consult database documentation on how to interpret the locking statistics.
3. Create tables and increase data store attributes.
   - Create tables for the data store’s schema. For more information see “Creating the tables” on page 1212

- Increase the data store's number of permanent tables or temporary tables, or both. For more information see "Configuring a messaging engine data store to use a data source" on page 1154

You can only increase the number of permanent tables or temporary tables, not decrease them.

4. Stop and restart the WebSphere Application Server so that configuration changes take effect. The extra tables are used when the messaging engine restarts.
5. Observe the effect on throughput and lock statistics by checking performance monitoring tools. Consider whether any improvement is sufficient and modifying the data store attributes further would be beneficial

Increasing the number of item tables for a messaging engine when tables are automatically created

If a concurrency bottleneck had occurred on the item tables, increasing the number of them will in turn increase the throughput of the messaging engine.

Before you begin

This task only applies if the messaging engine is using a data store, and its *Create tables automatically* option is set to *True*. The purpose of this task is to relieve concurrency bottleneck, which is documented in Increasing the number of data store tables to relieve concurrency bottleneck. For more information on the creation of tables consult "Creating the tables" on page 1212.

1. Relevant performance monitoring tools show that the throughput of a messaging engine is insufficient.
2. Use your database performance monitoring tools to examine lock statistics for the item tables for evidence of a bottleneck. Consult your database documentation on how to interpret the locking statistics.
3. Increase the attributes for the messaging engine's data store: the number of permanent tables or temporary tables, or both. For more information see "Configuring a messaging engine data store to use a data source" on page 1154. You can only increase the number of permanent tables or temporary tables, not decrease them.
4. Stop and restart the messaging engine so that configuration changes take effect. The extra tables are created when the messaging engine starts again.
5. Observe the effect on throughput and lock statistics by checking performance monitoring tools. Consider whether any improvement is sufficient and modifying the data store attributes further would be beneficial

Data store tables

A data store consists of the set of tables that a messaging engine uses to store data persisted in a database. These data are important when backing up or restoring a data store. Users can spread the data store across multiple tables.

Table name	Purpose
SIBOWNER	Ensures exclusive access to the data store by an active messaging engine
SIBOWNERO	Used for locking the data store This table stores no data in its one EMPTY_COLUMN column
SIBCLASSMAP	Catalogs the different object types in the data store
SIBLISTING	Catalogs the SIBnnn tables
SIBXACTS	Maintains the status of active two-phase commit transactions
SIBKEYS	Assigns unique identifiers to objects in the messaging engine
SIBnnn, where nnn is a number	Contains persisted objects such as messages and subscription information These tables hold both persistent and nonpersistent objects, using separate tables for the different types of data.

Note: The SIBOWNERO table is new for WebSphere Application Server Version 7.0 and must be created when you are migrating from an earlier version of WebSphere Application Server. See Migrating a messaging engine based on a data store for things to consider when you are migrating a messaging engine based on a data store.

Database privileges

In order for a messaging engine to use its data store, the database user ID that the messaging engine uses must have sufficient privilege to access the data store tables.

The following table describes the database privileges that the messaging engine user requires to access the data store.

Database management system	Minimum privilege required for the messaging engine to use the data store tables	Additional privilege required for the messaging engine to create the data store tables
DB2	The messaging engine user ID needs **SELECT**, **INSERT**, **UPDATE**, and **DELETE** privileges on the tables	The messaging engine user ID needs **CREATETAB** authority on the database and **USE** privilege on the table space as well as **CREATEIN** privilege on the schema.
Oracle	The messaging engine user ID needs at least **SESSION** privilege to connect to the database. If the same user ID owns both the data store schema and the messaging engine that is connecting to the database, the messaging engine has sufficient privilege to manipulate the tables. Otherwise, the messaging engine needs **SELECT**, **INSERT**, **UPDATE** and **DELETE** object privileges on the tables that comprise the data store, and **DROP ANY TABLE** system privilege to enable use of the TRUNCATE TABLE statement.	The messaging engine user ID requires sufficient privilege to create relational tables and indexes in the data store schema. The messaging engine also requires a space quota in the default tablespace of the owner of that schema.
SQL Server	Configure the SQL Server for **SQL Server and Windows** authentication. This allows authentication to be based on an SQL server login ID and password. The messaging engine user ID can be the owner of the tables, or be a member of a group that has sufficient authority to issue TRUNCATE TABLE statements.	The messaging engine user ID needs **CREATE TABLE** statement privilege.
Sybase	The messaging engine user ID can be the owner of the tables, or be a member of a group that has sufficient authority to issue TRUNCATE TABLE statements.	The messaging engine user ID needs **CREATE TABLE** permission.
Informix	The messaging engine user ID must have **CONNECT** privilege on the database. It must also have **SELECT**, **INSERT**, **UPDATE** and **DELETE** authority on the tables.	The messaging engine user ID must have **RESOURCE** privilege on the database.
Derby	If user authentication is enabled, you must authorize the messaging engine user ID to access the database. **Note:** The default database that is generated by the messaging engine has no security mechanisms enabled.	You need no additional privileges.

Avoiding message store errors when creating a messaging engine

Using different combinations of parameters can create a file store or a data store according your requirements. The outcome varies in server and cluster scopes.

Server scope

When you add a server as a new bus member take note of the following:

- If you do not specify the type of message store, then a file store is created by default. If you set **Create default data source** to *True* or supply a **Data source JNDI name**, then a data store is created.
- If you choose to use a **file store**, then only file store attributes are presented to be specified. For example the **log file directory**.
- If you choose to use a **data store**:
  - Only data store attributes are presented to be specified. For example the **Data source JNDI name**.
  - If you set **Create default data source** to *False* then you must specify a **Data source JNDI name**.

For more information about file store and data store refer to “Message stores” on page 1204.

Cluster scope

When you add a cluster as a new bus member take note of the following:

- If you choose to use a **file store**:
  - You must not use the default log file, permanent store file and temporary store file directories because they are not suitable for cluster engines.
  - You must specify the **Log directory**, **Permanent store directory** and **Temporary store directory** to be at locations that all members of the cluster can access on your file system.
- If you choose to use a **data store**:
  - You must not use the default data source because it is not suitable for cluster engines.
  - You must specify the **Data source JNDI name** of an existing data source.

For more information about file store and data store refer to “Message stores” on page 1204.

Avoiding errors when creating a messaging engine with a file store or a data store by using the wsadmin tool

Using different combinations of parameters can create a file store or a data store according your requirements. The outcome varies in server and cluster scopes.

Server scope

When you add a server as a new bus member using administrative commands (by specifying `createSIBEngine -server`) take note of the following:

- If you do not specify the type of message store, then a file store is created by default. If you specify `-createDefaultDatasource` or `-dataSourceJndiName`, then a data store is created.
- If you choose to use a **file store** (by specifying `-filestore`), then only file store attributes can be specified.
- If you choose to use a **data store** (by specifying `-datastore`):
  - Only data store attributes can be specified.
  - If you set `-createDefaultDatasource` to `False` then you must specify `-dataSourceJndiName`.

Cluster scope

When you add a cluster as a new bus member using administrative commands (by specifying `createSIBEngine -cluster`) take note of the following:

- If you choose to use a **file store** (by specifying `-filestore`):
  - You must not use the default log file, permanent store file and temporary store file directories because they are not suitable for cluster engines.
  - You must specify `-logDirectory`, `-permanentStoreDirectory` and `-temporaryStoreDirectory` to be at locations that all members of the cluster can access on your file system.
- If you choose to use a **data store** (by specifying `-datastore`):
  - You must not specify `-createDefaultDatasource` because the default data source is not suitable for cluster engines.
  - You must specify `-dataSourceJndiName`, giving the name of an existing data source.

Bus destinations

This topic is the entry-point into a set of topics about bus destinations within a service integration bus, to which applications can attach as producers, consumers, or both to exchange messages.

- Learning about bus destinations
- “Configuring bus destinations” on page 1159
- “Configuring message points” on page 1248
- “Managing messages on message points” on page 1194
- “Administering durable subscriptions” on page 1251

Configuring bus destinations

Use the following tasks to configure permanent bus destinations on service integration buses.

About this task

The steps involved in configuring a bus destination depend on the intended usage of the destination.

For example, the following figure shows a basic scenario based on an application using a JMS queue for point-to-point messaging.

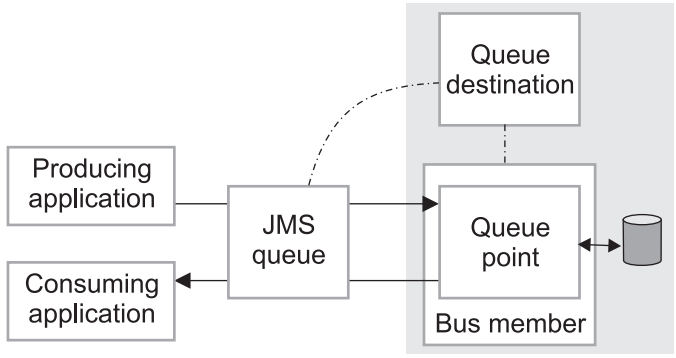

Figure 16. Application use of destinations - basic case

To enable the JMS applications to use a queue destination, you configure the following administrative destination objects:

1. A queue destination on a service integration bus. This configures the properties of the queue, such as the name, and associates the queue with one bus member (an application server). This also automatically configures, on the bus member, a queue point where messages for the queue are held and processed.

2. A JMS queue, which configures the name that applications can use to look up the queue in JNDI. The JMS queue encapsulates the name of the queue destination, as defined in the queue destination above, together with other properties to be used by applications.

After you have created a queue destination, you can optionally configure the queue point to override some properties configured on the queue destination. You can also perform other configuration tasks on the destination and its queue point, and can act on the runtime view.

Each messaging engine has a default exception destination, named `_SYSTEM.Exception.Destinaton.`*`me_name`*. This exception destination can be used to handle messages that cannot be delivered for all bus destination that are localized to the messaging engine. Each bus destination can be configured with a non-default exception destination.

For more information about configuring bus destinations, see the following topics:
- Listing bus destinations
- Creating a bus destination
- Configuring qualities of service for a destination
- Deleting a non-topicspace bus destination
- Deleting a topicspace

Listing bus destinations

Use this task to display administrative lists of bus destinations for a service integration bus.

About this task

From the panel that lists bus destinations you can use the buttons provided to create, delete, or change the mediation of destinations, or can select a destination to browse details and options for that destination.

To list bus destinations on a bus, use the administrative console to complete the following steps.

Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations**. This displays a list of the bus destinations on the bus.
Any temporary destination in the list is identified by the prefix `_Q` for temporary queues or `_T` for temporary topics.

What to do next

To browse or change the properties of a destination, click its name in the list displayed.

To act on one or more of the destination listed, select the check boxes next to the names of the destinations that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

Creating a bus destination

Use the following tasks to create a new bus destination on a service integration bus.

About this task

The steps involved in defining a new destination depend on the intended usage of the destination.

These are permanent destinations, with their properties defined by administrative resources, and are in addition to any temporary destinations created at runtime by the bus for applications.
- Defining a bus destination for JMS queues.
- Defining a bus destination for JMS topics.

- Defining an alias bus destination.
- Defining a new exception bus destination

Creating a queue for point-to-point messaging:

Use this task to create a new queue, which is a bus destination configured for point-to-point messaging.

Before you begin

During this task you must specify the name of a bus member to which the bus destination is assigned. That bus member is to host the queue point for the new bus destination, and must already have been configured.

About this task

To define a new queue for point-to-point messaging use the administrative console to complete the following steps. To define a queue, you need to specify only a minimum set of properties; you can change these and other properties after you have completed this task.

1. In the navigation pane, click **Service integration** → **Buses**.
2. In the content pane, click the name of the bus that is to provide the message point for the queue.
3. In the content pane, under Destination resources, click **Destinations**. This displays a list of any existing destinations in the content pane.
4. To create a new destination, click **New** in the content pane.
   a. On the Create New Destination page, leave the type of destination as Queue.
   b. Click **Next**.
   c. In the **Identifier** field, type the name that you want to give the queue destination for administrative purposes. Restrict the name to 48 characters or less, and restrict its character set to: numerics (0–9), period (.), forward slash (/), underscore (_), percent sign (%), uppercase A–Z, lowercase a–z (but there are restrictions on the use of lowercase letters for z/OS console support). On systems using EBCDIC Katakana you cannot use lowercase characters.
5. Optional: Specify the following properties for the destination:

   Description
   An optional description of the destination, for administrative purposes.

   Maximum reliability
   The maximum reliability of messages accepted by this destination.

   Best effort nonpersistent
   Messages are discarded when a messaging engine stops or fails. Messages may also be discarded if a connection used to send them becomes unavailable and as a result of constrained system resources.

   For non-transactional JMS message-driven beans and MessageListeners that use a JMS destination configured on the default messaging provider, best-effort nonpersistent messages are not recoverable. In this case, if a message is unlocked because the message-driven bean or MessageListener threw an exception, then the message is not redelivered or sent to the exception destination because it was deleted from the message store when it was passed to the listener. If you require higher message reliability for non-transactional JMS message-driven beans and MessageListeners, configure a different option for the Maximum reliability property of the bus destination.

   Express nonpersistent
   Messages are discarded when a messaging engine stops or fails. Messages may also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages may be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

6. Click **Next**.
7. On the Select Assigned Bus Member page, select the bus member that is to provide the queue point for the destination. The queue point is where the messages for the queue are held.

   If the bus member is a WebSphere MQ server, perform the next step, otherwise omit it.
8. If the bus member is a WebSphere MQ server, set the WebSphere MQ queue point attributes:
   a. Specify a value in the **WebSphere MQ queue name filter** field, then click **Go**.

      The wizard automatically discovers available WebSphere MQ queues. However, some WebSphere MQ topologies have many thousands of queues defined to a queue manager. Use this filter to limit the number of queues that are listed.

      The default filter value is an asterisk (*). If this value (or no value) is set then all queues, or all queues of a specific type (based on any queue type custom property that is set), are listed. Any other value that you specify must meet the following criteria:

      - It must contain between 1 and 48 characters.
      - It must conform to the WebSphere MQ queue naming rules (see the WebSphere MQ topic Rules for naming WebSphere MQ objects).

      You can also use the wildcard character (*) in conjunction with other text. For example, if you enter a value of `PAYROLL*`, then all available queues with names that start with PAYROLL are displayed.

   b. Specify a WebSphere MQ queue name.

      Select a queue name from the filtered list. If the list does not include the queue that you want, select the last entry in the list labeled “other, please specify”. A text entry box is displayed next to the list box. Type the queue name into the text entry box.

      If the queue is found on the remote WebSphere MQ system, the properties of the queue as defined within WebSphere MQ are displayed as read-only fields. This should help you to confirm that you have found the queue that you want, and that it is configured as you intend. If the queue is not found, these read-only fields are removed from view.

   c. Specify the reliability levels that you require when inbound nonpersistent and inbound persistent WebSphere MQ messages are converted to service integration format messages. Applications receive messages direct from the specified WebSphere MQ queue, so in general the reliability level for a message is of no interest to the receiver because the message has already been delivered successfully. However, the message is converted to a service integration format message (and typically to a JMS format service integration message) as it is received, and this option specifies the reliability level for the service integration format message. For information about the available reliability levels, see WebSphere MQ queue points [Settings].

   d. Specify whether you want WebSphere MQ to include an MQRFH2 message header when sending messages to the queue.

      The MQRFH2 header stores service integration messaging information that does not have a corresponding WebSphere MQ message header field. When a message is sent to the destination, service integration instructs WebSphere MQ to write the message to the queue. This option specifies whether or not service integration instructs WebSphere MQ to write the message with an MQRFH2 header.

      If the consumer of the message is a JMS application running in WebSphere MQ or service integration, or a WebSphere MQ XMS application, or a WebSphere MQ MQI application that expects an MQRFH2 header, select this option. If the consumer is a WebSphere MQ MQI application that does not expect an MQRFH2 header, do not select this option.

9. Click **Next**.
10. On the Confirm Queue Creation page, review the summary of actions.
    - To create the queue, click **Finish**.
    - If you want to change any of the properties that you have specified, click **Previous**, then change the properties on the preceding pages.
11. Save your changes to the master configuration.

What to do next

If you want to change properties of the queue, see “Configuring bus destination properties” on page 1230.

By default, messages that cannot be delivered to the queue are sent to the default exception destination for the messaging engine that hosts the queue point. If you want to use a non-default exception destination for messages that cannot be delivered to this queue destination, you must have already defined that exception destination. For more information about configuring exception destinations, see Configuring an exception bus destination.

If the queue is to be used for JMS point-to-point messaging, specify the queue identifier on a JMS queue as described in “Configuring a JMS queue for the default messaging provider” on page 1590.

Creating a topic space for publish/subscribe messaging:

Use this task to create a new topic space for publish/subscribe messaging.

About this task

You need to create topic space when deploying JMS applications that use publish/subscribe messaging.

To create a topic space, you need to specify only a minimum set of required properties; you can change these and other properties after you have completed this task.

To create a topic space, use the administrative console to complete the following steps.
1. In the navigation pane, click **Service integration** → **Buses**.
2. In the content pane, click the name of the bus that is to provide the publication points for the topic space.
3. In the content pane, under **Destination resources**, click **Destinations**. This displays any existing destinations in the content pane.
4. To create a topic space, click **New** in the content pane.
   a. On the Create New Destination page, select the **Topic space** option.
   b. Click **Next**.
   c. In the **Identifier** field, type the name that you want to give the topic space for administrative purposes.
5. Optional: Specify the following properties for the topic space:

   Description
   An optional description of the topic space, for administrative purposes.

   Maximum reliability
   The maximum reliability of messages accepted by this destination.

   Best effort nonpersistent
   Messages are discarded when a messaging engine stops or fails. Messages may also be discarded if a connection used to send them becomes unavailable and as a result of constrained system resources.

For non-transactional JMS message-driven beans and MessageListeners that use a JMS destination configured on the default messaging provider, best-effort nonpersistent messages are not recoverable. In this case, if a message is unlocked because the message-driven bean or MessageListener threw an exception, then the message is not redelivered or sent to the exception destination because it was deleted from the message store when it was passed to the listener. If you require higher message reliability for non-transactional JMS message-driven beans and MessageListeners, configure a different option for the Maximum reliability property of the bus destination.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages may also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages may be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

6. Click **Next**.
7. On the Confirm Topic space creation page, review the summary of actions.
   - To create the topic space, click **Finish**.
   - If you want to change any of the properties that you have specified, click **Previous**, then change the properties on the preceding pages.
8. Save your changes to the master configuration.

What to do next

If you want to change properties of the topic space, see “Configuring bus destination properties” on page 1230.

By default, messages that cannot be delivered to the topic space are sent the default exception destination for the messaging engine that is publishing the message. If you want to use a non-default exception destination for messages that cannot be delivered to this topic space, you must have already defined that exception destination. For more information about configuring exception destinations, see Configuring an exception bus destination.

If the topic space is to be used for JMS publish/subscribe messaging, specify the topic space identifier on a JMS topic as described in “Configuring a JMS topic for the default messaging provider” on page 1591.

Creating an alias bus destination:

Use this task to create a new alias destination on a service integration bus. The alias destination can be used to route messages to a target destination in the same bus, or another (foreign) bus (including across a WebSphere MQ link to a WebSphere MQ queue). You can set its own destination properties which will override the destination defaults.

About this task

To define a new alias destination, use the administrative console to complete the following steps.

1. In the navigation pane, click **Service integration** → **Buses**.
2. In the content pane, click the name of the bus on which the alias destination is to be created.

3. In the content pane, under **Destination resources**, click **Destinations**. This displays any existing destinations in the content pane.
4. To create a new destination, click **New** in the content pane.
   a. On the Create New Destination page, select Alias Destination.
   b. Click **Next**.
   c. In the **Identifier** field, type the name that you want to give the alias destination for administrative purposes.
5. Specify the following properties for the destination:

   Bus The name of the bus used by applications when referring to the alias destination. If you leave this field empty, the alias destination is created on the local bus.

   Target identifier
   The identifier of the target destination that this alias destination should route messages to.

   If the alias destination is targeting a queue provided by WebSphere MQ, type the value as a concatenation of the queue name and the queue manager name, *queue_name@qmanager_name*; for example: `Queue1@Qmgr2`.

   Target bus
   The name of the service integration bus (or foreign bus) that hosts the target destination. This can be the name of a foreign bus that represents a WebSphere MQ network. The default is the name specified for the **Bus** property.
6. Optional: Specify the following properties for the destination. These will override the destination defaults.

   Description
   An optional description of the destination, for administrative purposes.

   Enable producers to override default reliability
   Controls the quality of service for message flows between producers and the destination. Select this option to use the quality of service specified by producers instead of the quality defined for the destination.

   Default reliability
   The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

   INHERIT
   Use the reliability configured on the target destination.

   Best effort nonpersistent
   Messages are discarded when a messaging engine stops or fails. Messages may also be discarded if a connection used to send them becomes unavailable and as a result of constrained system resources.

   For non-transactional JMS message-driven beans and MessageListeners that use a JMS destination configured on the default messaging provider, best-effort nonpersistent messages are not recoverable. In this case, if a message is unlocked because the message-driven bean or MessageListener threw an exception, then the message is not redelivered or sent to the exception destination because it was deleted from the message store when it was passed to the listener. If you require higher message reliability for non-transactional JMS message-driven beans and MessageListeners, configure a different option for the Default reliability property of the bus destination.

   Express nonpersistent
   Messages are discarded when a messaging engine stops or fails. Messages may also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages may be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Maximum reliability
The maximum reliability of messages accepted by this destination.

Producers cannot send messages to this destination with a reliability higher than the value specified for this property.

INHERIT
Use the reliability configured on the target destination.

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages may also be discarded if a connection used to send them becomes unavailable and as a result of constrained system resources.

For non-transactional JMS message-driven beans and MessageListeners that use a JMS destination configured on the default messaging provider, best-effort nonpersistent messages are not recoverable. In this case, if a message is unlocked because the message-driven bean or MessageListener threw an exception, then the message is not redelivered or sent to the exception destination because it was deleted from the message store when it was passed to the listener. If you require higher message reliability for non-transactional JMS message-driven beans and MessageListeners, configure a different option for the Maximum reliability property of the bus destination.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages may also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages may be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Send allowed
Clear this option (setting it to false) to stop producers from being able to send messages to this destination..

INHERIT
Use the value configured on the target destination.

TRUE Producers can send messages to this destination.

FALSE
Producers cannot send messages to this destination.

Receive allowed
Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination.

INHERIT
Use the value configured on the target destination.

TRUE Consumers can receive messages from this destination.

FALSE
Consumers cannot receive messages from this destination.

Default priority
The default priority for messages sent to the target destination, in the range 0 (lowest) through 9 (highest), or -1. The value -1 indicates that messages should use the default priority defined on the target destination. The default priority is used only if a message does not specify its own priority.

7. Click **Next**.
8. On the Confirm Destination Creation page, review the summary of actions.
   - To create the alias destination , click **Finish**.
   - If you want to change any of the destination properties, click **Previous**, then change the properties on the preceding pages.
9. Save your changes to the master configuration.

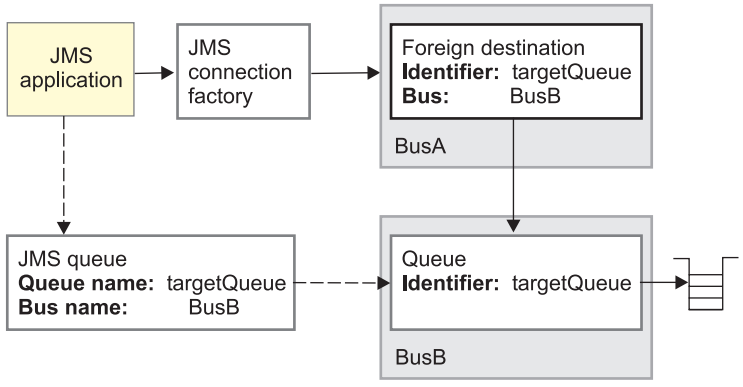
What to do next

If you want to change properties of the alias destination, see “Configuring bus destination properties” on page 1230. Further advanced configuration to the alias can be made using the “Configuring alias bus destination properties” on page 1234 panel, if required.

Creating a foreign bus destination:

Use this task to create a new foreign destination on a service integration bus. A foreign destination provides a mapping to a destination of the same name on a different bus, and enables applications on one bus to access directly the destination on another bus. You can set its own destination properties which will override the destination defaults.

About this task



The foreign destination encapsulates the name of the target destination that exists in the foreign bus (Identifier property) and the name of that foreign bus (Bus property). An application that wants to use the foreign destination to exchange messages with the target destination must specify the Identifier and Bus properties.

For example, an administrator wants JMS applications to connect to one bus, BusA, and send messages to a JMS queue backed by a queue, targetQueue, on another bus, BusB. The administrator connects the buses, creates a foreign destination on BusA and sets the following properties on the foreign destination and JMS queue:

JMS queue	Foreign destination (on BusA)	Queue (on BusB)
Queue name targetQueue **Bus name** BusB	**Identifier** targetQueue **Bus** BusB	**Identifier** targetQueue

To define a new foreign destination, use the administrative console to complete the following steps.

1. In the navigation pane, click **Service integration** → **Buses**.
2. In the content pane, click the name of the bus on which the foreign destination is to be created.
3. In the content pane, under **Destination resources**, click **Destinations**. This displays any existing destinations in the content pane.
4. To create a new destination, click **New** in the content pane.
   a. On the Create New Destination page, select Foreign Destination.
   b. Click **Next**.
   c. In the **Identifier** field, type the name of the target destination that exists in the foreign bus. The Identifier must match the name of the target destination that exists in the foreign bus.
   d. In the **Bus** field, type the name of the foreign bus that hosts the target destination. This must be the name of a foreign bus administrative object that is already defined on the bus on which the foreign destination is to be created.
5. Optional: Specify the following properties for the destination. These will override the destination defaults.

   Description
   An optional description of the destination, for administrative purposes.

   Default reliability
   The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

   Best effort nonpersistent
   Messages are discarded when a messaging engine stops or fails. Messages may also be discarded if a connection used to send them becomes unavailable and as a result of constrained system resources.

   For non-transactional JMS message-driven beans and MessageListeners that use a JMS destination configured on the default messaging provider, best-effort nonpersistent messages are not recoverable. In this case, if a message is unlocked because the message-driven bean or MessageListener threw an exception, then the message is not redelivered or sent to the exception destination because it was deleted from the message store when it was passed to the listener. If you require higher message reliability for non-transactional JMS message-driven beans and MessageListeners, configure a different option for the Maximum reliability property of the bus destination.

   Express nonpersistent
   Messages are discarded when a messaging engine stops or fails. Messages may also be discarded if a connection used to send them becomes unavailable.

   Reliable nonpersistent
   Messages are discarded when a messaging engine stops or fails.

   Reliable persistent
   Messages may be discarded when a messaging engine fails.

   Assured persistent
   Messages are not discarded.

Maximum reliability
The maximum reliability of messages accepted by this destination.

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages may also be discarded if a connection used to send them becomes unavailable and as a result of constrained system resources.

For non-transactional JMS message-driven beans and MessageListeners that use a JMS destination configured on the default messaging provider, best-effort nonpersistent messages are not recoverable. In this case, if a message is unlocked because the message-driven bean or MessageListener threw an exception, then the message is not redelivered or sent to the exception destination because it was deleted from the message store when it was passed to the listener. If you require higher message reliability for non-transactional JMS message-driven beans and MessageListeners, configure a different option for the Maximum reliability property of the bus destination.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages may also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages may be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Default priority
The default priority for messages sent to the target destination, in the range 0 (lowest) through 9 (highest), or -1. The value -1 indicates that messages should use the default priority defined on the target destination. The default priority is used only if a message does not specify its own priority.

6. Click **Next**.
7. On the Confirm Destination Creation page, review the summary of actions.
   - To create the foreign destination , click **Finish**.
   - If you want to change any of the destination properties, click **Previous**, then change the properties on the preceding pages.
8. Save your changes to the master configuration.

What to do next

Ensure that you have defined a foreign bus (to identify the target bus) and the target destination on that bus.

Configuring bus destination properties

Use this task to browse or change the configuration properties of a bus destination.

About this task

To browse or change the properties of a destination, use the administrative console to complete the following steps:

1. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations** → ***destination_name***.

2. Change the destination properties to suit your needs. See Learning about bus destinations for detailed description of bus destinations.
3. Click **OK**.
4. Save your changes to the master configuration.

Specifying an exception bus destination:

Specify an exception destination if you want to prevent messages that cannot be delivered to their original intended destination from being lost.

About this task

Complete this task if you want a bus destination to use a non-default exception destination for undeliverable messages. The bus destination for which you are specifying an exception destination is referred to as the “intended bus destination”.

Note:

- It is not possible to configure an exception destination for the entire bus; you must configure an exception destination for each destination on the bus.
- You should not modify or delete the default system destination.
- Configuring an exception destination prevents guaranteed ordering throughout the bus. For more information on ensuring ordering, see Message ordering.

For more information on exception destinations see **Related links**.

To specify a new exception destination for a bus destination, use the administrative console to complete the following steps:

1. Create the exception destination, as a queue. For information about creating a queue, see “Creating a queue for point-to-point messaging” on page 1222.
2. Type the name of the exception destination in the **Exception destination** field of the intended bus destination.
   a. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations** → ***destination_name***.
   b. Under **Exception destination**, select the **Specify** radio button.
   c. Type the name of the exception destination in the **Exception destination** field.
3. Save your changes to the master configuration.

Controlling whether applications can send or receive messages for a bus destination:

Use this task to change the configuration properties of a bus destination to control whether applications can send messages to, or receive messages from, the destination.

About this task

For example, some destinations only exist in order to be associated with mediations; applications should not be able to put to or get from such a destination.

The changes made in this task affect the configuration of a bus destinations and when saved, are automatically applied to all message points for that destination. You can make the same changes to an individual destination localization point to control access to only that one point.

When you save changes that affect the access to a bus destination, this affects producers or consumers attached to message points for that destination. For more information about the effect on producers or consumers, see The effect on producers or consumers of changing access to a bus destination.

To prevent applications from either sending messages to, or receiving messages from, a destination, use the administrative console to complete the following steps:

1. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations** → ***destination_name***.
2. Optional: Change one or more of the following properties:

   Receive allowed

   Clear this check box (setting to the option to false) to prevent messages from being received from message points for this destination. The effect depends on the type of destination:

   - Queue point. Any open consumers change state and an exception is thrown when the consumer requests a message.
   - Publication point. Any messages that have been published to the messaging engine for a publication point are stopped from proceeding either to local consumers or onwards to other messaging engines. Local consumers get the same exception as for a queue point.
   - Mediation point of a mediated destination. The bus stops the mediation instance that is running locally to the mediation point; other instances of the mediation running on other messaging engines continue as normal.

   In all cases, messages can continue to be sent, and accumulate on the destination localization point.

   Send allowed

   Clear this check box (setting the option to false) to prevent messages from being accepted onto the message points for this destination.

   - For a queue point of a non-mediated destination, or a mediation point of a mediated destination, new messages (from attached producers or forwarded from another destination) are redirected to any available message point. If no message points are available, then messages that have already been accepted onto the bus, and new messages from attached producers, are preserved by the bus until a message point becomes available. The only exception to this is the case of a destination with only one message point (queue point or mediation point depending on whether the destination is mediated or non-mediated), where the producer is attached to the same messaging engine. In this case, an exception is thrown on each send call. The exception message indicates that the reason for the exception is that the only extant localization has been disabled for send. The producer remains open as normal, and any more send calls succeed if the **Send allowed** property of the localization is reselected (reset to true).
   - For a queue point of a mediated destination, clearing this **Send allowed** property alters the behavior of the mediation instances that are sending to the destination in the same way as setting it to false on a non-mediated destination affects producing applications: Messages are sent instead to any alternative message point. If no localizations are available, are preserved by the bus until a message point becomes available. For any mediation instance (that is, on any server that has a mediation point), if the same server hosts a queue point, and that queue point is the only queue point for the destination, then the mediation changes to the “stopped on error” state.
   - For a publication point, clearing this **Send allowed** property stops applications attached locally to the topic space from publishing messages. The send calls receive an exception, and the producer remains open.

   Receive exclusive

   If you select this check box (setting to the option to true), then only one consumer can be attached to any message point. This property is particularly intended for use with queues, but can be used with any type of destination.

   - For a queue, the bus chooses a queue point for each request to create a consumer. If the selected queue point already has an attached consumer, then the call fails with an exception

(containing an exception message and linked exception that indicate the precise nature of the failure). There is no guarantee that all available queue points are used before the exception is thrown.

- For a topic space, only one consumer can attach to any given messaging engine.

If you change the **Receive exclusive** property from false to true, some consumers are selected to be the exclusive receivers in accordance with the rules above. All other consumers are detached from the destination, in the same way as is described above for a transition of the **Receive allowed** property from true to false.

3. Click **OK**.
4. Save your changes to the master configuration.

Specifying whether strict message order is preserved for a bus destination:

Use this task to change the configuration properties of a bus destination to control whether strict message order is preserved.

Before you begin

The changes made in this task affect the configuration of a bus destination. Before you begin this task, make sure that you fully understand the restrictions that apply to ordered destinations. For further details see Strict message ordering for bus destinations.

About this task

Although messages produced by a single producer to a single destination are seen by a consumer to that destination in the same order as they are produced, there are certain topologies and events, such as system failures, that can change the order of messages (see Message ordering). If strict message order is essential, you can configure a destination to preserve the order of the messages in a much more rigorous manner. Configuring a destination in this way, when used in conjunction with restricted topologies, maintains message order in all circumstances (for further information, see Strict message ordering for bus destinations).

To preserve the order of the messages that are delivered to a destination, use the administrative console to complete the following steps:

1. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations** → ***destination_name***.
2. Select the **Maintain strict message order** check box (setting the option to true).
3. Click **OK**.
4. Save your changes to the master configuration.

Results

An ordered destination has priority over several other configuration properties, such as the number of consumers that are allowed to attach to the destination. The system overrides these configuration properties at run time, and generates a system log warning. For more information about the configuration properties that the system overrides at run time, and the impact of including an ordered destination in your system, see Strict message ordering for bus destinations.

Specifying whether messages are forwarded to WebSphere MQ as JMS messages:

Use this task to create a destination context property that determines whether an MQRFH2 header is added to WebSphere MQ JMS messages produced by foreign or alias destinations.

Before you begin

This task assumes that you have created an alias bus destination or a foreign bus destination. For more information, see “Creating an alias bus destination” on page 1225 or “Creating a foreign bus destination” on page 1228.

About this task

You only need to carry out this task if you want JMS messages produced by foreign bus destinations or alias bus destinations forwarded to WebSphere MQ. In this task, you define a destination context property called _MQRFH2Allowed that adds an MQRFH2 header to JMS messages. If you do not configure _MQRFH2Allowed, the default value is NO, and an MQRFH2 header is not added to the message. WebSphere Application Server Version 5.1 users may be aware of a WebSphere MQ flag called TARGCLIENT that was used to add RFH2 headers to JMS messages. For more information about the use of the MQRFH2 header in interoperating with WebSphere MQ, see How service integration converts the message body to and from WebSphere MQ format and Point-to-point messaging with a WebSphere MQ network.

To create and configure a context property called _MQRFH2Allowed on a foreign or alias destination, use the administrative console to complete the following steps:

1. Display the context properties for a selected foreign or alias destination:
   a. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations**.
   b. Select the foreign or alias destination for which you want to create the context property.
   c. Under **Additional Properties**, click **Context properties**.
2. Click **New** to create a new context property.
3. Specify the following context information:

   Name Type the name `_MQRFH2Allowed`.

   Context type
   Select the information type `Boolean` in the selection list.

   Context value
   Type the value `true` .
4. Click **OK**.
5. Save your changes to the master configuration.

Results

An MQRFH2 header is added to all messages produced by the foreign or alias destination. This means that JMS messages will be forwarded to WebSphere MQ as JMS messages.

Configuring alias bus destination properties:

Use this task to browse or change the configuration properties of an alias bus destination. The alias destination can be used to route messages to a target destination in the same bus, or another (foreign) bus (including across a WebSphere MQ link to a WebSphere MQ queue). Any alias bus destination properties that you set will override the properties of the target destination, otherwise the target destination’s properties will apply.

About this task

To browse or change the properties of an alias destination, use the administrative console to complete the following steps.

1. In the navigation pane, click **Service integration** → **Buses**.

2. In the content pane, click the name of the bus on which the alias destination was created.
3. In the content pane, under **Destination resources**, click **Destinations**. This displays any existing destinations in the content pane.
4. Select the alias destination that you want to configure.
5. You can change the following alias destination properties to suit your needs. These values will override the destination defaults.

Description
An optional description for the bus destination, for administrative purposes.

Target identifier
The name of the destination for which this is an alias.

Target bus
The name of the bus on which the destination for which this is an alias exists.

Use all target queue points
This property box is displayed only if the destination identified by the Target identifier and Target bus properties has multiple queue points configured (that is, deployed to a cluster bus member with multiple messaging engines) and the Target bus is the local bus.Whether to use all target queue points indicates whether all the queue points of the target queue can be used, including any queue points created after the alias is configured. When selected, the **Target queue points** menu is disabled.

Unselected queue points
A list of the queue points that are not addressable by the alias definition. The list is generated from the complete list of queue points for this queue. This list is enabled only when **Use all target queue points** is unchecked.

Selected queue points
A list of the queue points that are addressable by the alias definition. This list is enabled only when **Use all target queue points** is unchecked

Enable producers to override default reliability
Controls the quality of service for message flows between producers and the destination. Select this option to use the quality of service specified by producers instead of the quality defined for the destination.

Default reliability
The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

INHERIT
Use the reliability configured on the target destination.

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages may also be discarded if a connection used to send them becomes unavailable and as a result of constrained system resources.

For non-transactional JMS message-driven beans and MessageListeners that use a JMS destination configured on the default messaging provider, best-effort nonpersistent messages are not recoverable. In this case, if a message is unlocked because the message-driven bean or MessageListener threw an exception, then the message is not redelivered or sent to the exception destination because it was deleted from the message store when it was passed to the listener. If you require higher message reliability for non-transactional JMS message-driven beans and MessageListeners, configure a different option for the Maximum reliability property of the bus destination.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages may also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages may be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Maximum reliability
The maximum reliability of messages accepted by this destination.

Producers cannot send messages to this destination with a reliability higher than the value specified for this property.

INHERIT
Use the reliability configured on the target destination.

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages may also be discarded if a connection used to send them becomes unavailable and as a result of constrained system resources.

For non-transactional JMS message-driven beans and MessageListeners that use a JMS destination configured on the default messaging provider, best-effort nonpersistent messages are not recoverable. In this case, if a message is unlocked because the message-driven bean or MessageListener threw an exception, then the message is not redelivered or sent to the exception destination because it was deleted from the message store when it was passed to the listener. If you require higher message reliability for non-transactional JMS message-driven beans and MessageListeners, configure a different option for the Maximum reliability property of the bus destination.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages may also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages may be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Default priority
The default priority for messages sent to the target destination, in the range 0 (lowest) through 9 (highest), or -1. The value -1 indicates that messages should use the default priority defined on the target destination. The default priority is used only if a message does not specify its own priority.

Send allowed
Clear this option (setting it to false) to stop producers from being able to send messages to this destination..

INHERIT
Use the value configured on the target destination.

TRUE Producers can send messages to this destination.

FALSE
Producers cannot send messages to this destination.

Receive allowed
Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination.

INHERIT
Use the value configured on the target destination.

TRUE Consumers can receive messages from this destination.

FALSE
Consumers cannot receive messages from this destination.

Reply destination
The name of a destination to be appended to any non-empty reverse routing path of messages sent to this destination.

Reply destination bus
The bus on which the reply destination exists.

Default forward routing path
The value to which a message's forward routing path will be set if the message contains no forward routing path. This identifies a sequential list of intermediary bus destinations that messages must pass through to reach a target bus destination. The format of the field is a list of line-delimited bus destinations specified as *bus*:*name*.

Delegate authorization check to target destination
Indicates whether the destination access role checked when a user accesses the alias destination is that of the target destination (checked) or the alias destination (unchecked). ″

WebSphere MQ RFH2 allowed
WebSphere MQ RFH2 is allowed.

6. Click **OK**.
7. Save your changes to the master configuration.

What to do next

If you want to enable correct processing of messages, under Additional Properties click **Context properties**. This information adds to the context information derived from processing the message header. If you want an expandable tree view of all the applications and messaging resources that reference the current destination, both directly and indirectly, under Related Items click **Application resources topology**. As many of the references as possible are resolved to links to the associated configuration panel for the referenced object.

Configuring mediations

Use this task to configure one or more mediations for a selected bus destination in a service integration bus.

About this task

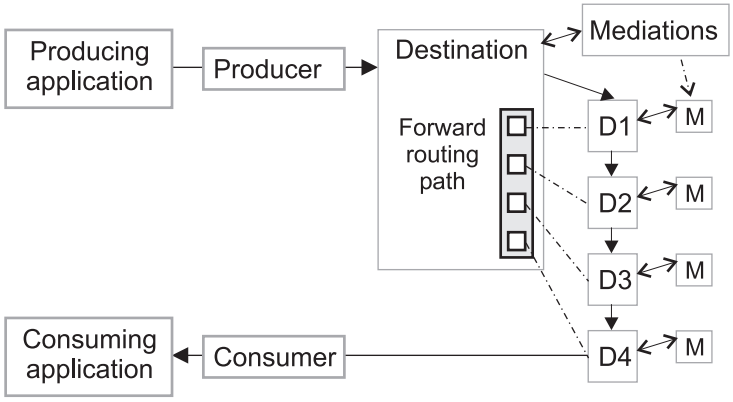
You can configure a destination with one or more mediations that refine how messages are handled by the destination, and can configure destination properties that affect how the mediations are used; for example, that they should run within a global transaction.

For more information about configuring mediations, see "Mediating a destination" on page 1264.

Configuring a destination forward routing path

Use this task to configure a forward routing path for a selected bus destination. The forward routing path identifies a sequence of bus destinations that a message should pass through after it has been delivered to the bus destination to which the producer is attached.

About this task



If producing and consuming applications both attach directly to the destination that is to host and process their messages, you do not need to use routing paths. You can still use mediations assigned to the destination to manipulate messages. However, if you want a more flexible architecture, you can assign mediations to several destinations then specify those destinations as the forward routing path for another destination. For example in the above diagram, on the destination called Destination, on the bus called myBus, you would set the Default forward routing path property to:

```
mybus:D1
mybus:D2
mybus:D3
mybus:D4
```

For each destination that should be visited by a reply message on its ways back to the producer application, you can specify the name of a *reply destination*, which is the next destination in the reverse routing path. If the same destinations are used for both the forward and return routing paths, you can configure the return routing path when you configure the forward routing path, as described in this topic. Otherwise, see “Configuring a destination reverse routing path” on page 1239.

To configure a forward routing path, you only need to change the properties of the destinations you want to use. This topic contains optional steps to create destinations, in case you have not already done so.

To configure a forward routing path for a destination, use the administrative console to complete the following steps:

1. Optional: If you have not already done so, create the destination to which the producer applications attach. For this destination, you can create a queue or create a topic space.
2. Optional: If you have not already done so, create each destination in the path. Only the last destination in the path can be a topic space; all other destinations in the path must be queues.

   If the destination is also to be part of the return routing path for reply messages, specify the name of the next destination in the return routing path:

   a. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations** → ***destination_name***.
   b. In the Reply destination bus field, type the name of the next destination in the return routing path.
   c. Save your changes to the master configuration.

3. Optional: If you have not already done so, assign mediations to the destinations in the path. You can include a destination without mediations in a routing path, to provide a future option to apply a mediation assigned to that destination.
4. Edit the properties of the destination to which the producer applications attach, to configure the forward routing path.
   a. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations** → ***destination_name***.
   b. In the Default forward routing path field, type the names of the destinations in the path. Type a list of bus destinations, each on a separate line, of the form *bus_name*:*destination_name*

      Where

      bus_name
      Is the name of the service integration bus on which the destination is configured.

      destination_name
      is the name of the bus destination.

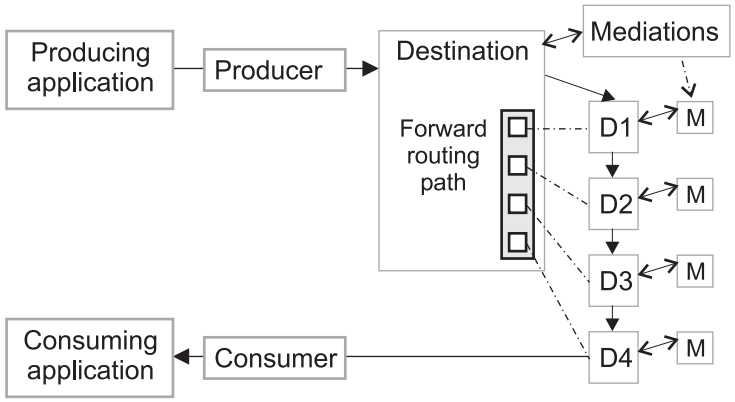
      For example:

      ```
      mybusA:queueA
      anobusB:queueB
      busC:queueC
      ```
   c. Save your changes to the master configuration.

Configuring a destination reverse routing path

Use this task to configure a reverse routing path between two bus destinations. The reverse routing path identifies the list of destinations that any reply message should sent to from the consumer back to the producer.

About this task



If producing and consuming applications both attach directly to the destination that is to host and process their messages, you do not need to use routing paths. You can still use mediations assigned to the destination to manipulate messages. However, if you want a more flexible architecture, you can assign mediations to several destinations then specify those destinations as the forward routing path for another destination.

For each destination that is to be part of a reverse routing path back to the producer application, you can specify the name of a *reply destination*, which is the next destination in the reverse routing path. For example in the above diagram, if reply messages are to retrace the forward routing path back to the producing application, you would set reverse routing path as follows:

Destination	Reply destination bus
D4	D3
D3	D2
D2	D1
D1	Destination

You can specify a different reverse routing path to the forward routing path, to enable more mediations to be applied to reply messages, or to apply mediations in a different destination sequence.

If the same destinations are used for both the forward and reverse routing paths, you can configure the reverse routing path when you configure the forward routing path, as described in “Configuring a destination forward routing path” on page 1238. Otherwise, you can configure (or change) the reverse routing path as described in this topic.

To configure a reverse routing path, you only need to change the properties of the destinations you want to use. This topic contains optional steps to create destinations, in case you have not already done so.

To configure a reverse routing path for a destination, use the administrative console to complete the following steps:

1. Optional: If you have not yet done so, create the destination to which the producer applications attaches. For this destination, you can create a queue or create a topic space.
2. Optional: If you have not already done so, create each destination in the path.
3. Optional: If you have not already done so, assign mediations to the destinations in the path. You can include a destination without mediations in a routing path, to provide a future option to apply a mediation assigned to that destination.
4. On each destination in the reverse routing path, specify the name of the next destination in the path:
   a. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations** → ***destination_name***.
   b. In the Reply destination field, type the name of the next destination in the reverse routing path.
   c. In the Reply destination bus field, type the name of the next destination in the reverse routing path.
   d. Save your changes to the master configuration.

Configuring context properties for a bus destination

Use this task to configure context properties for a bus destination.

About this task

The context properties contribute to the mediation context that is used in conjunction with the message header information to ensure that messages are processed correctly by a mediation assigned to this bus destination.

Note: Context properties on the destination take precedence over context properties on a mediation. For example, if a property with the same name is configured for a destination and a mediation, the property on the destination takes precedence.

To configure context information for a bus destination, use the administrative console to complete the following steps:

1. Display the context properties for a selected bus destination:
   a. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations** → ***destination_name***.
   b. Under **Additional Properties**, click **Context properties**.

2. Choose whether to create a new context property, configure an existing property, or delete one or more existing properties.
   - To create a new context property, click **New**.
   - To browse or change an existing context property, click the property name.
   - To delete one or more existing context properties, select the check box for each property you want to delete, then click **Delete**.
3. To create or change a context property, specify the following context information:

   Name Type a name for the context property.

   Context type
   Select the information type for the context property in the selection list.

   Context value
   Type a value for the context property.
4. Click **OK**.
5. Save your changes to the master configuration.

Administering destination roles

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups must have authority to perform messaging operations, at a bus destination. By administering destination roles, you can control which users and groups can perform operations at a bus destination, and the type of operation that they can perform.

About this task

You use the administrative console to administer users and groups in access roles for a destination. The access roles available for a destination depend on the type of destination. The table below lists the roles that you can assign for each destination type:

Destination type	Access roles
queue	sender, receiver, browser, creator
port	sender, receiver, browser, creator
webService	sender, receiver, browser, creator
topicSpace	sender, receiver
foreignDestination	sender
alias	sender, receiver, browser

In addition to controlling which users and groups have access to a specific local or foreign destination, you can also control the inheritance of access roles for a specific local destination. In this case, the default access roles that apply to all the destinations in the local bus namespace are added to any access roles that have been added for a specific destination.

Use the following tasks to administer destination roles.
- Listing users and groups in bus destination roles by using the wsadmin tool
- Adding users and groups to bus destination roles by using the wsadmin tool
- Removing users and groups from bus destination roles by using the wsadmin tool
- Defining destination defaults inheritance by using the wsadmin tool
- Determining destination defaults inheritance by using the wsadmin tool

Adding users and groups to destination roles:

Service integration bus security uses role-based authorization. By adding users and groups to the destination roles for a secured bus, you can control which users and group members can perform messaging operations at a bus destination.

Before you begin

Ensure that the following conditions are met:

- Security is enabled for the bus. For more information, refer to “Securing buses” on page 1272.
- The users and groups that you want to add to destination roles must exist already in the user repository.

About this task

By adding users or groups to destination role, you grants the users or groups authority to perform the operation defined by the role at a selected destination. The destination roles are sender, receiver, browser, and creator, depending on the destination type.

In this task you use the administrative console Security wizard to retrieve selected users or groups from the user repository, and add them to destination roles for selected bus destinations.

Note: To add a large number of users to destination roles, it is advisable to create a group in the user repository, and add the group to the destination roles.

1. Start the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage destination access roles**. A list of the destinations defined for the selected bus is displayed in the Destinations panel.
3. Select one or more destination to work with:
   - Click a single destination name.
   - Select the check boxes next to multiple destination names, and then click **Manage Access Roles**.

   The Destination access roles panel is displayed. The information for each destination you have selected is displayed in a collapsed section.
4. Expand a destination header to list the users and groups that have been assigned to roles for this destination. You can verify that the user or group you want to add does not already have a role at this destination.
5. Click **Add** to launch the Security wizard. The wizard takes you through the following steps to add selected users or groups to access roles for the expanded destination:
   a. Search for the users or groups that you want to add to access roles for the expanded destination:

      Users or Groups
      Select either **Users** or **Groups** to specify whether you want to grant access roles to users or groups.

      Search pattern
      This field is mandatory. Specify a search string that is matched against user IDs or group names in the user repository. Only user IDs or group names that match the search pattern are retrieved, subject to the maximum number of search results. Wildcard characters are allowed.

      Maximum number of search results to display
      This field is mandatory. Specify the maximum number of user IDs or group names you want the administrative console to display.

   b. Click **Next**. The wizard displays the users or groups in the user repository that match the information that you provided in the previous step.
   c. Select the check boxes next to the user IDs or group names that you want to add to access roles for the currently expanded destination, and click **Next**. A list of user IDs or group names that you can add to destination roles is displayed. Note that some users or groups may already be assigned to access roles for this destination.
   d. Select the appropriate access role icon for the user ID or group name that you want to add to the role at this destination. For example, select the **Receiver** icon for a user ID or group name that you

want to add to the receiver role. The icon changes from  to  to show that you have added the user or group to the access role for the resource.

e. Repeat the previous step to add more users or groups to access roles for the currently expanded destination, and then click **Next**. A summary of your access role assignments is displayed.

f. Click **Previous** to review and change your assignments, if required.

g. Click **Finish** to confirm your assignments.

6. Repeat steps 4 and 5 for each destination you want to work with.
7. Save your changes to the master configuration.

Results

The selected users and groups are added to the access roles for the currently expanded destination. The new access role assignments are displayed in the Destination access roles panel.

Example

A group called MyGroup receives messages from three queues, Queue 1, Queue 2, and Queue 3. If you want the group MyGroup to produce and consume messages at an additional destination, Queue 4, you add MyGroup to Queue 4, and then add MyGroup to the sender and receiver roles for Queue 4.

What to do next

Use the administrative console to perform other security administrative tasks.

Removing users and groups from destination roles:

Service integration bus security uses role-based authorization. By removing users and groups from the destination roles for a secured bus, you can prevent those users and group members from performing messaging operations on the bus.

About this task

When selected users and groups no longer require access to a destination, you can remove them from all the roles for that destination.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage destination access roles** A list of the destinations defined for the selected bus is displayed in the Destinations panel.
3. Select one or more destinations to work with:
   - Click a single destination name.
   - Select the check boxes next to multiple destination names, and then click **Manage Access Roles**.

   The Destination access roles panel is displayed. The information for each destination you have selected is displayed in a collapsed section.
4. Expand a destination header to list the users and groups that have been assigned to roles at this destination, and verify that the user or group that you want to remove has a role at this destination.
5. Select the users and groups that you want to remove from all role types at this destination, and click **Remove**.
6. Save your changes to the master configuration.

Results

The selected users and groups are removed from all role types at the selected destination. The Manage access roles for users and groups panel displays the updated role type assignments.

Example

The members of three groups, Group A, Group B, and Group C, belong to the sender role and the receiver role for two queue destination, Queue 1 and Queue 2. If Group B is no longer required to send and receive messages on Queue 2, you can use this task to remove Group B from all the role types on Queue 2.

What to do next

You can perform other security administration tasks by using the administrative console.

Listing users and groups in destination roles:

Service integration bus security uses role-based authorization. By listing the users and groups in the destination roles for a selected secured bus, you can find out which users and groups are authorized to access the bus, and its resources.

About this task

In this task you use the administrative console to list all the users and groups in destination roles for selected destinations. The list includes users and groups that have references in the service integration role-based configuration; it does not include all the users and groups that exist in the user repository. The permitted destination roles are sender, receiver, browser and creator, depending on the destination type. Icons are used in the administrative console to represent the roles to which users and groups have been assigned. For example, if the role type set icon () is displayed in the sender role for a group called Group 1, it means that Group 1 has been assigned to the sender role for a selected destination. For a complete description of all the icons used to represent role assignments in the administrative console, refer to Access role assignments for bus security resources.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage destination access roles**. The Destinations panel lists all the destinations defined for the selected bus.
3. Select one or more destinations to work with:
   - Click the name of a single destination.
   - Select the check boxes next to multiple destinations, and click **Manage Access Roles**.

   The Destination access roles panel is displayed. The information for each selected destination is displayed in a collapsed section.
4. Expand a destination header.

Results

The Destination access roles panel lists the users and groups in access roles for the expanded destination.

What to do next

You can now administer the users and groups in destination roles at this destination.

Restoring default inheritance for a destination:

Service integration bus security uses role-based authorization. By default, all local destinations inherit access roles from the default resource. If default inheritance has been previously overridden, you can restore it for a selected destination.

Before you begin

Default inheritance has been overridden for a selected secured destination. For more information, refer to Overriding inheritance from the default resource for a destination.

About this task

If default inheritance has been overridden for a particular destination, you can override it. In this task, you use the administrative console to restore the role type assignments from the default resource to a selected destination. A destination can only inherit access roles that are allowed for that particular type of destination. For example, a topic space can inherit the sender and receiver roles, but it cannot inherit the browser role. Inherited access roles are added to any existing access roles for the destination.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage destination access roles**. The Destinations panel lists all the destinations defined for the selected bus.
3. Select one or more destinations to work with:
   - Click the name of a single destination.
   - Select the check boxes next to multiple destinations, and click **Manage Access Roles**.

   The Destination access roles panel is displayed. The information for each selected destination is displayed in a collapsed section.
4. Expand a destination to list the users and groups that have been assigned to roles for this destination.
5. Select the **Inherit from default** check box.
6. Click **OK** to save your changes.
7. Save your changes to the master configuration.

Results

The role type assignments for the default resource are inherited by the selected destination. The Destination access roles panel displays the newly inherited default access roles for the destination, and any existing access roles.

What to do next

You can perform other security administration tasks by using the administrative console.

Disabling inheritance from the default resource:

This task enables you to disable the inheritance of security access roles from the default resource for selected resources.

Before you begin

About this task

In this task, you use the administrative console to disable the inheritance of access roles from the default resource for selected resources. Disabling inheritance from the default access roles means that users or groups that have roles in the default access role no longer have access to this destination.

Use the administrative console to disable the inheritance of access roles from selected resources as follows:

1. Use the administrative console to navigate to a list of the resources you want to work with for a specific bus. For example, to list all the known destinations for a selected bus, click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage destination access roles**. The Destination panel lists all the destinations defined on the selected bus.
2. Do one of the following to select one or more resources:
   - Click the name of a single resource.
   - Select the check boxes next to multiple resources, and click **Manage Access Roles**.

   The Access Roles panel displays access role information for each selected resource within a collapsed section.
3. Expand a resource header to list the users and groups that have been assigned to roles for this resource.
4. Clear the **Inherit from default** checkbox.
5. Click **OK** to save your changes. The role types for the default resource are removed from the selected resource, and the Access Roles panel is updated.
6. Save your changes to the master configuration.

Deleting a bus destination

Use these tasks to delete a bus destination from a service integration bus.

About this task

The steps required depend on the type of destination.

Deleting a non-topic space bus destination:

Use this task to delete, from a service integration bus, a bus destination that is not for a topic space.

Before you begin

You cannot delete bus destinations that are required by the system; for example, the default exception destination for a messaging engine: `_SYSTEM.Exception.Destination.`*`me_name`*.

Before you can completely delete a bus destination, you must ensure that the destination message point is empty of all messages. A delete action is rejected if there are any messages on the message point, either committed, uncommitted, indoubt or locked.

Any reliable or durable messages sent after the delete action, but before the close of producers, are sent to one of the following destinations:

- Another message point of the destination, if possible.
- The exception destination for the deleted destination.

Note: Any attached producers or consumers are closed asynchronously, and do not prevent the delete action. Any messages sent after the delete action, but before close of producers might not be discarded. Depending on the options set, the messages may be moved to the exception destination. For more information see “Specifying an exception bus destination” on page 1231 and Exception destination.

About this task

To delete a destination, use the administrative console to complete the following steps.

1. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations**.

2. Click the check box next to the destination name.
3. Check for and resolve any locked messages. Messages that are locked, as part of in-flight transactions or as in-doubt messages, are not deleted.
4. To clear all messages from the destination, click **Clear**. This action deletes all of the messages that it can access. Messages that are locked, part of in-flight transactions or in-doubt are not deleted. If there are messages that cannot be deleted, they are skipped and the operation indicates that it was partially successful.
5. To delete the empty destination, click **Delete**.
6. To confirm that you want to delete the destination click **OK**.

Results

The bus destination is deleted.

What to do next

Monitor the exception queue for the messaging engine to which the destination was assigned, to see if there are any in-transit messages that were not handled by clearing the destination before it was deleted.

Deleting a topic space:

Use this task to delete, from a service integration bus, a topic space.

Before you begin

Before you can delete a topic space, you must ensure that the publication points are empty. A delete action is rejected if there are any indoubt or uncommitted publications for a publication point.

Note: Any attached producers are closed asynchronously, and do not prevent the delete action. However, any messages sent after the delete action, but before close of producers are discarded.

The service integration bus topic space is the primary messaging object upon which WS-Notification depends at run time. For information about the effect that deleting a topic space has upon new and existing WS-Notification applications, see Failures as a result of changes in topic space and topic namespace configurations.

About this task

To delete a topic space, use the administrative console to complete the following steps.

1. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations**.
2. Click the check box next to the destination name.
3. Check for and resolve any undelivered publications (indoubt or uncommitted) for the topic space. Messages that are locked, as part of in-flight transactions or as in-doubt messages, are not deleted.
4. To delete the empty topic space, click **Delete**.
5. To confirm that you want to delete the topic space, click **OK**.
6. Save your changes to the master configuration.

Results

The topic space is deleted.

Resetting a destination

Use this task to reset a bus destination.

About this task

You may want to reset a destination if, for example, it has become corrupt. To do this, you use a wsadmin AdminControl command.

1. Use a wsadmin AdminControl command of the following form to find the name of the messaging engine.
   - Using Jython:
     ```
     me = AdminControl.queryNames("type=SIBMessagingEngine,name=messaging_engine_name,* " )
     ```
   - Using Jacl:
     ```
     set me [$AdminControl queryNames type=SIBMessagingEngine,name=messaging_engine_name,*]
     ```

   Where *messaging_engine_name* is the name of the messaging engine.
2. Use the wsadmin AdminControl command of the following form to reset the destination.
   - Using Jython:
     ```
     AdminControl.invoke(me, "resetDestination", ["destination"] )
     ```
   - Using Jacl:
     ```
     $AdminControl invoke $me resetDestination {"destination"}
     ```

   Where *destination* is the name of the destination.

Results

The bus destination is reset ready for use.

Managing bus destinations with administrative commands

You can use these commands to manage bus destinations.

About this task

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and JACL.

1. Open a wsadmin command session in local mode For example:
   ```
   wsadmin -conntype none -lang jython
   ```

   Note: The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.
2. Type `AdminTask.`*command*

   Where *command* is the command format as indicated in the related reference topics; for example:
   ```
   wsadmin>AdminTask.listSIBDestinations(["-bus", "abus"])
   '(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBTopicSpace_1098181446388)
   (cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBQueue_1098181503600)
   (cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBQueue_1098184221748)'

   wsadmin>AdminTask.listSIBDestinations(["-bus", "abus", "-type", "TopicSpace"])
   '(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBTopicSpace_1098181446388)'
   ```

Configuring message points

Use the following tasks to configure message points on service integration buses.

About this task

A message point is the location (for example, queue point or publication point) at which messages for a bus destination are held in a messaging engine. The runtime state of the message point represents a runtime instance of the destination.

When you define a new bus destination, its message point is created. You can then configure some properties of the message point to override the general properties defined for the destination.

You can also administer the messages on the runtime view of the message point.
- "Configuring a message point"
- "Listing message points for a bus destination"
- "Listing message points for a messaging engine"

Listing message points for a messaging engine

Use this task to list the message points for bus destinations on a selected messaging engine.

About this task

To display a list of message points for a messaging engine, use the administrative console to complete the following steps.

1. Click **Service integration** → **Buses** → ***bus_name*** → **[Topology] Messaging engines**. This displays a list of messaging engines on the bus.
2. Click the name of the messaging engine.
3. Under Message Points, click the link for the type of point you want to list.

Results

A list of message points for the selected messaging engine is displayed in the content pane.

Listing message points for a bus destination

Use this task to list the message points for a selected bus destination.

About this task

To display a list of message points for a bus destination, use the administrative console to complete the following steps.

1. Display the bus destination.
2. In the content pane, under Message Points, click the link for the type of point you want to list.

Results

A list of message points for the selected bus destination is displayed in the content pane.

Configuring a message point

Use this task to browse or change the configuration properties of a message point for a bus destination.

About this task

You can configure some properties of the message point to override the general properties defined for the destination.

To browse or change the properties of a message point, use the administrative console to complete the following steps:

1. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations** → ***destination_name***.
2. Under Message Points, click the link for the type of message point:
   - **Queue points**, for a queue
   - **Publication points**, for a topic space
   - **Mediation points**, for a mediated queue or topic space

3. In the content pane, click the name of the message point.
4. Optional: Change the message point settings.
5. Click **OK**.
6. Save your changes to the master configuration.

Managing messages on message points

Use these tasks to list and act on runtime messages that exist on message points in a service integration bus.

About this task

You can list the message points for bus destinations and messaging engines, and list the messages on a selected message point. You can use the list of messages as part of a troubleshooting task to find messages that need to be deleted.

- "Listing messages on a message point"
- "Deleting messages on a message point" on page 1251

Listing messages on a message point

Use this task to list the messages that exist on a message point for a selected bus destination or messaging engine.

About this task

To display a list of messages on a message point, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Buses**.
2. In the content pane, click the name of the service integration bus.
3. Optional: To list the message points for a bus destination, complete the following steps:
   a. In the content pane, under **Destination resources**, click **Destinations**.
   b. Click the destination name.
4. Optional: To list the message points for a messaging engine, complete the following steps:
   a. In the content pane, under **Topology**, click **Messaging engines**
   b. Click the messaging engine name.
5. Under Additional Properties, click **Message points** This displays a list of message points in the content pane.
6. Click the message point name. This displays the properties of the destination localization in the content pane.
7. Click the Runtime tab.
8. Under Additional Properties, click **Messages**

Results

A list of messages on the selected message point is displayed in the content pane.

What to do next

You can select one or more messages to act on; for example, to display the message content, delete messages.

Deleting messages on a message point

Use this task to delete one or messages that exist on a message point for a selected bus destination or messaging engine.

About this task

You should not normally need to delete messages on a message point. This task is intended as part of a troubleshooting procedure.

To delete one or messages on a message point, use the administrative console to complete the following steps:

1. List the messages on the message point.
2. In the content pane, click the check box next to each message you want to delete. Alternatively, you can select all messages in the list by clicking the Select all items button 
3. Click **Delete**

Results

The selected messages are removed from the list.

Administering durable subscriptions

Use the following tasks to display the durable subscriptions that exist, to enable a subscription to be changed, or to delete a subscription.

About this task

The default messaging provider supports the use of durable subscriptions to topics. This enables a subscriber to receive a copy of all messages published to a topic, even messages published during periods of time when the subscriber is not connected to the server.

If an application creates a durable subscription, it is added to the list that administrators can display and act upon by using the administrative console. Each durable subscription is created with a unique subscription identifier, *clientID##subName* where:

clientID
: The client identifier used to associate a connection and its objects with the messages maintained for applications (as clients of the JMS provider). You should use a naming convention that helps you identify the applications, in case you need to relate durable subscriptions to the associated applications for runtime administration. For more information about client identifiers, see section 4.3.2 of the JMS 1.1 specification.

subName
: The JMS durable subscription name used to uniquely identify a durable subscription within a given client identifier. For more information about JMS durable subscription names, see section 6.11.1 of the JMS 1.1 specification.

For durable subscriptions created by message-driven beans, the subscription name value is set on the JMS activation specification. For other durable subscriptions, the value is set by the administrator on the JMS connection factory and by the JMS application on the createDurableSubscriber operation.

- Listing durable subscriptions
- Stopping active subscribers for durable subscriptions
- Enabling providers to stream messages to cloned durable subscriptions
- Deleting durable subscriptions

Listing subscriptions

Use this task to list the subscriptions that exist at runtime for a topic space.

About this task

The runtime state of a subscription is linked to the publication point for the messaging engine that is used to store messages delivered to the subscription. You can list subscriptions by first displaying the publication point, either from the messaging engine panel or the list of all publication points for a service integration bus.

To display a list of subscriptions for a publication point, use the administrative console to complete the following steps:

1. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations**. This displays any existing destinations in the content pane.
2. Click the name of the topic space.
3. Under Message Points, click **Publication points**. This displays the publication points for the topic space.
4. Click the name of the publication point.
5. Click the Runtime tab.
6. Under Additional Properties, click **Subscriptions**

Results

The list of subscriptions for the selected topic space is displayed in the content pane. For more information about the list of subscriptions, see Subscriptions [Collection].

Each subscription has a unique subscription identifier that has the form, *clientID##subName* where:

clientID
: The client identifier used to associate a connection and its objects with the messages maintained for applications (as clients of the JMS provider). You should use a naming convention that helps you identify the applications, in case you need to relate subscriptions to the associated applications for runtime administration. For more information about client identifiers, see section 4.3.2 of the JMS 1.1 specification.

subName
: The JMS subscription name used to uniquely identify a durable subscription within a given client identifier. For more information about JMS subscription names, see section 6.11.1 of the JMS 1.1 specification.

What to do next

To display details of a subscription, click the name of the subscription in the list. To delete one or more subscriptions, click the check box next to the subscription names then click **Delete**.

Stopping active subscribers for durable subscriptions

Use this task to enable applications to change a cloned durable subscription. This task enables applications to connect to an existing cloned durable subscription, but specify parameters that differ from those that were used to create the existing subscription.

About this task

When an application connects to an existing durable subscription, but specifies parameters that differ from those that were used to create the existing subscription, **the subscription is deleted then recreated with the new parameters**. A durable subscription can be changed in this way only when it has no active consumers.

To stop active subscribers for one or more durable subscriptions, complete the following steps:

1. Use the administrative console to list the durable subscriptions
2. From the list, identify the client identifier of the durable subscription. The name column lists the unique subscription name for each durable subscription, in the form *clientID##subName* where:

   clientID
   The client identifier used to associate a connection and its objects with the messages maintained for the client by the JMS provider.

   subName
   The name used to uniquely identify a durable subscription within a given client identifier.
3. Use your client identifier naming convention to identify the application assigned to the client identifier.
4. List the applications that have active consumers for the durable subscription. In the navigation pane of the administrative console, click **Applications** → **Application Types** → **WebSphere enterprise applications**.
5. In the console pane, select the check box next to the name of each application that you want to stop.
6. Click **Stop**

Results

This stops the active consumers created by the applications, so applications can reconnect to the durable subscriptions with different parameters from those that were used to create the previous subscriptions.

Deleting durable subscriptions

Use this task to delete a durable subscription.

About this task

To delete one or more durable subscriptions, complete the following steps:

1. Display the durable subscriptions
2. Select the check box for each subscription you want to delete.
3. Click **Delete**

Results

The selected durable subscriptions are deleted.

Mediations

These topics provide information about mediations, which are used to change how messages are handled at destinations on a service integration bus.

- Learning about mediations
- Learning about programming mediations
- Programming mediations
- “Securing mediations” on page 1254
- “Configuring mediations” on page 1256

- “Configuring mediation points” on page 1266
- “Managing mediations with administrative commands” on page 1268
- “Operating mediations at mediation points” on page 1268
- “Administering messages on mediation points” on page 1270
- Message properties support for mediations
- Error handling in mediations
- Mediation thread pool properties

Securing mediations

Use the following tasks to secure mediations at an operations level. For example, a mediation inherits its identity from a the messaging engine, but you might want to specify an alternative identity for the mediation to use.

Configuring an alternative mediation identity for a mediation handler

Use this task to configure an alternative mediation identity for a mediation handler

About this task

By default, a mediation inherits the identity used by the messaging engine. In some cases, you might want to specify an alternative identity for a mediation handler to use. For example, for a single mediation that sends messages to a destination. To do this, you specify a ″run-as″ identity for the mediation handler at deployment, and map the mediation handler to an identity other than the default mediation identity using a role name. Follow the steps below to specify an alternative mediation identity:

1. Package your mediation handler as an EAR file.
2. Edit the deployment descriptor file to define the roles. For more information, see Securing enterprise bean applications using the assembly tools.
3. Assign users to the role. For more information, see Mapping users to RunAs roles using an assembly tool and Assembling secured applications.
4. Deploy the mediation handler in WebSphere Application Server, and assign users to the RunAs role. For more information, see Assigning users to RunAs roles. You can confirm the mappings of users to roles, add new users and groups, and modify existing information during this step. For more information, see Deploying secured applications.

Example

What to do next

Next, you are ready to authorize mediations to access destinations. For more information, see “Administering authorization permissions” on page 1281.

Configuring the bus to access secured mediations

Use this task to ensure that the service integration bus is authorized to access secured mediations.

Before you begin

The mediation is secured using a Java Platform, Enterprise Edition (Java EE) Connector Architecture authentication alias. For information about creating a Java EE authentication alias, refer to Managing J2EE Connector Architecture authentication data entries.

About this task

To configure the bus to access a secured mediation, you must add the mediation authentication alias for the secured mediation to the properties for the bus:

- If the bus has a Version 6.x bus member, you must provide the principal and its associated password.
- If the bus has WebSphere Application Server Version 7.0 bus members only, you need only provide the principal.

1. Log into the navigation pane.
2. Click **Service integration** → **Buses** → ***security_value***. The bus security configuration panel is displayed.
3. In the **Mediations authentication alias** field, select the principal for the mediation, and its associated password if required.
4. Click **OK**.
5. Save your changes to the master configuration.

Results

The selected bus is configured to access secured mediations.

What to do next

You can assign security roles to your mediation handlers to protect them from use by unauthorized users. For more information, see Deploying secured applications.

Configuring a bus to run mediations in a multiple security domain environment

Use this task to configure a secured bus so that it can run mediations successfully on bus members in different security domains.

Before you begin

The secured bus must be configured to use a non-global security domain. For more information about securing buses using multiple security domains, refer to “Securing buses” on page 1272.

About this task

If your bus topology has bus members in different security domains, you can configure the bus to allow mediations to run under the server identity. This means that a mediation can run on any server in any domain. You do not have to add a dedicated user ID for each mediation to the user repository, or maintain a mediation authentication alias.

Use the administrative console to configure a secured bus to run mediations successfully as follows:

1. In the navigation pane, click **Service integration** → **Buses** → ***security_value***. The security settings for the selected bus are displayed.
2. Check the option **Use the Server ID when running mediations**.
3. Click **Apply**.
4. Save your changes to the master configuration.

Results

You have configured the bus to run mediations successfully across servers in multiple security domains.

What to do next

You can use the administrative console to control access to the bus by administering users and groups in the bus connector role.

Configuring mediations

Use the following tasks if you want to modify the behavior of a mediation, control which messages are mediated, or influence how messages are processed.

Installing a mediation into WebSphere Application Server

This task describes how to make a mediation available to destinations on a service integration bus. The mediation is an enterprise application that you can deploy on WebSphere Application Server.

Before you begin

- You have an enterprise application (EAR file) that you can deploy into WebSphere Application Server (base). The EAR file contains a mediation handler enterprise bean. You can use the tooling provided with IBM Rational Application Developer to assemble EAR files.
- For guidance on selecting the target application server for your mediation, see Considerations for installing a mediation.

About this task

In this task, you use the administrative console to install a mediation application into WebSphere Application Server (base). For additional information about installing enterprise applications, see Installing application files with the console. For information about installing a secure mediation handler, see Deploying secured applications.

1. Log into the administrative console.
2. Click **Applications** → **New Application** → **New Enterprise Application**.
3. Prepare to install the mediation handler application:
   a. Specify the file path for the mediation handler application.
   b. Select **Detailed - Show all installation options and parameters**.
   c. Expand **Choose to generate default bindings and mappings**.
   d. Select **Generate default bindings and mappings**.
   e. Click **Next**.
4. Type the name of the mediation handler in the **Application name** field, if not already specified, and click **Next**.
5. Select the target application server where you want to install the modules in the mediation handler application, and click **Next**.
6. Optional: If the panel **Deploy enterprise beans** is displayed, click**Apply**, and then click **Next**.
7. Click **Finish**.
8. Save your changes to the master configuration.

Results

The mediation application is installed on the target WebSphere Application Server.

What to do next

Create the mediation in the administrative console. For more information, see “Defining a mediation.”

Defining a mediation

Use this task to define a mediation in the administrative console.

Before you begin

This task assumes that you have installed your mediation handler module on the WebSphere Application Server server where you intend to use your mediation. For more information, see “Installing a mediation into WebSphere Application Server” on page 1256.

About this task

Defining a mediation in the administrative console makes it available for the administrator to use to mediate destinations.

To define a mediation, use the administrative console to complete the following steps:

1. Display the **Mediations** page. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Mediations**
2. In the content pane, click **New**.
3. Specify the following properties for the mediation:

   Mediation name
   Type a name for the mediation that is unique to the service integration bus. This name is used to identify the mediation for administrative purposes.

   Description
   Optionally, type a description of the behavior of the mediation, taking into account any properties specified for the mediation.

   Handler list name
   Type the handler list name. This is the name used by the programmer who deployed the mediation handler. Handler list names are unique within the WebSphere Application Server administrative cell.

   Global transaction
   Optionally, select this option (setting it to true) if you want to start a global transaction for each message mediated by the mediation. By default, Global transaction is set to false, and a global transaction is not started when a message is mediated.

   Allow concurrent mediation
   Optionally, select this option (setting it to true) if you want to mediate multiple messages at the mediated destination.

   By default, Allow concurrent mediation is set to false, and concurrent mediations are not allowed.

   Note: Do not allow concurrent mediation if message ordering is important.

   Selector
   Optionally, type a message selector to control which messages are mediated by the mediation. The selector operates on the content of the message header. The syntax of the message selector is defined by the JMS specification.

   If the message meets the conditions of the selector, the message is mediated. Otherwise, the message is not mediated.

   Discriminator
   Optionally, type a message discriminator to control which messages are mediated by the mediation. Message discriminators conform to the publish/subscribe topicspace syntax.

   If the message meets the conditions of the discriminator, the message is mediated. Otherwise, the message is not mediated.
4. Click **OK**.
5. Save your changes to the master configuration.

Results

A named mediation is defined for the deployed handler list.

What to do next

Next, you can add the mediation to a destination, see “Mediating a destination” on page 1264.

Deleting a mediation

Use this task to delete a selected mediation in the administrative console.

Before you begin

Before deleting a mediation, you must ensure that it is not in use at a bus destination. You cannot delete a mediation that is in use at a destination; you must first unmediate the destination. For more information, see “Unmediating a destination” on page 1265.

About this task

Deleting a mediation removes it from the administrative console. To delete a mediation, use the administrative console to complete the following steps

1. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Mediations**.
2. Select the mediations that you want to delete.
3. Click **Delete**.
4. Save your changes to the master configuration.

Results

The mediations are deleted.

Configuring mediation properties

Use this task to configure the properties of a mediation in the administrative console.

Before you begin

This task assumes that you have defined a new mediation. For more information, see “Defining a mediation” on page 1256.

About this task

Configuring the properties of a mediation controls how it behaves at run-time. To configure the properties of a selected mediation, use the administrative console to complete the following steps.

1. Display a selected mediation. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Mediations** → ***mediation_name***.
2. Specify the following properties for the mediation:

   Description
   Optionally, type a description of the behavior of the mediation, taking into account any properties specified for the mediation.

   Handler list name
   Type the name of the handler list that was defined when the mediation was deployed. Handler list names start with an uppercase letter, and are unique within the service integration bus.

Global transaction
Optionally, select this option (setting it to true) if you want to start a global transaction for each message mediated by the mediation.

By default, Global transaction is set to false, and a global transaction is not started when a message is mediated.

Allow concurrent mediation
Optionally, select this option (setting it to true) if you want to mediate multiple messages at the mediated destination.

By default, Allow concurrent mediation is set to false, and concurrent mediations are not allowed.

Note: Do not allow concurrent mediation if message ordering is important.

Selector
Optionally, type a message selector to control which messages are mediated by the mediation. The selector operates on the content of the message header. The syntax of the message selector is defined by the JMS specification.

If the message meets the conditions of the selector, the message is mediated. Otherwise, the message is not mediated.

For information about the properties that can be used in selectors, see Message properties support for mediations.

Discriminator
Optionally, type a message discriminator to control which messages are mediated by the mediation. Message discriminators conform to the publish/subscribe topic space syntax.

If the message meets the conditions of the discriminator, the message is mediated. Otherwise, the message is not mediated.

3. Specify any additional properties.
4. Click **OK**.
5. Save your changes to the master configuration.

Results

The configuration properties for the mediation are created.

What to do next

If you want to configure the mediation context information, see “Configuring mediation context properties” on page 1261. To use the configured mediation at a destination, see “Mediating a destination” on page 1264.

Adding mediation context information

Use this task to add a mediation context property for a selected mediation.

Before you begin

The mediation for which you want to add context information must exist in the administrative console. To create a mediation, see “Defining a mediation” on page 1256.

About this task

Mediation context information is used, in addition to the message header information, to determine how a message is processed at run time. New context information is defined by adding a mediation context

property. A destination can also have context properties. If you add a context property for a mediation that has the same name as a destination context property, the property on the destination takes precedence.

You can add the following mediation context properties:

Property name	Description	Value	Additional information
sib:SkipWellFormedCheck	Omits the well formed check that is performed on messages after they have been processed by the mediation.	True or false	This property is overridden by the message delivery option assured persistent. A well formed check is always performed for messages that have the delivery option assured persistent.
sib:GlobalTransactionLPSEnabled	Allows a mediation to contain resources for which Last Participant Support (LPS) is enabled. This enables a one phase commit resource to participate in a global transaction that has two phase commit resources.	True or false	

To add new mediation context information for a selected mediation, use the administrative console to complete the following steps:

1. Display the Context Properties panel for a selected mediation: click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Mediations** → ***mediation_name*** → **[Additional Properties] Context properties**. Any mediation context properties that have already been defined for the selected mediation are displayed.
2. Click **New** in the content pane.
3. Specify the following information for the mediation context property:

   Name Type a name for the mediation context property. You must type the name exactly as it appears in the table above.

   Context type
   Select the type `Boolean` for the mediation context property.

   Context value
   Type `True` to set the property. The value is not case sensitive.
4. Click **OK**.
5. Save your changes to the master configuration.

Results

You have added new mediation context information for the selected mediation.

What to do next

You can repeat this task to add another mediation context property.

Listing mediation context properties

Use this task to list context properties for a selected mediation.

About this task

Mediation context information is used, in addition to the message header information, to determine how a message is processed at run time. The context information is provided by one or more of the following mediation context properties:

Property name	Description	Value	Additional information
sib:SkipWellFormedCheck	Omits the well formed check that is performed on messages after they have been processed by the mediation.	True or false	This property is overridden by the message delivery option assured persistent. A well formed check is always performed for messages that have the delivery option assured persistent.
sib:GlobalTransactionLPSEnabled	Allows a mediation to contain resources for which Last Participant Support (LPS) is enabled. This enables a one phase commit resource to participate in a global transaction that has two phase commit resources.	True or false	

In this task, you use the administrative console to list the mediation context properties for a selected mediation, as follows:

1. Log in to the administrative console.
2. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Mediations** → ***mediation_name*** → **[Additional Properties] Context properties**.

Results

The mediation context properties for the selected mediation are displayed.

What to do next

You can configure or delete the context information, or add a new context property for the selected mediation.

Configuring mediation context properties

Use this task to configure context properties for a selected mediation.

Before you begin

The mediation context property you want to configure must exist in the administrative console. To add a new mediation context property, see “Defining a mediation” on page 1256.

About this task

Mediation context information is used, in addition to the message header information, to determine how a message is processed at run time. By configuring the mediation context properties, you ensure that messages are processed correctly. A destination can also have context properties. If a context property is configured for both a destination and a mediation, with the same name for the property, the property on the destination takes precedence.

You can configure the following mediation context properties:

Property name	Description	Value	Additional information
sib:SkipWellFormedCheck	Omits the well formed check that is performed on messages after they have been processed by the mediation.	True or false	This property is overridden by the message delivery option assured persistent. A well formed check is always performed for messages that have the delivery option assured persistent.

Property name	Description	Value	Additional information
sib:GlobalTransactionLPSEnabled	Allows a mediation to contain resources for which Last Participant Support (LPS) is enabled. This enables a one phase commit resource to participate in a global transaction that has two phase commit resources.	True or false	

To configure an existing mediation context property, use the administrative console to complete the following steps:

1. Display the mediation context property for a selected mediation: click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Mediations** → ***mediation_name*** → **[Additional Properties] Context properties**. The mediation context properties for the selected mediation are displayed.
2. Select the mediation context property you want to configure.
3. Specify the following information for the mediation context property:

   Name Type a name for the mediation context property. You must type the name exactly as it appears in the table above.

   Context type
   Select the type `Boolean` for the mediation context property.

   Context value
   Type a value for the mediation context property: either `True` to set the property, or `False` to unset it. The value is not case sensitive.
4. Click **OK**.
5. Save your changes to the master configuration.

Results

The context property is configured for the selected mediation.

What to do next

You can repeat this task to configure additional mediation context properties.

Deleting mediation context information

Use this task to delete a mediation context property for a selected mediation.

About this task

In this task, you delete a mediation context property. The mediation context information provided by the property is no longer used at runtime to process messages.

You can delete the following mediation context properties:

Property name	Description	Value	Additional information
sib:SkipWellFormedCheck	Omits the well formed check that is performed on messages after they have been processed by the mediation.	True or false	This property is overridden by the message delivery option assured persistent. A well formed check is always performed for messages that have the delivery option assured persistent.

Property name	Description	Value	Additional information
sib:GlobalTransactionLPSEnabled	Allows a mediation to contain resources for which Last Participant Support (LPS) is enabled. This enables a one phase commit resource to participate in a global transaction that has two phase commit resources.	True or false	

To delete mediation context information for a selected mediation, use the administrative console to complete the following steps:

1. Display the Context Properties panel for a selected mediation: click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Mediations** → ***mediation_name*** → **[Additional Properties] Context properties**. The mediation context properties for the selected mediation are displayed.
2. Select the property you want to delete, and click **Delete**.
3. Click **OK**.
4. Save your changes to the master configuration.

Results

Your chosen mediation context property is deleted for the selected mediation.

What to do next

You can repeat this task to delete another mediation context property.

Configuring the mediation thread pool

Use this task to configure the mediation thread pool.

Before you begin

The wsadmin tool must be running. For more information, see Starting the wsadmin scripting client.

About this task

You need to configure the mediation thread pool if you want to change the number of threads used when running mediations concurrently. The maximum size of the thread pool determines the maximum number of messages that can be mediated concurrently for a messaging engine.

The mediations thread pool, attribute name `mediationsThreadPool`, is an attribute of the messaging engine. By default, `mediationsThreadPool` does not exist, and a default thread pool is created and used at run time. In this task, use the wsadmin tool to create a thread pool object, and then modify its properties using JACL, as shown in the examples below:

Note: You use the wsadmin tool from within Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

1. Use this example to create a mediationThreadPool object:

```
AdminConfig.create("ThreadPool" , messagingEngine,
                   [["name" , "stitch.server1-bus2-mediationThreadPool"]] ,
                   "mediationThreadPool")
```

   Note: In this case, the thread pool name is based on the name of the messaging engine. Although it is not required to do this, it makes it easier to find the thread pool name when using Performance Monitoring Infrastructure (PMI).

2. Use this example to modify a mediationThreadPool object:

```
AdminConfig.modify(AdminConfig.showAttribute(messagingEngine,
  "mediationThreadPool"), [["maximumSize" , "10"]])
```

`maximumSize` can contain any of the mediationsThreadPool properties. To add additional parameters, insert [*attribute_name attribute_value*] within the outer brackets ([]).

Note: There is a space between *attribute_name* and *attribute_value*.

Setting tuning properties for a mediation

Use this task to tune a mediation for performance by using the administrative console.

Before you begin

Review the guidance on when it is appropriate to tune a mediation for performance in the topic Guidance for tuning mediations for performance.

About this task

You can set the following tuning property in the administrative console to improve the performance of a mediation:

sib:SkipWellFormedCheck
Whether you want to omit the well formed check that is performed on messages after they have been processed by the mediation. Either true or false.

Note: This property is overridden for messages that have the delivery option assured persistent, and a well formed check is always performed.

To set, or unset, one or more tuning properties for a mediation, use the administrative console to complete the following steps:

1. Display the mediation context information:
   a. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Mediations**.
   b. In the content pane, select the name of the mediation for which you want to configure tuning information.
   c. Click **[Additional Properties] Context information**.
2. In the content pane, click **New**.
3. Type the name of the property in the **Name** field.
4. Select the type `Boolean` in the list box.
5. Type **true** in the **Context Value** field to set the property, or type **false** to unset the property.
6. Click **OK**.
7. Save your changes to the master configuration.

Mediating a destination

Use this task to mediate a selected bus destination.

Before you begin

This task assumes that your mediation is installed and configured on the same bus member as the destination you want to mediate. For more information, see “Defining a mediation” on page 1256.

About this task

mediations

Mediating a destination associates a mediation with a selected bus destination. At run time, the mediation applies some message processing to the messages handled by the bus destination. Note that you can only mediate a destination with a single mediation at a time. You can mediate more than one destination with the same mediation. To mediate a destination, use the administrative console to complete the following steps:

1. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations**. This displays a list of bus destinations.
2. In the content pane, select the bus destination you want to mediate, and click **Mediate**.
3. Select the mediation to associate with the destination, and click **Next**.
4. Select the bus member where the mediation is installed, and click **Next**.
5. Click **Finish** to mediate the destination, or **Previous** to make any changes to your selections.
6. Save your changes to the master configuration.

Results

The destination is mediated, and a mediation point is created for the destination on the bus member.

What to do next

Next, you can configure properties that affect how messages are processed at the mediated destination; for example, whether it runs within a global transaction, or processes multiple messages concurrently. For more information, see “Configuring mediation properties” on page 1258.

Unmediating a destination

Use this task to unmediate a selected bus destination.

Before you begin

Before you start this task, you should consider whether you want to preserve message ordering at the bus destination you intend to unmediate.

About this task

Unmediating a selected bus destination breaks the association between the bus destination and the mediation, and the mediation stops processing messages at the bus destination at run time. This task unmediates a bus destination, and optionally preserves message ordering at the bus destination.

To unmediate a bus destination use the administrative console to complete the following steps:

Note: If you want to preserve message ordering, complete all the following steps. If message ordering is not important, you can omit steps 2 and 4:

1. Display the bus destination you want to unmediate. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations** → ***destination_name***.
2. Optional: If you want to preserve message ordering at the destination, take the following steps:
   a. Clear the **Send Allowed** check box (setting it to false) to stop sending messages to the message points for this destination.
   b. Wait until there are no messages listed for the mediation points.
   c. Stop all the mediation points, and wait for all the mediation points to enter the `stopped` state.
   d. Optional: If it is not already selected, select the bus destination you want to unmediate.
3. Click **Unmediate** to unmediate the destination.
4. Optional: Select the **Send Allowed** check box (setting it to true) to resume sending messages to the mediation points for this destination.

5. Save your changes to the master configuration.

Results

The destination is unmediated, and the mediation point is deleted from the destination.

If you did not preserve message ordering, any messages that remain on the mediation point after you have unmediated the destination are processed as for a non-mediated destination. Messages with an empty forward routing path are placed on the next appropriate message point for the destination. Messages with a non-empty forward routing path are sent to the destination specified in the forward routing path.

The unmediated destination now operates as a non-mediated destination, and new messages are sent to a message point on the destination.

Configuring mediation points

In service integration technologies, messages are held at specialized message points called mediation points before they are processed by a mediation. Use the following tasks to set properties at mediation points to route messages and start and stop mediations:

Configuring a mediation point

This task uses the administrative console to browse or change the configuration properties for a selected mediation point for a selected bus destination.

Before you begin

You must first create a mediation point on a bus destination. For more information, see “Mediating a destination” on page 1264.

About this task

A mediation point is a specialized message point on a bus location where messages are stored and mediated. Configuring the properties of a mediation point enables you to control some aspects of how messages are sent to and received from a bus destination. In this task you use the administrative console to configure the properties for a selected mediation point for a selected bus destination.

Note: You should be aware that the mediation point properties Send allowed and Initial state override the general properties defined for the bus destination.

To browse or change the properties for a selected mediation point, use the administrative console to complete the following steps:

1. Start the administrative console, and click **Service integration** → **Buses** → ***bus_name*** → **[Topology] Messaging engines** → ***engine_name*** → **[Message points] Mediation points** → ***mediation_point_name***. The properties for the selected mediation point are displayed.
2. Optional: Browse or change the following properties for the mediation point:

   Identifier
   The identifier by which this message point is known for administrative purposes. This field is for display purposes only.

   UUID The universal unique identifier assigned to this mediation point for administrative purposes. This field is for display purposes only.

   High message threshold
   The maximum total number of messages that can be placed on this mediation point. This field is for display purposes only.

Send allowed
This property specifies whether or not messages are sent to this mediation point. By default, `True` is selected, and messages are sent to this mediation point. Select `False` to prevent messages from being sent to this mediation point.

Initial state
This property specifies the state of the mediation point when the host messaging engine is started for the first time. Permitted values are `Started` or `Stopped`. The default state is `Started`. The mediation does not start mediating messages until Initial state is `Started`.

Target UUID
The UUID of the bus destination where this mediation point is created. This field is for display purposes only.

3. Click **OK**.
4. Save your changes to the master configuration.

Results

You have browsed or changed the configuation properties for the selected mediation point.

Listing mediation points for a bus destination

Use this task to list mediation points for a selected bus destination.

About this task

This task lists the mediation points for a selected bus destination. You might want to do this, for example, to check that a destination is mediated.

To display a list of mediation points for a bus destination, use the administrative console to complete the following steps:

1. Click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations** → ***destination_name***.
2. Click **[Message Points] Mediation Points**.

Results

All the mediation points for the selected bus destination are displayed.

Listing mediation points for a messaging engine

This task displays a list of mediation points for a selected messaging engine.

About this task

This task uses the administrative console to list all the known mediation points for a selected messaging engine. You can then view the properties for a mediation point, administer messages for a mediation point, or operate mediations at a mediation point.

To list the mediation points for a selected messaging engine, use the administrative console to complete the following steps:

Start the administrative console, and click **Service integration** → **Buses** → ***bus_name*** → **[Topology] Messaging engines** → ***engine_name*** → **[Message points] Mediation points**.

Results

The Mediation points panel displays a list of all the mediation points for the selected messaging engine.

What to do next

You can click the name of a mediation point in the list to work with its properties, administer its messages or operate mediations.

Managing mediations with administrative commands

You can use wsadmin commands to administer service integration technologies mediations. For example you can create, delete and view mediations, configure mediation properties and mediate destinations.

About this task

These commands provide an alternative to using the administrative console.

1. Open a wsadmin command session in local mode For example:

   ```
   wsadmin -conntype none -lang jython
   ```

   Note: The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

2. Type `AdminTask.`*`command`* where *command* is the command format as indicated in the related reference topics. For example:

   ```
   wsadmin>AdminTask.listSIBMediations("-bus abus")
   (cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098217858584)
   (cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098220051588)
   ```

Operating mediations at mediation points

Use these tasks to start, stop and restart mediations at runtime at specialized message points called mediation points.

Before you begin

These tasks assume that mediations are configured in the administrative console. For more information, see “Configuring mediations” on page 1256.

Starting a mediation

Use this task to start a selected mediation at a mediation point.

Before you begin

Before you can start a mediation, it must be associated with a destination. For more information, see “Mediating a destination” on page 1264.

About this task

You start a mediation when you want the mediation to start mediating messages. Starting a mediation, like all runtime operations on mediations, is carried out at a specialized message point on the destination, called a mediation point. A mediations starts operating on messages after the server has started and no new messages are mediated after server shutdown begins.

Note: If you want to ensure that the mediation starts processing a specific message, remove existing messages from the mediation point before you start the mediation. For more information, see “Deleting messages on a mediation point” on page 1270.

To start a mediation, use the administrative console to complete the following steps:

1. List the mediation points.

- To list the mediation points for a bus destination, click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations** → ***destination_name*** → **[Message Points] Mediation points**.
- To list the mediation points for a messaging engine, click **Service integration** → **Buses** → ***bus_name*** → **[Topology] Messaging engines** → ***engine_name*** → **[Message points] Mediation points**.

2. Select the mediation name.
3. Click **Start**.

Results

The mediation starts processing messages mediation point that arrive at the mediation point.

Stopping a mediation

Use this task to stop a selected mediation at a mediation point.

Before you begin

Before you can operate a mediation, it must be associated with a destination. For more information, see "Mediating a destination" on page 1264.

About this task

Stopping a mediation, like all runtime operations on mediations, is carried out at a specialized message point on the destination, called a mediation point. By stopping a mediation, you stop any further messages from being delivered to the mediation point. Messages sent to the destination are held at the pre-mediated part of the destination. The messages are not mediated and are not made available to message consumers until the mediation is restarted. Note that mediations starts operating on messages after the server has started and no new messages are mediated after server shutdown begins.

To stop a selected mediation, use the administrative console to complete the following steps:

1. List the mediation points.
   - To list the mediation points for a bus destination, click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations** → ***destination_name*** → **[Message Points] Mediation points**.
   - To list the mediation points for a messaging engine, click **Service integration** → **Buses** → ***bus_name*** → **[Topology] Messaging engines** → ***engine_name*** → **[Message points] Mediation points**.
2. Select the mediation name.
3. Click **Stop**.

Results

The mediation is stopped at the mediation point. Messages arriving at the mediation point are not processed by the mediation. The messages are stored at the mediation point until the mediation is restarted.

Restarting a mediation that has stopped on error

This topic describes how to restart a mediation that has stopped on error.

About this task

You need to restart a mediation that has stopped on error so that the mediation can continue processing messages. When the mediation is restarted, the mediation resumes mediating messages on the pre-mediated part of the destination.

Changes in the state of a mediation normally occur as the result of operations performed by the administrator. If the state of a mediation moves from `Started` to `Stopped on error`, and you have not stopped it intentionally, you should investigate the cause of the problem, and resolve it before attempting to restart the mediation.

To restart a mediation that has stopped on error, use the administrative console to complete the following steps:

1. List the mediation points.
   - To list the mediation points for a bus destination, click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations** → ***destination_name*** → **[Message Points] Mediation points**.
   - To list the mediation points for a messaging engine, click **Service integration** → **Buses** → ***bus_name*** → **[Topology] Messaging engines** → ***engine_name*** → **[Message points] Mediation points**.
2. In the content pane, select the mediation name.
3. Click the **Runtime** tab.
4. Under **General Properties**, view the information in the **Reason** field.
5. Resolve the problem.
6. Restart the mediation so that it can continue processing messages.

Administering messages on mediation points

Use these tasks to list and delete runtime messages held at mediation points in a service integration bus.

Listing messages at a mediation point

Use this topic to list messages at a mediation point.

About this task

The mediation point is a specialized message point that defines the association between a mediation and a destination. You can browse and delete messages on a mediation point for a selected bus destination or messaging engine.

To display a list of messages on a selected mediation point, use the administrative console to complete the following steps:

1. List the mediation points.
   - To list the mediation points for a bus destination, click **Service integration** → **Buses** → ***bus_name*** → **[Destination resources] Destinations** → ***destination_name*** → **[Message Points] Mediation points**.
   - To list the mediation points for a messaging engine, click **Service integration** → **Buses** → ***bus_name*** → **[Topology] Messaging engines** → ***engine_name*** → **[Message points] Mediation points**.
2. Click the mediation point name. This displays the properties of the mediation point.
3. Click the **Runtime** tab.
4. Click **[Additional Properties] Messages**.

Results

A list of messages on the selected mediation point is displayed in the content pane.

Deleting messages on a mediation point

Use this topic to delete messages that exist on a mediation point for a selected bus destination.

About this task

The mediation point is a specialized message point that defines the association between a mediation and a destination. Like other message points, you can delete messages on a mediation point for a selected bus destination or messaging engine. For example, if you want to preserve message ordering at a destination before it is unmediated, you can delete all the messages at that destination.

1. List the messages at the mediation point. For more information, see “Listing messages at a mediation point” on page 1270.
2. In the content pane, click the check box next to each message you want to delete. Alternatively, select all the messages in the list by clicking **Select All Items**.
3. Click **Delete**.

Results

The selected messages are removed from the destination.

Example: Using mediations to trace, monitor and log messages

The most straightforward use of a mediation is for tracing, monitoring or logging messages that pass through a destination or topics spaces. This type of mediation does not modify the message; it simply extracts information from the message and saves or displays the information elsewhere.

For example, the following mediation handler displays the API message and correlation IDs for each message it is sent:

```
public boolean(MessageContext context)
{
  SIMessageContext   msgCtx  = (SIMessageContext)context;
  SIMediationSession session = msgCtx.getSession();
  SIMessage          msg     = msgCtx.getMessage();
  String             msgId   = msg.getApiMessageId();
  String             corrId  = msg.getCorrelationId();
  String             dest    = session.getDestinationName();

  System.out.println(msgId+" (correlation id="+corrid) is passing through "+dest+".");

  return true;
}
```

Security

This topic is an overview of the tasks for administering messaging security for a service integration bus.

Before you begin

Review the security requirements for the bus. For guidance, see Planning your security requirements.

About this task

Messaging security protects the bus from unauthorized access. By default, messaging security is enabled for the bus. Providing administrative security is also enabled, messaging security enforces a security policy that prevents unauthorized client applications from connecting to the bus, and accessing bus resources. There may be circumstances when you do not require messaging security, for example on a development system. In this case, you can disable messaging security.

You can customize the security configuration for the bus using the administrative console, or wsadmin scripting commands. The security configuration controls the following aspects of bus security:

- Authorizing groups of users in the user registry to perform selected operations on bus destinations.
- The transport policies that maintain the integrity of messages in transit on the bus.
- The use of global, and multiple custom security domains.
- The integrity of links between messaging engines, foreign buses and databases.

Use the following tasks to administer messaging security:
- “Securing buses”
- “Enabling client SSL authentication” on page 1279
- “Adding unique names to the bus authorization policy” on page 1281
- “Administering authorization permissions” on page 1281
- “Administering permitted transports for a bus” on page 1307
- “Securing messages between messaging buses” on page 1311
- “Securing access to a foreign bus” on page 1312
- “Securing links between messaging engines” on page 1313
- “Controlling which foreign buses can link to your bus” on page 1314
- “Securing database access” on page 1314
- “Securing mediations” on page 1254

Securing buses

Securing a service integration bus provides the bus with an authorization policy to prevent unauthorized users from gaining access. If a bus is configured to use multiple security domains, the bus also has a security domain and user realm to further enforce its authorization policy.

Before you begin

- If administrative security for the cell in which the bus resides is not already enabled, you must enable it. The tasks below use an administrative console wizard that detects if administrative security is not enabled, and takes you through the steps to enable it. You need to supply the type of user repository used by the server, and the administrative security username and password.
- If the bus contains a bus member at WebSphere Application Server Version 6.x, you must provide an authentication alias to establish trust between bus members, and to enable the bus to operate securely. The administrative console wizard detects if an authentication alias is required, and prompts you to supply one. If you want to specify a new authentication alias, you must provide a username and password.

About this task

When you secure a bus, consider the following points:

- If you are securing a WebSphere Application Server Version 7.0 bus that contains only Version 7.0 bus members, you can use a non-global security domain for the bus. If the bus has a WebSphere Application Server Version 6.x bus member, or might have a Version 6.x bus member in the future, you must assign the bus to the global security domain.
- If you want to assign the bus to a custom domain, you can select an existing security domain, or create a new one.
- If you assign the bus to a custom domain, you must specify a user realm. You can select an existing user realm, or use the global user realm.

What to do next

- The bus is secured after you restart all the servers that are members of the bus, or in the case of a bus that has bootstrap members, servers for which the SIB service is enabled.
- Use the administrative console to control access to the bus by administering users and groups in the bus connector role.

Disabling bus security

If you do not want to protect the bus from unauthorized access, you can disable messaging security.

Before you begin

- Ensure that there are no indoubt transactions on the messaging engine because incomplete transactions cannot be recovered after the bus security is disabled. For more information, refer to Resolving indoubt transactions.
- Stop all servers on which the SIB Service enabled before you disable bus security. This ensures that the bus security configuration is applied consistently when the servers are restarted. For more information, refer to Stopping an application server.

About this task

Messaging security protects the bus from access by unauthorized client applications. Messaging security is enabled by default, providing administrative security for the cell is enabled. However, there may be circumstances when you do not require messaging security, for example on a development system. In this case, you can use the administrative console to disable messaging security. If you want to re-enable bus security, refer to “Securing buses” on page 1272.

1. In the navigation pane, click **Service integration** → **Buses**. A list of buses is displayed.
2. Find the bus for which you want to disable security, and click **Enabled** in the security column. The security settings for the selected bus are displayed.
3. Clear the checkbox **Enable bus security**.
4. Click **Apply**.
5. Save your changes to the master configuration.

Results

You have disabled security for the selected bus.

What to do next

You must restart the servers. Starting an application server provides more information.

Adding a secured bus

This task uses an administrative console wizard to add a new service integration bus that uses a security domain. A bus can use the global security settings, inherit the security settings that exist at cell level, or use a set of customized settings that are unique to the bus, or shared with another resource.

Before you begin

You must decide which type of security domain to use for the bus. For more information, refer to Planning your security requirements and Messaging security and multiple security domains.

About this task

By default, administrative security for the cell is enabled. If the wizard detects that administrative security is disabled, the wizard prompts you to enable it. You must specify the type of user repository, and the administrative security username and password.

Security settings are held in a security domain. If the bus might contain a WebSphere Application Server Version 6.x bus member, you must select the global domain. You can select any type of domain for a bus that contains only WebSphere Application Server Version 7.0 bus members.

1. Log into the administrative console.
2. Click **Service integration** → **Buses**. A list of buses is displayed.

3. In the content pane, click **New**.
4. Type a name for the new bus. It is advisable to choose bus names that are compatible with the WebSphere MQ queue manager naming restrictions. You cannot change a bus name after a bus is created, so if you need to interoperate with WebSphere MQ in the future, it will be much simpler if you use compatible names. See the topic about WebSphere MQ naming restrictions in the related links.
5. Ensure that the **Bus security** checkbox is checked.
6. Click **Next**. The Bus Security Configuration wizard is launched.
7. Read the Introduction panel, and click **Next**.
8. If administrative security is disabled, follow the instructions in the wizard to select, and configure the appropriate user repository.
9. Click **Next**. A summary of the administrative security settings for the bus is displayed.
10. Review the summary, and click **Finish**. Administrative security for the cell is now enabled.
11. By default, clients are required to use SSL protected transports to ensure data confidentiality and integrity. If you do not want clients to use SSL protected transports, clear the checkbox **Require clients use SSL protected transports** .
12. Select a security domain for the bus. The domain you specify depends on the versions of the bus members. If the bus may contain a Version 6.x bus member, you must select the global domain. If the bus will only contain Version 7.0 bus members, you can select the cell-level or a custom domain. If you select a custom security domain, you must also follow the instructions to specify a user realm.
13. Review the summary of your choices, and click **Finish**.
14. Save your changes to the master configuration.

Results

Administrative security is enabled, and a new bus is created with your chosen security settings.

What to do next

You can now add bus members to the bus.

Securing an existing bus using multiple security domains

You can configure an existing service integration bus so that it uses a security domain other than the default global security domain. Using non-global security domains provides the scope to use multiple security domains. The bus can inherit security settings from the cell, or have a unique security configuration.

Before you begin

- For more information about using security domains, refer to Planning your security requirements and Messaging security and multiple security domains.
- The bus you want to secure must exist in the administrative console. If you want to create a new secured bus, refer to “Adding a secured bus” on page 1140.
- All the bus members must be at WebSphere Application Server Version 7.0; use of multiple security domains is not supported for earlier versions of WebSphere Application Server. If the bus you want to secure has a WebSphere Application Server Version 6.x bus member, refer to “Securing an existing bus using the global security domain” on page 1275.

About this task

This task uses the Bus Security Configuration wizard to secure a selected bus, and assign it to a security domain. If administrative security for the cell is disabled, the wizard prompts you to enable it. You need to know the type of user repository, and the administrative security username and password. If you specify a custom domain, you must also specify a user realm.

1. In the navigation pane, click **Service integration** → **Buses** → ***security_value***. The general properties for the selected bus are displayed.
2. Click **Configure Bus Security** to launch the Bus Security Configuration wizard.
3. Read the Introduction panel, and click **Next**.
4. If administrative security is disabled, follow the instructions to configure the appropriate user repository, and click **Next**.
5. Review the summary of your choices:
   a. If you want to make changes, click **Previous** to return to an earlier panel, and make the changes you require.
   b. Click **Finish** when you are ready to confirm your choices.

   Administrative security for the cell is now enabled.
6. If you do not want clients to use SSL protected transports, clear the checkbox **Require clients use SSL protected transports** . By default, clients are required to use SSL protected transports to ensure data confidentiality and integrity.
7. Select the cell-level or custom security domain for the bus. You can only select a non-global security domain if all the bus members are at Version 7.0.
8. Optional: To create a new custom security domain:
   a. Use the name suggested for the security domain, or type a new one.
   b. Optional: Provide a description of the security domain.
   c. Select a user realm for the domain. You can use the user realm configured in the global security domain, or follow the steps to configure a new user realm.
9. Click **Next**.
10. Review the summary of your choices:
    a. Optional: If you want to make changes, click **Previous** to return to an earlier panel, and make the changes you require.
    b. Click **Finish** to confirm your choices.
11. Save your changes to the master configuration.

Results

You have specified that the selected bus uses a non-global security domain. The security settings configured for the bus are displayed in the updated Bus Security Settings panel. The bus is secured after you restart all the servers that are members of the bus, or in the case of a bus that has bootstrap members, servers for which the SIB service is enabled.

What to do next

You can use the administrative console to control access to the bus by administering users and groups in the bus connector role.

Securing an existing bus using the global security domain

Use this task to secure an existing service integration bus using the global security domain.

Before you begin

- The bus you want to secure must exist in the administrative console. If you want to create a new secured bus, refer to “Adding a secured bus” on page 1140.
- If administrative security for the cell in which the bus resides is disabled, the wizard prompts you to enable it. You need to know the type of user repository, and the administrative security username and password.

- If the service bus contains a bus member at WebSphere Application Server Version 6.x, the wizard prompts you to select an existing authentication alias, or specify a new one. If you want to specify a new authentication alias, you must provide a username and password.

About this task

Use this task if you want to secure a bus that exists already in the administrative console, and you want to use the global (default) security domain. For example, you are securing a Version 7.0 bus that has a bus member at WebSphere Application Server Version 6.x; mixed version buses cannot use multiple security domains.

This task uses an administrative console wizard to guide you through the steps to secure a bus. The following steps are conditional, depending on the bus environment:

- If administrative security for the cell in which the bus resides is disabled, the wizard prompts you to enable administrative security.
- If the bus has a bus member at WebSphere Application Server Version 6.x, the wizard prompts you for an authentication alias to establish trust between bus members, and to enable the bus to operate securely.

Use the administrative console to secure a selected bus using the global security domain as follows:

1. In the navigation pane, click **Service integration** → **Buses** → ***security_value***. The general properties for the selected bus are displayed.
2. Click **Configure Bus Security** to launch the Bus Security Configuration wizard.
3. Read the Introduction panel, and click **Next**. The next step is conditional, depending on whether administrative security is enabled or disabled:
   - If administrative security is disabled, complete all the following steps.
   - If administrative security is already enabled, continue from step 7.
4. Select the appropriate user repository, and click **Next**.
5. Depending on the type of user registry you selected, do one of the following:
   - For a federated repository, specify a username and password for administrative security, and click **Next**.
   - For all other types of repository, follow the wizard prompts, and click **Next**.
6. Review the summary of your choices:
   a. If you want to make changes, click **Previous** to return to an earlier panel, and make the changes you require.
   b. Click **Finish** when you are ready to confirm your choices.

   Administrative security for the cell is now enabled.
7. If you do not want clients to use SSL protected transports, clear the checkbox **Require clients use SSL protected transports** . By default, clients are required to use SSL protected transports to ensure data confidentiality and integrity.
8. Select the global security domain option, and click **Next**.
9. If at least one bus member is at Version 6.x, you must specify an authentication alias. Specify either an existing authentication alias, or create a new one:
   - Select **Specify existing authentication alias**, and select the alias name from the list box.
   - Select **Create a new authentication alias**, type a unique alias name and password.
10. Review the summary of your choices:
    a. Optional: If you want to make changes, click **Previous** to return to an earlier panel, and make the changes you require.
    b. Click **Finish** to confirm your choices.
11. Save your changes to the master configuration.

Results

You have secured the bus using the global security domain. The new security settings for the bus are displayed in the updated Bus Security Settings panel. The bus is secured after you restart all the servers that are members of the bus, or in the case of a bus that has bootstrap members, servers for which the SIB service is enabled.

What to do next

You can use the administrative console to control access to the bus by administering users and groups in the bus connector role.

Configuring bus security using an administrative console panel

Use this task to enable or disable messaging security, and configure security properties for an existing service integration bus.

Before you begin

The bus must exist in the administrative console. If you want to create a new bus, refer to “Adding buses” on page 1140.

About this task

This task uses the Bus Security administrative console panel. You can launch the Bus security wizard from the panel, or specify individual security properties directly in the panel. The bus security properties are effective only when administrative security for the cell is enabled. If the wizard detects that administrative security is disabled, it prompts you to enable it.

The security properties available to a particular bus depend on the versions of the bus members. If the bus has a WebSphere Application Server Version 6.x bus member, you must specify the global security domain. The bus cannot use cell level, or custom security domains. You must also specify an inter-engine authentication alias to prevent unauthenticated messaging engines from establishing a connection with the bus. If the bus contains Version 7.0 bus members only, you can specify any type of security domain, and you do not need to specify an inter-engine or mediation authentication alias.

If you want to run mediations across multiple security domains, you can specify a single server identity for the bus, rather than specify a mediation authentication alias for each domain. You can also use a server identity to run mediations on the global domain.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value***. *security_value* is either `Enabled` or `Disabled`, depending on the security status of the bus.
3. Click **Launch Bus Security Wizard** to launch the wizard, or specify the following properties directly:

   Enable bus security
   Bus security is enabled by default. Clear this check box if you do not want a secure bus. The check box is read-only if administrative security is disabled.

   Inter-engine authentication alias
   The name of the authentication alias used to authorize communication between messaging engines on the bus. Specify an inter-engine authentication alias if the bus has a Version 6.x bus member, bus security is enabled, and you want to prevent unauthorized messaging engines from establishing a connection with the bus.

   Permitted transports
   Specify one of the following transports for the bus:

   - Any messaging transport chain defined to any bus member.

- Only messaging transport chains that are protected by an SSL chain.
- Only the transports specified in the list of permitted transports.

If you want to add and remove permitted transports, click **Service integration** → **Buses** → ***security_value*** → **[Additional Properties] Permitted Transports**.

Use the Server ID when running mediations
Check this option if you want to run mediations using the server identity, instead of using a mediation authentication alias.

Mediations are deployed as applications, and run in the domain used by the application server, not the bus domain. If you want to run a mediation on multiple servers in different domains, you must ensure that the user identity in the mediation authentication alias exists in the configuration for each domain. Alternatively, you can choose to use the server identity option. You can use this option when multiple domains are not in use.

Bus security domain
Specify one of the following security domains for the bus:

Global domain
You must specify the global domain if the bus contains a Version 6.x bus member, or you do not want the bus to use multiple domains.

Cell level domain
Specify the cell-level security domain if the bus has Version 7.0 bus members only, and you want the bus to share security settings with the administrative cell.

Custom domain
Specify a custom security domain if the bus has Version 7.0 bus members only, and you want the bus to use a security domain that is used by another resource, or you want to create a new security configuration for this bus.

4. Save your changes to the master configuration.

Results

You have configured security properties for the selected bus.

What to do next

You can use the administrative console to control access to the bus.

Configuring a bus to run mediations in a multiple security domain environment

Use this task to configure a secured bus so that it can run mediations successfully on bus members in different security domains.

Before you begin

The secured bus must be configured to use a non-global security domain. For more information about securing buses using multiple security domains, refer to “Securing buses” on page 1272.

About this task

If your bus topology has bus members in different security domains, you can configure the bus to allow mediations to run under the server identity. This means that a mediation can run on any server in any domain. You do not have to add a dedicated user ID for each mediation to the user repository, or maintain a mediation authentication alias.

Use the administrative console to configure a secured bus to run mediations successfully as follows:

1. In the navigation pane, click **Service integration** → **Buses** → ***security_value***. The security settings for the selected bus are displayed.
2. Check the option **Use the Server ID when running mediations**.
3. Click **Apply**.
4. Save your changes to the master configuration.

Results

You have configured the bus to run mediations successfully across servers in multiple security domains.

What to do next

You can use the administrative console to control access to the bus by administering users and groups in the bus connector role.

Enabling client SSL authentication

You can configure a service integration bus to allow connecting client JMS applications to authenticate using Secure Sockets Layer (SSL) certificates.

About this task

This is the parent task for the steps required to establish client SSL authentication for connections between messaging engines and JMS applications running in a client container. You need to configure the bus to allow client SSL authentication, and configure the JMS client application to perform client SSL authentication. See the following topics:

- "Configuring a bus to allow client SSL authentication."
- "Configuring JMS client applications to perform client SSL authentication" on page 1280.

Configuring a bus to allow client SSL authentication

This task describes how to configure a service integration bus to enable connecting client JMS applications to authenticate using Secure Sockets Layer (SSL) certificates.

Before you begin

You must ensure that the following tasks have been completed:

- Administrative security is enabled. For more information, see Enabling security.
- A standalone Lightweight Directory Access Protocol (LDAP) user registry has been configured for storing user and group IDs. To access the user registry, you must know a valid user ID that has the administrative role, and password, the server host and port of the registry server, and the base distinguished name (DN). For more information, see Configuring Lightweight Directory Access Protocol user registries.
- Bus security is enabled. For more information, see "Disabling bus security" on page 1273.
- JMS client applications have been configured to authenticate using client SSL certificates.

About this task

If you want to allow connecting JMS application clients to authenticate to the bus using client SSL certificates you need to define an SSL configuration. There are two parts to this task. First you use the administrative console to map SSL certificates to entries in the LDAP user registry. Secondly, you create a unique SSL configuration for each endpoint address for which you want to use client SSL authentication. Do not use the default SSL configuration for the bus.

1. Use the administrative console to define certificate filters to map an SSL certificate to an entry in the LDAP server. For more information, see Creating a Secure Sockets Layer configuration. The client SSL certificate is mapped to a user ID in the user registry.
2. Create a separate SSL configuration file for each endpoint address for server, bus member or cluster on the bus, and select that client authentication is required. For more information, see Creating a Secure Sockets Layer configuration

Results

The bus is configured to allow client SSL authentication.

What to do next

Connecting JMS client applications can now authenticate to the bus using client SSL certificates.

Configuring JMS client applications to perform client SSL authentication

This task describes how to configure JMS client applications to authenticate to the bus using client Secure Sockets Layer (SSL) authentication.

Before you begin

- You have already obtained a Secure Sockets Layer (SSL) certificate for the JMS client application.
- The JMS client application is already configured to use SSL. For more information, see SSL client properties file

About this task

This task has two objectives. First, you install the SSL certificate for the client application in the key store for the application client. Secondly, you modify the sib.client.ssl.properties file to use client SSL authentication. You use the Key Management (iKeyman) utility to work with SSL certificates. The iKeyman user interface is Java-based and uses the Java support that is installed with IBM HTTP Server.

Take the following steps to configure a JMS client application to use client SSL authentication:

1. Start the iKeyman user interface. Refer to the *iKeyman User's Guide* available from IBM developer kits for more information about using iKeyman.
2. When prompted, select the key store for the JMS client application.
3. When prompted for the type off certificate to work with, select the option **Personal certificates**. A list of personal certificates is displayed.
4. Select that you want to import a certificate to the selected key store.
5. When prompted, type the location and name for the certificate. You can provide an alias for the certificate. The certificate is installed into the keystore of the client application.
6. Close the iKeyman user interface.
7. Open a text editor to work with the sib.client.ssl.properties properties file. This file is located in the profile_root/properties directory of the application server installation, where profile_root is the directory in which profile-specific information is stored.
8. Set the value for the property com.ibm.ssl.client.clientAuthentication to *True*.
9. Set the value for the property com.ibm.ssl.client.keyStoreClientAlias to the alias name for the certificate in the client key store.
10. Save the sib.client.ssl.properties properties file.

Results

You have now configured a JMS client application to use client SSL authentication.

Adding unique names to the bus authorization policy

How to update the authorization policy for the service integration bus with unique name entries.

About this task

You should carry out this task if you are migrating from WebSphere Application Server Version 6.x to WebSphere Application Server Version 7.0. In this task, you manually run the populateUniqueNames command to query the user repository for a selected bus for unique names, and add them to the authorization policy. If you do not manually run this command, the messaging engine performs the query, and adds the missing unique names to the authorizations policy, which adversely affects the start up time.

When you migrate from a Version 6.x node to a Version 7.0 node, the authorization policy only contains the user and group security names; it does not contain the names in the user registry that uniquely define each user and group. If an LDAP user registry is in use, the unique name is the distinguished name (DN). By default, only missing unique names are added to the authorization policy. If you set the **-force** parameter, all unique name entries added to the authorization policy

1. Launch a scripting command. For more information, refer to Starting the wsadmin scripting client.
2. At the wsadmin command prompt, type the populateUniquenames command. The following example syntax queries the user repository for the unique names that match the security names for a bus called Bus 1, and adds the missing unique names to the authorization policy .

   ```
   AdminTask.populateUniquenames('[-bus Bus1]')
   ```
3. Save your changes to the master configuration repository. The following example presents the syntax:

   ```
   AdminConfig.save()
   ```

Results

The authorization policy for the bus is updated with the missing unique names.

Example

The following example updates all the unique name entries in the authorization policy for a bus called Bus 1.

```
AdminTask.populateUniqueNames(AdminTask.populateUniquenames('[-bus Bus1 -force TRUE]')
```

What to do next

Use the administrative console to administer bus security authorizations.

Administering authorization permissions

Service integration messaging security uses role-based authorization. When a user is assigned to a role, the user is granted all of the permissions that the role contains. By administering authorization permissions, you can control user access to a bus and its resources when messaging security is enabled.

Before you begin

For guidance on security authorization for a service integration bus, refer to Planning your security requirements.

About this task

When a bus is created, a set of default authorization roles is created. Default roles provide authenticated users who have the bus connector role with full access to all local destinations on the bus. By default, only members of the Server group have the bus connector role. If a specific user needs to connect to the bus, you must explicitly add that user to the bus connector role.

You can make changes to authorization permissions when messaging security is enabled or disabled. Any changes that you make when security is disabled do not have any effect until security is enabled, as described in “Disabling bus security” on page 1273.

Note: When you specify the group authorization permissions, the group distinguished name (DN) must be used. If you specify a common name (CN) for the group name, users in that group do not have the specified authorities. For more details see Standalone Lightweight Directory Access Protocol registries.

When security is enabled, by default users cannot connect to a foreign bus. If a specific user needs to connect to a foreign bus, you must explicitly add that user to the foreign bus access list.

Use the following tasks to administer authorization permissions for a bus to meet your security requirements.
- “Administering the bus connector role”
- “Administering default roles” on page 1285
- “Administering destination roles” on page 1241
- “Administering foreign bus roles” on page 1292
- “Administering topic space root roles” on page 1299
- “Administering topic roles” on page 1302
- Listing security roles for service integration by using the wsadmin tool
- Removing users and groups by using the wsadmin tool
- Removing authorization data by using the wsadmin tool

Administering the bus connector role

Service integration bus security uses role-based authorization. By administering groups of users in the bus connector role, you can control access to the local service integration bus and its resources when messaging security is enabled.

About this task

Adding a group of users to the bus connector role for a local bus grants the members of the group permission to access local bus destinations. The users and groups you want to work with must exist in the user repository.

Use the following tasks to list, add and remove groups of users in the bus connector roles using the administrative console.
- “Listing users and groups in the bus connector role”
- “Adding users and groups in the bus connector role” on page 1283
- “Removing users and groups from the bus connector role” on page 1284

Listing users and groups in the bus connector role:

Service integration bus security uses role-based authorization. By listing the users and groups in the bus connector role, you can find out which users and group members are authorized to connect to a selected secured local bus, and its resources.

Before you begin

Ensure that security is enabled for the bus. For more information, refer to “Securing buses” on page 1272.

About this task

In this task you use the administrative console to list the users and groups in the bus connector role for a selected local bus. By default, the list is empty for a new bus.

1. Log into the administrative console.

2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Users and groups in the bus connector role**.

Results

A list of the users and groups in the bus connector role for the selected bus is displayed. The list is empty for a new bus.

What to do next

You can add and delete users and groups in the bus connector role for the selected bus.

Adding users and groups in the bus connector role:

Service integration bus security uses role-based authorization. By adding users and groups to the bus connector role for a secured bus, you can control which users and group members have access to the bus and its resources.

Before you begin

- Ensure that security is enabled for the bus. For more information, refer to “Securing buses” on page 1272.
- The users and groups that you want to add to the bus connector role must exist already in the user repository.

About this task

Adding users and groups to the bus connector role enables them to connect to the bus to carry out messaging operations. You can add a user directly to the bus connector role, or indirectly by adding a group to which the user belongs. You can also add special groups of users. There are three special groups:

Server
The server identity is a WebSphere Application Server . You cannot specify the Server group for a JMS message-driven bean (MDB).

All Authenticated
This group comprises all user identities that authenticate successfully to the bus.

Everyone
The user identities in this group are anonymous, and connect to the bus without security authentication.

Note:

- If the user registry is an LDAP registry, you must use the group distinguished name (DN) when you specify a group name to add to a bus connector role. Using the common name (CN) causes problems in security authorization. For more information, refer to Service integration bus security: Troubleshooting tips and Standalone Lightweight Directory Access Protocol registries.
- If you attempt to add a user or a group that is already a member of the bus connector role, a warning message is displayed.

In this task you use an administrative console wizard to add groups and users to the bus connector role for a selected local bus.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Users and groups in the bus connector role**. A list of the users and groups already in the bus connector role for the selected bus is displayed. By default, the list is empty for a new bus.

3. Click **New** to launch the Security Resource Wizard.
4. Choose whether you want to add groups or users:
   - If you want to add a special group, select **The built-in special groups** option.
   - If you want to add other groups or users in the user repository, select the appropriate option, and complete the following mandatory fields:

     Search pattern
     Specify a string to match against user IDs or group names in the user repository. Only user IDs or group names that match the search pattern are retrieved, subject to the maximum number of search results. You can specify wildcard characters.

     Maximum number of search results to display
     Specify the maximum number of user IDs or group names to display.
5. Click **Next** to display a list of groups or users.
6. Select the names of the groups or users you want to add to the bus connector role, and click **Next**.
7. Click **Finish** to confirm you choices.
8. Save your changes to the master configuration.

Results

The selected users and groups are added to the bus connector role for the selected bus.

What to do next

You can perform other security administration tasks by using the administrative console.

Removing users and groups from the bus connector role:

Service integration bus security uses role-based authorization. By removing selected users and groups from the bus connector role for a selected secured bus you prevent those users and group members from connecting to the bus.

About this task

The users and groups that you remove from the bus connector role for a bus can no longer perform messaging operations on the bus. Note that removing a user from the bus connector role does not prevent that user from connecting to the bus if they are also a member of a group that is in the bus connector role.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Users and groups in the bus connector role**. A list of the users and groups in the bus connector role for the selected bus is displayed.
3. Select the check box next to the name of the user or group that you want to remove, and click **Delete**.
4. Save your changes to the master configuration.

Results

The selected users and groups are removed from the bus connector role.

What to do next

You can perform other security administration tasks by using the administrative console.

Administering default roles

Service integration bus security uses role-based authorization. By adding a user or a group to the default roles for a secured bus, you can control which users and group members have access to the bus and its resources in the default roles when messaging security is enabled.

About this task

The default roles are sender, receiver, browser, and creator. These roles apply to bus destinations that do not have a destination role, or have been configured to inherit the default roles. By default, all destinations inherit the default roles. Access in the default roles exists in addition to any specific access roles that have been configured for a destination.

Use the following tasks to list, add, and remove groups of users in default roles using the administrative console.

- "Adding users and groups to default roles"
- "Removing users and groups from default roles" on page 1286
- "Listing users and groups in default roles"

Listing users and groups in default roles:

Service integration bus security uses role-based authorization. By listing the users and groups in the default roles for a selected secured bus, you can find out which users and group members are authorized to perform messaging operations on a local bus destinations that is allowed to inherit default roles.

About this task

In this task you use the administrative console to list users and groups in the default access roles for a selected secured bus. The default role types are sender, receiver, browser and creator.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage default access roles**. The Default access roles panel is displayed. The information for the default access is displayed in a collapsed section.
3. Expand the Default access header.

Results

A list of users and groups in default roles for the selected bus is displayed.

What to do next

You can also add and remove users and groups in default roles.

Adding users and groups to default roles:

Service integration bus security uses role-based authorization. By adding selected users and groups to the default roles for all the local bus destinations on a secured bus, you provide those users and group members with access to the local bus destinations that are allowed to inherit default roles.

Before you begin

If a bus destination is not allowed to inherit the default roles, you must first add the user or group to the role that grants authorization permission for the specific local destination. For more information, see "Adding users and groups to destination roles" on page 1241.

About this task

The default roles are sender, receiver, creator and browser. In this task you use an administrative console wizard, the Security wizard, to add selected users or groups to the default roles. The Security wizard requests information to enable it to retrieve selected users or groups from the potentially very large number of users and groups in the user repository.

1. Log onto the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage default access roles**. The Default access roles panel is displayed.
3. Expand the Default access header to list the users and groups that have been assigned to default access roles.
4. Click **Add** to launch the Security wizard. The wizard takes you through the following steps to add selected users or groups to default access roles:
   a. Search for the users or groups that you want to add to default access roles:

      Users or Groups
      Select either **Users** or **Groups** to specify whether you want to grant access roles to users or groups.

      Search pattern
      This field is mandatory. Specify a search string that is matched against user IDs or group names in the user repository. Only user IDs or group names that match the search pattern are retrieved, subject to the maximum number of search results. Wildcard characters are allowed.

      Maximum number of search results to display
      This field is mandatory. Specify the maximum number of user IDs or group names you want the administrative console to display.

   b. Click **Next**. The wizard displays the users or groups in the user repository that match the information that you provided in the previous step.
   c. Select the check boxes next to the user IDs or group names that you want to add to the default access roles, and click **Next**. A list of user IDs or group names that you can add to the default access roles is displayed. Note that some users or groups may already be assigned to default access roles.
   d. Select the role types that you want to assign to a user or group. For example, to assign a group to the sender role, click the sender icon for the appropriate group name. The icon changes from  to  to show that you have added the user or group to the access role for the resource.
   e. Complete the previous step for each user or group that you want to add to access roles, and then click **Next**. A summary of your role type assignments is displayed.
   f. Click **Previous** to review and change your assignments, if required.
   g. Click **Finish** to confirm your assignments. The Default access roles panel is redisplayed and shows the new role type assignments.
5. Save your changes to the master configuration.

Results

The selected users and groups are added to selected default roles for the selected bus.

What to do next

You can perform other security administration tasks by using the administrative console.

Removing users and groups from default roles:

Service integration bus security uses role-based authorization. By removing selected users and groups from the default roles for a selected secured bus, you prevent those users and group members from accessing the bus using the default roles.

About this task

When you remove users and groups from the default roles for a bus, they can no longer access local bus destinations that inherit default access permissions. Note that removing a user from the default roles does not prevent that user from accessing the bus if they are also a member of a group that has been assigned to the default roles for that bus.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage default access roles**. The Default access roles panel is displayed.
3. Expand the Default access header to list the users and groups that have been assigned to default access roles for the selected bus.
4. Select the users and groups that you want to remove from the default access roles for this bus, and click **Remove**.
5. Save your changes to the master configuration.

Results

The selected users and groups are removed from the default roles for the selected bus. The Default access roles panel displays the changes to the default access role assignments.

What to do next

You can perform other security administration tasks by using the administrative console.

Administering destination roles

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups must have authority to perform messaging operations, at a bus destination. By administering destination roles, you can control which users and groups can perform operations at a bus destination, and the type of operation that they can perform.

About this task

You use the administrative console to administer users and groups in access roles for a destination. The access roles available for a destination depend on the type of destination. The table below lists the roles that you can assign for each destination type:

Destination type	Access roles
queue	sender, receiver, browser, creator
port	sender, receiver, browser, creator
webService	sender, receiver, browser, creator
topicSpace	sender, receiver
foreignDestination	sender
alias	sender, receiver, browser

In addition to controlling which users and groups have access to a specific local or foreign destination, you can also control the inheritance of access roles for a specific local destination. In this case, the default access roles that apply to all the destinations in the local bus namespace are added to any access roles that have been added for a specific destination.

Use the following tasks to administer destination roles.
- Listing users and groups in bus destination roles by using the wsadmin tool
- Adding users and groups to bus destination roles by using the wsadmin tool
- Removing users and groups from bus destination roles by using the wsadmin tool
- Defining destination defaults inheritance by using the wsadmin tool
- Determining destination defaults inheritance by using the wsadmin tool

Listing users and groups in destination roles:

Service integration bus security uses role-based authorization. By listing the users and groups in the destination roles for a selected secured bus, you can find out which users and groups are authorized to access the bus, and its resources.

About this task

In this task you use the administrative console to list all the users and groups in destination roles for selected destinations. The list includes users and groups that have references in the service integration role-based configuration; it does not include all the users and groups that exist in the user repository. The permitted destination roles are sender, receiver, browser and creator, depending on the destination type. Icons are used in the administrative console to represent the roles to which users and groups have been assigned. For example, if the role type set icon () is displayed in the sender role for a group called Group 1, it means that Group 1 has been assigned to the sender role for a selected destination. For a complete description of all the icons used to represent role assignments in the administrative console, refer to Access role assignments for bus security resources.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage destination access roles**. The Destinations panel lists all the destinations defined for the selected bus.
3. Select one or more destinations to work with:
   - Click the name of a single destination.
   - Select the check boxes next to multiple destinations, and click **Manage Access Roles**.

   The Destination access roles panel is displayed. The information for each selected destination is displayed in a collapsed section.
4. Expand a destination header.

Results

The Destination access roles panel lists the users and groups in access roles for the expanded destination.

What to do next

You can now administer the users and groups in destination roles at this destination.

Adding users and groups to destination roles:

Service integration bus security uses role-based authorization. By adding users and groups to the destination roles for a secured bus, you can control which users and group members can perform messaging operations at a bus destination.

Before you begin

Ensure that the following conditions are met:
- Security is enabled for the bus. For more information, refer to “Securing buses” on page 1272.

- The users and groups that you want to add to destination roles must exist already in the user repository.

About this task

By adding users or groups to destination role, you grants the users or groups authority to perform the operation defined by the role at a selected destination. The destination roles are sender, receiver, browser, and creator, depending on the destination type.

In this task you use the administrative console Security wizard to retrieve selected users or groups from the user repository, and add them to destination roles for selected bus destinations.

Note: To add a large number of users to destination roles, it is advisable to create a group in the user repository, and add the group to the destination roles.

1. Start the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage destination access roles**. A list of the destinations defined for the selected bus is displayed in the Destinations panel.
3. Select one or more destination to work with:
   - Click a single destination name.
   - Select the check boxes next to multiple destination names, and then click **Manage Access Roles**.

   The Destination access roles panel is displayed. The information for each destination you have selected is displayed in a collapsed section.
4. Expand a destination header to list the users and groups that have been assigned to roles for this destination. You can verify that the user or group you want to add does not already have a role at this destination.
5. Click **Add** to launch the Security wizard. The wizard takes you through the following steps to add selected users or groups to access roles for the expanded destination:
   a. Search for the users or groups that you want to add to access roles for the expanded destination:

      Users or Groups
      Select either **Users** or **Groups** to specify whether you want to grant access roles to users or groups.

      Search pattern
      This field is mandatory. Specify a search string that is matched against user IDs or group names in the user repository. Only user IDs or group names that match the search pattern are retrieved, subject to the maximum number of search results. Wildcard characters are allowed.

      Maximum number of search results to display
      This field is mandatory. Specify the maximum number of user IDs or group names you want the administrative console to display.

   b. Click **Next**. The wizard displays the users or groups in the user repository that match the information that you provided in the previous step.
   c. Select the check boxes next to the user IDs or group names that you want to add to access roles for the currently expanded destination, and click **Next**. A list of user IDs or group names that you can add to destination roles is displayed. Note that some users or groups may already be assigned to access roles for this destination.
   d. Select the appropriate access role icon for the user ID or group name that you want to add to the role at this destination. For example, select the **Receiver** icon for a user ID or group name that you want to add to the receiver role. The icon changes from  to  to show that you have added the user or group to the access role for the resource.
   e. Repeat the previous step to add more users or groups to access roles for the currently expanded destination, and then click **Next**. A summary of your access role assignments is displayed.

f. Click **Previous** to review and change your assignments, if required.
g. Click **Finish** to confirm your assignments.

6. Repeat steps 4 and 5 for each destination you want to work with.
7. Save your changes to the master configuration.

Results

The selected users and groups are added to the access roles for the currently expanded destination. The new access role assignments are displayed in the Destination access roles panel.

Example

A group called MyGroup receives messages from three queues, Queue 1, Queue 2, and Queue 3. If you want the group MyGroup to produce and consume messages at an additional destination, Queue 4, you add MyGroup to Queue 4, and then add MyGroup to the sender and receiver roles for Queue 4.

What to do next

Use the administrative console to perform other security administrative tasks.

Removing users and groups from destination roles:

Service integration bus security uses role-based authorization. By removing users and groups from the destination roles for a secured bus, you can prevent those users and group members from performing messaging operations on the bus.

About this task

When selected users and groups no longer require access to a destination, you can remove them from all the roles for that destination.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage destination access roles** A list of the destinations defined for the selected bus is displayed in the Destinations panel.
3. Select one or more destinations to work with:
   - Click a single destination name.
   - Select the check boxes next to multiple destination names, and then click **Manage Access Roles**.

   The Destination access roles panel is displayed. The information for each destination you have selected is displayed in a collapsed section.
4. Expand a destination header to list the users and groups that have been assigned to roles at this destination, and verify that the user or group that you want to remove has a role at this destination.
5. Select the users and groups that you want to remove from all role types at this destination, and click **Remove**.
6. Save your changes to the master configuration.

Results

The selected users and groups are removed from all role types at the selected destination. The Manage access roles for users and groups panel displays the updated role type assignments.

Example

The members of three groups, Group A, Group B, and Group C, belong to the sender role and the receiver role for two queue destination, Queue 1 and Queue 2. If Group B is no longer required to send and receive messages on Queue 2, you can use this task to remove Group B from all the role types on Queue 2.

What to do next

You can perform other security administration tasks by using the administrative console.

Enabling topic role inheritance:

Service integration bus security uses role-based authorization. When messaging security, and topic level security are enabled, and users and groups require access in the sender and receiver roles to access a topic in a publish/subscribe topic hierarchy. By default, topics inherit these roles from the parent topic. If topic role inheritance has been disabled for a particular topic, you can restore it by using the administrative console.

Before you begin

You must ensure that the following conditions are met:

- Messaging security is enabled. For more information, refer to “Disabling bus security” on page 1273.
- Topic level security is enabled for the topic space. Check the setting **Topic Access Check Required?** in the topic space destination configuration. For more information, refer to “Configuring bus destination properties” on page 1230.

About this task

In this task you use the administrative console to restore topic role inheritance for selected topics. A topic can only inherit the sender and receiver roles from the parent topic in the topic hierarchy.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage topic access roles** → ***topic_space_name*** → ***topic_name***. The Topic access roles panel lists users and groups that have been assigned role types for the selected topic.
3. Expand the topic name header to display details of the users and groups that have one or more access roles for this topic.
4. Select the **Inherit sender role from parent topic** check box.
5. Select the **Inherit receiver role from parent topic** check box.
6. Click **OK** to save your changes.
7. Save your changes to the master configuration.

Results

The select topic inherits access roles from the parent topic. The Topic access roles panel displays the inherited access roles for the topic.

What to do next

You can perform other security administration tasks by using the administrative console.

Disabling topic role inheritance:

Service integration bus security uses role-based authorization. When messaging security, and topic level security are enabled, users and groups require access in the sender and receiver roles to access a topic in a publish/subscribe topic hierarchy. By default, topics inherit these roles from the parent topic. If you do not want topics to inherit topic roles from the parent topic in the topic hierarchy, you can override topic role inheritance by using the administrative console.

Before you begin

About this task

In this task you use the administrative console to prevent a selected topic from inheriting authorization roles from its parent topic.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage topic access roles** → ***topic_space_name*** → ***topic_name***. The Topic access roles panel lists users and groups that have been assigned role types for the selected topic.
3. Expand the topic name header to display details of the users and groups that have access one or more access roles for the selected topic.
4. Clear the **Inherit sender role from parent topic** check box.
5. Clear the **Inherit receiver role from parent topic** check box.
6. Click **OK** to save your changes.
7. Save your changes to the master configuration.

Results

The selected topic cannot inherit access roles from its parent topic. The Topic access roles panel displays the changed access roles for the selected topic.

What to do next

You can perform other security administration tasks by using the administrative console.

Administering foreign bus roles

Service integration bus security uses role-based authorization. When messaging security is enabled, groups of users require authority to send messages from a local bus destination to a foreign bus. By listing, adding and removing users and groups in foreign bus roles, you can control who can send messages to foreign buses.

Before you begin

These tasks assumes that one or more foreign bus connections have been configured. For more information, refer to “Configuring foreign bus connections” on page 1155.

About this task

The foreign bus connection represents another service integration bus. The bus is either in the same cell as the local bus, or in a different cell, or it represents a WebSphere® MQ queue manager. From the local bus, every other bus is regarded as a foreign bus, even if it is a bus in the same cell. Messages route to a foreign bus either directly through a link between the local bus and the foreign bus, or indirectly through one or more intermediate buses. A member of a group that belongs to the sender role on the local bus and the foreign bus can send messages directly to the foreign bus. The sender role is the only foreign bus role.

For more information about how to list, add and remove groups of users in foreign bus roles using the administrative console, refer to the following tasks.
- "Adding users and groups to foreign bus roles"
- "Removing users and groups from foreign bus roles" on page 1295
- "Listing users and groups in foreign bus roles"

Listing users and groups in foreign bus roles:

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups require authority to send messages from a secured local bus destination to a secured foreign bus. By listing all the users and groups in foreign bus roles for a selected foreign bus, you can find out who has authority to send messages from the local bus to the selected foreign bus.

About this task

In this task you use the administrative console to list users and groups in the sender role for selected foreign buses. The list includes users and groups that have references in the service integration role-based configuration. It does not include all the users and groups that exist in the external user repository.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage foreign bus access roles**. A list of all the foreign buses defined for the selected bus is displayed.
3. Select one or more foreign buses:
   - Click the name of a single foreign bus.
   - Select the check boxes next to multiple foreign buses and click **Manage Access Roles**.

   The Foreign bus access roles panel is displayed. The access roles information for each foreign bus is displayed in a collapsible section.
4. Expand the section header for a foreign bus.

Results

A list of all the users and groups that have been assigned to the sender role for the currently expanded foreign bus is displayed.

What to do next

You can add and remove users and groups in the sender role for the selected foreign bus.

Adding users and groups to foreign bus roles:

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups require authority to send messages from a secured local bus destination to a secured foreign bus. By adding selected users and groups to the sender role for a selected foreign bus, you can control who has authority to send messages to the selected foreign bus.

Before you begin

This task assumes that the following conditions have been met:
- One or more foreign bus connections have been configured for the local bus. For more information, refer to "Configuring foreign bus connections" on page 1155.
- The users and groups that you want to add to foreign bus roles must exist in the user repository.

About this task

By default, when security is enabled, users and groups cannot send messages to a foreign bus. You need to add them to the sender role for the foreign bus. In this task you uses an administrative console wizard to select one or more foreign buses, retrieve selected users or groups from the potentially very large number of users and groups in the user repository, and add them to the sender role for the selected foreign buses.

1. Start the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage foreign bus access roles**. A list of the foreign buses defined for the selected bus is displayed in the Foreign buses panel.
3. Select one or more foreign buses to work with:
   - Click a single foreign bus name.
   - Select the check boxes next to multiple foreign bus names, and then click **Manage Access Roles**.

   The Foreign bus access roles panel is displayed. The access roles information for each foreign bus you have selected is displayed in a collapsed section.
4. Expand a foreign bus header to list the users and groups that have been assigned to roles for this foreign bus. You can verify that the user or group you want to add does not already have a role for this foreign bus.
5. Click **Add** to launch the Security wizard. The wizard takes you through the following steps to add selected users or groups to the sender role for the selected foreign bus:
   a. Search for the users or groups that you want to add to the sender role for the expanded foreign bus:

      Users or Groups
      Select either **Users** or **Groups** to specify whether you want to grant access roles to users or groups.

      Search pattern
      This field is mandatory. Specify a search string that is matched against user IDs or group names in the user repository. Only user IDs or group names that match the search pattern are retrieved, subject to the maximum number of search results. Wildcard characters are allowed.

      Maximum number of search results to display
      This field is mandatory. Specify the maximum number of user IDs or group names you want the administrative console to display.

   b. Click **Next**. The wizard displays the users or groups in the user repository that match the information that you provided in the previous step.
   c. Select the check boxes next to the user IDs or group names that you want to add to the sender role for the currently expanded foreign bus, and click **Next**. A list of users IDs or group names that you can add to the sender role is displayed. Note that some users or groups may already be assigned to the sender role for this foreign bus.
   d. Select the **Sender** icon for a user ID or group name that you want to add to the sender role. The icon changes from  to  to show that you have added the user or group to the access role for the resource.
   e. Repeat the previous step for each user or group you want to add to the sender role, and then click **Next**. A summary of your role assignments is displayed.
   f. Click **Previous** to review and change your assignments, if required.
   g. Click **Finish** to confirm your assignments.
6. Save your changes to the master configuration.

Results

The selected users and groups are added to the sender role for the selected foreign bus. The new access roles are displayed in the Foreign bus access roles panel.

What to do next

You can perform other security administration tasks by using the administrative console.

Removing users and groups from foreign bus roles:

Service integration bus security uses role-based authorization. By removing users and groups from the foreign bus roles for a selected secured local bus, you prevent those users and groups from sending messages to the foreign bus.

About this task

In this task you use the administrative console to remove selected users or groups from the sender role for a selected foreign bus.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage foreign bus access roles**. A list of all the foreign buses defined for the selected bus is displayed.
3. Select one or more foreign buses to work with:
   - Click a single foreign bus name.
   - Select the check boxes next to multiple foreign bus names, and then click **Manage Access Roles**.

   The Foreign bus access roles panel is displayed. The access roles information for each selected foreign bus is displayed in a collapsed section.
4. Expand the section header for a foreign bus to display details for all the users and groups that have the sender role for this foreign bus.
5. Select the users and groups that you want to remove from the sender role, and click **Remove**. The selected users and groups are removed from the sender role for this foreign bus.
6. Save your changes to the master configuration.

Results

The selected users and groups are removed from the sender role for the selected foreign bus. The Foreign bus access roles panel displays the changed access role assignments.

What to do next

You can perform other security administration tasks by using the administrative console.

Administering temporary destination prefix roles

Service integration bus security uses role-based authorization. A temporary destination prefix can have two role types: creator and sender. The messaging engine uses the temporary destination prefix at runtime to determine which users and groups have authority to create a temporary destination, and send messages to temporary destinations. By administering temporary destination prefix roles for a bus, you control which users and groups can create and send messages to temporary destinations for a selected bus.

Before you begin

Ensure that security is enabled for the bus. For more information, refer to “Securing buses” on page 1272.

About this task

By default, a bus does not contain any temporary destination prefixes. You use the administrative console to add a new temporary destination prefix to the bus, and then assign selected users and groups to the sender role for the new temporary destination prefix. The creator role is assigned by default. All authenticated users can create temporary destinations by default. You can remove selected users and groups from the sender role for a selected temporary destination prefix, and you can remove a selected temporary destination prefix.

Use the following tasks to administer temporary destination prefix roles.
- "Adding users and groups to temporary destination prefix roles"
- "Removing users and groups from temporary destination prefix roles" on page 1298
- "Listing users and groups in temporary destination prefix roles"
- "Removing a temporary destination prefix" on page 1298

Listing users and groups in temporary destination prefix roles:

Service integration bus security uses role-based authorization. Temporary destination prefix roles are used to authorize access to the temporary destinations for a bus. By listing the users and groups in the temporary destination prefix roles for a selected bus, you can find out which users and groups can create temporary destinations, and send messages to temporary destinations for a selected bus.

About this task

In this task you use the administrative console to list users and groups in temporary destination prefix roles for the selected bus. The list includes users and groups that have references in the role-based security configuration for service integration. It does not include all the users and groups that exist in the external user repository.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage temporary destination prefix access roles**. The Temporary destination prefixes panel lists all the temporary destination prefixes defined on the bus.
3. Select one or more temporary destination prefixes to work with:
   - Click the name of a single temporary destination prefix.
   - Select the check boxes next to multiple temporary destination prefixes, and click **Manage Access Roles**.

   The Temporary destination prefix access roles panel is displayed. The access roles information for each temporary destination prefix is displayed in a collapsed section.
4. Expand the header for a selected temporary destination prefix to show its access roles.

Results

The expanded section lists the users, groups and group members that are assigned to access roles for the selected temporary destination prefix.

What to do next

You can now administer the users and groups in the sender role for a selected temporary destination prefix.

Adding users and groups to temporary destination prefix roles:

Service integration bus security uses role-based authorization. The messaging engine uses the temporary destination prefix at runtime to determine whether a client application is authorize to create, or send

messages to a particular temporary destination. By adding users and groups to temporary destination prefix roles for a selected bus, you can control which users and groups can create temporary destinations, and send messages to them.

Before you begin

The users and groups that you want to add to temporary destination prefix roles must already exist in the user repository.

About this task

By default, the bus security configuration does not contain any temporary destination prefixes. In this task, you use the administrative console Security wizard to first add a new temporary destination prefix, and then add users and groups to the sender role for the new temporary destination prefix. Note that the creator role is assigned by default to the creator of the temporary destination; you cannot use the administrative console to add users and groups to the creator role. By default, members of the All Authenticated group have authority in the creator role for temporary destination prefixes.

1. Log into the administrative console. The Temporary destination prefixes panel lists all the temporary destination prefixes defined for the selected bus. By default, this list is empty.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage temporary destination prefix access roles**
3. Click **Add** to launch the Security wizard:
   a. Define the name of the temporary destination prefix, and identify the users or groups that you want to add to the sender role for the temporary destination prefix:

      Resource
      This field is mandatory. Specify a name for the new temporary destination prefix.

      Users or Groups
      Select either **Users** or **Groups** to specify whether you want to grant access roles to users or groups.

      Search pattern
      This field is mandatory. Specify a search string that is matched against user identities or group names in the user repository. Only user identities or group names that match the search pattern are retrieved, subject to the maximum number of search results. Wild card characters are allowed.

      Maximum number of search results to display
      This field is mandatory. Specify the maximum number of user identities or group names you want the administrative console to display.

   b. Click **Next**. The wizard displays the users or groups in the user repository that match the information that you provided in the previous step.
   c. Select the check boxes for the user identities or group names that you want to assign to the sender role for the temporary destination prefix, and click **Next**. Note that you cannot assign users and groups to the creator role; it is assigned by default.
   d. Select the **Sender** icon for each user identity or group name that you want to add to the sender role. The icon changes from  to  to show that you have added the user or group to the access role for the resource.
   e. Click **Next**. A summary of your role type assignments is displayed.
   f. Click **Previous** to review and change your role type assignments. Make your changes on the Select role types page, and then click **Next**. Note that you cannot change the name of the temporary destination prefix.
   g. Click **Finish** to confirm your assignments. The role type assignments are saved to the master configuration, and the new assignments are displayed in the Temporary destination prefixes panel.

4. Save your changes to the master configuration.

Results

The selected users, groups, and group members are added to the sender role for the selected temporary destination prefix roles. The Manage access roles panel displays the new access roles.

What to do next

You can perform other security administration tasks by using the administrative console.

Removing users and groups from temporary destination prefix roles:

Service integration bus security uses role-based authorization. When security is enabled, a temporary destination prefix role is used to authorize access to temporary destinations. The temporary destination prefix is used at runtime to create temporary destinations on the bus. By removing users and groups from temporary destination prefix roles for a selected bus, you can prevent selected users and groups from sending messages to temporary destinations on the bus.

About this task

In this task you use the administrative console to remove users, groups, and group members from the sender role for selected temporary destination prefixes. Note that you cannot use this task to remove users and groups from the creator role. If you want to remove the creator role from a user or group, refer to "Removing a temporary destination prefix."

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage temporary destination prefix access roles** The Temporary destination prefixes panel lists all the temporary destination prefixes defined for the selected bus.
3. Select one or more temporary destination prefixes to work with:
   - Click the name of a single temporary destination prefixes.
   - Select the check boxes next to multiple temporary destination prefixes, and click Manage Access Roles.

   The Temporary destination prefix access roles panel is displayed. The access roles information for each temporary destination prefix is displayed in a collapsed section.
4. Expand the header for a selected resource to show its role type assignments.
5. Select the users and groups that you want to remove from the sender role for the currently selected temporary destination prefix, and click **Remove**.
6. Save your changes to the master configuration.

Results

The selected users, groups, and group members are removed from the sender role for the selected temporary destination prefix. The Temporary destination prefix access roles panel is updated to show the changes to the access role assignments.

What to do next

You can perform other security administration tasks by using the administrative console.

Removing a temporary destination prefix:

A temporary destination prefix is used by the service integration bus security model to determine what operations the creator of the temporary destination can perform. By removing a temporary destination prefix, you remove the creator role from the identity of the user that created the temporary destination.

About this task

A temporary destination prefix can have two authorization role types: creator and sender. In this task you use the administrative console to remove a selected temporary destination prefix from a selected bus, which removes the creator role from the user identity that created the temporary destination.

If you want to remove users and groups from the sender role for a temporary destination prefix, refer to "Removing users and groups from temporary destination prefix roles" on page 1298.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage temporary destination prefix access roles** The Temporary destination prefixes panel lists all the temporary destination prefixes defined for the selected bus.
3. Select the temporary destination prefix you want to remove.
4. Click **Remove**.
5. Save your changes to the master configuration.

Results

The selected temporary destination prefix is removed, and the creator role is removed from the user identity that created the temporary destination.

What to do next

You can perform other security administration tasks by using the administrative console.

Administering topic space root roles

Service integration bus security uses role-based authorization. When messaging security is enabled, groups of users require authority to send and receive messages from the topic space root in a publish/subscribe topic hierarchy. By adding and removing users and groups in topic space root roles, you can control access to the topic space root.

About this task

Topic space root (/) is also called the virtual root, and it is the highest level topic in a publish/subscribe topic hierarchy. The hierarchy itself is called the topic space, and it is a type of destination. Note that these tasks apply only to the topic space root; they do not apply to topics or a topic space. For information about administering topic access roles, refer to "Administering topic roles" on page 1302, and for information about administering topic space access roles, refer to "Administering destination roles" on page 1241.

You can add and remove users and groups in the sender and receiver roles for the topic space root. The topic space root can also inherit access in the sender and receiver roles from the topic space, providing the topic space is configured to inherit the default destination roles. For more information about topic inheritance, refer to Topic security.

For the topic space root roles to have an effect, the **Topic Access Check Required** checkbox must be set in the topic space configuration. For more information, refer to "Configuring bus destination properties" on page 1230.

Use the following tasks to list, add and remove users and groups in the topic space root roles using the administrative console.

- "Listing users and groups in topic space root roles" on page 1300

- “Adding users and groups to topic space root roles”
- “Removing users and groups from topic space root roles” on page 1302

Listing users and groups in topic space root roles:

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups require authority to send and receive messages from the topic space root in a publish/subscribe topic hierarchy. By listing the users and groups in topic space root roles, you can find out who has access to the topic space root for a selected topic space.

About this task

Topic space root (/) is the highest level topic in a publish/subscribe topic hierarchy. The hierarchy itself is called the topic space. In this task you use the administrative console wizard to list users and groups in topic space root roles for a selected root topic.

This task applies to the topic space root only; it does not apply to the topics within the topic space, or to the topic space. If you want to list users and groups in topic roles, refer to “Listing users and groups in topic roles” on page 1303. If you want to list users and groups in a topic space (which is a type of destination), refer to “Listing users and groups in destination roles” on page 1244.

The users and groups listed in this task have references in the service integration bus security configuration. The list does not include all users and groups that exist in the external user repository.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage topic access roles**

Results

The Topic space root panel lists all the users and groups in topic space root roles for the selected bus.

What to do next

You can administer the role type assignments for the users and groups displayed.

Adding users and groups to topic space root roles:

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups require authority to send and receive messages from the topic space root in a publish/subscribe topic hierarchy. By adding users and groups to topic space root roles, you control access to the root topic in a selected topic space.

Before you begin

- The users and groups you want to add to topic space root roles must exist in the user repository.
- Topic space root roles are effective only when the **Topic Access Check Required** setting is enabled in the configuration for a topic space. For more information, refer to “Configuring bus destination properties” on page 1230.

About this task

Topic space root (/) is the highest level topic in a publish/subscribe topic hierarchy. The hierarchy itself is called the topic space. Note that this task applies only to the topic space root; it does not apply to adding users and groups to topics or a topic space. For information about adding users and groups to topic access roles, refer to “Adding users and groups to topic roles” on page 1303, and for adding users and groups to topic space access roles, refer to “Adding users and groups to destination roles” on page 1241.

You can add users and groups to the sender and receiver roles for the topic space root. The topic space root can also inherit access in the sender and receiver roles from the topic space, providing the topic space is configured to inherit the default destination roles. For more information about topic inheritance, refer to Topic security.

By default, a topic space does not contain a root topic. In this task you use an administrative console wizard to add a root topic to an existing topic space, retrieve the users and groups from the user repository that you want to assign to roles on the new root topic, and add them to the root topic.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage topic access roles**. The Topic spaces panel lists the topic spaces defined on the selected bus.
3. Select the name of the topic space where you want to add a new root topic. The Topics panel displays the selected topic space in a collapsible section.
4. Click **Add** to launch the Security wizard:
   a. Identify the users or groups that you want to add to the sender and receiver roles for the new root topic:

      Users or Groups
      Select either **Users** or **Groups** to specify whether you want to grant roles to users or groups.

      Search pattern
      This field is mandatory. Specify a search string that is matched against user IDs or group names in the user repository. Only user IDs or group names that match the search pattern are retrieved, subject to the maximum number of search results. You can use wildcard characters in the search string.

      Maximum number of search results to display
      This field is mandatory. Specify the maximum number of user IDs or group names that you want the administrative console to display.

   b. Click **Next**. The wizard displays the new root topic, and lists the users IDs or group names in the user repository that match the information that you provided in the previous step.
   c. Select the check boxes next to the user IDs or group names that you want to assign to roles on the new root topic.
   d. Click **Next**. The wizard displays the topic role types that you can assign for the users or groups you selected in the previous step. Role types might already have been assigned for a specific user or group.
   e. Select the role types for the selected users or groups. For example, to assign a user to the sender role, select the **Sender** icon for the appropriate user ID. The icon changes from  to  to show that you have added the user or group to the access role for the resource.
   f. Click **Next**. A summary of your role type assignments for the root topic is displayed.
   g. If you want to change your assignments, click **Previous** to return to the Select role types page, change your assignments, and then click **Next**.
   h. Click **Finish** to confirm your assignments. The role type assignments are saved to the master configuration, and the new assignments are displayed in the Topics panel.
5. Save your changes to the master configuration.

Results

The selected users and groups are added to topic space root roles for the new root topic. The **Manage access roles** panel displays the new access role assignments.

What to do next

You can perform additional security administration using the administrative console.

Removing users and groups from topic space root roles:

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups require authority to send and receive messages from the topic space root in a publish/subscribe topic hierarchy. By removing users and groups from topic space root roles, you prevent them from accessing the root topic in a selected topic space.

About this task

Topic space root (/) is the highest level topic in a publish/subscribe topic hierarchy. The hierarchy itself is called the topic space. Note that this task applies only to the topic space root; it does not apply to removing users and groups from topics or a topic space. For information about removing users and groups from topic access roles, refer to “Removing users and groups from topic roles” on page 1304, and for removing users and groups from topic space roles, refer to “Removing users and groups from destination roles” on page 1243.

In this task you use the administrative console to remove selected users and groups from the sender and receiver roles for the selected root topic.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage topic access roles**. The Topic spaces panel lists the topic spaces defined on the bus.
3. Select the topic space you want to work with. The selected topic space is displayed in the Topics panel. The root topic (/) is displayed by default.
4. Select the topic space root. The Topic access roles panel lists the role type assignments for the topic space root.
5. Select the names of the users, groups and group members that you want to remove from all role types for the selected root topic, and click **Remove**.
6. Save your changes to the master configuration.

Results

The selected users and groups are removed from all roles for the selected root topic. The Topic access roles panel is updated to show the changes to the access roles assignments.

What to do next

You can perform other security administration commands using the administrative console.

Administering topic roles

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups require authority to access a topic in a publish/subscribe topic hierarchy. By adding and removing users and groups in topic roles, you can control access to the topic.

About this task

You use the administrative console to list, add and remove users and groups in the sender and receiver roles, and to define topic role inheritance. By default, a child topic inherits its topic roles from its parent topic. You can change the default roles for a particular topic by adding or removing topic roles at the topic level. You can also allow or block inheritance of topic roles at topic level.

You can add access roles for a topic before it exists. Topics are created at runtime only, and exist only for as long as they are active.

For information about how to list, add, and remove users and groups in topic roles using the administrative console, refer to the following tasks.
- “Listing users and groups in topic roles”
- “Adding users and groups to topic roles”
- “Removing users and groups from topic roles” on page 1304
- “Enabling topic role inheritance” on page 1291
- “Disabling topic role inheritance” on page 1291

Listing users and groups in topic roles:

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups require authority to access topics in a publish/subscribe topic hierarchy. By listing the users and groups that are members of topic roles for a selected topic, you can find out who has authority to send messages to and from the topic.

About this task

In this task you use the administrative console to list users and groups that have access roles for a selected topic in a selected topic space. The list includes users, groups and group members that have references in the role-based security configuration for service integration. It does not list all the users and groups that exist in the external user repository.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage topic access roles** → ***topic_space_name*** → ***topic_name***. The Topics panel displays the information for the topic in a collapsed section.
3. Expand the section header to display the users and groups that are assigned to role types for the selected topic.

What to do next

You can add and remove users and groups in the topic roles for the selected topic.

Adding users and groups to topic roles:

Service integration bus security uses role-based authorization. When messaging security, and topic level authorization is enabled, users and groups must be authorized to access topics in a publish/subscribe topic hierarchy. By adding users and groups to topic roles, you control access to a topic in a selected topic space.

Before you begin

- The users and groups you want to add to topic space root roles must exist in the user repository.
- Topic roles are effective only when the **Topic Access Check Required** setting is enabled in the configuration for a topic space. For more information, refer to “Configuring bus destination properties” on page 1230.

About this task

Topics are organized into one or more hierarchies within a topic space. If the **Topic Access Check Required** setting is enabled for the topic space, a user must have authorization to access the topic itself. You can add access roles to a topic before it is created at runtime. A topic inherits access roles from its parent unless you explicitly block the inheritance. For more information, refer to “Enabling topic role inheritance” on page 1291.

In this task you use an administrative console wizard to add users or groups to the sender and receiver roles for a selected topic.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage topic access roles** → ***topic_space_name*** → ***topic_name***. The Topic space root panel lists the users and groups that are assigned to role types for the selected topic.
3. Click **Add** to launch the Security wizard:
   a. Provide the following information to enable the wizard to identify the users or groups that you want to add to role types for the selected topic:

      Resource
      Specify the name of the topic.

      Users or Groups
      Select either **Users** or **Groups** to specify whether you want to grant access roles to users or groups.

      Search pattern
      This field is mandatory. Specify a search string that is matched against user IDs or group names in the user repository. Only user IDs or group names that match the search pattern are retrieved, subject to the maximum number of search results. Wild card characters are allowed.

      Maximum number of search results to display
      This field is mandatory. Specify the maximum number of user IDs or group names you want the administrative console to display.

   b. Click **Next**. The wizard lists the users IDs or group names that match the information that you provided in the previous step.
   c. Select the check boxes for the user IDs or group names that you want to assign to roles for the selected topic.
   d. Click **Next**. The wizard lists the topic role types that you can assign for the users or groups you selected in the previous step. Role types may already have been assigned for a specific user or group.
   e. Select the role types for each of the selected users or groups. For example, to assign a user ID to the sender role, select the **Sender** icon for that user ID. The icon changes from  to  to show that you have added the user or group to the access role for the resource.
   f. Click **Next**. A summary of your role type assignments for the selected topic is displayed.
   g. If you want to change your assignments, click **Previous** to return to the Select role types step. Make changes to your assignments, and click **Next** to return to the Confirm step.
   h. Click **Finish** to confirm your assignments and save your changes to the master configuration.

Results

The updated role type assignments for the selected users or groups are displayed in the Topic access roles panel.

What to do next

You can perform other security administration tasks by using the administrative console.

Removing users and groups from topic roles:

Service integration bus security uses role-based authorization. When messaging security is enabled, and the **Topic access check required** setting is enabled for the topic space, users and groups require

authority to access a topic in the topic space. By removing users and groups from all topic roles for a selected topic, you prevent them from accessing the topic.

Before you begin

Topic roles are effective only when the **Topic Access Check Required** setting is enabled in the configuration for a topic space. For more information, refer to “Configuring bus destination properties” on page 1230.

About this task

This task uses the administrative console to remove users and groups from both the sender and receiver roles for a selected topic in a selected topic space.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage topic access roles** → ***topic_space_name*** → ***topic_name***. The Topic access roles panel is displayed. The information for the topic is displayed in a collapsed section.
3. Expand the section header to display the users and groups that are assigned to role types for the selected topic.
4. Select the users and groups that you want to remove from the sender and receiver roles for the selected topic, and click **Remove**.
5. Save your changes to the master configuration.

Results

The selected users and groups are removed from the sender and receiver roles for the selected topic. The Topic access roles panel is updated to show that the selected users and groups have no topic role type assignments.

Enabling topic role inheritance:

Service integration bus security uses role-based authorization. When messaging security, and topic level security are enabled, and users and groups require access in the sender and receiver roles to access a topic in a publish/subscribe topic hierarchy. By default, topics inherit these roles from the parent topic. If topic role inheritance has been disabled for a particular topic, you can restore it by using the administrative console.

Before you begin

You must ensure that the following conditions are met:

- Messaging security is enabled. For more information, refer to “Disabling bus security” on page 1273.
- Topic level security is enabled for the topic space. Check the setting **Topic Access Check Required?** in the topic space destination configuration. For more information, refer to “Configuring bus destination properties” on page 1230.

About this task

In this task you use the administrative console to restore topic role inheritance for selected topics. A topic can only inherit the sender and receiver roles from the parent topic in the topic hierarchy.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage topic access roles** → ***topic_space_name*** → ***topic_name***. The Topic access roles panel lists users and groups that have been assigned role types for the selected topic.

3. Expand the topic name header to display details of the users and groups that have one or more access roles for this topic.
4. Select the **Inherit sender role from parent topic** check box.
5. Select the **Inherit receiver role from parent topic** check box.
6. Click **OK** to save your changes.
7. Save your changes to the master configuration.

Results

The select topic inherits access roles from the parent topic. The Topic access roles panel displays the inherited access roles for the topic.

What to do next

You can perform other security administration tasks by using the administrative console.

Disabling topic role inheritance:

Service integration bus security uses role-based authorization. When messaging security, and topic level security are enabled, users and groups require access in the sender and receiver roles to access a topic in a publish/subscribe topic hierarchy. By default, topics inherit these roles from the parent topic. If you do not want topics to inherit topic roles from the parent topic in the topic hierarchy, you can override topic role inheritance by using the administrative console.

Before you begin

About this task

In this task you use the administrative console to prevent a selected topic from inheriting authorization roles from its parent topic.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage topic access roles** → ***topic_space_name*** → ***topic_name***. The Topic access roles panel lists users and groups that have been assigned role types for the selected topic.
3. Expand the topic name header to display details of the users and groups that have access one or more access roles for the selected topic.
4. Clear the **Inherit sender role from parent topic** check box.
5. Clear the **Inherit receiver role from parent topic** check box.
6. Click **OK** to save your changes.
7. Save your changes to the master configuration.

Results

The selected topic cannot inherit access roles from its parent topic. The Topic access roles panel displays the changed access roles for the selected topic.

What to do next

You can perform other security administration tasks by using the administrative console.

Removing access roles from unknown users and groups

Service integration bus security uses role-based authorization. Users and groups are assigned to access roles for specific bus resources. If a user or a group that has access roles is removed from the user repository, it becomes an unknown user. You can identify the unknown users and groups for a selected bus, and removes their access roles.

About this task

In this task, you use the administrative console to remove access roles from users and groups for unknown users and groups.

1. Click **Service integration** → **Buses** → ***security_value*** → **[Authorization Policy] Manage users and groups not known to the user repository** The Unknown users and groups panel lists all the users and groups that have access roles assigned to them, but they are not known in the user registry.
2. Select the check boxes next to multiple user and group names.
3. Click **Remove all roles**. The access role assignments for the selected users and groups are removed.
4. Save your changes to the master configuration.

Results

The access role assignments are removed from the selected users and groups. The Unknown users and groups panel is updated to show the changes to the role type assignments.

Administering permitted transports for a bus

Use these tasks to configure a transport policy for a service integration bus, and to administer the transports chains that remote applications clients can use to connect to a service integration bus.

About this task

- "Administering permitted transports for a bus"
- "Listing permitted transports for a bus" on page 1308
- "Adding a permitted transport to a bus" on page 1308
- "Removing a permitted transport from a bus" on page 1309

Configuring a transport policy for a bus

By configuring a transport policy for the bus you can affect the security of messages in transit.

Before you begin

There are no prerequisites for this task.

About this task

The transport policy for a bus controls which transport mechanism remote application clients can use to connect to the bus.

1. Log onto the administrative console.
2. Click **Service integration** → **Buses** → ***security_value***. The configuration panel for the selected bus is displayed
3. Choose one of the following transport policies for the bus:

   Allow the use of all defined transport channel chains
   Select this option to allow the bus to use unsecured ports.

   Restrict the use of defined transport channel chains to those protected by SSL
   Select this option to prevent the use of the InboundBasicMessaging port.

Restrict the use of defined transport channel chains to the list of permitted transports
Select this option if you want connecting client applications to use named transport channel chains. This provides the highest level of control over the use of transport channel chains.

4. Click **Apply**.
5. Save your changes to the master configuration.

Results

The transport policy you have configured for the selected bus controls how application clients connect to the bus.

What to do next

You can use the administrative console to add and remove transport chains in the list of permitted transports for the bus.

Listing permitted transports for a bus

Use this task to display a list of the transport chains that are available for a remote client application to use to connect to a selected service integration bus.

Before you begin

The transport policy for the bus must be set to the option **Restrict the use of defined transport channel chains to the list of permitted transports** for this task to have an effect. For more information about how to configure the transport policy for the bus, refer to “Configuring a transport policy for a bus” on page 1307.

About this task

A permitted transport is a transport chain that a remote client application can use to connect to the bus. In this task, you use the administrative console to list all the permitted transports for a selected bus.

1. Log onto the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Additional Properties] Permitted Transports**.

Results

The Permitted transports panel displays the list of permitted transports for the selected bus.

What to do next

You can use the administrative console to add and remove transport chains in the list of permitted transports to control which transport chains a remote client application can use to connect to the bus.

Adding a permitted transport to a bus

Use this task to make a new transport chain available to a remote client application to use to connect to a service integration bus.

Before you begin

The transport policy for the bus must be set to the option **Restrict the use of defined transport channel chains to the list of permitted transports** for this task to have an effect. For more information about how to configure the transport policy for the bus, refer to “Configuring a transport policy for a bus” on page 1307.

About this task

A permitted transport is a transport chain that a remote client application can use to connect to the bus. If you want to allow remote client applications to connect to the bus using a new transport chain, you must add the new transport chain to the list of permitted transports for the bus. In this task, you use the administrative console to add a new transport chain to the list of permitted transports for a selected bus.

1. Log onto the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Additional Properties] Permitted Transports**. The Permitted transports panel displays the list of permitted transports for the selected bus.
3. Click **New**.
4. Select the name of the transport chain you want to add in the list box.
5. Click **OK**.
6. Save your changes to the master configuration.

Results

The new transport name is displayed in the list of permitted transports, and its is available for use by a remote client application to connect to the bus.

What to do next

You can use the administrative console to remove transport chains from a bus.

Removing a permitted transport from a bus

Use this task to remove a selected transport chain from the list of permitted transport chains for a selected service integration bus.

Before you begin

The transport policy for the bus must be set to the option **Restrict the use of defined transport channel chains to the list of permitted transports** for this task to have an effect. For more information about how to configure the transport policy for the bus, refer to “Configuring a transport policy for a bus” on page 1307.

About this task

A permitted transport is a transport chain that a remote client application can use to connect to the bus. If you want to prevent a remote client application from using a particular transport chain to connect to the bus, you can remove the transport chain from the list of permitted transports for the bus. In this task, you use the administrative console to remove a transport chain from the list of permitted transports for a selected bus.

1. Log onto the administrative console.
2. Click **Service integration** → **Buses** → ***security_value*** → **[Additional Properties] Permitted Transports**. The Permitted transports panel displays the list of permitted transports for the selected bus.
3. Select the name of the transport chain you want to remove.
4. Click **Delete**. The Permitted transports panel displays an updated list of permitted transports for the selected bus.
5. Save your changes to the master configuration.

Results

The selected transport chain is removed from the list of permitted transports for the selected bus, and a remote client can no longer use it to connect to the bus.

What to do next

You can use the administrative console to manage the transport policy for the bus.

Configuring bus security using an administrative console panel

Use this task to enable or disable messaging security, and configure security properties for an existing service integration bus.

Before you begin

The bus must exist in the administrative console. If you want to create a new bus, refer to “Adding buses” on page 1140.

About this task

This task uses the Bus Security administrative console panel. You can launch the Bus security wizard from the panel, or specify individual security properties directly in the panel. The bus security properties are effective only when administrative security for the cell is enabled. If the wizard detects that administrative security is disabled, it prompts you to enable it.

The security properties available to a particular bus depend on the versions of the bus members. If the bus has a WebSphere Application Server Version 6.x bus member, you must specify the global security domain. The bus cannot use cell level, or custom security domains. You must also specify an inter-engine authentication alias to prevent unauthenticated messaging engines from establishing a connection with the bus. If the bus contains Version 7.0 bus members only, you can specify any type of security domain, and you do not need to specify an inter-engine or mediation authentication alias.

If you want to run mediations across multiple security domains, you can specify a single server identity for the bus, rather than specify a mediation authentication alias for each domain. You can also use a server identity to run mediations on the global domain.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → ***security_value***. *security_value* is either `Enabled` or `Disabled`, depending on the security status of the bus.
3. Click **Launch Bus Security Wizard** to launch the wizard, or specify the following properties directly:

   Enable bus security
   Bus security is enabled by default. Clear this check box if you do not want a secure bus. The check box is read-only if administrative security is disabled.

   Inter-engine authentication alias
   The name of the authentication alias used to authorize communication between messaging engines on the bus. Specify an inter-engine authentication alias if the bus has a Version 6.x bus member, bus security is enabled, and you want to prevent unauthorized messaging engines from establishing a connection with the bus.

   Permitted transports
   Specify one of the following transports for the bus:
   - Any messaging transport chain defined to any bus member.
   - Only messaging transport chains that are protected by an SSL chain.
   - Only the transports specified in the list of permitted transports.

If you want to add and remove permitted transports, click **Service integration** → **Buses** → ***security_value*** → **[Additional Properties] Permitted Transports**.

Use the Server ID when running mediations
Check this option if you want to run mediations using the server identity, instead of using a mediation authentication alias.

Mediations are deployed as applications, and run in the domain used by the application server, not the bus domain. If you want to run a mediation on multiple servers in different domains, you must ensure that the user identity in the mediation authentication alias exists in the configuration for each domain. Alternatively, you can choose to use the server identity option. You can use this option when multiple domains are not in use.

Bus security domain
Specify one of the following security domains for the bus:

Global domain
You must specify the global domain if the bus contains a Version 6.x bus member, or you do not want the bus to use multiple domains.

Cell level domain
Specify the cell-level security domain if the bus has Version 7.0 bus members only, and you want the bus to share security settings with the administrative cell.

Custom domain
Specify a custom security domain if the bus has Version 7.0 bus members only, and you want the bus to use a security domain that is used by another resource, or you want to create a new security configuration for this bus.

4. Save your changes to the master configuration.

Results

You have configured security properties for the selected bus.

What to do next

You can use the administrative console to control access to the bus.

Securing messages between messaging buses

Use these tasks to administer the access control security associated with sending messages between buses.

About this task

- "Protecting messages transmitted between buses"
- "Administering access to foreign destinations" on page 1312

Protecting messages transmitted between buses

Use this task to protect the integrity of the data that is transmitted between secured linked service integration buses.

Before you begin

- Review the information in the topics Secure transport considerations and Configuring transport chains.
- Configure a transport policy for the bus, as described in the topic "Configuring a transport policy for a bus" on page 1307.

About this task

In this task, you configure transport chains for the remote bus to ensure that only secured inbound transport chains can contact the messaging engines on the server. The remote bus may be a foreign bus, or an WebSphere MQ link.

1. Ensure that the linked buses are secured. For further information, see “Securing buses” on page 1272.
2. Configure the Target inbound transport chain property for the foreign bus, or WebSphere MQ link, as appropriate:
   - For connections to a foreign bus, refer to “Connecting service integration buses to use point-to-point messaging” on page 1165 or “Connecting service integration buses to use publish-subscribe messaging” on page 1167
   - For connections to WebSphere MQ, refer to “Creating a new WebSphere MQ link” on page 1615.

Results

You have configured the Target inbound transport chains for the remote service integration bus.

What to do next

Administering access to foreign destinations

Use these tasks to administer the access control security associated with sending messages to foreign bus destinations.

About this task

To define the authentication information used in the access control checks that are performed when a message is sent to a destination in a foreign bus, complete the following steps:

- Define the required authorization permissions to allow a sender to access a destination on a foreign bus. These can be defined using either a foreign bus definition, as described in “Administering foreign bus roles” on page 1292, or a foreign bus destination definition, as described in “Administering destination roles” on page 1241. These permissions are used when the message is sent, to check that the sender is allowed to access the foreign bus.
- The administrator of the foreign bus must define the required authorization permissions to allow the messages to access the destination on the foreign bus. These permissions are used when the message enters the foreign bus.
- Define the authorization permissions to allow any messages entering your bus from the foreign bus to access the required destinations.

Securing access to a foreign bus

You can secure the link between a local bus and a foreign bus.

Before you begin

Before you can secure the link between a local bus and a foreign bus, there must be foreign bus connection on the local bus, and therefore a link between the buses.

About this task

This task summarizes the significant tasks to secure the link between a local bus and a foreign bus. For more general information about service integration bus security, see “Security” on page 1128.

When you create a foreign bus connection, there are some options to secure the connection during that procedure.

1. Enable security on the service integration bus and the foreign bus. See “Disabling bus security” on page 1273.
2. Secure the link between the buses. See “Securing messages between messaging buses” on page 1311.
3. Grant access to the local bus for users who will be sending messages to the foreign bus. See “Administering the bus connector role” on page 1282.
4. Grant access to the foreign bus for users who will be sending messages to it. See “Administering foreign bus roles” on page 1292.
5. Optional: Give users access to foreign or alias destinations that will forward messages to a foreign bus. See “Administering destination roles” on page 1241.

Securing links between messaging engines

When security is enabled, messaging engines in a mixed version bus establish trust using an authentication alias.

Before you begin

You must ensure that the user ID that you intend to use for the authentication alias meets the following conditions:

- It exists in the user registry
- It is used only for the purpose of messaging engine to messaging engine authentication.
- It has not been added to the bus connector access role.

About this task

If you have a secure, mixed version bus, you must define an Inter-engine authentication alias for use in preventing unauthorized messaging engines from establishing a connection. The Inter-engine authentication alias is used by messaging engines to establish trust in the following scenarios:

- A WebSphere Application Server Version 6.x messaging engine initiates a link with a Version 7.0 messaging engine.
- A Version 7.0 messaging engine initiates a link with a Version 6.x messaging engine.

Trust between Version 7.0 messaging engines is established using a Lightweight Third Party Authentication (LTPA) token.

1. In the navigation pane, click **Service integration** → **Buses** → ***security_value***. The bus security configuration panel is displayed.
2. In the **Inter-engine authentication alias** field, select an authentication alias.
3. Click **OK**.
4. Save your changes to the master configuration.

Results

You have selected an Inter engine authentication alias for the bus to use in establishing trust between mixed version messaging engines.

What to do next

If you require additional security, you can configure the SSL certificate stores to restrict objects that can make an SSL connection, and thereby connect to the bus. For more information see Configuring secure sockets layer.

Controlling which foreign buses can link to your bus

Use this task to control which foreign buses are allowed to link to your bus.

About this task

When messaging security is enabled, it is important that only authorized foreign buses are allowed to link to your bus.

To control which foreign buses can create a link to your bus, complete the following steps:

1. Set the authentication alias property on the foreign bus connection to be used for authentication of the foreign bus joining your bus, as described in “Connecting service integration buses to use point-to-point messaging” on page 1165 or “Connecting service integration buses to use publish-subscribe messaging” on page 1167.
2. If you require extra security, configure the SSL certificate stores to restrict who can make an SSL connection, and hence link to the bus. For more information, see Configuring secure sockets layer.

Securing database access

How to protect the data store from access by unauthorized users.

About this task

To secure access to the data store, you must configure a user name and password on the data store for the messaging engine. If you want to apply additional levels of security such as encrypting the contents of the database, use the specific security features provided by your database.

Securing mediations

Use the following tasks to secure mediations at an operations level. For example, a mediation inherits its identity from a the messaging engine, but you might want to specify an alternative identity for the mediation to use.

Chapter 7. Data access resources

Task overview: Accessing data from applications

Various enterprise information systems (EIS) use different methods for storing data. These *backend* data stores might be relational databases, procedural transaction programs, or object-oriented databases.

About this task

IBM WebSphere Application Server provides several options for accessing an information system's backend data store:

- Programming directly to the database through the JDBC 4.0 API, JDBC 3.0 API, or JDBC 2.0 optional package API.
- Programming to the procedural backend transaction through various Jave EE Connector Architecture (JCA) 1.0 or 1.5 compliant connectors.
- Programming in the bean-managed persistence (BMP) bean or servlets indirectly accessing the backend store through either the JDBC API or JCA compliant connectors.
- Using container-managed persistence (CMP) beans.
- Using the IBM data access beans, which also use the JDBC API, but give you a rich set of features and function that hide much of the complexity associated with accessing relational databases.

For all of these options, except for using the JCA 1.0 or 1.5 compliant connectors, the prerequisite Web site details which databases and drivers are currently supported.

1. Develop data access applications. Develop your application to access data using the various ways available through the application server. You can access data through APIs, container-managed persistence beans, bean-managed persistence beans, session beans, or Web components.
2. Assemble data access applications using the assembly tool. Assemble your application by creating and mapping resource references.
3. Prepare for deployment: Ensure that the appropriate database objects are available. Create or configure any databases or tables required, set necessary configuration parameters to handle expected load, and configure any necessary JDBC providers and data source objects for servlets, enterprise beans, and client applications to use.
4. Install the application on your application server.

Resource adapters

A resource adapter is a system-level software driver that a Java application uses to connect to an enterprise information system (EIS). A resource adapter plugs into an application server and provides connectivity between the EIS, the application server, and the enterprise application.

WebSphere Application Server supports JCA versions 1.0 and 1.5 including additional, configurable features for JCA 1.5 resource adapters with activation specifications that handle inbound requests.

Data access for container-managed persistence (CMP) beans is indirectly managed by the WebSphere Persistence Manager. The JCA specification supports persistence manager delegation of the data access to the JCA resource adapter without knowing the specific backend store. For the relational database access, the persistence manager uses the relational resource adapter to access the data from the database.

You can find the supported database platforms for the JDBC API at the WebSphere Application Server prerequisite Web site.

Java EE Connector Architecture resource adapters

An application server vendor extends its system once to support the Java Platform, Enteprise Edition Connector Architecture (JCA) and is then assured of seamless connectivity to multiple EISs. Likewise, an EIS vendor provides one standard resource adapter with the capability to plug into any application server that supports the connector architecture.

The product supports any resource adapter that implements version 1.0 or 1.5 of this specification. IBM supplies resource adapters for many enterprise systems separately from the WebSphere Application Server package, including (but not limited to): the Customer Information Control System (CICS®), Host On-Demand (HOD), Information Management System (IMS™), and Systems, Applications, and Products (SAP) R/3 .

The general approach to writing an application that uses a JCA resource adapter is to develop EJB session beans or services with tools such as Rational Application Developer. The session bean uses the *javax.resource.cci* interfaces to communicate with an enterprise information system through the resource adapter.

WebSphere Relational Resource Adapter

WebSphere Application Server provides the WebSphere Relational Resource Adapter implementation. This resource adapter provides data access through JDBC calls to access the database dynamically. The connection management is based on the JCA connection management architecture and provides connection pooling, transaction, and security support. The WebSphere RRA is installed and runs as part of WebSphere Application Server, and needs no further administration.

The RRA supports both the configuration and use of JDBC data sources and Java EE Connection Architecture (JCA) connection factories. The RRA supports the configuration and use of data sources implemented as either JDBC data sources or Java EE Connector Architecture connection factories. Data sources can be used directly by applications, or they can be configured for use by container-managed persistence (CMP) entity beans.

For more information about the WebSphere Relational Resource Adapter, see the following topics:

- For information about resource adapters and data access, see “Data access portability features” on page 1317
- For RRA settings, see “WebSphere relational resource adapter settings”
- For information about enterprise beans, see EJB applications

WebSphere relational resource adapter settings

Use this page to view the settings of the WebSphere relational resource adapter. This adapter is preinstalled in the product to provide access to relational databases.

Note: Although the default relational resource adapter settings are viewable, you cannot make changes to them.

To view this administrative console page, click **Resources** > **Resource adapters** > **Resource adapters**. Expand the **Preferences** section at the top of the page. Select **Show built-in resources**. The table of configured resource adapters now displays the **WebSphere Relational Resource Adapter**.

Name:

Specifies the name of the resource provider.

Data type String

Description:

Specifies a description of the relational resource adapter.

Data type String

Archive path:

Specifies the path to the Resource Adapter Archive (RAR) file containing the module for this resource adapter.

Data type String

Class path:

Specifies a list of paths or Java Archive (JAR) file names, which together form the location for the resource provider classes.

Data type String

Native path:

Specifies a list of paths that forms the location for the resource provider native libraries.

Data type String

Data access portability features

These interfaces work with the relational resource adapter (RRA) to make database-specific functions operable on connections between the application server and that database.

In other words, your applications can access data from different databases, and use functions that are specific to the database, without any code changes. Additionally, WebSphere Application Server enables you to plug in a data source that is not supported by WebSphere persistence. However, the data source *must* be implemented as either the *XADataSource* type or the *ConnectionPoolDataSource* type, and it must be in compliance with the JDBC 2.x specification.

You can achieve application portability through the following:

DataStoreHelper interface

With this interface, each data store platform can plug in its own private datastore specific functions that the relational resource adapter runtime uses. WebSphere Application Server provides an implementation for each supported JDBC provider.

The interface also provides a GenericDataStoreHelper class for unsupported data sources to use. You can subclass the GenericDataStoreHelper class or other WebSphere provided helpers to support any new data source.

Note: If you are configuring data access through a user-defined JDBC provider, do not implement the DataStoreHelper interface directly. Either subclass the GenericDataStoreHelper class or subclass one of the DataStoreHelper implementation classes provided by IBM (if your database behavior or SQL syntax is similar to one of these provided classes).

For more information, see the API documentation **DataStoreHelper** topic (as listed in the API documentation index).

The following code segment shows how a new data store helper is created to add new error mappings for an unsupported data source.

```
public class NewDSHelper extends GenericDataStoreHelper
{
  public NewDSHelper(java.util.Properties dataStoreHelperProperties)
  {
    super(dataStoreHelperProperties);
    java.util.Hashtable myErrorMap = null;
    myErrorMap = new java.util.Hashtable();
    myErrorMap.put(new Integer(-803), myDuplicateKeyException.class);
    myErrorMap.put(new Integer(-1015), myStaleConnectionException.class);
    myErrorMap.put("S1000", MyTableNotFoundException.class);
    setUserDefinedMap(myErrorMap);
    ...
  }
}
```

WSCallHelper class

This class provides two methods that enable you to use vendor-specific methods and classes that do not conform to the standard JDBC APIs (and are not part of WebSphere Application Server extension packages).

- **jdbcCall() method**

  By using the static jdbcCall() method, you can invoke vendor-specific, nonstandard JDBC methods on your JDBC objects. (For more information, see the API documentation **WSCallHelper** topic.) The following code segment illustrates using this method with a DB2 data source:

  ```
  Connection conn = ds.getConnection();
  // get connection attribute
  String connectionAttribute =(String) WSCallHelper.jdbcCall(DataSource.class, ds,
   "getConnectionAttribute", null, null);
  // setAutoClose to false
  WSCallHelper.jdbcCall(java.sql.Connection.class,
  conn, "setAutoClose",
  new Object[] { new Boolean(false)},
  new Class[] { boolean.class });
  // get data store helper
  DataStoreHelper dshelper = WSCallHelper.getDataStoreHelper(ds);
  ```

- **jdbcPass() method**

  Use this method to exploit the nonstandard JDBC classes that some database vendors provide. These classes contain methods that require vendors' proprietary JDBC objects to be passed as parameters.

  In particular, implementations of Oracle can involve use of nonstandard classes furnished by the vendor. Methods contained within these classes include:

  ```
  oracle.sql.ArrayDescriptor ArrayDescriptor.createDescriptor(java.lang.String, java.sql.Connection)
  oracle.sql.ARRAY new ARRAY(oracle.sql.ArrayDescriptor, java.sql.Connection, java.lang.Object)
  oracle.xml.sql.query.OracleXMLQuery(java.sql.Connection, java.lang.String)
  oracle.sql.BLOB.createTemporary(java.sql.Connection, boolean, int)
  oracle.sql.CLOB.createTemporary(java.sql.Connection, boolean, int)
  oracle.xdb.XMLType.createXML(java.sql.Connection, java.lang.String)
  ```

  The following code sample demonstrates how to use jdbcPass to call the Oracle method `XMLType.createXML` on a connection. This Oracle function creates an XML type object out of the XML data that the database passes to your application.

  ```
  XMLType poXML = (XMLType)(WSCallHelper.jdbcPass(XMLType.class,
  "createXML", new Object[]{conn,poString},
   new Class[]{java.sql.Connection.class, java.lang.String.class},
   new int[]{WSCallHelper.CONNECTION,WSCallHelper.IGNORE}));
  ```

  For more examples of using jdbcPass and a complete list of method parameters, see the API documentation for the WSCallHelper class. In this information center, access the API documentation with the following steps:

1. Click **Reference** > **Developer API documentation** > **Application programming interfaces**
2. Click **com.ibm.websphere.rsadapter**
3. Under the Class Summary heading, click **WSCallHelper**

The first section on jdbcPass discusses using the method to call database static methods. The second section on jdbcPass addresses database non-static methods.

Note: Use of the jdbcPass() method causes the JDBC object to be used outside of the protective mechanisms of WebSphere Application Server. Performing certain operations (such as setting autoCommit, or transaction isolation settings, etc.) outside of these protective mechanisms will cause problems with the future use of these pooled connections. IBM does not guarantee stability of the object after invocation of this method; it is the user's responsibility to ensure that invocation of this method does not perform operations that harm the object. Use at your own risk.

Because of these potential problems, WebSphere Application Server strictly controls which methods are allowed to be invoked using the jdbcPass() method support. If you require support for a method that is not listed previously in this document, contact WebSphere Application Server Support with information on the method you require.

JDBC providers

Installed applications use JDBC providers to interact with relational databases.

The JDBC provider object supplies the specific JDBC driver implementation class for access to a specific vendor database. To create a pool of connections to that database, you associate a data source with the JDBC provider. Together, the JDBC provider and the data source objects are functionally equivalent to the Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) connection factory, which provides connectivity with a non-relational database.

For a current list of supported providers, see the WebSphere Application Server prerequisite Web site. For detailed descriptions of the providers, including the supported data source classes and their required properties, refer to the topics on data source required minimum required settings, by vendor.

Data sources

Installed applications use a *data source* to obtain connections to a relational database. A data source is analogous to the Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) connection factory, which provides connectivity to other types of enterprise information systems (EIS).

A data source is associated with a JDBC provider, which supplies the driver implementation classes that are required for JDBC connectivity with your specific vendor database. Application components transact directly with the data source to obtain connection instances to your database. The connection pool that corresponds to each data source provides connection management.

You can create multiple data sources with different settings, and associate them with the same JDBC provider. For example, you might use multiple data sources to access different databases within the same vendor database application. WebSphere Application Server requires JDBC providers to implement one or both of the following data source interfaces, which are defined by Sun Microsystems. These interfaces enable the application to run in a single-phase or two-phase transaction protocol.

- *ConnectionPoolDataSource* - a data source that supports application participation in local and global transactions, excepting two-phase commit transactions. When a connection pool data source is involved in a global transaction, transaction recovery is not provided by the transaction manager. The application is responsible for providing the backup recovery process if multiple resource managers are involved.

  Note: A connection pool data source does support two-phase commit transactions in these cases:

  - the data source is making use of *Last participant* support. Last participant support enables a single one-phase commit resource to participate in a global transaction with one or more two-phase commit resources.

    For more information, consult the article Using one-phase and two-phase commit resources in the same transaction.
- *XADataSource* - a data source that supports application participation in any single-phase or two-phase transaction environment. When this data source is involved in a global transaction, the product transaction manager provides transaction recovery.

Prior to version 5.0 of the application server, the function of data access was provided by a single connection manager (CM) architecture. This connection manager architecture remains available to support Java 2 Platform, Enterprise Edition (J2EE) 1.2 applications, but another connection manager architecture is provided, based on the JCA architecture supporting the J2EE 1.3 application style, J2EE 1.4 and Java EE applications.

These architectures are represented by two types of data sources. To choose the right data source, administrators must understand the nature of their applications, EJB modules, and enterprise beans.
- Data source (WebSphere Application Server V4) - This data source runs under the original CM architecture. Applications using this data source behave as if they were running in Version 4.0.
- Data source - This data source uses the JCA standard architecture to provide support for J2EE version 1.3 and 1.4, as well as Java EE applications. It runs under the JCA connection manager and the relational resource adapter.

Choice of data source
- J2EE 1.2 application - all EJB 1.1 enterprise beans, JDBC applications, or Servlet 2.2 components must use the **4.0** data source.
- J2EE 1.3 (and subsequent releases) application -
  - EJB 1.1 module - all EJB 1.x beans must use the **4.0** data source.
  - EJB 2.0 (and subsequent releases) module - enterprise beans that include container-managed persistence (CMP) Version 1.x, 2.0, and beyond must use the **new** data source.
  - JDBC applications and Servlet 2.3+ components - must use the **new** data source.

Data access beans
Data access beans provide a rich set of features and function, while hiding much of the complexity associated with accessing relational databases.

They are Java classes written to the Enterprise JavaBeans specification.

You can use the data access beans in JavaBeans-compliant tools, such as the IBM *Rational Application Developer*. Because the data access beans are also Java classes, you can use them like ordinary classes.

The data access beans (in the package *com.ibm.db*) offer the following capabilities:

Feature
: **Details**

Caching query results
: You can retrieve SQL query results all at once and place them in a cache. Programs using the result set can move forward and backward through the cache or jump directly to any result row in the cache.

  For large result sets, the data access beans provide ways to retrieve and manage *packets*, subsets of the complete result set.

Updating through result cache
: Programs can use standard Java statements (rather than SQL statements) to change, add, or delete rows in the result cache. You can propagate changes to the cache in the underlying relational table.

Querying parameter support

The base SQL query is defined as a Java String, with parameters replacing some of the actual values. When the query runs, the data access beans provide a way to replace the parameters with values made available at run time. Default mappings for common data types are provided, but you can specify whatever your Java program and database require.

Supporting metadata

A *StatementMetaData* object contains the base SQL query. Information about the query (*metadata*) enables the object to pass parameters into the query as Java data types.

Metadata in the object maps Java data types to SQL data types (as well as the reverse). When the query runs, the Java-datatyped parameters are automatically converted to SQL data types as specified in the metadata mapping.

When results return, the metadata object automatically converts SQL data types back into the Java data types specified in the metadata mapping.

Connection management architecture

The connection management architecture for both relational and procedural access to enterprise information systems (EIS) is based on the Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) specification. The Connection Manager (CM), which pools and manages connections within an application server, is capable of managing connections obtained through both resource adapters (RAs) defined by the JCA specification, and data sources defined by the Java Database Connectivity (JDBC) 2.0 (and later) Extensions specification.

To make data source connections manageable by the CM, the WebSphere Application Server provides a resource adapter (the WebSphere Relational Resource Adapter) that enables JDBC data sources to be managed by the same CM that manages JCA connections. From the CM point of view, JDBC data sources and JCA connection factories look the same. Users of data sources do not experience any programmatic or behavioral differences in their applications because of the underlying JCA architecture. JDBC users still configure and use data sources according to the JDBC programming model.

Applications migrating from previous versions of WebSphere Application Server might experience some behavioral differences because of the specification changes from various Java EE requirements levels. These differences are not related to the adoption of the JCA architecture.

If you have Java 2 Platform, Enterprise Edition (J2EE) 1.2 applications using the JDBC API that you wish to run in WebSphere Application Server 6.0 and later, the JDBC CM from Application Server version 4.0 is still provided as a configuration option. Using this configuration option enables J2EE 1.2 applications to run unaltered. If you migrate a Version 4.0 application to Version 6.0 or later, using the latest migration tools, the application automatically uses the Version 4.0 connection manager after migration. However, EJB 2.x modules in J2EE 1.3, J2EE 1.4 and Java Platform, Enterprise Edition (Java EE) applications cannot use the JDBC CM from WebSphere Application Server Version 4.0.

Connection pooling

Using connection pools helps to both alleviate connection management overhead and decrease development tasks for data access.

Each time an application attempts to access a backend store (such as a database), it requires resources to create, maintain, and release a connection to that datastore. To mitigate the strain this process can place on overall application resources, the Application Server enables administrators to establish a pool of backend connections that applications can share on an application server. Connection pooling spreads the connection overhead across several user requests, thereby conserving application resources for future requests.

The application server supports JDBC 4.0 APIs for connection pooling and connection reuse. The connection pool is used to direct JDBC calls within the application, as well as for enterprise beans using the database.

Benefits of connection pooling

Connection pooling can improve the response time of any application that requires connections, especially Web-based applications. When a user makes a request over the Web to a resource, the resource accesses a data source. Because users connect and disconnect frequently with applications on the Internet, the application requests for data access can surge to considerable volume. Consequently, the total datastore overhead quickly becomes high for Web-based applications, and performance deteriorates. When connection pooling capabilities are used, however, Web applications can realize performance improvements of up to 20 times the normal results.

With connection pooling, most user requests do not incur the overhead of creating a new connection because the data source can locate and use an existing connection from the pool of connections. When the request is satisfied and the response is returned to the user, the resource returns the connection to the connection pool for reuse. The overhead of a disconnection is avoided. Each user request incurs a fraction of the cost for connecting or disconnecting. After the initial resources are used to produce the connections in the pool, additional overhead is insignificant because the existing connections are reused.

When to use connection pooling

Use connection pooling in an application that meets any of the following criteria:
- It cannot tolerate the overhead of obtaining and releasing connections whenever a connection is used.
- It requires Java Transaction API (JTA) transactions within the Application Server.
- It needs to share connections among multiple users within the same transaction.
- It needs to take advantage of product features for managing local transactions within the application server.
- It does not manage the pooling of its own connections.
- It does not manage the specifics of creating a connection, such as the database name, user name, or password

Note: Connection pooling is not supported in an application client. The application client calls the database directly and does not go through a data source. If you want to use the getConnection() request from the application client, configure the JDBC provider in the application client deployment descriptors, using Rational Application Developer or an assembly tool. The connection is established between application client and the database. Application clients do not have a connection pool, but you can configure JDBC provider settings in the client deployment descriptors.

How connections are pooled together

When you configure a unique data source or connection factory, you must give it a unique Java Naming and Directory Interface (JNDI) name. This JNDI name, along with its configuration information, is used to create the connection pool. A separate connection pool exists for each configured data source or connection factory.

Furthermore, the application server creates a separate instance of the connection pool in each application server that uses the data source or connection factory. For example:
- If you run a three server cluster in which all of the servers use *myDataSource*, and *myDataSource* has a Maximum Connections setting of 10, then you can generate up to 30 connections (three servers times 10 connections).

Consider how this behavior potentially impacts the number of connections that your backend resource can support. See “Connection pool settings” on page 1400 for more information.

Other considerations for determining the maximum connections setting:

- Each entity bean transaction requires an additional database connection, dedicated to handling the transaction.
- If clones are used, one data pool exists for each clone.

It is also important to note that when using connection sharing, it is only possible to share connections obtained from the same connection pool.

Connection and connection pool statistics:

WebSphere Application Server supports use of PMI APIs to monitor the performance of data access applications.

Performance Monitoring Infrastructure (PMI) method calls that are supported in the two existing Connection Managers (JDBC and J2C) are supported in this version of WebSphere Application Server. The calls include:

- ManagedConnectionsCreated
- ManagedConnectionsAllocated
- ManagedConnectionFreed
- ManagedConnectionDestroyed
- BeginWaitForConnection
- EndWaitForConnection
- ConnectionFaults
- Average number of ManagedConnections in the pool
- Percentage of the time that the connection pool is using the maximum number of ManagedConnections
- Average number of threads waiting for a ManagedConnection
- Average percent of the pool that is in use
- Average time spent waiting on a request
- Number of ManagedConnections that are in use
- Number of Connection Handles
- FreePoolSize
- UseTime

Java Specification Request (JSR) 77 requires statistical data to be accessed through managed beans (Mbeans) to facilitate this. The Connection Manager passes the ObjectNames of the Mbeans created for this pool. In the case of Java Message Service (JMS) *null* is passed in. The interface used is:

```
PmiFactory.createJ2CPerf(
    String pmiName, // a unique Identifier for JCA /JDBC.  This is the
                    // ConnectionFactory name.

    ObjectName providerName,// the ObjectName of the J2CResourceAdapter
                             // or JDBCProvider Mbean

    ObjectName factoryName // the ObjectName of the J2CConnectionFactory
                           // or DataSourceMbean.
)
```

The following Unified Modeling Language (UML) diagram shows how JSR 77 requires statistics to be reported:

JCAConnectionPoolStats and JDBCConnectionPoolStats objects do not have a direct implementing Mbean; the statistics are gathered through a call to PMI. A J2C resource adapter, and JDBC provider each contain a list of ConnectionFactory or DataSource ObjectNames, respectively. The ObjectNames are used by PMI to find the appropriate connection pool in the list of PMI modules.

The JCA 1.5 Specification allows an exception from the matchManagedConnection() method that indicates that the resource adapter requests that the connection not be pooled. In that case, statistics for that connection are provided separately from the statistics for the connection pool.

Connection life cycle

A ManagedConnection object is always in one of three states: *DoesNotExist*, *InFreePool*, or *InUse*.

Before a connection is created, it must be in the DoesNotExist state. After a connection is created, it can be in either the InUse or the InFreePool state, depending on whether it is allocated to an application.

Between these three states are *transitions*. These transitions are controlled by *guarding conditions*. A guarding condition is one in which *true* indicates when you can take the transition into another legal state. For example, you can make the transition from the InFreePool state to InUse state only if:

- the application has called the data source or connection factory getConnection() method (the *getConnection* condition)
- a free connection is available in the pool with matching properties (the *freeConnectionAvailable* condition)
- and one of the two following conditions are true:
  - the getConnection() request is on behalf of a resource reference that is marked unsharable
  - the getConnection() request is on behalf of a resource reference that is marked shareable but no shareable connection in use has the same properties.

This transition description follows:

InFreePool > InUse:
getConnection AND
freeConnectionAvailable AND
NOT(shareableConnectionAvailable)

Here is a list of guarding conditions and descriptions.

Condition	Description
ageTimeoutExpired	Connection is older then its ageTimeout value.
close	Application calls close method on the Connection object.
fatalErrorNotification	A connection has just experienced a fatal error.
freeConnectionAvailable	A connection with matching properties is available in the free pool.
getConnection	Application calls getConnection method on a data source or connection factory object.
markedStale	Connection is marked as stale, typically in response to a fatal error notification.
noOtherReferences	There is only one connection handle to the managed connection, and the Transaction Service is not holding a reference to the managed connection.
noTx	No transaction is in force.
poolSizeGTMin	Connection pool size is greater than the minimum pool size (minimum number of connections)
poolSizeLTMax	Pool size is less than the maximum pool size (maximum number of connections)
shareableConnectionAvailable	The getConnection() request is for a shareable connection, and one with matching properties is in use and available to share.
TxEnds	The transaction has ended.
unshareableConnectionRequest	The getConnection() request is for an unshareable connection.
unusedTimeoutExpired	Connection is in the free pool and not in use past its unused timeout value.

Getting connections

The first set of transitions covered are those in which the application requests a connection from either a data source or a connection factory. In some of these scenarios, a new connection to the database results. In others, the connection might be retrieved from the connection pool or shared with another request for a connection.

DoesNotExist

Every connection begins its life cycle in the DoesNotExist state. When an application server starts, the connection pool does not exist. Therefore, there are no connections. The first connection is not created until an application requests its first connection. Additional connections are created as needed, according to the guarding condition.

```
getConnection AND
NOT(freeConnectionAvailable) AND
poolSizeLTMax AND
(NOT(shareableConnectionAvailable) OR
unshareableConnectionRequest)
```

This transition specifies that a connection object is not created unless the following conditions occur:
- The application calls the getConnection() method on the data source or connection factory
- No connections are available in the free pool (NOT(freeConnectionAvailable))
- The pool size is less than the maximum pool size (poolSizeLTMax)
- If the request is for a sharable connection and there is no sharable connection already in use with the same sharing properties (NOT(shareableConnectionAvailable)) OR the request is for an unsharable connection (unshareableConnectionRequest)

All connections begin in the DoesNotExist state and are only created when the application requests a connection. The pool grows from 0 to the maximum number of connections as applications request new connections. The pool is **not** created with the minimum number of connections when the server starts.

If the request is for a sharable connection and a connection with the same sharing properties is already in use by the application, the connection is shared by two or more requests for a connection. In this case, a new connection is not created. For users of the JDBC API these sharing properties are most often *userid/password* and *transaction context*; for users of the Resource Adapter Common Client Interface (CCI) they are typically *ConnectionSpec*, *Subject*, and *transaction context*.

InFreePool

The transition from the InFreePool state to the InUse state is the most common transition when the application requests a connection from the pool.

```
InFreePool>InUse:
getConnection AND
freeConnectionAvailable AND
(unshareableConnectionRequest OR
NOT(shareableConnectionAvailable))
```

This transition states that a connection is placed in use from the free pool if:
- the application has issued a getConnection() call
- a connection is available for use in the connection pool (freeConnectionAvailable),
- and one of the following is true:
  - the request is for an unsharable connection (unsharableConnectionRequest)
  - no connection with the same sharing properties is already in use in the transaction. (NOT(sharableConnectionAvailable)).

Any connection request that a connection from the free pool can fulfill does not result in a new connection to the database. Therefore, if there is never more than one connection used at a time from the pool by any number of applications, the pool never grows beyond a size of one. This number can be less than the minimum number of connections specified for the pool. One way that a pool grows to the minimum number of connections is if the application has multiple concurrent requests for connections that must result in a newly created connection.

InUse

The idea of connection sharing is seen in the transition on the InUse state.

```
InUse>InUse:
getConnection AND
ShareableConnectionAvailable
```

This transition indicates that if an application requests a shareable connection (getConnection) with the **same** sharing properties as a connection that is already in use (ShareableConnectionAvailable), the existing connection is shared.

The same user (*user name* and *password*, or *subject*, depending on authentication choice) can share connections but only within the same transaction and only when all of the sharing properties match. For JDBC connections, these properties include the *isolation level*, which is configurable on the

resource-reference (IBM WebSphere extension) to data source default. For a resource adapter factory connection, these properties include those specified on the ConnectionSpec object. Because a transaction is normally associated with a single thread, you should **never** share connections across threads.

Note: It is possible to see the same connection on multiple threads at the same time, but this situation is an error state usually caused by an application programming error.

Returning connections

All of the transitions discussed previously involve getting a connection for application use. With that goal, the transitions result in a connection closing, and either returning to the free pool or being destroyed. Applications should explicitly close connections (note: the connection that the user gets back is really a connection handle) by calling close() on the connection object. In most cases, this action results in the following transition:

```
InUse>InFreePool:
(close AND
noOtherReferences AND
NoTx AND
UnshareableConnection)
OR
(ShareableConnection AND
TxEnds)
```

Conditions that cause the transition from the InUse state are:

- If the application or the container calls close() (producing the close condition) and there are no references (the noOtherReferences condition) either by the application (in the application sharing condition) or by the transaction manager (in the NoTx condition, meaning that the transaction manager holds a reference when the connection is enlisted in a transaction), the connection object returns to the free pool.
- If the connection was enlisted in a transaction but the transaction manager ends the transaction (the txEnds condition), and the connection was a shareable connection (the ShareableConnection condition), the connection closes and returns to the pool.

When the application calls close() on a connection, it is returning the connection to the pool of free connections; it is **not** closing the connection to the data store. When the application calls close() on a currently shared connection, the connection is *not returned* to the free pool. Only after the application drops the last reference to the connection, and the transaction is over, is the connection returned to the pool. Applications using unsharable connections must take care to close connections in a timely manner. Failure to do so can starve out the connection pool, making it impossible for any application running on the server to get a connection.

When the application calls close() on a connection enlisted in a transaction, the connection is not returned to the free pool. Because the transaction manager must also hold a reference to the connection object, the connection cannot return to the free pool until the transaction ends. Once a connection is enlisted in a transaction, you cannot use it in any other transaction by any other application until after the transaction is complete.

There is a case where an application calling close() can result in the connection to the data store closing and bypassing the connection return to the pool. This situation happens if one of the connections in the pool is considered stale. A connection is considered stale if you can no longer use it to contact the data store. For example, a connection is marked stale if the data store server is shut down. When a connection is marked as stale, the entire pool is cleaned out by default because it is very likely that all of the connections are stale for the same reason (or you can set your configuration to clean just the failing connection). This cleansing includes marking all of the currently InUse connections as stale so they are destroyed upon closing. The following transition states the behavior on a call to close() when the connection is marked as stale:

```
InUse>DoesNotExist:
close AND
markedStale AND
NoTx AND
noOtherReferences
```

This transition states that if the application calls close() on the connection and the connection is marked as stale during the pool cleansing step (markedStale), the connection object closes to the data store and is not returned to the pool.

Finally, you can close connections to the data store and remove them from the pool.

This transition states that there are three cases in which a connection is removed from the free pool and destroyed.

1. If a fatal error notification is received from the resource adapter (or data source). A fatal error notification (FatalErrorNotification) is received from the resource adaptor when something happens to the connection to make it unusable. All connections currently in the free pool are destroyed.
2. If the connection is in the free pool for longer than the unused timeout period (UnusedTimeoutExpired) and the pool size is greater than the minimum number of connections (poolSizeGTMin), the connection is removed from the free pool and destroyed. This mechanism enables the pool to shrink back to its minimum size when the demand for connections decreases.
3. If an age timeout is configured and a given connection is older than the timeout. This mechanism provides a way to recycle connections based on age.

Unshareable and shareable connections

The application server supports both unshareable and shareable connections. An unshareable connection is not shared with other components in the application. The component using this connection has full control of this connection.

Access to a resource marked as unshareable means that there is a one-to-one relationship between the connection handle a component is using and the physical connection with which the handle is associated. This access implies that every call to the getConnection method returns a connection handle solely for the requesting user. Typically, you must choose unshareable if you might do things to the connection that could result in unexpected behavior occurring in another application that is sharing the connection (for example, unexpectedly changing the isolation level).

Marking a resource as shareable allows for greater scalability. Instead of creating new physical connections on every getConnection() invocation, the physical connection (that is, managed connection) is shared through multiple connection handles, as long as each getConnection request has the same connection properties. However, sharing a connection means that each user must not do anything to the connection that could change its behavior and disrupt a sharing partner (for example, changing the isolation level). The user also cannot code an application that assumes sharing to take place because it is up to the run time to decide whether or not to share a particular connection.

Connection property requirements

To permit sharing of connections used within the same transaction, the following data source properties must be the same:

- Java Naming and Directory Interface (JNDI) name. While not actually a connection property, this requirement simply means that you can only share connections from the same data source in the same server.
- Resource authentication
- In relational databases:
  - Isolation level (corresponds to access intent policies applied to CMP beans)
  - Readonly
  - Catalog
  - TypeMap

For more information on sharing a connection with a CMP bean, see “Sharing a connection with a CMP bean.”

To permit sharing of connections within the same transaction, the following properties must be the same for the connection factories:
- JNDI name. While not actually a connection property, this requirement simply means that you can only share connections from the same connection factory in the same server.
- Resource authentication

In addition, the ConnectionSpec object that is used to get the connection must also be the same.

Note: Java Message Service (JMS) connections cannot be shared with non-JMS connections.

Sharing a connection with a CMP bean

The application server allows you to share a physical connection among a CMP bean, a BMP bean, and a JDBC application to reduce the resource allocation or deadlock scenarios. There are several ways to ensure that all of these entity beans and the JDBC applications are sharing the same physical connection.

- **Sharing a connection between CMP beans or methods**

  When all CMP bean methods use the same access intent, they all share the same physical connection. A different access intent policy triggers the allocation of a different physical connection. For example, a CMP bean has two methods; method 1 is associated with `wsPessimisticUpdate` intent, whereas method 2 has `wsOptimisticUpdate` access intent. Method 1 and method 2 cannot share the same physical connection within a transaction. In other words, an XA data source is required to run in a global transaction.

  You can experience some deadlocks from a database if both methods try to access the same table. Therefore, sharing a connection is determined by the access intents that are defined in the CMP methods.

- **Sharing a connection between CMP and BMP beans**

  Remember to first verify that the **getConnection** methods of both the BMP bean and the CMP bean set the same connection properties. To match the authentication type of the CMP bean resource, set the authentication type of the BMP bean resource to container-managed, which is designated in the deployment descriptor as `res-auth = Container`.

  Additionally, use one of the following options to ensure connection-sharing between the bean types:

  – Define the same access intent on both CMP and BMP bean methods. Because both use the same access intent, they share the same physical connection. The advantage to using this option is that the backend is transparent to a BMP bean. However, this option also makes the BMP non-portable because it uses the WebSphere extended API to handle the isolation level. For more information, refer to the code example in Example: Accessing data using IBM extended APIs to share connections between container-managed and bean-managed persistence beans.

  – Determine the isolation level that the access intent uses on a CMP bean method, then use the corresponding isolation level that is specified on the resource reference to look up a data source and a connection. This option is more of a manual process, and the isolation level might be different from database to database. For more information refer to the isolation level and access intent mapping table: Access intent isolation levels and update locks and the Isolation level and resource reference section.

- **Sharing a connection between CMP and a JDBC application that is used by a servlet or a session bean**

  Determine the isolation level that the access intent uses on a CMP bean method, then use the corresponding isolation level specified on the resource reference to look up a data source and a connection. For more information refer to Access intent isolation levels and update locks and Isolation level and resource reference.

Factors that determine sharing

The listing here is not an exhaustive one. The product might or might not share connections under different circumstances.

- Only connections acquired with the same resource reference (resource-ref) that specifies the res-sharing-scope as shareable are candidates for sharing. The resource reference properties of res-sharing-scope and res-auth and the IBM extension isolationLevel help determine if it is possible to share a connection. IBM extension isolationLevel is stored in IBM deployment descriptor extension file; for example: ibm-ejb-jar-ext.xmi.
- You can only share connections that are requested with the same properties.
- Connection sharing only occurs between different component instances if they are within a transaction (container- or user-initiated transaction).
- Connection sharing only occurs within a sharing boundary. Current® sharing boundaries include *Transactions* and *LocalTransactionContainment* (LTC) boundaries.
- Connection sharing rules within an LTC Scope:
  - For shareable connections, only *Connection Reuse* is allowed within a single component instance. Connection reuse occurs when the following actions are taken with a connection: get, use, commit/rollback, close; get, use, commit/rollback, close. Note that if you use the LTC resolution-control of *ContainerAtBoundary* then no start/commit is needed because that action is handled by the container.

    The connection returned on the second *get* is the same connection as that returned on the first *get* (if the same properties are used). Because the connection use is serial, only one connection handle to the underlying physical connection is used at a time, so true connection sharing does not take place. The term *"reuse"* is more accurate.

    More importantly, the *LocalTransactionContainment* boundary enclosing both *get* actions is not complete; no cleanUp() method is invoked on the ManagedConnection object. Therefore the second *get* action inherits all of the connection properties set during the first getConnection() call.
- Shareable connections between transactions (either container-managed transactions (CMT), bean-managed transactions (BMT), or LTC transactions) follow these caching rules:
  - In general, setting properties on shareable connections is not allowed because a user of one connection handle might not anticipate a change made by another connection handle. This limitation is part of the Java Platform, Enterprise Edition (Java EE) standard.
  - General users of resource adapters can set the connection properties on the connection factory getConnection() call by passing them in a ConnectionSpec.

    However, the properties set on the connection during one transaction are not guaranteed to be the same when used in the next transaction. Because it is not valid to share connections outside of a sharing scope, connection handles are moved off of the physical connection with which they are currently associated when a transaction ends. That physical connection is returned to the free connection pool. Connections are cleaned before going in the free pool. The next time the handle is used, it is automatically associated with an appropriate connection. The appropriateness is based on the security login information, connection properties, and (for the JDBC API) the isolation level specified in the extended resource reference, passed in on the original request that returned the current handle. Any properties set on the connection after it was retrieved are lost.
  - For JDBC users, the application server provides an extension to enable passing the connection properties through the ConnectionSpec.

    Use caution when setting properties and sharing connections in a local transaction scope. Ensure that other components with which the connection is shared are expecting the behavior resulting from your settings.
- You cannot set the isolation level on a shareable connection for the JDBC API using a relational resource adapter in a global transaction. The product provides an extension to the resource reference to enable you to specify the isolation level. If your application requires the use of multiple isolation levels, create multiple resource references and map them to the same data source or connection factory.

Maximal connection sharing

To maximize connection sharing opportunities for an application, ensure that each component has the local transaction containment (LTC) Resolver attribute set to **ContainerAtBoundary**. This setting specifies that the component container, rather than the application code, resolves all resource manager local transactions (RMLTs) within the LTC scope. The container begins an RMLT when a connection is first used within the LTC scope, and completes it automatically at the end of the LTC scope.

Consult the topic Configuring transactional deployment attributes for instructions on setting the transaction resolution control and other attributes.

Connection sharing violations

There is a new exception, the sharing violation exception, that the resource adapter can issue whenever an operation violates sharing requirements. Possible violations include changing connection attributes, security settings, or isolation levels, among others. When such a mutable operation is performed against a managed connection, the sharing violation exception can occur when both of the following conditions are true:

- The number of connection handles associated with the managed connection is more than one.
- The managed connection is associated with a transaction, either local or XA.

Both the component and the J2C run time might need to detect this sharing violation exception, depending on when and how the managed connection becomes unshareable. If the managed connection becomes unshareable because of an operation through the connection handle (for example, you change the isolation level), then the component needs to process the exception. If the managed connection becomes unshareable without being recognized by the application server (due to some component interaction with the connection handle), then the resource adapter can reject the creation of a connection handle by issuing the sharing violation exception.

Connection handles

A connection handle is a representation of a physical connection. To use a backend resource (such as a relational database) in WebSphere Application Server you must get a connection to that resource. When you call the *getConnection()* method, you get a *connection handle* returned. The handle is not the physical connection. The physical connection is managed by the connection manager.

There are two significant configurations that affect how connection handles are used and how they behave. The first is the *res-sharing-scope*, which is defined by the resource-reference used to look up the DataSource or Connection Factory. This property tells the connection manager whether or not you can share this connection.

The second factor that affects connection handle behavior is the *usage pattern*. There are essentially two usage patterns. The first is called the *get/use/close* pattern. It is used within a single method and without calling another method that might get a connection from the same data source or connection factory. An application using this pattern does the following:

1. gets a connection
2. does its work
3. commits (if appropriate)
4. closes the connection.

The second usage pattern is called the *cached handle* pattern. This is where an application:

1. gets a connection
2. begins a global transaction
3. does work on the connection
4. commits a global transaction
5. does work on the connection again

A cached handle is a connection handle that is held across transaction and method boundaries by an application. Keep in mind the following considerations for using cached handles:

- Cached handle support requires some additional connection handle management across these boundaries, which can impact performance. For example, in a JDBC application, *Statements*, *PreparedStatements*, and *ResultSets* are closed implicitly after a transaction ends, but the connection remains valid.
- You are encouraged **not** to cache the connection across the transaction boundary for shareable connections; the get/use/close pattern is preferred.
- Caching of connection handles across servlet methods is limited to JDBC and Java Message Service (JMS) resources. Other non-relational resources, such as Customer Information Control System (CICS) or IMS objects, currently cannot have their connection handles cached in a servlet; you need to get, use, and close the connection handle within each method invocation. (This limitation only applies to single-threaded servlets because multithreaded servlets do not allow caching of connection handles.)
- You **cannot** pass a cached connection handle from one instance of a data access client to another client instance. Transferring between client instances creates the problematic contingency of one instance using a connection handle that is referenced by another. This relationship can only cause problems because connection handle management code processes tasks for each client instance *separately*. Hence, connection handle transfers result in run-time scenarios that trigger exceptions. For example:
  1. The application code of a client instance that receives a transferred handle closes the handle.
  2. If the client instance that retains the original reference to the handle tries to reclaim it, the application server issues an exception.

The following code segment shows the cached connection pattern.

```
Connection conn = ds.getConnection();
ut.begin();
conn.prepareStatement("....."); --> Connection runs in global transaction mode
...
ut.commit();
conn.prepareStatement(".....");   ---> Connection still valid but runs in autoCommit(True);
...
```

Unshareable connections

Some characteristics of connection handles retrieved with a *res-sharing-scope* of **unshareable** are described in the following sections.

- **The possible benefits of unshared connections**
  - Your application always maintains a direct link with a physical connection (managed connection).
  - The connection always has a one-to-one relationship between the connection handle and the managed connection.
  - In most cases, the connection does not close until the application closes it.
  - You can use a cached unshared connection handle across multiple transactions.
  - The connection can have a performance advantage in some cached handle situations. Because unshared connections do not have the overhead of moving connection handles off managed connections at the end of the transaction, there is less overhead in using a cached unshared connection.
- **The possible drawbacks of unshared connections**
  - Inefficient use of your connection resources. For example, if within a single transaction you get more than one connection (with the same properties) using the same data source or connection factory (same resource-ref) then you use multiple physical connections when you use unshareable connections.
  - Wasted connections. It is important not to keep the connection handle open (that is, your application does not call the *close()* method) any longer then it is needed. As long as an unshareable connection

is open, the physical connection is unavailable to any other component, even if your application is not currently using that connection. Unlike a shareable connection, an ushareable connection is not closed at the end of a transaction or servlet call.

– Deadlock considerations. Depending on how your components interact with the database within a transaction, using unshared connections can lead to deadlock in the database. For example, within a transaction, component A gets a connection to data source X and updates table 1, and then calls component B. Component B gets another connection to data source X, and updates/reads table 1 (or even worse the same row as component A). In some circumstances, depending on the particular database, its locking scheme, and the transaction isolation level, a deadlock can occur.

  In the same scenario, but with a *shared* connection, deadlock does not occur because all the work is done on the same connection. It is worth noting that when writing code that uses shared connections, you use a strategy that calls for multiple work items to be performed on the same connection, possibly within the same transaction. If you decide to use an unshareable connection, you must set the *maximum connections* property on the connection factory or data source correctly. An exception might occur for waiting connection requests if you exceed the maximum connections value, and unshareable connections are not being closed before the connection wait time-out is exceeded.

Shareable connections

Some characteristics of connection handles that are retrieved with a *res-sharing-scope* of **shareable** are described in the following sections.

- **The possible benefits of shared connections**
  – Within an instance of connection sharing, application components can share a managed connection with one or more connection handles, depending on how the handle is retrieved and which connection properties are used.
  – They can more efficiently use resources. Shareable connections are not valid outside of their sharing boundary. For this reason, at the end of a sharing boundary (such as a transaction) the connection handle is no longer associated with the managed connection it was using within the sharing boundary (this applies only when using the cached handle pattern). The managed connection is returned to the free connection pool for reuse. Connection resources are not held longer than the end of the current sharing scope.

    If the cached handle pattern is used, then the next time the handle is used within a new sharing scope, the application server run time ensures that the handle is reassociated with a managed connection that is appropriate for the current sharing scope, and has the same properties with which the handle was originally retrieved. Remember that it is not appropriate to change properties on a shareable connection. If properties are changed, other components that share the same connection might experience unexpected behavior. Futhermore, when using cached handles, the value of the changed property might not be remembered across sharing scopes.
- **The possible drawbacks of shared connections**
  – Sharing within a single component (such as an enterprise bean and its related Java objects) is not always supported. The current specification allows resource adapters the choice of only allowing one active connection handle at a time.

    If a resource adapter chooses to implement this option then the following scenario results in an *invalid handle exception*: A component using shareable connections gets a connection and uses it. Without closing the connection, the component calls a utility class (Java object) that gets a connection handle to the same managed connection and uses it. Because the resource adapter only supports one active handle, the first connection handle is no longer valid. If the utility object returns without closing its handle, the first handle is not valid and triggers an exception at any attempt to use it.

    Note: This exception occurs only when calling a utility object (a Java object).

    Not all resource adapters have this limitation; it occurs only in certain implementations. The WebSphere Relational Resource Adapter (RRA) does not have this limitation. Any data source used

through the RRA does not have this limitation. If you encounter a resource adapter with this limitation you can work around it by serializing your access to the managed connection. If you always close your connection handle before getting another (or close your handle before calling code that gets another handle), and before returning from a method, you can allow two pieces of code to share the same managed connection. You simply cannot use the connection for both events at the same time.
- Trying to change the *isolation level* on a shareable JDBC-based connection in a global transaction (that is supported by the RRA) causes an exception. The correct way to get connections with different transaction isolation levels is by configuring the IBM extended resource-reference.
- Closing connection handles for shareable connections by an application is NOT supported and causes errors. However, you can avoid this limitation by using the Relational Resource Adapter.

Lazy connection association optimization

The Java Platform, Enterprise Edition (Java EE) Connector (J2C) connection manager implemented *smart handle* support. This technology enables allocation of a connection handle to an application while the managed connection associated with that connection handle is used by other applications (assuming that the connection is not being used by the original application). This concept is part of the Java EE Connector Architecture (JCA) 1.5 specification. (You can find it in the JCA 1.5 specification document in the section entitled ″Lazy Connection Association Optimization.″) Smart handle support introduces use a method on the ConnectionManager object, the *LazyAssociatableConnectionManager()* method, and a new marker interface, the *DissociatableManagedConnection* class. You must configure the provider of the resource adapter to make this functionality available in your environment. (In the case of the RRA, WebSphere Application Server itself is the provider.) The following code snippet shows how to include smart handle support:

```
package javax.resource.spi;
import javax.resource.ResourceException;

interface LazyAssociatableConnectionManager { // application server
    void associateConnection(
        Object connection, ManagedConnectionFactory mcf,
        ConnectionRequestInfo info) throws ResourceException;
}

interface DissociatableManagedConnection { // resource adapter
    void dissociateConnections() throws ResourceException;
}
```

This DissociatableManagedConnection interface introduces another state to the Connection object: *inactive*. A Connection can now be active, closed, and inactive. The connection object enters the inactive state when a corresponding ManagedConnection object is cleaned up. The connection stays inactive until an application component attempts to re-use it. Then the resource adapter calls back to the connection manager to re-associate the connection with an active ManagedConnection object.

Transaction type and connection behavior

All connection usage occurs within the scope of either a global transaction or a local transaction containment (LTC) boundary. Each transaction type places different requirements on connections and impacts connection settings differently.

Connection sharing and reuse

You can share connections within a global transaction scope (assuming other sharing rules are met). You can also share connections within a shareable LTC. You can *serially reuse* connections within an LTC scope. A get/use/close connection pattern followed by another instance of get/use/close (to the same data source or connection factory) enables you to reuse the same connection. See the “Unshareable and shareable connections” on page 1328 topic for more details.

JDBC AutoCommit behavior

All JDBC connections, when first obtained through a getConnection() call, contain the setting AutoCommit = TRUE by default. However, different transaction scope and settings can result in changing, or simply overriding, the AutoCommit value.

- If you operate within an LTC and have its resolution-control set to *Application*, AutoCommit remains *TRUE* unless changed by the application.
- If you operate within an LTC and have its resolution-control set to *ContainerAtBoundary*, the application must **not** touch the AutoCommit setting. The WebSphere Application Server run time sets the AutoCommit value to *FALSE* before work begins, then commits or rolls back the work, as appropriate, at the end of the LTC scope.
- If you use a connection within a global transaction, the database ignores the AutoCommit setting so that the transaction service that controls the commit and rollback processing can manage the transaction. This action takes place upon first use of the connection to do work, regardless of the user changing the AutoCommit setting. After the transaction completes, the AutoCommit value returns to the value it had before the first use of the connection. So even if the AutoCommit value is set to *TRUE* before the connection is used in a global transaction, you need not set the value to *FALSE* because the value is ignored by the database. In this example, after the transaction completes, the AutoCommit value of the connection returns to *TRUE*.
- If you use multiple distinct connections within a global transaction, all work is guaranteed to commit or roll back together. This is not the case for a local transaction containment (LTC scope). Within an LTC, work done on one connection commits or rolls back independently from work done on any other connection within the LTC.

One-phase commit and two-phase commit connections

The type and number of resource managers, such as a database server, that must be accessed by an application often determines the application transaction requirements. Consequently each type of resource manager places different requirements on connection behavior.

- A two-phase commit resource manager can support two-phase coordination of a transaction. That support is necessary for transactions that involve other resource managers; these transactions are global transactions. See “Transaction support in WebSphere Application Server” on page 2125 for further explanation.
- A one-phase commit resource manager supports only one-phase transactions, or LTC transactions, in which that resource is the sole participating datastore. Again, see “Transaction support in WebSphere Application Server” on page 2125 for further explanation.

One-phase commit resources are such that work being done on a one phase connection cannot mix with other connections and ensure that the work done on all of the connections completes or fails atomically. The product does not allow more than one one-phase commit connection in a global transaction. Futhermore, it does not allow a one-phase commit connection in a global transaction with one or more two-phase commit connections. You can coordinate only multiple two-phase commit connections within a global transaction.

WebSphere Application Server provides *last participant support*, which enables a single one-phase commit resource to participate in a global transaction with one or more two-phase commit resources.

Note that any time that you do multiple getConnection() calls using a resource reference that specifies res-sharing-scope=Unshareable, you get multiple physical connections. This situation also occurs when res-sharing-scope=Shareable, but the sharing rules are broken. In either case, if you run in a global transaction, ensure the resources involved are enabled for two-phase commit (also sometimes referred to as *JTA Enabled*). Failure to do so results in an XA exception that logs the following message:

```
WTRN0063E: An illegal attempt to enlist a one phase capable resource with existing two phase capable
resources has occurred.
```

Application scoped resources

Use this page to view brief descriptions of the resources that are bundled with your application. You can view individual resource settings by clicking on the resource name.

To view this administrative console page, click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***application_name*** → **Application scoped resources**.

Each table row corresponds to a resource that is bundled with your application. Click a resource name or the corresponding provider name to view an administrative console page where you can edit the object configuration settings.

Name:

Specifies the administrative name that was assigned to this resource.

Click this name to view a page where you can edit the configuration settings.

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name of the resource.

Data type	String

Resource type:

Specifies the type of resource, such as a data source or a J2C connection factory.

Provider:

Specifies the resource provider that supplies the class information for this resource object.

Click the provider name to view a page where you can edit the configuration settings.

Description:

Specifies a text description of the resource.

Cache instances

An application uses a cache instance to store, retrieve, and share data objects within the dynamic cache.

Each cache instance can be configured independently for Java Naming and Directory Interface (JNDI) name, cache size, priority, and disk offload. Objects that are stored in a particular cache instance are not affected by other cache instances. This means that if you store an object named **object_1** with a value of `object_data` in *cache_instance_x*, you can also store an object with the same name, but different value in *cache_instance_y*.

Objects that are stored in a particular cache instance are available to applications on other servers by accessing a cache instance of the same name. The two servers must be within the same replication domain to share data.

There are two types of cache instances, object cache instances and servlet cache instances.

An object cache instance is a location in addition to the default shared dynamic cache where Java 2 Platform, Enterprise Edition (J2EE) applications can store, distribute, and share objects. After configuring

object cache instances, you can use the DistributedMap or DistributedObjectCache interfaces in the `com.ibm.websphere.cache` package to programmatically access your cache instances.

See the Additional Application Programming Interfaces (APIs) for more information about the DistributedMap or DistributedObjectCache interfaces.

Servlet cache instances are locations in addition to the default dynamic cache where dynamic cache can store, distribute, and share the output and the side effects of an invoked servlet. By configuring a servlet cache instance, your applications have greater flexibility and better tuning of cache resources. The Java Naming and Directory Interface (JNDI) name that is specified for the cache instance in the administrative console maps to the <cache-instance> element in the `cachespec.xml` configuration file. Any <cache-entry> elements that are specified within a <cache-instance> element are created in that specific cache instance. Any <cache-entry> elements that are specified outside of a <cache-instance> element are stored in the default dynamic cache instance.

See “Using servlet cache instances” on page 2277 for more information.

Data access: Resources for learning

Use the following links to find relevant supplemental information about data access. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to this product, but it can be useful for understanding concepts or functions used by the application server. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Configuring data access with scripting

Use these topics to learn about using scripting to configure data access.

About this task

This topic contains the following tasks:

- "Configuring a JDBC provider using scripting"
- "Configuring new data sources using scripting" on page 1340
- "Configuring new connection pools using scripting" on page 1341
- "Changing connection pool settings with the wsadmin tool" on page 1342
- "Configuring new data source custom properties using scripting" on page 1348
- "Configuring new Java 2 Connector authentication data entries using scripting" on page 1349
- "Configuring new WAS40 data sources using scripting" on page 1350
- "Configuring new WAS40 connection pools using scripting" on page 1351
- "Configuring new WAS40 custom properties using scripting" on page 1353
- "Configuring new J2C resource adapters using scripting" on page 1354
- "Configuring custom properties for J2C resource adapters using scripting" on page 1355
- "Configuring new J2C connection factories using scripting" on page 1356
- "Configuring new J2C administrative objects using scripting" on page 1360
- "Configuring new J2C activation specifications using scripting" on page 1358
- "Managing the message endpoint lifecycle using scripting" on page 1361
- "Testing data source connections using scripting" on page 1362

Configuring a JDBC provider using scripting

You can configure a JDBC provider using the wsadmin tool and scripting.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

1. There are two ways to perform this task. Perform one of the following:
   - Using the AdminTask object:

– Using Jacl:

```
$AdminTask createJDBCProvider {-interactive}
```

– Using Jython:

```
AdminTask.createJDBCProvider (['-interactive'])
```

- Using the AdminConfig object:

a. Identify the parent ID and assign it to the node variable. The following example uses the node configuration object as the parent. You can modify this example to use the cell, cluster, server, or application configuration object as the parent.

– Using Jacl:

```
set node [$AdminConfig  getid  /Cell:mycell/Node:mynode/]
```

– Using Jython:

```
node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
print node
```

Example output:

```
mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
```

b. Identify the required attributes:

Note: For supported JDBC drivers, you can also script JDBC providers according to the same pre-configured templates that are used by the administrative console logic. Consult the article Creating configuration objects using the wsadmin tool for details.

– Using Jacl:

```
$AdminConfig required JDBCProvider
```

– Using Jython:

```
print AdminConfig.required('JDBCProvider')
```

Example output:

```
Attribute     Type
name     String
implementationClassName   String
```

c. Set up the required attributes and assign it to the jdbcAttrs variable. You can modify the following example to setup non-required attributes for JDBC provider.

– Using Jacl:

```
set n1 [list name JDBC1]
set implCN [list implementationClassName myclass]
set  jdbcAttrs [list  $n1  $implCN]
```

Example output:

```
{name {JDBC1}} {implementationClassName {myclass}}
```

– Using Jython:

```
n1 = ['name', 'JDBC1']
implCN = ['implementationClassName', 'myclass']
jdbcAttrs = [n1,  implCN]
print jdbcAttrs
```

Example output:

```
[['name', 'JDBC1'], ['implementationClassName', 'myclass']]
```

d. Create a new JDBC provider using node as the parent:

– Using Jacl:

```
$AdminConfig create JDBCProvider $node $jdbcAttrs
```

– Using Jython:

```
AdminConfig.create('JDBCProvider', node, jdbcAttrs)
```

Example output:

```
JDBC1(cells/mycell/nodes/mynode|resources.xml#JDBCProvider_1)
```

2. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

What to do next

If you modify the class path or native library path of a JDBC provider: After saving your changes (and synchronizing the node in a network deployment environment), you must restart every application server within the scope of that JDBC provider for the new configuration to work. Otherwise, you receive a data source failure message.

Configuring new data sources using scripting

You can configure new data sources using scripting and the wsadmin tool.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

In WebSphere Application Server, any JDBC driver properties that are required by your database vendor must be set as data source properties. Consult the article Vendor-specific data sources minimum required settings in the *Troubleshooting and support* PDF to see a list of these properties and setting options, ordered by JDBC provider type. Consult your database vendor documentation to learn about available optional data source properties. Script them as *custom properties* after you create the data source. In the Related links section of this article, click the ″Configuring new data source custom properties using scripting″ link for more information.

About this task

There are two ways to perform this task; use either of the following wsadmin scripting objects:

- AdminTask object
- AdminConfig object

AdminConfig gives you more configuration control than the AdminTask object. When you create a data source using AdminTask, you supply universally required properties only, such as a JNDI name for the data source. (Consult the article “JDBCProviderManagement command group for the AdminTask object” on page 1364 for more information.) Other properties that are required by your JDBC driver are assigned default values by Application Server. You cannot use AdminTask commands to set or edit these properties; you must use AdminConfig commands.

- Using the AdminConfig object to configure a new data source:
  1. Identify the parent ID, which is the name and location of the JDBC provider that supports your data source.
     - Using Jacl:

       ```
       set newjdbc [$AdminConfig getid /Cell:mycell/Node:mynode/JDBCProvider:JDBC1/]
       ```

     - Using Jython:

       ```
       newjdbc = AdminConfig.getid('/Cell:mycell/Node:mynode/JDBCProvider:JDBC1/')
       print newjdbc
       ```

       Example output:

       ```
       JDBC1(cells/mycell/nodes/mynode|resources.xml#JDBCProvider_1)
       ```

  2. Obtain the required attributes.

     Note: For supported JDBC drivers, you can also script data sources according to the same pre-configured templates that are used by the administrative console logic. Consult the article Creating configuration objects using the wsadmin tool for details.

– Using Jacl:

```
$AdminConfig required DataSource
```

– Using Jython:

```
print AdminConfig.required('DataSource')
```

Example output:

```
Attribute   Type
name    String
```

Note: If the database vendor-required properties (which are referenced in the article "Data source minimum required settings, by vendor" on page 1433) are not displayed in the resulting list of required attributes, script these properties as data source custom properties after you create the data source.

3. Set up the required attributes.
   – Using Jacl:

```
set name [list name DS1]
set dsAttrs [list $name]
```

   – Using Jython:

```
name = ['name', 'DS1']
dsAttrs = [name]
```

4. Create the data source.
   – Using Jacl:

```
set newds [$AdminConfig create DataSource $newjdbc $dsAttrs]
```

   – Using Jython:

```
newds = AdminConfig.create('DataSource', newjdbc, dsAttrs)
print newds
```

   Example output:

```
DS1(cells/mycell/nodes/mynode|resources.xml#DataSource_1)
```

- Using the AdminTask object to configure a new data source:
  – Using Jacl:

```
$AdminTask createDatasource {-interactive}
```

  – Using Jython:

```
AdminTask.createDatasource (['-interactive'])
```

- Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

What to do next

To set additional properties that are supported by your JDBC driver, script them as data source custom properties.

Configuring new connection pools using scripting

You can use scripting and the wsadmin tool to configure new connection pools.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps:

1. Identify the parent ID:
   - Using Jacl:
     ```
     set newds [$AdminConfig getid /Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/]
     ```
   - Using Jython:
     ```
     newds = AdminConfig.getid('/Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/')
     ```

   Example output:
   ```
   DS1(cells/mycell/nodes/mynode|resources.xml$DataSource_1)
   ```
2. Creating connection pool:
   - Using Jacl:
     ```
     $AdminConfig create ConnectionPool $newds {}
     ```
   - Using Jython:
     ```
     print AdminConfig.create('ConnectionPool', newds, [])
     ```

   Example output:
   ```
   (cells/mycell/nodes/mynode|resources.xml#ConnectionPool_1)
   ```
3. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

Changing connection pool settings with the wsadmin tool

You can use the wsadmin scripting tool to change connection pool settings.

About this task

The WebSphere Application Server wsadmin tool provides the ability to run scripts. You can use the wsadmin tool to manage a WebSphere Application Server installation, as well as configuration, application deployment, and server run-time operations. The WebSphere Application Server only supports the Jacl and Jython scripting languages. To learn more about the wsadmin tool see Starting the wsadmin scripting client.

To use the wsadmin tool to change connection pool settings:

1. Launch a scripting command. There are several options for you to run scripting commands, ranging from running them interactively to running them in a profile.

   To change connection pool settings, you use the *getAttribute* and *setAttribute* commands, run against the various settings objects.

   For example, to change the connection timeout setting, the commands are:
   ```
   $AdminControl getAttribute $objectname connectionTimeout
   $AdminControl setAttribute $objectname connectionTimeout 200
   ```

   where:
   - $ is a Jacl operator for substituting a variable name with its value
   - getAttribute and setAttribute are the commands
   - connectionTimeout is the object whose value you are resetting
2. For Jacl code examples of each of the connection pool settings, see “Example: Changing connection pool settings with the wsadmin tool”

Example: Changing connection pool settings with the wsadmin tool

Using the wsadmin AdminControl object, you can script changes to connection pool settings.

The WebSphere Application Server wsadmin tool provides the ability to run scripts in the Jacl and Jython languages only. You must start the wsadmin scripting client to perform any scripting task. (See the article ″Starting the wsadmin scripting client.″)

For more information about the AdminControl scripting object, refer to the article ″Using the AdminControl object for scripted administration.″ See the links section at the end of this article.

Connection Timeout

The Connection timeout can be changed at any time while the pool is active. All connection requests that are waiting for a connection are changed to the new value minus the time already waited, and are returned to the wait state if there are no available connections.

For example, if the connection timeout is changed to 300 seconds and a connection request has waited 100 seconds, the connection request waits for 200 more seconds if no connection becomes available.

```
$AdminControl getAttribute $objectname connectionTimeout
$AdminControl setAttribute $objectname connectionTimeout 200
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

Maximum Connections

The maximum connections can be changed at any time except in the case where stuck connection support is active.

If stuck connection support is active, an attempt to change the maximum connections is made. If the attempt fails, an `IllegalState` exception occurs. See the Connection pool advanced settings topic in the *Administering applications and their environment* PDF for more information.

If stuck connection support is not active, the maximum connections are changed to the new value. If the new value is greater than the current value, the number of connections increases to the new value and any requests waiting are notified. If the new value is less than the current value and Aged Timeout or Reap Time is used, the number of connections decreases to the new value depending on pool activity. If agedTimeout or Reap Time are not used, no automatic attempt will be made to reduce the total number of connections. To manually reduce the number of connections to the new maximum connections, use the Mbean function purgePoolContents.

```
$AdminControl getAttribute $objectname maxConnections
$AdminControl setAttribute $objectname maxConnections 200
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

Minimum Connections

The minimum connections can be changed at any time

```
$AdminControl getAttribute $objectname minConnections
$AdminControl setAttribute $objectname minConnections 200
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

Reap Time

The reap time can be changed at any time. The reap time interval is changed to the new value at the next interval.

```
$AdminControl getAttribute $objectname reapTime
$AdminControl setAttribute $objectname reapTime 30
```

Unused Timeout

The unused timeout can be changed at any time.

```
$AdminControl getAttribute $objectname unusedTimeout
$AdminControl setAttribute $objectname unusedTimeout 900
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

Aged Timeout

The Aged Timeout can be changed at any time.

```
$AdminControl getAttribute $objectname agedTimeout
$AdminControl setAttribute $objectname agedTimeout 900
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

Purge Policy

The purge policy can be changed at any time.

```
$AdminControl getAttribute $objectname purgePolicy
$AdminControl setAttribute $objectname purgePolicy "Failing Connection Only"
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

Surge Protection Support

Surge connection support starts if surgeThreshold is > -1 and surgeCreationInterval is > 0. The surge protection properties can be changed at any time.

```
$AdminControl getAttribute $objectname surgeCreationInterval
$AdminControl setAttribute $objectname surgeCreationInterval 30
$AdminControl getAttribute $objectname surgeThreshold
$AdminControl setAttribute $objectname surgeThreshold 15
```

For more information about this setting, see the Connection pool advanced settings topic in the *Administering applications and their environment* PDF.

Stuck connection Support

An attempt is made to change the stuckTime, stuckTimerTime or stuckThreshold properties. If the attempt fails, an `IllegalState` exception occurs. The pool cannot have any active requests or active connections during this request. For the stuck connection support to start, all three stuck property values must be greater than 0, and the maximum connections value must be > 0.

If the connection pool is stuck, you cannot change the stuck or the maximum connection properties. If you are stuck, there are active connections.

```
$AdminControl getAttribute $objectname stuckTime
$AdminControl setAttribute $objectname stuckTime 30
$AdminControl getAttribute $objectname stuckTimerTime
$AdminControl setAttribute $objectname stuckTimerTime 15
$AdminControl getAttribute $objectname stuckThreshold
$AdminControl setAttribute $objectname stuckThreshold 10
```

For more information about this setting, see the Connection pool advanced settings topic in the *Administering applications and their environment* PDF.

Test Connection Support (This is only supported for a DataSource)

The test connection support starts when the testConnection property is set to true, and the interval is > 0. The test connection properties can be changed at any time.

```
$AdminControl getAttribute $objectname testConnection
$AdminControl setAttribute $objectname testConnection 30
$AdminControl getAttribute $objectname testConnectionInterval
$AdminControl setAttribute $objectname testConnectionInterval 15
```

For more information about this setting, see the Test connection service topic in the *Administering applications and their environment* PDF.

Connection Pool Partition Support

```
$AdminControl invoke $objectname freePoolDistributionTableSize
$AdminControl invoke $objectname numberOfFreePoolPartitions
$AdminControl invoke $objectname numberOfSharedPoolPartitions
$AdminControl invoke $objectname gatherPoolStatisticalData
$AdminControl invoke $objectname enablePoolStatisticalData
```

For more information about this setting, see the Connection pool advanced settings topic in the *Administering applications and their environment* PDF.

Show Pool Information Support

The show pool operations can be changed at any time.

```
$AdminControl invoke $objectname showAllPoolContents
$AdminControl invoke $objectname showPoolContents
$AdminControl invoke $objectname showAllocationHandleList
```

Purge Connection Support

PurgePool can be changed at any time.

```
$AdminControl invoke $objectname purgePoolContents normal
$AdminControl invoke $objectname purgePoolContents immediate
```

Pool Control Support

Pause and resume can be changed at any time.

```
$AdminControl invoke $objectname pause
$AdminControl invoke $objectname resume
```

Example: Accessing MBean connection factory and data sources using wsadmin

Wsadmin commands are used to access connection factory and data source MBeans. MBeans can retrieve or update properties for a connection factory or data source.

To get a list of J2C connection factory or data source Mbean object names, from the wsadmin command line use one of the following administrative control commands:

```
$AdminControl queryNames *:type=J2CConnectionFactory,*
$AdminControl queryNames *:type=DataSource,*
```

Example output from DataSource query:

```
wsadmin>$AdminControl queryNames *:type=DataSource,*
"WebSphere:name=Default Datasource,process=server1,platform=dynamicproxy,node=
system1Node01,JDBCProvider=Derby JDBC Provider,j2eeType=JDBCDataSource,J2EESe
```

```
rver=server1,Server=server1,version=6.0.0.0,type=DataSource,mbeanIdentifier=cell
s/system1Node01Cell/nodes/system1Node01/servers/server1/resources.xml#DataSource
_1094760149902,JDBCResource=Derby JDBC Provider,cell=system1Node01Cell"
```

By using the J2C connection factory or data source MBean object name, you can access the MBean. The name follows the `webSphere:name=` expression. In the following example, for the first set, the default data source name is set on variable name. For the second set, the object name is set on variable *objectName*.

Example using the Default Datasource

```
- wsadmin>set name [list Default Datasource]

Default Datasource

- wsadmin>set objectName [$AdminControl queryNames *:name=$name,*]

"WebSphere:name=Default Datasource,process=server1,platform=dynamicproxy,node=
system1Node01,JDBCProvider=Derby JDBC Provider,j2eeType=JDBCDataSource,J2EESe
rver=server1,Server=server1,version=6.0.0.0,type=DataSource,mbeanIdentifier=cell
s/system1Node01Cell/nodes/system1Node01/servers/server1/resources.xml#DataSource
_1094760149902,JDBCResource=Derby JDBC Provider,cell=system1Node01Cell"
```

Now you can use the objectName for getting help on attributes and operations available for this mbean.

```
$Help attributes $objectName
$Help operations $objectName
```

To get or set an attribute or to use an operation, use one of the following commands:

```
$AdminControl getAttribute $objectName "attribute name"
$AdminControl setAttribute $objectName "attribute name" value
$AdminControl invoke $objectName "operation"
```

Attribute, operation examples:

```
Get and set a attribute maxConnections (Note, if you get no value, a null value, or
a java.lang.IllegalStateException, the connection factory or data source for this
MBean has not been created. The connection factory or data source is created at first
JNDI lookup. For this example, the Default Datasource needs to be used before get,
set and invoke will work.)

wsadmin>$AdminControl getAttribute $objectName maxConnections
10

wsadmin>$AdminControl setAttribute $objectName maxConnections 20

wsadmin>$AdminControl getAttribute $objectName maxConnections
20

Using invoke

wsadmin>$AdminControl invoke $objectName showPoolContents

PoolManager name:DefaultDatasource
PoolManager object:746354514
Total number of connections: 3 (max/min 20/1, reap/unused/aged 180/1800/0,
connectiontimeout/purge 1800/EntirePool)
                            (testConnection/inteval false/0, stuck timer/time
/threshold 0/0/0, surge time/connections 0/-1)
Shared Connection information (shared partitions 200)
  No shared connections

Free Connection information (free distribution table/partitions 5/1)
  (2)(0)MCWrapper id 5c6af75b  Managed connection WSRdbManagedConnectionImpl@4b5
a775b  State:STATE_ACTIVE_FREE
```

```
  (2)(0)MCWrapper id 3394375a  Managed connection WSRdbManagedConnectionImpl@328
5f75a  State:STATE_ACTIVE_FREE
  (2)(0)MCWrapper id 4795b75a  Managed connection WSRdbManagedConnectionImpl@46a
4b75a  State:STATE_ACTIVE_FREE

  Total number of connection in free pool: 3
UnShared Connection information
  No unshared connections
```

Here is an example Java program using the wsadmin tool to invoke showPoolContents: the Example: using wsadmin to invoke showPoolContents topic in the *Administering applications and their environment* PDF.

Example: Invoking showPoolContents using the wsadmin tool:

This example Java program uses the wsadmin tool to invoke showPoolContents.

```

Related tasks

"Changing connection pool settings with the wsadmin tool" on page 1342
You can use the wsadmin scripting tool to change connection pool settings.

Configuring new data source custom properties using scripting

You can configure new data source custom properties using the wsadmin tool and scripting.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a new data source custom property:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newds [$AdminConfig getid /Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/]
     ```
   - Using Jython:

```
newds = AdminConfig.getid('/Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/')
print newds
```

Example output:

```
DS1(cells/mycell/nodes/mynode|resources.xml$DataSource_1)
```

2. Get the J2EE resource property set:
   - Using Jacl:

     ```
     set propSet [$AdminConfig showAttribute $newds propertySet]
     ```

   - Using Jython:

     ```
     propSet = AdminConfig.showAttribute(newds, 'propertySet')
     print propSet
     ```

   Example output:

   ```
   (cells/mycell/nodes/mynode|resources.xml#J2EEResourcePropertySet_8)
   ```

3. Get required attribute:
   - Using Jacl:

     ```
     $AdminConfig required J2EEResourceProperty
     ```

   - Using Jython:

     ```
     print AdminConfig.required('J2EEResourceProperty')
     ```

   Example output:

   ```
   Attribute     Type
   name         String
   ```

4. Set up attributes:
   - Using Jacl:

     ```
     set name [list name RP4]
     set rpAttrs [list $name]
     ```

   - Using Jython:

     ```
     name = ['name', 'RP4']
     rpAttrs = [name]
     ```

5. Create a J2EE resource property:
   - Using Jacl:

     ```
     $AdminConfig create J2EEResourceProperty $propSet $rpAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
     ```

   Example output:

   ```
   RP4(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_8)
   ```

6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

Configuring new Java 2 Connector authentication data entries using scripting

You can configure new Java 2 Connector (J2C) authentication data entries with the wsadmin tool and scripting.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a new J2C authentication data entry:

1. Identify the parent ID:
   - Using Jacl:
     ```
     set security [$AdminConfig getid /Cell:mycell/Security:/]
     ```
   - Using Jython:
     ```
     security = AdminConfig.getid('/Cell:mycell/Security:/')
     print security
     ```

   Example output:
   ```
   (cells/mycell|security.xml#Security_1)
   ```
2. Get required attributes:
   - Using Jacl:
     ```
     $AdminConfig required JAASAuthData
     ```
   - Using Jython:
     ```
     print AdminConfig.required('JAASAuthData')
     ```

   Example output:
   ```
   Attribute       Type
   alias           String
   userId          String
   password        String
   ```
3. Set up required attributes:
   - Using Jacl:
     ```
     set alias [list alias myAlias]
     set userid [list userId myid]
     set password [list password secret]
     set jaasAttrs [list $alias $userid $password]
     ```

     Example output:
     ```
     {alias myAlias} {userId myid} {password secret}
     ```
   - Using Jython:
     ```
     alias = ['alias', 'myAlias']
     userid = ['userId', 'myid']
     password = ['password', 'secret']
     jaasAttrs = [alias, userid, password]
     print jaasAttrs
     ```

     Example output:
     ```
     [['alias', 'myAlias'], ['userId', 'myid'], ['password', 'secret']]
     ```
4. Create JAAS auth data:
   - Using Jacl:
     ```
     $AdminConfig create JAASAuthData $security $jaasAttrs
     ```
   - Using Jython:
     ```
     print AdminConfig.create('JAASAuthData', security, jaasAttrs)
     ```

   Example output:
   ```
   (cells/mycell|security.xml#JAASAuthData_2)
   ```
5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

Configuring new WAS40 data sources using scripting

Use scripting to configure a new WAS40 data source.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps:

1. Identify the parent ID:
   - Using Jacl:
     ```
     set newjdbc [$AdminConfig getid "/JDBCProvider:Apache Derby JDBC Provider/"]
     ```
   - Using Jython:
     ```
     newjdbc = AdminConfig.getid('/JDBCProvider:Apache Derby JDBC Provider/')
     print newjdbc
     ```

   Example output:
   ```
   JDBC1(cells/mycell/nodes/mynode|resources.xml$JDBCProvider_1)
   ```
2. Get required attributes:
   - Using Jacl:
     ```
     $AdminConfig required WAS40DataSource
     ```
   - Using Jython:
     ```
     print AdminConfig.required('WAS40DataSource')
     ```

   Example output:
   ```
   Attribute    Type
   name    String
   ```
3. Set up required attributes:
   - Using Jacl:
     ```
     set name [list name was4DS1]
     set ds4Attrs [list $name]
     ```
   - Using Jython:
     ```
     name = ['name', 'was4DS1']
     ds4Attrs = [name]
     ```
4. Create WAS40DataSource:
   - Using Jacl:
     ```
     set new40ds [$AdminConfig create WAS40DataSource $newjdbc $ds4Attrs]
     ```
   - Using Jython:
     ```
     new40ds = AdminConfig.create('WAS40DataSource', newjdbc, ds4Attrs)
     print new40ds
     ```

   Example output:
   ```
   was4DS1(cells/mycell/nodes/mynode|resources.xml#WAS40DataSource_1)
   ```
5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

Configuring new WAS40 connection pools using scripting

You can use scripting to configure a new WAS40 connection pool.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a new WAS40 connection pool:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set new40ds [$AdminConfig getid /Cell:mycell/Node:mynode/
     Server:server1/JDBCProvider:JDBC1/WAS40DataSource:was4DS1/]
     ```

   - Using Jython:

     ```
     new40ds = AdminConfig.getid('/Cell:mycell/Node:mynode/
     Server:server1/JDBCProvider:JDBC1/WAS40DataSource:was4DS1/')
     print new40ds
     ```

   Example output:

   ```
   was4DS1(cells/mycell/nodes/mynodes:resources.xml$WAS40DataSource_1)
   ```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required WAS40ConnectionPool
     ```

   - Using Jython:

     ```
     print AdminConfig.required('WAS40ConnectionPool')
     ```

   Example output:

   ```
   Attribute       Type
   minimumPoolSize     Integer
   maximumPoolSize     Integer
   connectionTimeout   Integer
   idleTimeout        Integer
   orphanTimeout       Integer
   statementCacheSize  Integer
   ```

3. Set up required attributes:
   - Using Jacl:

     ```
     set mps [list minimumPoolSize 5]
     set minps [list minimumPoolSize 5]
     set maxps [list maximumPoolSize 30]
     set conn [list connectionTimeout 10]
     set idle [list idleTimeout 5]
     set orphan [list orphanTimeout 5]
     set scs [list statementCacheSize 5]
     set 40cpAttrs [list $minps $maxps $conn $idle $orphan $scs]
     ```

     Example output:

     ```
     {minimumPoolSize 5} {maximumPoolSize 30}
     {connectionTimeout 10} {idleTimeout 5}
     {orphanTimeout 5} {statementCacheSize 5}
     ```

   - Using Jython:

     ```
     minps = ['minimumPoolSize', 5]
     maxps = ['maximumPoolSize', 30]
     conn = ['connectionTimeout', 10]
     idle = ['idleTimeout', 5]
     orphan = ['orphanTimeout', 5]
     scs = ['statementCacheSize', 5]
     cpAttrs = [minps, maxps, conn, idle, orphan, scs]
     print cpAttrs
     ```

     Example output:

     ```
     [[minimumPoolSize, 5], [maximumPoolSize, 30],
     [connectionTimeout, 10], [idleTimeout, 5],
     [orphanTimeout, 5], [statementCacheSize, 5]]
     ```

4. Create was40 connection pool:
   - Using Jacl:

```
$AdminConfig create WAS40ConnectionPool $new40ds $40cpAttrs
```

- Using Jython:

```
print AdminConfig.create('WAS40ConnectionPool', new40ds, 40cpAttrs)
```

Example output:

```
(cells/mycell/nodes/mynode:resources.xml#WAS40ConnectionPool_1)
```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

Configuring new WAS40 custom properties using scripting

You can use scripting and the wsadmin tool to configure a new WAS40 custom property.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a new WAS40 custom properties:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set new40ds [$AdminConfig getid /Cell:mycell/Node:mynode/
     JDBCProvider:JDBC1/WAS40DataSource:was4DS1/]
     ```

   - Using Jython:

     ```
     new40ds = AdminConfig.getid('/Cell:mycell/Node:mynode/
     JDBCProvider:JDBC1/WAS40DataSource:was4DS1/')
     print new40ds
     ```

   Example output:

   ```
   was4DS1(cells/mycell/nodes/mynodes|resources.xml$WAS40DataSource_1)
   ```

2. Get required attributes:
   - Using Jacl:

     ```
     set propSet [$AdminConfig showAttribute $newds propertySet]
     ```

   - Using Jython:

     ```
     propSet = AdminConfig.showAttribute(newds, 'propertySet')
     print propSet
     ```

   Example output:

   ```
   (cells/mycell/nodes/mynode|resources.xml#J2EEResourcePropertySet_9)
   ```

3. Get required attribute:
   - Using Jacl:

     ```
     $AdminConfig required J2EEResourceProperty
     ```

   - Using Jython:

     ```
     print AdminConfig.required('J2EEResourceProperty')
     ```

   Example output:

   ```
   Attribute    Type
   name         String
   ```

4. Set up required attributes:
   - Using Jacl:

     ```
     set name [list name RP5]
     set rpAttrs [list $name]
     ```

   - Using Jython:

```
name = ['name', 'RP5']
rpAttrs = [name]
```

5. Create J2EE Resource Property:
   - Using Jacl:

     ```
     $AdminConfig create J2EEResourceProperty $propSet $rpAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
     ```

   Example output:

   ```
   RP5(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_9)
   ```

6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

Configuring new J2C resource adapters using scripting

Use the wsadmin tool to configure resource adapters with Resource Adapter Archive (RAR) files. A RAR file provides the classes and other code to support a resource adapter for access to a specific enterprise information system (EIS), such as the Customer Information Control System (CICS). Configure resource adapters for an EIS only after you install the appropriate RAR file.

Before you begin

A RAR file, which is often called a J2EE Connector Architecture (JCA) connector, must comply with the JCA Specification. Meet these requirements by using a supported assembly tool (as described in the Assembly tools article) to assemble a collection of Java archive (JAR) files, other runnable components, utility classes, and so on, into a deployable RAR file. Then you are ready to install your RAR file in Application Server.

There are two ways to complete this task. This topic uses the AdminConfig object to install resource adapters. Alternatively, you can use the installJ2CResourceAdapter script in the AdminJ2C script library to install a J2C resource adapter in your configuration, as the following example demonstrates:

```
AdminJ2C.installJ2CResourceAdapter("myNode", "C:\temp\jca15cmd.rar", "J2CTest")
```

The scripting library provides a set of procedures to automate the most common administration functions. You can run each script procedure individually, or combine several procedures to quickly develop new scripts.

1. Launch the wsadmin scripting tool using the Jython scripting language.
2. Identify the configuration ID of the node to which the resource adapter is installed, as the following examples demonstrate:
   - Using Jacl:

     ```
     set node [$AdminConfig getid /Cell:mycell/Node:mynode/]
     ```

   - Using Jython:

     ```
     node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
     print node
     ```

   Example output:

   ```
   mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
   ```

3. Identify the optional attributes.

   The J2CResourceAdapter object does not require specific arguments. Use the following command to display the optional attributes for the J2CResourceAdapter object:
   - Using Jacl:

     ```
     $AdminConfig defaults J2CResourceAdapter
     ```

   - Using Jython:

     ```
     print AdminConfig.defaults('J2CResourceAdapter')
     ```

The following displays the command output that displays each optional attribute and the data type for the attribute, and denotes the default attributes:

```
Attribute                       Type
name                            String
description                     String
classpath                       String
nativepath                      String
providerType                    String
archivePath                     String
threadPoolAlias                 String
propertySet                     J2EEResourcePropertySet
jaasLoginConfiguration          JAASConfigurationEntry
deploymentDescriptor            Connector
connectionDefTemplateProps      ConnectionDefTemplateProps
activationSpecTemplateProps     ActivationSpecTemplateProps
j2cAdminObjects                 J2CAdminObject
adminObjectTemplateProps        AdminObjectTemplateProps
j2cActivationSpec               J2CActivationSpec
```

4. Set up the attributes of interest.

   Determine the attributes to configure for the J2C resource adapter. In the following examples, the commands set the RAR file path to the `rarFile` variable and the name and description configuration options to the `option` variable:

   - Using Jacl:

     ```
     set rarFile /currentScript/cicseci.rar
     set option {-rar.name  RAR1 -rar.desc "New resource adapter"}
     ```

   - Using Jython:

5. Create a resource adapter.

   Use the installResourceAdapter command for the AdminConfig object to install the resource adapter with the previously set configuration options, as the following examples demonstrate:

   - Using Jacl:

     ```
     $AdminConfig installResourceAdapter $rarFile mynode $option
     ```

   - Using Jython:

     ```
     AdminConfig.installResourceAdapter(rarFile, 'mynode', option)
     ```

   Example output:

   ```
   RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
   ```

6. Save the configuration changes.

Configuring custom properties for J2C resource adapters using scripting

You can configure custom properties for J2C resource adapters with scripting and the wsadmin tool.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a new custom property for a J2C resource adapters:

1. Identify the parent ID and assign it to the newra variable.

   - Using Jacl:

     ```
     set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
     ```

   - Using Jython:

```
newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
print newra
```

Example output:

```
RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
```

2. Get the J2EE resource property set:
   - Using Jacl:

     ```
     set propSet [$AdminConfig showAttribute $newra propertySet]
     ```

   - Using Jython:

     ```
     propSet = AdminConfig.showAttribute(newra, 'propertySet')
     print propSet
     ```

   Example output:

   ```
   (cells/mycell/nodes/mynode|resources.xml#PropertySet_8)
   ```

3. Identify the required attributes:
   - Using Jacl:

     ```
     $AdminConfig required J2EEResourceProperty
     ```

   - Using Jython:

     ```
     print AdminConfig.required('J2EEResourceProperty')
     ```

   Example output:

   ```
   Attribute     Type
   name          String
   ```

4. Set up the required attributes:
   - Using Jacl:

     ```
     set name [list name RP4]
     set rpAttrs [list $name]
     ```

   - Using Jython:

     ```
     name = ['name', 'RP4']
     rpAttrs = [name]
     ```

5. Create a J2EE resource property:
   - Using Jacl:

     ```
     $AdminConfig create J2EEResourceProperty $propSet $rpAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
     ```

   Example output:

   ```
   RP4(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_8)
   ```

6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

Configuring new J2C connection factories using scripting

Use scripting and the wsadmin tool to configure new J2C connection factories.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a new J2C connection factory:

1. Identify the parent ID and assign it to the newra variable.
   - Using Jacl:

```
set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
```

- Using Jython:

```
newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
print newra
```

Example output:

```
RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
```

2. There are two ways to configure a new J2C connection factory. Perform one of the following:
   - Using the AdminTask object:
     a. List the connection factory interfaces:
        - Using Jacl:

          ```
          $AdminTask listConnectionFactoryInterfaces $newra
          ```

        - Using Jython:

          ```
          AdminTask.listConnectionFactoryInterfaces(newra)
          ```

          Example output:

          ```
          javax.sql.DataSource
          ```

     b. Create a J2CConnectionFactory:
        - Using Jacl:

          ```
          $AdminTask createJ2CConnectionFactory $newra { -name cf1
          -jndiName eis/cf1 -connectionFactoryInterface
          avax.sql.DataSource
          ```

        - Using Jython:

          ```
          AdminTask.createJ2CConnectionFactory(newra, '['-name', 'cf1',
          '-jndiName', 'eis/cf1', '-connectionFactoryInterface',
          'avax.sql.DataSource']')
          ```

   - Using the AdminConfig object:
     a. Identify the required attributes:
        - Using Jacl:

          ```
          $AdminConfig required J2CConnectionFactory
          ```

        - Using Jython:

          ```
          print AdminConfig.required('J2CConnectionFactory')
          ```

          Example output:

          ```
          Attribute Type
          connectionDefinition ConnectionDefinition@
          ```

     b. If your resource adapter is JCA1.5 and you have multiple connection definitions defined, it is required that you specify the ConnectionDefinition attribute. If your resource adapter is JCA1.5 and you have only one connection definition defined, it will be picked up automatically. If your resource adapter is JCA1.0, you do not need to specify the ConnectionDefinition attribute. Perform the following command to list the connection definitions defined by the resource adapter:
        - Using Jacl:

          ```
          $AdminConfig list ConnectionDefinition $newra
          ```

        - Using Jython:

          ```
          print AdminConfig.list('ConnectionDefinition', $newra)
          ```

     c. Set up the required attributes:
        - Using Jacl:

          ```
          set name [list name J2CCF1]
          set jname [list jndiName eis/j2ccf1]
          set j2ccfAttrs [list $name]
          ```

        - Using Jython:

```
name = ['name', 'J2CCF1']
jname = ['jndiName', 'eis/j2ccf1']
j2ccfAttrs = [name,jname]
```

d. If you are specifying the ConnectionDefinition attribute, also set up the following:
   - Using Jacl:
     ```
     set cdattr [list connectionDefinition $cd]
     ```
   - Using Jython:
     ```
     cdattr = ['connectionDefinition', $cd]
     ```

e. Create a J2C connection factory:
   - Using Jacl:
     ```
     $AdminConfig create J2CConnectionFactory $newra $j2ccfAttrs
     ```
   - Using Jython:
     ```
     print AdminConfig.create('J2CConnectionFactory', newra, j2ccfAttrs)
     ```

   Example output:
   ```
   J2CCF1(cells/mycell/nodes/mynode|resources.xml#J2CConnectionFactory_1)
   ```

3. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

Configuring new J2C activation specifications using scripting

You can configure new J2C activation specifications using scripting and the wsadmin tool.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a J2C activation specifications:

1. Identify the parent ID and assign it to the `newra` variable.
   - Using Jacl:
     ```
     set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
     ```
   - Using Jython:
     ```
     newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
     print newra
     ```

   Example output:
   ```
   RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
   ```

2. There are two ways to configure a new J2C administrative object. Perform one of the following:
   - Using the AdminTask object:
     a. List the administrative object interfaces:

        Using Jacl:
        ```
        $AdminTask listMessageListenerTypes $newra
        ```
        Using Jython:
        ```
        AdminTask.listMessageListenerTypes(newra)
        ```
        Example output:
        ```
        javax.jms.MessageListener
        ```
     b. Create a J2C administrative object:

        Using Jacl:

```
$AdminTask createJ2CActivationSpec $newra { -name ac1
-jndiName eis/ac1 -messageListenerType
javax.jms.MessageListener}
```

Using Jython:

```
AdminTask.createJ2CActivationSpec(newra, ['-name', 'ao1',
'-jndiName', 'eis/ao1', '-messageListenerType',
'javax.jms.MessageListener'])
```

- Using the AdminConfig object:
  a. Using Jacl:

```
$AdminConfig required J2CActivationSpec
```

Using Jython:

```
print AdminConfig.required('J2CActivationSpec')
```

Example output:

```
Attribute Type
activationSpec ActivationSpec@
```

  b. If your resource adapter is JCA V1.5 and you have multiple activation specifications defined, it is required that you specify the activation specification attribute. If your resource adapter is JCA V1.5 and you have only one activation specification defined, it will be picked up automatically. If your resource adapter is JCA V1.0, you do not need to specify the activationSpec attribute. Perform the following command to list the activation specifications defined by the resource adapter:

Using Jacl:

```
$AdminConfig list ActivationSpec $newra
```

Using Jython:

```
print AdminConfig.list('ActivationSpec', $newra)
```

  c. Set the administrative object that you need to a variable:

Using Jacl:

```
set ac [$AdminConfig list ActivationSpec $newra]
set name [list name J2CAC1]
set jname [list jndiName eis/J2CAC1]
set j2cacAttrs [list $name $jname $cdcttr]
```

Using Jython:

```
ac = AdminConfig.list('ActivationSpec', $newra)
name = ['name', 'J2CAC1']
jname = ['jndiName', 'eis/j2cac1']
j2cacAttrs = [name, jname,cdattr]
```

  d. If you are specifying the ActivationSpec attribute, also set up the following:

Using Jacl:

```
set cdcttr [list activationSpec $ac]
```

Using Jython:

```
cdattr = ['activationSpec', ac]
```

  e. Create a J2C activation specification object:

Using Jacl:

```
$AdminConfig create J2CActivationSpec $newra $j2cacAttrs
```

Using Jython:

```
print AdminConfig.create('J2CActivationSpec', newra,j2cacAttrs)
```

Example output:

```
J2CAC1(cells/mycell/nodes/mynode|resources.xml#J2CActivationSpec_1)
```

3. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

Configuring new J2C administrative objects using scripting

You can use scripting and the wsadmin tool to configure new J2C administrative objects.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a J2C administrative object:

1. Identify the parent ID and assign it to the `newra` variable.
   - Using Jacl:

     ```
     set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
     ```
   - Using Jython:

     ```
     newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
     print newra
     ```

   Example output:

   ```
   RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
   ```
2. There are two ways to configure a new J2C administrative object. Perform one of the following:
   - Using the AdminTask object:
     a. List the administrative object interfaces:

        Using Jacl:

        ```
        $AdminTask listAdminObjectInterfaces $newra
        ```

        Using Jython:

        ```
        AdminTask.listAdminObjectInterfaces(newra)
        ```

        Example output:

        ```
        com.ibm.test.message.FVTMessageProvider
        ```

     b. Create a J2C administrative object:

        Using Jacl:

        ```
        $AdminTask createJ2CAdminObject $newra { -name ao1 -jndiName eis/ao1
        -adminObjectInterface com.ibm.test.message.FVTMessageProvider }
        ```

        Using Jython:

        ```
        AdminTask.createJ2CAdminObject(newra, ['-name', 'ao1', '-jndiName', 'eis/ao1',
        '-adminObjectInterface', 'com.ibm.test.message.FVTMessageProvider'])
        ```
   - Using the AdminConfig object:
     a. Using Jacl:

        ```
        $AdminConfig required J2CAdminObject
        ```

        Using Jython:

        ```
        print AdminConfig.required('J2CAdminObject')
        ```

        Example output:

        ```
        Attribute Type
        adminObject AdminObject@
        ```

     b. If your resource adapter is JCA V1.5 and you have multiple administrative objects defined, it is required that you specify the administrative object attribute. If your resource adapter is JCA V1.5 and you have only one administrative object defined, it will be picked up automatically. If your resource adapter is JCA V1.0, you do not need to specify the administrative object attribute. Perform the following command to list the administrative objects defined by the resource adapter:

        Using Jacl:

```
$AdminConfig list AdminObject $newra
```

Using Jython:

```
print AdminConfig.list('AdminObject', $newra)
```

c. Set the administrative objects that you need to a variable:

Using Jacl:

```
set ao AdminObjectId
set name [list name J2CAO1]
set jname [jndiName eis/j2cao1]
set j2caoAttrs [list $name $jname]
```

Using Jython:

```
ao = AdminObjectId
name = ['name', 'J2CAO1']
set jname = ['jndiName', eis/j2cao1]
j2caoAttrs = [name, jname]
```

d. If you are specifying the AdminObject attribute, also set up the following:

Using Jacl:

```
set cdattr [list adminObject $ao]
```

Using Jython:

```
cdattr = ['adminObject', ao]
```

e. Create a J2C administrative object:

Using Jacl:

```
$AdminConfig create J2CAdminObject $newra $j2caoAttrs
```

Using Jython:

```
print AdminConfig.create('J2CAdminObject', newra, j2caoAttrs)
```

Example output:

```
J2CAO1(cells/mycell/nodes/mynode|resources.xml#J2CAdminObject_1)
```

3. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

Managing the message endpoint lifecycle using scripting

Use the Jython scripting language to manage your message endpoints with the wsadmin tool. Use this topic to query your configuration for message endpoint properties, and to deactivate or reactivate a message endpoint.

About this task

The Java EE Connector Architecture (JCA) allows the application server to link inbound requests from messaging resource adapters to message endpoints. The message endpoint managed bean (MBean) is a Java Management Extensions (JMX) framework MBean that the application server associates with a message endpoint instance.

Use this topic to manage situations where messaging providers fail to deliver messages to their intended destinations. For example, a provider might fail to deliver messages to a message endpoint when its underlying Message Driven Bean attempts to commit transactions against a database server that is not responding. To troubleshoot the problem, use the wsadmin tool to temporarily disable the message endpoint from handling messages. After troubleshooting the issue, use the wsadmin tool to reactivate the message endpoint.

The steps in this topic display how to use the AdminControl object and the wsadmin tool to invoke a Message Endpoint MBean to:

- Display properties of the a message endpoint
- Temporarily deactivate a message endpoint

- Reactivate a message endpoint

Note: Starting in Version 7.0, you can use the AdminControl object and the wsadmin tool to deactivate message endpoints to pause the endpoints from receiving messages, and to reactivate message endpoints to resume message handling. Previously, the application server activated and deactivated message endpoints when the application or resource adapter was started and stopped.

- Display properties of a message endpoint.

  Use the following command to display a list of all message endpoints in your configuration:

```
AdminControl.queryNames('*:type=J2CMessageEndpoint,*')
```

  For the previous example, the command returns the following information for the `JMSMDB_MessageEndpoint`:

```
WebSphere:name=JMSMDB_J2CMessageEndpoint,
process=myServer,
platform=dynamicproxy,
cell=myNode01Cell,
node=myNode01,
version=6.1.0.0,
type=J2CMessageEndpoint,
mbeanIdentifier=cells/myNode01Cell/nodes/myNode01/servers/myServer/resources.xml#example#example.jar#JMSMDB_J2CMessageEndpoint,
spec=1.0,
Server=server1,
diagnosticProvider=false,
j2eeType=JCAMessageEndpoint,
J2EEApplication=example
J2EEServer=myServer,
J2CResourceAdapter=SIB JMS Resource Adapter,
MessageDrivenBean=example#example.jar#JMSMDBActivationSpec=3727AS1
```

- Temporarily deactivate the message endpoint.

  Use the following commands to cache the instance and deactivate the message endpoint:

```
objectName=AdminControl.queryNames('*:name=JMSMDB_MessageEndpoint,*')
AdminControl.invoke(objectName, 'pause')
```

  The command returns the following output:

```
Message Endpoint JMSMDB_J2CMessageEndpoint is deactivated
```

- Reactivate the message endpoint.

  Use the following commands to cache the instance and reactivate the message endpoint:

```
objectName=AdminControl.queryNames('*:name=JMSMDB_MessageEndpoint,*')
AdminControl.invoke(objectName, 'resume')
```

  The command returns the following output:

```
Message Endpoint JMSMDB_J2CMessageEndpoint is activated
```

Testing data source connections using scripting

You can test connections for data sources with the wsadmin tool and scripting. After you have defined and saved a data source, you can test the data source connection to ensure that the parameters in the data source definition are correct.

About this task

You can use the testConnection command for the AdminControl object to test data source connections for a cell, node, server, application, or cluster scope. This topic provides an example that tests the data source connection for the application scope.

- Test the data source connection for a cell, node, or server scope.
  1. Launch the wsadmin scripting tool using the Jython scripting language.
  2. Identify the DataSourceCfgHelper MBean and assign it to the dshelper variable.
     - Using Jacl:

```
set ds [$AdminConfig getid /DataSource:DS1/]
$AdminControl testConnection $ds
```

– Using Jython:

```
ds = AdminConfig.getid('/DataSource:DS1/')
AdminControl.testConnection(ds)
```

Example output:

```
WASX7217I: Connection to provided datasource was successful.
```

3. Test the connection. The following example invokes the testConnectionToDataSource operation on the MBean, passing in the classname, userid, password, database name, JDBC driver class path, language, and country.
   – Using Jacl:
   – Using Jython:

   Example output:

```
WASX7217I: Connection to provided data source was successful.
```

- Test the data source connection for an application scope.
  1. Launch the wsadmin scripting tool using the Jython scripting language.
  2. Get the data source for the application of interest.

     Use the AdminConfig object to determine the configuration IDs of the `myApplication` application and `DSA1` data source, as the following examples demonstrate:

     – Using Jacl:

```
set appID [$AdminConfig getid /Deployment:myApplication/]
set ds [$AdminConfig list DataSource $appID]
```

     – Using Jython:

```
appID = AdminConfig.getid("/Deployment:myApplication/")
ds = AdminConfig.list("DataSource", appID)
```

  3. Test the connection.

     Use the AdminConfig object to test the connection for the data source of interest, as the following examples demonstrate:

     – Using Jacl:

```
$AdminControl testConnection $ds
```

     – Using Jython:

```
AdminControl.testConnection(ds)
```

  The command returns output that indicates whether the connection is successful, as demonstrated in the following sample output:

```
WASX7467I: Connection to provided datasource on node myNode processnodeagent was successful.
WASX7217I: Connection to provided datasource was successful.
```

- Test the data source connection for a cluster scope.

  In the following example, the `Cluster1` server cluster contains cluster members on the `node1`, `node2`, and `node3` nodes. The `Cluster1` server cluster contains the `DSC1` data source.

  1. Launch the wsadmin scripting tool using the Jython scripting language.
  2. Get the data source configuration ID for the cluster of interest.

     Use the AdminConfig object to determine the configuration IDs of the `Cluster1` cluster and `DSA1` data source, as the following examples demonstrate:

     – Using Jacl:

```
set cluster [$AdminConfig getid /ServerCluster:Cluster1/]
set ds [$AdminConfig list DataSource $cluster]
```

     – Using Jython:

```
cluster = AdminConfig.getid("/ServerCluster:Cluster1/")
ds = AdminConfig.list("DataSource", cluster)
```

  3. Test the connection.

Use the AdminConfig object to test the connection for the data source of interest, as the following examples demonstrate:

– Using Jacl:

```
$AdminControl testConnection $ds
```

– Using Jython:

```
AdminControl.testConnection(ds)
```

The command returns output that indicates whether the connection is successful, as demonstrated in the following sample output:

```
WASX7467I: Connection to provided datasource on node node1 process nodeagent was successful.
WASX7467I: Connection to provided datasource on node node2 process nodeagent was successful.
WASX7467I: Connection to provided datasource on node node3 process nodeagent was successful.
WASX7217I: Connection to provided datasource was successful.
```

JDBCProviderManagement command group for the AdminTask object

You can use the Jython or Jacl scripting languages in interactive mode to configure data access and data sources with scripting. The commands and parameters in the JDBCProviderManagement group can be used to create or list data sources and Java database connectivity (JDBC) providers.

The JDBCProviderManagement command group for the AdminTask object includes the following commands:

- "createDatasource"
- "createJDBCProvider" on page 1365
- "listDatasources" on page 1367
- "listJDBCProviders" on page 1367

createDatasource

The createDatasource command creates a new data source to access the back end data store. Application components use the data source to access connection instances to your database.

Target object

JDBC Provider Object ID - The configuration object of the JDBC provider to which the new data source will belong.

Required parameters

- name
The name of the data source. (String, required)

-jndiName
The Java Naming and Directory Interface (JNDI) name. (String, required)

-dataStoreHelperClassName
The name of the DataStoreHelper implementation class that extends the capabilities of the selected JDBC driver implementation class to perform data-specific functions. WebSphere Application Server provides a set of DataStoreHelper implementation classes for each of the JDBC provider drivers it supports. (String, required)

configureResourceProperties
This command step configures the resource properties that are required by the data source. (Required) You can specify the following parameters for this step:

name
The name of the resource property. (String, required)

type
The type of the resource property. (String, required)

value
The value of the resource property. (String, required)

Optional parameters

-description
The description of the data source. (String, optional)

-category
The category that you can use to classify a group of data sources. (String, optional)

-componentManagedAuthenticationAlias
The alias used for database authentication at run time. This alias is only used when the application resource reference is using res-auth=Application. (String, optional)

-containerManagedPersistence
Specifies if the data source is used for container managed persistence for enterprise beans. The default value is true. (Boolean, optional)

Examples

Batch mode example usage:

- Using Jacl:

```
$AdminTask createDatasource "DB2 Universal JDBC Driver Provider (XA)(cells/myCell|resources.xml#JDBCProvider_1180538152781)" {-name
"DB2  Universal JDBC Driver XA DataSource" -jndiName s1 -dataStoreHelperClassName com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper
 -componentManagedAuthenticationAlias myCellManager01/a1 -xaRecoveryAuthAlias myCellManager01/a1 -configureResourceProperties
{{databaseName java.lang.String db1} {driverType java.lang.Integer 4} {serverName java.lang.String  dbserver1} {portNumber java.lang.Integer 50000}}}
```

- Using Jython string:

```
AdminTask.createDatasource('DB2 Universal JDBC Driver Provider(XA) (cells/myCell|resources.xml#JDBCProvider_1180501752515)', '[-name
"DB2 Universal JDBC Driver XA DataSource 2" -jndiName ds2 -dataStoreHelperClassName com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper
 -componentManagedAuthenticationAlias myCellManager01/a1 -xaRecoveryAuthAlias myCellManager01/a1 -configureResourceProperties
[[databaseName java.lang.String db1] [driverType java.lang.Integer 4] [serverName java.lang.String  dbserver1] [portNumber java.lang.Integer 50000]]]')
```

- Using Jython list:

```
AdminTask.createDatasource('DB2 Universal JDBC Driver Provider(XA) (cells/myCell|resources.xml#JDBCProvider_1180501752515)', ['-name', '
DB2  Universal JDBC Driver XA DataSource 2', '-jndiName', 'ds2', '-dataStoreHelperClassName',
 'com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper', '-componentManagedAuthenticationAlias', 'myCellManager01/a1',
 '-xaRecoveryAuthAlias', 'myCellManager01/a1', '-configureResourceProperties', '[[databaseName java.lang.String db1]
[driverType java.lang.Integer 4] [serverName java.lang.String  dbserver1] [portNumber java.lang.Integer 50000]]']
```

Interactive mode example usage:

- Using Jacl:

```
$AdminTask createDatasource {-interactive}
```

- Using Jython:

```
AdminTask.createDatasource('-interactive')
```

createJDBCProvider

The createJDBCProvider command creates a new Java database connectivity provider (JDBC) that you can use to connect to a relational database for data access.

Target object

None

Required parameters

-scope
The scope for the new JDBC provider. Provide the scope in the form `type=name`. `Type` can be Cell,

Node, Server, Application, or Cluster, and `name` is the name of the specific instance of the cell, node, server, application, or cluster that you are using. The default is `none`. (String, required)

-databaseType
The type of database that will be used by the JDBC provider. For example, DB2, Derby, Informix, Oracle, and so on. (String, required)

-providerType
The JDBC provider type that will be used by the JDBC provider. (String, required)

-implementationType
The implementation type for this JDBC provider. Use `Connection pool data source` if your application runs in a single phase or a local transaction. Otherwise, use `XA data source` to run in a global transaction. (String, required)

Optional parameters

-classpath
Specifies a list of paths or JAR file names that form the location for the resource provider classes. (String, optional)

-description
The description for the JDBC provider. (String, optional)

-implementationClassName
Specifies the Java class name for the JDBC driver implementation. (String, optional)

-isolated
Specifies that the JDBC provider will load in its own class loader. The default value is false. You cannot specify a native path for an isolated JDBC provider. (Boolean, optional)

-name
The name of the JDBC provider. The default is the value from the provider template. (String, optional)

-nativePath
Specifies a list of paths that form the location for the resource provider native libraries. (String, optional)

-isolated
Specifies whether the JDBC provider loads within the class loader. The default value is `false`. You cannot specify a native path for an isolated JDBC provider. (Boolean, optional)

Examples

Batch mode example usage:

- Using Jacl:

```
$AdminTask createJDBCProvider {-scope Cell=my02Cell -databaseType DB2 -providerType "DB2 Universal JDBC Driver Provider"
-implementationType "XA data source" -name "DB2 Universal JDBC Driver Provider (XA)" -description "XA DB2 Universal JDBC Driver-compliant
Provider. Datasources created under this provider support the use of XA to perform 2-phase commit processing. Use of driver type 2 on WAS z/OS is not
supported for datasources created under this provider." -classpath
${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar;${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cu.jar;${DB2UNIVERSAL_JDBC_DRIVER_PATH}/
db2jcc_license_cisuz.jar -nativePath ${DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH}}
```

- Using Jython string:

```
AdminTask.createJDBCProvider('[-scope Cell=myCell -databaseType DB2 -providerType "DB2 Universal JDBC Driver Provider"
 -implementationType "XA datasource" -name "DB2 Universal JDBC Driver Provider (XA)" -description "XA DB2 Universal JDBC
Driver-compliant Provider. Datasources created under this provider support the use of XA to perform 2-phase commit processing. Use of driver
 type 2 on WAS z/OS is not supported for datasources created under this provider." -classpath
 ${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar;${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cu.jar;${DB2UNIVERSAL_JDBC_DRIVER_PATH}/
db2jcc_license_cisuz.jar -nativePath ${DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH}]')
```

- Using Jython list:

```
AdminTask.createJDBCProvider(['-scope', 'Cell=myCell', '-databaseType', 'DB2', '-providerType', 'DB2 Universal JDBC Driver Provider',
 '-implementationType', 'XA data source', '-name', 'DB2 Universal JDBC Driver Provider (XA)', '-description', 'XA DB2 Universal
JDBC Driver-compliant Provider. Datasources created under this provider support the use of XA to perform 2-phase commit processing. Use of
driver type 2 on WAS z/OS is not supported for datasources created under this provider.', '-classpath',
  '${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar;${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cu.jar;${DB2UNIVERSAL_JDBC_DRIVER_PATH}/
db2jcc_license_cisuz.jar', '-nativePath', '${DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH}'])
```

Interactive mode example usage:

- Using Jacl:

```
$AdminTask createJDBCProvider {-interactive}
```

- Using Jython:

```
AdminTask.createJDBCProvider('-interactive')
```

listDatasources

Use the listDatasources command to list data sources that are contained in the specified scope.

Target object

None

Required parameters

None.

Optional parameters

-scope
The scope for the data sources that will be listed. Provide the scope in the form `type=name`. `Type` can be Cell, Node, Server, Application, or Cluster, and `name` is the name of the specific instance of the cell, node, server, application, or cluster that you are using. The default is `All`. (String, optional)

Examples

Batch mode example usage:

- Using Jacl:

```
$AdminTask listDatasources {-scope Cell=my02Cell}
```

- Using Jython string:

```
AdminTask.listDatasources('[-scope Cell=my02Cell]')
```

- Using Jython list:

```
AdminTask.listDatasources('-scope', 'Cell=my02Cell')
```

Interactive mode example usage:

- Using Jacl:

```
$AdminTask listDatasources {-interactive}
```

- Using Jython:

```
AdminTask.listDatasources('-interactive')
```

listJDBCProviders

The listJDBCProviders command lists JDBC providers that are contained in the specified scope.

Target object

None

Required parameters

None.

Optional parameters

-scope

The scope for the JDBC providers that will be listed. Provide the scope in the form `type=name`. `Type` can be Cell, Node, Server, Application, or Cluster, and `name` is the name of the specific instance of the cell, node, server, application, or cluster that you are using. The default is `All`. (String, optional)

Examples

Batch mode example usage:

- Using Jacl:

```
$AdminTask listJDBCProviders {-scope Cell=my02Cell}
```

- Using Jython string:

```
AdminTask.listJDBCProviders('-scope Cell=my02Cell')
```

- Using Jython list:

```
AdminTask.listJDBCProviders(['-scope', 'Cell=my02Cell'])
```

Interactive mode example usage:

- Using Jacl:

```
$AdminTask listJDBCProviders {-interactive}
```

- Using Jython:

```
AdminTask.listJDBCProviders('-interactive')
```

Configuring Persistence Provider support in the application server

Persistence providers are implementations of the Java Persistence API (JPA) specification and can be deployed in the Java EE compliant application server that supports JPA persistence.

About this task

The Enterprise JavaBeans (EJB) 3.0 specifications require that an application server container that supports the EJB 3.0 programming model must provide a JPA implementation. This is also referred to as a persistence provider. There are two built-in JPA persistence providers: the JPA persistence provider for the application server and the OpenJPA persistence provider. If an explicit provider element is not specified in the persistence unit definitions, the application server will use the default persistence provider, which is the JPA persistence provider for the application server.

The application server provides both the default persistence provider and the Apache OpenJPA persistence provider to support the open source implementation of JPA and allow for easy migration of existing OpenJPA applications to the application server's solution for JPA.

- **Configuring a default persistence provider**

  Use the default persistence provider, or specify a persistence provider for your application. With the application server's JPA persistence provider, you can take advantage of the stability and application extensions that are provided with the application server's implementation of JPA. You can decide which persistence implementation best fits your needs. If an application relies on a specific persistence provider for certain functions and settings, you should specify the provider in the persistence unit definition to avoid any incompatibilities.
- **Using third-party persistence providers**

Use third-party persistence providers in the application server environment.

Configuring the Java Persistence API (JPA) default persistence provider

Two persistence providers are included in WebSphere Application Server: *JPA for WebSphere Application Server persistence provider* and *Apache OpenJPA persistence provider*. The JPA for WebSphere Application Server persistence provider is the default provider for WebSphere Application Server. You can use one of the two providers, or a third-party persistence provider, as the default provider.

About this task

On the application server's feature pack for enterprise beans (EJB) 3.0 the default persistence provider, default Java Transaction API (JTA) datasource Java Naming and Directory Interface (JNDI) name, and default non-JTA datasource JNDI name, values are set through the following Java virtual machine (JVM) properties: com.ibm.websphere.jpa.default.provider, com.ibm.websphere.jpa.default.jta.datasource, and com.ibm.websphere.jpa.default.nonjta.datasource. Support for these properties has been deprecated. Any values that were set through these properties will be displayed as default values on this panel. Any change to these values through the Administrative Console panel will override any values set via the JVM properties.

While built from the Apache OpenJPA persistence provider, the JPA for WebSphere Application Server persistence provider contains the following enhancements and differences:

- Enhanced tracing support
- Version ID generation
- ObjectGrid cache plug-in support
- WebSphere product-specific commands and scripts
- Translated message files
- Static SQL support using the DB2 pureQuery feature
- Access intent support
- The following table shows how the default values for the JPA for WebSphere Application Server provider configuration properties are different from the Apache OpenJPA provider:

Property	**Apache OpenJPA default value**	**JPA for WebSphere Application Server default value**
openjpa.Compatibility	StrictIdentityValues=false	StrictIdentityValues=true
openjpa.RuntimeUnenhancedClasses	supported	warn

If no JPA provider is configured in the <provider> element of the `persistence.xml` file within an EJB module, the default JPA provider that is currently configured for this server is used. The WebSphere Application Server is packaged with the JPA for WebSphere Application Server persistence provider defined as the default provider. However, it is possible to override this default and specify a different default via the Websphere Administrative Console.

You can set your default persistence provider in one of two ways. Use one of the following procedures.

1. Select the default JPA provider from a list of providers included with WebSphere Application Server.
   a. Open the administrative console.
   b. From the left-hand navigation, navigate to **Servers** → **Application Servers**
   c. Select a *server*.
   d. Navigate to **Container Services** → **Default Java Persistence API Settings**

e. Select **Select a default persistence provider that is included with WebSphere Application Server**.
f. Click the slider and select from the list.
g. Click **Apply** and save the configuration.

2. Specify an alternative default persistence provider via the Administrative Console
   a. Open the administrative console.
   b. From the left-hand navigation, navigate to **Servers** → **Application Servers**
   c. Select a *server*.
   d. Navigate to **Container Services** → **Default Java Persistence API Settings**
   e. Select **Specify an alternative default persistence provider** .
   f. Enter the fully qualified JPA implementation class name of a JPA persistence provider in the box.
   g. Click **Apply** and save the configuration.

Related tasks

"Configuring Persistence Provider support in the application server" on page 1368
Persistence providers are implementations of the Java Persistence API (JPA) specification and can be deployed in the Java EE compliant application server that supports JPA persistence.

"Using third-party persistence providers" on page 1371
Java Persistence API (JPA) for WebSphere Application Server allows users to specify third-party persistence providers in their application server environment.

Default Java Persistence API settings

The Java Persistence API (JPA) specification requires a default provider to be defined. If you have applications that use JPA, it is recommended you use this page to provide default values. To increase the portability of your applications, you can use this page to configure the default JPA settings for applications running on this server instead of defining the <provider> element in each persistence unit in your applications. The JPA settings defined here are used for the persistence unit of an application only when the application does not define the JPA settings for that persistence unit.

Note: Application JPA settings always override the settings on this page.

To view this administrative console page, click **Applications** → **server** → **Container Services** → **Default Java Persistence API settings**.

Default persistence provider:

Specify the default persistence provider for the application server container. The default persistence provider can be selected either from a list of providers that are included with the product or a user-specified alternate persistence provider.

Select a persistence provider from the product list or specify a fully package qualified JPA implementation class name of an alternate persistence provider.

Default

com.ibm.websphere.persistence.PersistenceProviderImpl

Note: If an alternate persistence provider is specified as the default, make sure the alternate persistence provider is created in the server. See the information center topic on using a third-party persistence provider.

Default Java Transaction API (JTA) data source Java Naming and Directory Interface (JNDI) name:

Specify the default JTA data source used by persistence units for the application server container.

Select the JNDI name for the data source from the drop down box. The JTA data sources that are currently configured and visible to the application server are available in the drop down box selection.

Default
None

Note: If a default JTA data source is not specified, ensure an appropriate JTA data source is specified in the <jta-data-source> or connection properties field in the <properties> element in the persistence unit.

Default non-JTA data source JNDI name:

Specify the default non-JTA data source used by persistence units for the application server container.

Select the JNDI name for the data source from the drop down box. The data sources that are currently configured, visible to the application server, and are set to ″non-transactional″ are available in the drop down box selection.

Default
None

Note: Some JPA entity features will require a non-JTA data source to be specified. An example of this is automatic entity identity generation. Ensure a non-JTA data source is configured to match your application needs. For information on configuring a non-JTA data source, see the information center topic on associating persistence units and data sources.

Configuring the default JTA and non-JTA data source JNDI Names

The Java Transaction API (JTA) and non-JTA data sources to be used for an application can be specified through the <jta-data-source> and <non-jta-data-source> elements of the `persistence.xml` file within an Enterprise JavaBeans (EJB) module.

About this task

If these elements are not configured in the persistence.xml file, then the default JTA and non-JTA data sources configured for the server are used. These values are null by default. However, the default JTA and non-JTA data source Java Naming and Directory Interface (JNDI) names to be used by applications running on this server can be defined using the administrative console.

1. Open the administrative console.
2. Select **Servers** → **Application server** → ***server*** → **Container Services**.
3. Click **Default Java Persistence API settings**.
4. Select the **Default JTA data source JNDI name** or the **Default non-JTA data source JNDI name** field.
5. Click **Apply** to save the configuration.

Related tasks

“Configuring the Java Persistence API (JPA) default persistence provider” on page 1369
Two persistence providers are included in WebSphere Application Server: *JPA for WebSphere Application Server persistence provider* and *Apache OpenJPA persistence provider*. The JPA for WebSphere Application Server persistence provider is the default provider for WebSphere Application Server. You can use one of the two providers, or a third-party persistence provider, as the default provider.

Using third-party persistence providers

Java Persistence API (JPA) for WebSphere Application Server allows users to specify third-party persistence providers in their application server environment.

About this task

Java EE applications that use JPA functions can employ third-party persistence providers other than those that are included with the application server. Applications can also specify an Apache OpenJPA provider that is other than the version that is included with the application server. There are two basic means to incorporate third-party providers into an application:

- Embedding the persistence provider inside an application
- Making use of shared libraries.

Depending on your requirements, you can embed a persistence provider inside an application, or place the persistence provider into a shared library.

- **Embedding a third-party persistence provider within an application** Sometimes an application design must rely on the implementation of a specific persistence provider. The JPA specification permits embedding of a specific JPA provider within a persistence archive. When building the application, you can assemble a specific version of a provider's implementation in the application enterprise archive (EAR) file or in a web application (WAR) file. To embed a third-party persistence provider into an application, you need to inspect the application design and all dependent prerequisites. Use the following steps to embed a persistence provider inside an application:
  1. Modify the <provider> element to specify explicitly which persistence provider to use to access the persistence entity.
  2. Build the specific version of the third-party persistence provider into the application. To manage the persistence correctly, verify that the EntityManagerFactory and the EntityManager are calling the correct provider. Many providers write startup and version information to standard output, which gets included in the SystemOut.log of the application server. This information can be helpful to determine if a third-party provider is being used by your application.
  3. To use a third-party JPA provider that was not bundled with the application server, configure the class loader order for your application to load the classes with the application class loader first. This is also required if the third-party JPA provider is defined in a shared library that is assigned to a user-defined classloader on the server. If the class loader is not configured properly, the third-party JPA provider that is included with the application server will be loaded and used by your application.
  4. Depending on how you packaged the provider, perform one of the following steps:
     – If you packaged the provider in an EAR file, specify the third-party persistence provider binaries in the Manifest.mf classpath in those application modules that needs JPA access.
     – If the provider was bundled in a WAR file, include the necessary provider binaries in the WEB-INF/lib directory of the web application.
  5. Install your application normally.

  This configuration localizes the availability of the provider and limiting it to the application alone. While sometimes necessary, embedding persistence providers will increase the application's memory footprint accordingly.
- **Using shared libraries to implement a third-party persistence provider** Persistence providers accessed by applications in a global environment can be installed as a shared library for the application server. Depending on your requirements, you can share the library to the server and application. Use the following steps to implement a third-party persistence provider using shared libraries:
  1. Modify the <provider> element to specify explicitly which persistence provider to use to access the persistence entity.
  2. Define the persistence provider in a shared library. See the topic on creating shared libraries for more information.
  3. Associate the shared library with the application class loader, or associate the shared library with the server class loader if the library is accessed by many applications.
  4. Configure the class loader order for your application to load the classes with the application class loader first. This is required if the third-party JPA provider is included in the application or if it is

defined in a shared library. If the class loader is not configured properly, the JPA provider that is included with the application server will be used by your application instead of the third-party JPA provider.

When the application starts, the specified persistence provider will be resolved. From this point on, all persistence requests will be handled by this provider.

- If the shared library persistence provider is overriding an existing persistence provider that is the same type and exists in your application's classloader hierarchy (example: attempting to override the version of OpenJPA that is shipped with WebSphere), using an isolated classloader for the shared library is recommended. See the topic on creating shared libraries for more information.

Related tasks

Creating shared libraries
Shared libraries are files used by multiple applications. Create a shared library to reduce the number of duplicate library files on your system.

Configuring class loaders of a server
You can configure the application class loaders for an application server. Class loaders enable applications that are deployed on the application server to access repositories of available classes and resources.

Task overview: Data Studio pureQuery

Data Studio pureQuery provides Java Persistence API (JPA) users an alternative way to access a DB2 database. PureQuery supports static Structured Query Language (SQL).

About this task

Note: JPA in the Java EE and Java SE environments provides optional support for the DB2 pureQuery runtime environment. PureQuery is a high performance Java data access platform that helps manage applications that access data. PureQuery provides an alternate set of APIs that can be used instead of Java Database Connectivity (JDBC) to access the DB2 database.

To use this feature on the application server, Data Studio pureQuery runtime version 1.2 must be installed. If you plan on performing the DB2 bind command from the administrative console or with the wsadmin tool, you must have pureQuery v1.2 or later. Refer to the Data Studio information center topic on installing pureQuery Runtime for more information.

The application server offers support for static SQL for Enterprise JavaBeans (EJB) 2.x entity beans with the ejbdeploy SQLj option. With JPA, this feature is offered through pureQuery.

DB2 pureQuery offers a number of benefits over JDBC and SQLJ. Static SQL offers greater security and control over access to data because applications are only granted authority to execute known SQL. Static SQL offers better resource utilization on the DB2 server because it avoids runtime parsing and optimizing of the SQL statements.

PureQuery makes use of DB2 packages. These packages consist of information for one or more SQL statements and are stored in the DB2 catalog. To create the packages, the user must first run the wsdb2gen command on a JPA application. The wsdb2gen command creates a *persistence_unit_name*.pdqxml file. This file contains pre-generated SQL statements for Create, Update, Delete, and Retrieve, NamedQueries and NamedNativeQueries of JPA entities. The *persistence_unit_name*.pdqxml file must be bound against database. Associated DB2 packages are generated and the SQL statement is executed statically at runtime. This *persistence_unit_name*.pdqxml file must be included into the application Java archive (JAR) file.

When doing the bind process and when you define your JDBC provider, the following four JAR files must be in the class path:

- db2jcc_license_cisuz.jar

- db2jcc_license_cu.jar
- pdq.jar
- pdqmgmt.jar

WebSphere Application Server support for pureQuery

Note:

- There is no support for the `QueryTimeout` property specified either through the FetchPlan API or through the property plug-in string for `wsjpa.ConnectionFactoryProperties`. The `QueryTimeout` value is ignored if specified.
- OpenJPA large result processing uses JDBC APIs for scrollable cursors.

Note:

- JPA sets the pureQuery property, `pdq.executionMode`, to the value `STATIC`.
- In addition to the JDBC driver JAR file, the JDBC provider configuration must include the JAR file for the pureQuery runtime environment.
- OpenJPA provides support to allow application programs to programmatically access and alter the FetchPlan at run time. Altering the fetch plan might result in SQL that has not been generated by the wsdb2gen command at application build time. If this occurs, the SQL is executed dynamically rather than using static SQL from the DB2 package.
- If the user makes changes to the application queries, entity mapping or persistence properties, then run the wsdb2gen command and bind again. This process generates and binds the updated DB2 packages.
- Input parameter values in JPA queries (with both EJB SQL queries and native SQL queries) cannot be `NULL` values except in the case of update statements `SET` expression values. To search for `NULL` values in a WHERE clause of SELECT, UPDATE or DELETE, then enter the `is null` predicate instead.

- Learn how to **"Configuring to use pureQuery in a Java EE environment"**.
- Learn how to **"Configuring to use pureQuery in Java SE environment" on page 1377**.

wsenhancer command
The entity enhancer tool for Java Persistence API (JPA) applications in the application server inserts bytecode into an entity class file that allows the JPA provider to manage the state of an entity.

Developing and packaging JPA applications for a Java EE environment
Containers in the application server can provide many of the necessary functions for the Java Persistence API (JPA) in a Java Enterprise Edition (Java EE) environment. The application server also provides JPA tools to assist you with developing applications in a Java EE environment.

Developing and packaging JPA applications for a Java SE environment
Prepare and package persistence applications to test outside of the application server container in a Java SE environment.

Configuring to use pureQuery in a Java EE environment

Use this task to configure the application data source Java Database Connectivity (JDBC) provider to use pureQuery to access DB2.

Before you begin

If you need to use multiple DB2 package collections, see the information center topic configure pureQuery to use multiple package collections before continuing with this task.

About this task

PureQuery makes use of DB2 packages. These packages consist of information for one or more SQL statements and are stored in the DB2 catalog. You must first run the wsdb2gen command on a JPA application to create the packages. The wsdb2gen command creates an XML file containing SQL statement information. This XML file must be included into the application Java archive (JAR) file. The DB2 bind command uses this file as input to create the DB2 package .

Note:

- JPA sets the pureQuery property `pdq.executionMode` to the value `STATIC`.
- The JDBC provider configuration must include the JAR file for the pureQuery runtime environment. This JAR file is in addition to the JDBC driver JAR file. See the information center topic on installing pureQuery runtime for more information.
- If this is an XA data source, define a new custom property on the data source where *property_name* = `downgradeHoldCursorsUnderXa` and boolean value = `true`.

1. Update the application data source JDBC provider configuration to include the pureQuery runtime JAR file. Either define an new JDBC provider or modify an existing provider to include the following JAR files. See information center topics on JDBC provider settings and installing pureQuery Runtime for more information.
   - `pdq.jar`
   - `pdqmgmt.jar`
2. Using the DB2 bind command, bind the XML file to the database. This creates the DB2 packages. There are three ways to do this:
   - Use the wsadmin command. Refer to the information center topic on application management command group for the AdminTask object for more information.
   - Using the administrative console. Refer to the information center topic on SQLj profiles and pureQuery bind files settings for more information.
   - Using the DB2 bind command provided by Data Studio. Refer to the information center topic on the pureQuery Bind utility for more information.

What to do next

If you want to reconfigure the data source for JDBC, just remove the `pdq.jar` and `pdqmgmt.jar` from the class path.

Configuring pureQuery to use multiple package collections:

Set up a pureQuery Java Persistence API (JPA) application to use multiple DB2 package collections.

About this task

It is possible for multiple copies of a database schema to exist. This situation might happen in a partitioned database schema where there is one database for east coast employee data and another database for west coast employee data. In this case, the two databases have the same schema. There might be two databases with two database catalogs. Or there might be only one database, in which case, the high-level qualifier of the table names (the schema name) must be different. Since the schemas are the same, there can be a single set of JPA entities that are used to access both sets of data. There are several ways to configure JPA to handle these situations.

Note: When there are multiple persistence units, either with separate databases or a single database, you must run the wsdb2gen command once for each persistence unit.

The following three scenarios exist that require the use of multiple DB2 package collections. If you need more information on configuring pureQuery, read about configuring an application to use pureQuery.

1. When there are two persistence units with different data source names, using static SQL, two sets of DB2 packages exist: one DB2 package in each database. Since two persistence units exist, two *persistence_unit_name*.pdqxml files for the JPA runtime environment exist.
2. If the tables are in a single database, then two persistence units can also be used. In this case, the data source is the same in both persistence units. However, the schema name property, wsjpa.jdbc.Schema must be different. There are two sets of DB2 packages. Each DB2 package must

have a different package name or a different package collection name. Both the wsdb2gen and the DB2 bind command have options to specify the package collection and package names.

3. You can create a single persistence unit, which will eliminate the need to maintain two persistence unit configurations and run the wsdb2gen command multiple times. This configuration requires a common package name. Thus the package collection names must be different. Use the createEntityManager(Map map) method, where the map contains the values for the `wsjpa.jdbc.Schema` and `wsjpa.jdbc.CollectionId` properties to specify the package collection name and schema name.

Configuring to use pureQuery in Java SE environment

Use this task to configure the application data source Java Database Connectivity (JDBC) provider to use pureQuery to access DB2.

Before you begin

If you need to use multiple DB2 package collections, see the information center topic configure pureQuery to use multiple package collections before continuing with this task.

About this task

PureQuery makes use of DB2 packages. These packages consist of information for one or more Structured Query Language (SQL) statements and are stored in the DB2 catalog. You must first run the wsdb2gen command on a Java Persistence API (JPA) application to create the packages. The wsdb2gen command creates an XML file containing SQL statement information. This XML file must be included into the application Java archive (JAR) file. The DB2 bind command uses this file as input to create the DB2 package .

Note:

- JPA sets the pureQuery property `pdq.executionMode` to the value `STATIC`.
- The class path must include the install location for the pureQuery Runtime. See the information center topic on installing pureQuery Runtime for more information.
- The JPA provider implementation must be JPA for the application server (`com.ibm.websphere.persistence.PersistenceProviderImpl`). The OpenJPA persistence provider does not provide support for pureQuery.
- The wsdb2gen command requires the URL of a database. The wsdb2gen command forces a synchronize mapping function that creates or alters the required tables. For DB2 zOS, V8 unique indexes and LOB tables must be manually created prior to executing the wsdb2gen command.

PureQuery properties are specified in a `pdq.properties` file in the META-INF directory of the application jar. The `pdq.ExecutionMode` property is defaulted to STATIC for JPA applications. PDQ properties, if specified, pass on to the pureQuery runtime. See Data Studio pureQuery runtime documentation for list of properties and valid values.

- **wsjpa.jdbc.CollectionId** : String value specifying the collection id to use. This overrides any collection id used during wsdb2gen.

1. Update the application data source JDBC provider configuration to include the pureQuery Runtime JAR files. Include the `pdq.jar` and `pdqmgmt.jar` files on the class path in addition to the JDBC driver jar files. Either define an new JDBC provider or modify an existing provider to include the JAR files. The

class path must include the install location for the pureQuery Runtime. See the information center topics on JDBC provider settings and installing pureQuery Runtime for more information.

2. Using the DB2 bind command provided by Data Studio, bind the XML file to the database. This creates the DB2 packages. Refer to the information center topic on the pureQuery Bind utility for more information.

What to do next

If you want to reconfigure the data source for JDBC, remove the `pdq.jar` and `pdqmgmt.jar` from the class path.

Associating persistence units and data sources

Java Persistence API (JPA) applications allow you to specify the underlying data source used by the persistence provider to access the database.

About this task

The application server provides three methods for defining the data sources in the persistence.xml file.

- Explicitly specify the Java Naming and Directory Interface (JNDI) name in the persistence.xml file, and the application will directly reference the data source. Switching to another data source requires an update to the persistence.xml file.

  JPA has two transactional patterns for accessing a data source:

  – The Java Transaction API (JTA) resource pattern depends on global transactions. The JTA resource pattern is typically used within the scope of an Enterprise JavaBeans (EJB) session facade. This allows the session bean to control transaction and security contexts while JPA handles the persistence mappings. In this case, the application does not use the EntityTransaction interface but relies on the EntityManager enlisted with the global transaction when it is accessed.

  – The non-JTA resource pattern is generally used when dealing with a single resource in the absence of global transactions. The non-JTA resource pattern is typically used within the scope of a web application or an application client. The application controls the transaction with the data source with the EntityTransaction interface.

    Within the application server, the use of the <non-jta-data-source> element requires a special configuration for a non-transactional data source. Data sources that are configured for the application server will not function as a <non-jta-data-source>, because all data sources that are configured by the application server are automatically enlisted with the current transactional context. To prevent this automatic enlistment, add an additional data source custom property nonTransactionalDataSource=true:

1. Select **Resources** → **JDBC** → **Data sources**
2. Select the name of the data source that you want to configure.
3. Select **WebSphere Application Server data source properties** from the **Additional Properties** heading.
4. Select **Non-transactional data source**.
5. Click **OK**.

Note: The JPA specification assumes that connections will be obtained with an isolation level that does not hold long term locks in the database, such as `READ_COMMITTED`. This may not match the WebSphere Application Server default isolation level, which is `REPEATABLE_READ` for most databases. You can check the level which is used for your database by referring to the topic Requirements for setting isolation level.

If the default for your database is not `READ_COMMITTED`, you may change the default by adding an additional data source custom property `webSphereDefaultIsolationLevel`. The following table shows the valid values.

Table 9. Isolation level values

Value	Isolation Level
1	READ_UNCOMMITTED
2	READ_COMMITTED (JPA default)
4	REPEATABLE_READ (WebSphere Application Server default)
8	SERIALIZABLE

If the isolation level is set to a value that will hold long-term read locks, you need to configure the JPA provider to use Pessimistic Locking instead of the default Optimistic Locking. For the JPA provider included with WebSphere Application Server, you may do this by adding the following properties to `persistence.xml` file:

```
<property name="openjpa.Optimistic"="false"/>
<property name="openjpa.LockManager"=pessimistic"/>
```

The JPA specification mandates that the data sources that are defined in the `<jta-data-source>` and `<non-jta-data-source>`elements of a persistence unit register in the JNDI name space. For example, the persistence.xml file should contain an entry similar to the following:

```
<jta-data-source>jdbc/FooBarDataSourceJNDI</jta-data-source>
```

- The JPA solution for the application server extends the implementation to allow you to reference data sources in component name space. In the EJB or Web module deployment descriptor file, this is the <resource-ref> element. You can prefix the data source with java:comp/env/ so the application indirectly references the data source by using the local JNDI name. In this association, the application does not require updates, you change the <resource-ref> to use another data source. See the following example:

  ```
  <jta-data-source>java:comp/env/jdbc/FooBarDataSourceJNDI</jta-data-source>
  ```

  Note: JPA specifications do not require implementations to include data sources referenced through local JNDI names, so this method of reference may not be portable to other implementations of JPA.

- You can declare openjpa.Connection* properties in the persistence unit. If you are not using JPA inside the application server, you need to use this method:

  Example

  ```
  <property name="openjpa.ConnectionDriverName" value="org.apache.derby.jdbc.EmbeddedDriver" />
  <property name="openjpa.ConnectionURL" value="jdbc:derby:target/database/jpa-test-database;create=true"/>
  ```

What to do next

For information about configuring data sources, see the topic on creating and configuring a data source.

For information about data sources and JPA, see the section on persistence in the Apache OpenJPA User's Guide.

Configuring OpenJPA caching to improve performance

The OpenJPA implementation allows users the option of storing frequently used data in the memory to improve performance. OpenJPA provides concurrent data and concurrent query caches that allow applications to save persistent object data and query results in memory to share among threads and for use in future queries.

About this task

OpenJPA data cache functionality

The OpenJPA data cache is a cache of persistent object data that operates at the EntityManagerFactory level. This optional-use cache is designed to increase performance while remaining in full compliance with the Java Persistence API (JPA) standard. This means that enabling the caching option can increase the performance of your application, with no changes to your code. The OpenJPA data cache is designed to provide significant performance increases over cacheless operations and ensures that behavior will be identical in both cache-enabled and cacheless operations.

When enabled, the cache is examined before accessing the datastore. The cache stores data when objects are committed and when persistent objects are loaded from the datastore. If operating in a single Java virtual machine (JVM) environment, the JVM maintains and shares a data cache across all EntityManager instances obtained from a particular EntityManagerFactory. The OpenJPA data cache cannot do this in a distributed environment because caches in different JVMs, created from different EntityManagerFactory objects will not be synchronized. Using the OpenJPA cache in a multi-JVM environment requires either using the event notification framework or through custom integrations with a third-party distributed cache utilities such as IBM ObjectGrid.

Enabling and configuring the OpenJPA data cache

You can enable the OpenJPA data cache for a single or a multiple JVM environment, set its default element size, including soft references, and specify timeout values.

To set up and configure the OpenJPA data cache, do the following:

1. To enable the cache for a single JVM, set the openjpa.DataCache property to true, and set the openjpa.RemoteCommitProvider property to sjvm:

   ```
   <property name="openjpa.DataCache" value="true"/>
   <property name="openjpa.RemoteCommitProvider" value="sjvm"/>
   ```

   To enable the data cache in a distributed environment, the openjpa.RemoteCommitProvider must be configured specifically for the environment, or a third-party cache management utility can be used.
2. The maximum cache size can be adjusted by setting the CacheSize property:

   ```
   <property name="openjpa.DataCache" value=true(CacheSize=5000...
   ```

   By default, the OpenJPA data cache holds 1000 elements. Objects that are pinned into the cache are not counted when determining if the cache size exceeds its maximum size. If the cache overflows, it evicts random elements. You can preserve evicted elements longer with the SoftReferenceSize property. By default, soft references are unlimited. If you need to, you can limit the number of soft references or set to 0 to disable soft references completely:

   ```
   <property name="openjpa.DataCache" value="true(CacheSize=5000 SoftReferenceSize=0 ...
   ```
3. You can specify that a cache should be cleared at certain times. The EvictionSchedule property of the OpenJPA cache implementation accepts a cron style eviction schedule. The cron format specifies the

minute, hour of day, day of month, day of month, and day of the week beginning with 1 for Sunday; the * symbol (asterisk), indicates match all. To schedule a cache to evict at 45 minutes past 3 PM on Sunday every month you would add this property:

```
<property name="openjpa.DataCache" value="true(CacheSize=5000 SoftReferenceSize=0 EvictionSchedule='15,45 * * 1'")/>
```

Note: You also can specify a cache timeout value for a single class by setting the timeout metadata extension to the amount of time in milliseconds that the data of the class is valid. Refer to the org.apache.openjpa.persistence.DataCache Javadoc for more information.

After configuring your data cache, you can use it after you restart your application.

Refresh with active DataCache

Refreshing an entity may lead to different behavior with or without a DataCache when a separate process or part of the same application are updated or even deleted the corresponding record in the database. By default, entities are refreshed from the database even when DataCache is active. Therefore, with the default configuration the refresh behaves identically with or without a DataCache. However, a persistence unit can be configured to refresh entities from DataCache with the property `openjpa.RefreshFromDataCache` for improved performance. Under this configuration, any out-of-band changes that occur in the database record will not appear in the refreshed state of the entity.

Note: Regardless of the `openjpa.RefreshFromDataCache` setting, the DataCache is always bypassed for refresh when locks are active, such as for a pessimistic transaction, in a persistence context. An application may activate `openjpa.RefreshFromDataCache` but can still bypass the DataCache while refreshing an entity by explicitly evicting the entity from DataCache prior to refresh.

Query Caching functions

OpenJPA provides a concurrent query cache that allows applications to save persistent object data and query results in memory to share among threads and for use in future queries. The query cache stores the object ids returned by query executions. When you run a query, OpenJPA assembles a key based on the query properties and the parameters used at execution time, and checks for a cached query result. If one is found, the object ids in the cached result are looked up, and the resultant persistence-capable objects are returned. Otherwise, the query is executed against the database, and the object ids loaded by the query are put into the cache.

Configuring or disabling the query cache

You can configure the query cache settings in a similar way to the data cache. The interface provided to the query cache is the org.apache.openjpa.persistence.QueryResultCache class. You can access this class through the OpenJPAEntityManagerFactory.

The default query cache implementation caches 100 query executions in a least-recently-used cache. This can be changed by setting the cache size in the CacheSize plugin property. Like the data cache, the query cache also has a backing soft reference map that can be changed using the SoftReferenceSize property. To keep queries in the cache at all times, you can pin them to a cache. To change the query cache properties do the following:

1. Modify the CacheSize property of the openjpa.QueryCache:

   ```
   <property name="openjpa.QueryCache" value=("CacheSize=1000, ...
   ```

2. Change the SoftReferenceSize property to enable and control the size of this map:

   ```
   <property name="openjpa.QueryCache" value=("CacheSize=1000, SoftReferenceSize=100")/>
   ```

   The SoftReferenceSize table is disabled by default. Setting the size enables it.

3. Pin or unpin queries in the cache through the QueryResultCache with this syntax:

```
public void pin(Query q);
public void unpin(Query q);
```

Modifying these properties allows you to make better use of the query cache.

Extending a cache

OpenJPA provides classes that may be extended for further functionality.

- As previously mentioned, if you want to implement a distributed cache that uses an unsupported method for communications, create an implementation of org.apache.openjpa.event.RemoteCommitProvider.
- If you are adding new behavior, you should extend org.apache.openjpa.datacache.DataCacheImpl.
- To use your own storage mechanism, extend org.apache.openjpa.datacache.AbstractDataCache.
- To add query functionality, you can extend the default org.apache.openjpa.datacache.QueryCacheImpl.
- Implement your own storage mechanism for query results by extending org.apache.openjpa.datacache.AbstractQueryCache

OpenJPA query SQL cache

OpenJPA provides a cache that provides caching of SQL strings used by find operations performed on the entity manager and some queries to manage eagerly fetched relationships. When this cache is enabled, SQL queries used by these operations are generated once per entity manager factory and may be reused. This cache is enabled by default but can also be configured through the `openjpa.jdbc.QuerySQLCache` configuration property.

Configuring or disabling the SQL query cache

The query SQL cache can be configured or disabled through the `openjpa.jdbc.QuerySQLCache` property. By default, this property is set to true. When set to true the cache is enabled and uses the `org.apache.openjpa.util.CacheMap` class for its cache store. The CacheMap is a managed cache, meaning that it limits the number of cache entries and has a cache eviction scheme to manage memory usage. If the cache is set to all the `org.apache.openjpa.lib.util.ConcurrentHashMap` class is used as a cache store. The ConcurrentHashMap is not a managed cache so entries will remain in the cache for the lifetime of an entity manager factory. This caching mechanism may provide better performance at the expense of increased memory usage. A custom cache store class can also be specified provided that it implements the java.util.Map interface. To disable the cache, specify the value false. See the following examples on how to configure or disable the SQL query cache:

- To use an unmanaged cache:
  ```
  <property name="openjpa.jdbc.QuerySQLCache" value="all"/>
  ```
- To specify a custom cache class:
  ```
  <property name="openjpa.jdbc.QuerySQLCache" value="com.mycompany.MyCustomCache"/>
  ```
- To use an unmanaged cache:
  ```
  <property name="openjpa.jdbc.QuerySQLCache" value="false"/>
  ```

What to do next

Refer to chapter 10, Caching in the OpenJPA reference for all caching extensions.

Related tasks

Developing and packaging JPA applications for a Java SE environment
Prepare and package persistence applications to test outside of the application server container in a Java SE environment.

Troubleshooting Java Persistence API (JPA) applications

Use this information to find various known problems with JPA applications.

- Review messages that are related to transactions.

  Under certain conditions, a message similar to the following might be logged:

  ```
  Unable to execute {0} on a WebSphere managed transaction. WebSphere does not support direct manipulation of managed transactions.
  ```

  This error is probably caused by a data source that is not configured correctly as <non-jta-data-source>. See the information center topic on how to configure a data source to be used as a <non-jta-data-source>.

- Troubleshoot classes that have not been enhanced by run time.

  It is difficult to diagnose these situations. Sometimes you can trace the problem back to a lack of OpenJPA enhancement of entity classes. Examples of these situations might be detecting when entities are not ″persistence capable″. Look for a message similar to the following in the log:

  ```
  This configuration disallows runtime optimization, but the following  listed types were not enhanced at build time or at class load time  with a javaagent: "{0}".
  ```

  This message indicates that the expected runtime enhancement did not take place on the listed entity types. In most cases, this is just a build time failure and the PCEnhancer needs to be run on the listed classes. It can also indicate a more involved problem, especially if you are expecting the container classloader transform to do the entity enhancement.

- Troubleshoot issues with closed cursors.

  The following is an exception from DB2 in the log org.apache.openjpa.persistence.PersistenceException:

  ```
  [ibm][db2][jcc][10120][10898] Invalid operation: result set is closed can be a WebSphere Application Server configuration problem.
  ```

  By default, the application server configures the resultSetHoldability custom property with a value of 2 (CLOSE_CURSORS_AT_COMMIT). This property causes DB2 to close its resultSet/cursor at transaction boundaries. Despite DB2's default resultSetHoldability value of 1 (HOLD_CURSORS_OVER_COMMIT), the application server retains the default value of 2 to avoid breaking compatibilities with previous releases of the application server. You can change the default if the need arises.

  Note: If this is an XA datasource, define a new custom property on the datasource where `property_name = downgradeHoldCursorsUnderXa` and `boolean value = true`.

  Note: In Version 7.0, if a DB2 XA Data source is used, the following configuration are required to overcome the ″result set closed″ problem:

  1. Apply DB2 Version 8.1 FP17 for APAR IZ18070 or Version 9 FP4 for APAR IZ18072.
  2. Add custom property `name="downgradeHoldCursorsUnderXa"`, `value="true"` and `type="java.lang.Boolean"`
  3. Add custom property `name="resultSetHoldability"`, `value="1"`, and `type="java.lang.Integer"`

- Avoid multi-threaded EntityManager usage. If you experience an exception with the following message text, you might be accidentally allowing the usage of an EntityManager across multiple threads.

Per the JPA specification, EntityManagers are meant to be used by a single thread. You might receive an exception message that is similar to the following (in this context, brokers and EntityManagers are essentially the same thing):

```
Multiple concurrent threads attempted to access a single broker. By default brokers are not
thread safe; if you require and/or intend a broker to be accessed by more than one thread,
set the openjpa.Multithreaded property to true to override the default behavior.
```

There are some ways to address this issue:

– As documented in this exception text, an easy workaround to the situation is to tell OpenJPA that you are requiring multi-threaded access to the EntityManagers through the openjpa.Multithreaded property. This can introduce unnecessary overhead if multi-threaded access occurs that is not intentional.

–

Note: Utilize the get-use-close pattern when using application-managed (extended) persistence contexts. Remember to close the EntityManager before leaving the method that used the EntityManager. Leaving the EntityManager open can accidentally allow other threads to use the same EntityManager instance at the same time.

– Change the application to use container-managed persistence contexts by injecting the EntityManager instance through the @PersistenceContext annotation, if the programming model for the application is amenable to this change. Essentially, this enforces the get-use-close pattern by allowing the container to do the management.

• Be aware of versioning conditions if you are using optimistic locking. In the JPA architecture, the persistence provider uses the version property to perform optimistic locking and concurrency semantics for a persisting entity. For example:

```
@Entity
public class VersionedTimestampEntity
{     @Id      private int id;
      @Version private java.sql.Timestamp version;
       ....
}
```

The provider updates the versioned property to a new value when an entity is written to the database. During an entity merge operation, the persistence provider examines this versioned property to determine if the entity that is being merged is a stale copy of the entity. If the operation failed due to the stale versioning condition, an OptimisticLockException will be thrown. The versioned property can be one of these types:

– int
– Integer
– short
– Short
– long
– Long
– Timestamp.

Note: If you use the Timestamp type for the versioned property, the application needs to be aware of behavior that can be exhibited due from the implementation precision that is used for creating the Timestamp object. The typical implementation uses System.currentTimeMills(), and the time precision of this method is platform specific. For example, the precision is approximately 15ms for 32-bit Windows and 2ms for z/OS.

If an entity is persisted, and the entity is then fetched and updated in a separate persistence context that is within the precision window of the platform, the persistence provider will not be able to detect the optimistic locking and concurrent condition. As a result, an OptimisticLockException may not be thrown and data integrity could be compromised.

- Troubleshoot database constraint violations when working with entities.

  The JPA providers included with WebSphere Application Server use a constraint update manager to determine the order of SQL requests to the database based on each entity's configuration. This update manager may rearrange the order of SQL requests to the database. This alleviates an application from knowing the order of entity manager operations required to perform its business logic and optimizes database performance using underlying batching support.

  Since the JPA provider does not assume that there are implied database constraints for relationships between entities, if there are constraints in the database (for example, a foreign key constraint) the JPA provider may not issue SQL statements in the desired order. Under these conditions, the following or similar exception may be observed:

  ```
  com.ibm.db2.jcc.b.SqlException: DB2 SQL error: SQLCODE: -530, SQLSTATE: 23503, SQLERRMC: xxxxxx
  ```

  There are some ways to address this issue:

  – The JPA provider can be configured to read constraint information from the database and apply to the update manager at runtime by adding the following configuration property to the persistence unit.

    ```
    <property name="openjpa.jdbc.SchemaFactory" value="native(ForeignKeys=true)" />
    ```

  – The application can enhanced entity to use @ForeignKey annotation to indicate to the JPA provider which relationships have foreign key constraints.

    ```
    public class Person {
         @ManyToOne
         @ForeignKey
         private Address address;
         ....
     }
    ```

  – The application can take on the responsibility of ordering the SQL statements by adding the following configuration property to the persistence unit.

    ```
    <property name="openjpa.jdbc.UpdateManager" value="operation-order" />
    ```

    With this configuration option present, the JPA provider will execute the SQL statements in the same order as the entity operations were requested. The application must be aware of any interdependencies between entities.

  – Remove the constraints from the database.

- Troubleshoot using the OpenJPA MappingTool ANT task.

  The MappingTool ANT task provided by OpenJPA uses a temporary classloader to load the JDBC driver classes. This temporary classloader may have trouble loading some JDBC drivers such as DB2.

  When you run the MappingTool ANT task, you could see something similar to the following error:

  ```
  [mappingtool] java.lang.UnsatisfiedLinkError: com/ibm/jvm/Trace.initTrace([Ljava/lang/
  String;[Ljava/lang/String;)V [mappingtool] at
  com.ibm.jvm.Trace.initializeTrace(Trace.java:94) [mappingtool] at
  com.ibm.jvm.Trace.<clinit>(Trace.java:59) [mappingtool] at
  java.lang.J9VMInternals.initializeImpl(Native Method) [mappingtool] at
  java.lang.J9VMInternals.initialize(J9VMInternals.java:200) [mappingtool] at
  java.lang.Class.forNameImpl(Native Method) [mappingtool] at
  java.lang.Class.forName(Class.java:136) [mappingtool] at com.ibm.db2.jcc.a.o.n(o.java:577)
  [mappingtool] at com.ibm.db2.jcc.a.o.<clinit>(o.java:329)
  ```

  In order to use the mapping tool, you can disable the temporary classloader by adding the tmpClassLoader=false argument to the ANT task. Two example ANT scripts follow :

  This example will exhibit the problem:

  ```
  <taskdef name="mapping" classname="org.apache.openjpa.jdbc.ant.MappingToolTask" classpathref="jpa.cp"/>
      . . .
   <target name="map.broken">
       <mapping>
           <!-- this will exhibit the problem -->
           . . .
       </mapping>
   </target>
  ```

This example will prevent the problem:

```
<taskdef name="mapping" classname="org.apache.openjpa.jdbc.ant.MappingToolTask" classpathref="jpa.cp"/>
    . . .
 <target name="map.fixed">
    <mapping tmpClassLoader="false">
        <!-- this will work -->
        . . .
    </mapping>
</target>
```

- Impact of DataCache on inconsistent domain models

  When an application persists an inconsistent domain model and later retrieves the entities in a separate persistence context, the retrieved entities will differ depending on whether DataCache is active or not.

  For example, consider bi-directional, one-to-one relationship between two entities mapped by a single foreign key column in the database. It is possible for an application to set the relation fields in the entities inconsistently. When such inconsistent values are mapped to the database, the database records become consistent only because a single foreign key column expresses the bi-directional relationships DataCache is active, however, then DataCache captures the inconsistent in-memory entity states. Therefore, when an application persists a pair of entities related in a bi-directional relation but their relation fields are set to inconsistent values and later retrieves the entities in a different persistence context, the bi-directional relationship either remains inconsistent or becomes consistent depending on whether DataCache is used or not.

  When multiple fields are mapped to the same column but set to different values is another example where an inconsistent entity state is persisted but retrieved as consistent in a separate persistence context. In this case, the introduction of DataCache will also cause an entity realized in a separate persistence context to retain different and inconsistent values while without a DataCache, an entity will hold the same value for both the fields.

  Note: The best practice is to avoid populating the application domain model inconsistently. It is also possible to configure `openjpa.InverseManager` property to detect certain inconsistencies such as bi-directional relationship.

Related tasks

Task overview: Storing and retrieving persistent data with the Java Persistence API (JPA)
The Java Persistence API (JPA) for the application server defines the management of persistence and object/relational mapping within Java Enterprise Edition (Java EE) and Java Standard Edition (Java SE) environments.

Logging with the Java Persistence API (JPA) and the application server

Logging allows you to view, trace, and troubleshoot the runtime behavior of an application. JPA provides a flexible logging system that is integrated with the application server to assist you in troubleshooting problems.

About this task

Logging channels

Note: Logging can have a negative impact on performance. Limit or disable logging when you run any performance tests.

In additional to the channels used by OpenJPA, a trace group named openjpa enables channels that are prefixed with “openjpa.” Specifying “openjpa” for a trace group will override any other trace group specification that is specific to a channel. **Example**

```
openjpa.Runtime=debug:openjpa.jdbc.SQL=all

    openjpa=all
```

Note: The openjpa.Log property will be ignored if it is defined in a container-managed persistence unit that uses the persistence providers that are provided with the application server. In this case, you must use the standard trace specification for the application server.

OpenJPA and JPA for WebSphere Application Server implement logging channels to which message data, trace data, and debugging data can be recorded to a configurable repository. The JPA component creates the logging channel at run time and assigns a channel name for identification. The component writes information to the configured repository through the channel. OpenJPA and JPA for WebSphere Application Server create the following channels:

- **openjpa.Tools** - Command line and Ant server tools
- **openjpa.MetaData** - Meta data information
- **openjpa.Enhance** - Enhancement and runtime class generation
- **openjpa.Runtime** - Messages generated during runtime
- **openjpa.Query** - Query information
- **openjpa.DataCache** - L2 data cache plugin information
- **openjpa.jdbc.JDBC** - JDBC connection information
- **openjpa.jdbc.SQL**- Detailed SQL execution statements and information
