How to send your comments

Your feedback is important in helping to provide the most accurate and highest quality information.

- To send comments on articles in the WebSphere Application Server Information Center
  1. Display the article in your Web browser and scroll to the end of the article.
  2. Click on the **Feedback** link at the bottom of the article, and a separate window containing an e-mail form appears.
  3. Fill out the e-mail form as instructed, and click on **Submit feedback** .
- To send comments on PDF books, you can e-mail your comments to: **wasdoc@us.ibm.com** or fax them to 919-254-5250.

  Be sure to include the document name and number, the WebSphere Application Server version you are using, and, if applicable, the specific page, table, or figure number on which you are commenting.

When you send information to IBM, you grant IBM a nonexclusive right to use or distribute the information in any way it believes appropriate without incurring any obligation to you.

Changes to serve you more quickly

Print sections directly from the information center navigation

PDF books are provided as a convenience format for easy printing, reading, and offline use. The information center is the official delivery format for IBM WebSphere Application Server documentation. If you use the PDF books primarily for convenient printing, it is now easier to print various parts of the information center as needed, quickly and directly from the information center navigation tree.

To print a section of the information center navigation:

1. Hover your cursor over an entry in the information center navigation until the **Open Quick Menu** icon is displayed beside the entry.
2. Right-click the icon to display a menu for printing or searching your selected section of the navigation tree.
3. If you select **Print this topic and subtopics** from the menu, the selected section is launched in a separate browser window as one HTML file. The HTML file includes each of the topics in the section, with a table of contents at the top.
4. Print the HTML file.

For performance reasons, the number of topics you can print at one time is limited. You are notified if your selection contains too many topics. If the current limit is too restrictive, use the feedback link to suggest a preferable limit. The feedback link is available at the end of most information center pages.

Under construction!

The Information Development Team for IBM WebSphere Application Server is changing its PDF book delivery strategy to respond better to user needs. The intention is to deliver the content to you in PDF format more frequently. During a temporary transition phase, you might experience broken links. During the transition phase, expect the following link behavior:

- Links to Web addresses beginning with http:// work
- Links that refer to specific page numbers within the same PDF book work
- The remaining links will *not* work. You receive an error message when you click them

Thanks for your patience, in the short term, to facilitate the transition to more frequent PDF book updates.

Chapter 1. Web applications

Tuning URL invocation cache

The URL invocation cache holds information for mapping request URLs to servlet resources. A cache of the requested size is created for each worker thread that is available to process a request. The default size of the invocation cache is 50. If more than 50 unique URLs are actively being used (each JavaServer Page is a unique URL), you should increase the size of the invocation cache.

Before you begin

A larger cache uses more of the Java™ heap, so you might also need to increase the maximum Java heap size. For example, if each cache entry requires 2KB, maximum thread size is set to 25, and the URL invocation cache size is 100; then 5MB of Java heap are required.

The invocation cache is now Web container based instead of thread-based, and shared for all Web container threads.

About this task

To change the size of the invocation cache:

1. In the administrative console, click **Servers** → **Server Types** → **WebSphere application servers** and select the application server that you are tuning.
2. Click **Java and Process Management**.
3. Click **Process Definition** under Additional Properties.
4. Click **Java Virtual Machine** under Additional Properties.
5. Click **Custom Properties** under Additional Properties.
6. Specify **invocationCacheSize** in the Name field and the size of the cache in the Value field. The default size for the invocation cache is 500 entries. Since the invocation cache is no longer thread-based, the invocation cache size specified by the user is multiplied by ten to provide similar function from previous releases. For example, if you specify an invocation cache size of 50, the Web container will create a cache size of 500.
7. Click **Apply** and then **Save** to save your changes.
8. Stop and restart the application server.

Results

The new cache size is used for the URL invocation cache.

Developing servlet applications using asynchronous request dispatcher

Web modules can dispatch requests concurrently on separate threads. Requests can be dispatched by the server or client.

Before you begin

For additional information about the AsyncRequestDispatcherConfig and the AsyncRequestDispatcher interfaces, review the com.ibm.websphere.webcontainer.async package in the application programming interfaces (API) documentation. The generated API documentation is available in the information center table of contents from the path Reference > APIs - Application Programming Interfaces.

Review the asynchronous request dispatcher application (ARD) design considerations topic before completing the following steps.

About this task

Concurrent dispatching can improve servlet response time. If operations are dependant on each other, do not enable asynchronous request dispatching, therefore, select Disabled. Concurrent dispatching might result in errors when operations are dependant. Select Server side to enable the server to aggregate requests dispatched concurrently. Select Client side to enable the client to aggregate requests dispatched concurrently.

1. Logically separate resource intensive operations.
2. Develop servlets that use an asynchronous request dispatcher to include these operations.
3. Enable asynchronous request dispatching on an application server.
4. Deploy the application in an application server that has asynchronous request dispatching enabled.
5. Select an aggregation type for the application that needs ARD.
6. Optional: Configure the AsyncRequestDispatcherWorkManager work manager that is used for the request dispatch threads.
7. Restart the application server.

What to do next

Restart the modified applications if already installed or start newly installed applications to enable ARD on each application.

Asynchronous request dispatcher

Asynchronous request dispatcher (ARD) can improve Servlet response time when slow operations can be logically separated and performed concurrently with other operations required to complete the response. ARD enables Java™ servlet programmers to perform standard javax.servlet.RequestDispatcher include calls for the same request concurrently on separate threads. These javax.servlet.RequestDispatcher include calls are completed sequentially on the same thread. ARD is also useful in low CPU, long wait situations like waiting for a database connection.

If there are large CPU or memory requirements, ARD alone does not alleviate those issues. However, in combination with the remote request dispatcher, operations driven by one servlet request that can be performed concurrently on multiple application servers, alleviating resource demand on a single server and decreasing the risk of a system down situation.

Servlets, portlets, and JavaServer Pages (JSP) files can all utilize ARD. This functionality is an extension beyond the requirements of the Java Servlet Specification , which only describes synchronous request dispatching. ARD requires a new channel, called the ARD channel, between the HTTP and Web container channels to form a new channel chain. These new chains correspond only to the existing default host chains and reuse the same ports.

Each include can write output to the client and because ordering is important for valid results, there must be some aggregation of the data written. Typically, a servlet writes data to a buffer and once full, it is flushed to client. For server-side aggregation, the ARD channel cannot flush until any includes that had placeholders written to the current buffer are finished.

Client-side aggregation of the asynchronous include is also supported. Web 2.0 programmers often use Asynchronous JavaScript™ and XML (Ajax) in the Web browser of the client to dynamically retrieve and aggregate remote resources. Unfortunately, this puts the burden on the programmer to aggregate the contents and learn new technologies. Client-side aggregation automatically adds the necessary JavaScript

to dynamically update the page. For non-JavaScript clients, you can switch ARD to server-side aggregation, which gives equivalent results. You can deny non-JavaScript clients when using client-side aggregation.

ARD uses the Web container APIs to plug in unique request dispatching logic. It interacts with WCCM to read in configuration information for enablement status per enterprise application as well as a global appserver setting. You can use the administrative console and wsAdmin to enable or disable ARD. Servlets, portlets, and JSP files can all utilize ARD.

Asynchronous request dispatcher application design considerations

Asynchronous request dispatcher (ARD) is not a one-size-fits-all solution to servlet programming. You must evaluate the needs of your application and the caveats of using ARD. Switching all includes to start asynchronously is not the solution for every scenario, but when used wisely, ARD can increase response time. This article contains important details about the ARD implementation and issues to consider when you design an application that leverages ARD.

Asynchronous request dispatcher client-side implementation

- JavaScript is dynamically written to the response output.
- This JavaScript results in Ajax requests back to a server-side results provider.
- Because of the Asynchronous Input/Output (AIO) features of the channel, the Ajax request does not tie up a thread and instead is notified for completion through an include callback.
- The client only makes one request at a time for the asynchronous includes because of browser limitations in the number of connections.
- Original connection has to be valid for the lifetime of the includes. It cannot be reused for the Ajax requests.
- Comment nodes, such as following,

  ```
  <!--uniquePlaceholderID--><!--1-->
  ```

  are placed in the browser object model since comment nodes have no effect on the page layout.
- Whenever a complete fragment exists, a response can be sent to the client and the comment node with the same ID is replaced. Requests are made until all the fragments are retrieved.
- Verify applications on all supported browsers when using client-side aggregation. Object oriented JavaScript principles are used so that applications only need avoid using the method name getDynamicDataIBMARD. Any previously specified window.onload is started before the ARD onload method.

Asynchronous request dispatcher channel results service

Requests for include data from the asynchronous JavaScript code are sent to known Uniform Resource Identifiers, URIs also known as URLs, that the ARD channel can intercept to prevent traveling through Web container request handling. These URIs are unique for the each server restart.

For example, `/IBMARD01234567/asyncInclude.js` is the URI for the JavaScript that forces the retrieval of the results, and `/IBMARD01234567/IBMARDQueryStringEntries?=12000` is used to retrieve the results for the entry with ID 12000.

To prevent unauthorized results access, unique IDs are generated for the service URI and for the ARD entries. A common ID generator is shared among the session and ARD, so uniqueness is configurable through session configuration. Session IDs are considered secure, but they are not as secure as using a Lightweight Third-Party Authentication (LTPA) token.

Custom client-side aggregation

If you want to perform your own client-side aggregation, the isUseDefaultJavascript method must return as false. The isUseDefaultJavascript method is part of the AsyncRequestDispatcherConfig method, which is set on the AsyncRequestDispatcher or for the AsyncRequestDispatcherConfigImpl.getRef method. The AsyncRequestDispatcherConfigImpl.getRef method is the global configuration object. You might want to perform your own client-side aggregation if the back button functionality is problematic. You must remove the results from the generic results service to prevent memory leaks, so that multiple requests with the same response results through an XMLHttpRequest fail. To facilitate proper location of position, placeholders are still written in the code as

```
<!--uniquePlaceholderID--><!--x-->
```

where x is the order of the includes. The endpoint to retrieve results are retrieved from the request attribute com.ibm.websphere.webcontainer.ard.endpointURI.

When making a request to the endpoint, ARD sends as many response fragments as possible when the request is made. Therefore, the client needs to re-request if all fragments are not initially returned. Trying to display the results directly in a browser without using an XMLHttpRequest can result in errors related to non well-formed XML. The response data is returned in the following format with a content type of text/xml:

```
<div id="2"><BR>Servlet 3--dispatcher3 requesting Servlet3 to sleep for 0 seconds at: 1187967704265
<BR> Servlet 3--Okay, all done!  This should print pop up: third at: 1187967704281 </div>
```

For additional information about the AsyncRequestDispatcherConfig and the AsyncRequestDispatcher interfaces, review the com.ibm.websphere.webcontainer.async package in the application programming interfaces (API) documentation. The generated API documentation is available in the information center table of contents from the path **Reference** → **APIs - Application Programming Interfaces**.

Server-side aggregation

Like client-side aggregation, server-side aggregation uses the ARD channel as a results service. The ARD channel knows which asynchronous includes have occurred for certain set of buffers. Those buffers can then be searched for an include placeholder. Because of the issues of JSP buffering, the placeholder for the include might not be in the searched buffers. If this occurs, the next set of buffers must also look for any include placeholders missed in the previous set. ARD attempts to iteratively aggregate as includes return so that response content can be sent to the client as soon as possible.

Asynchronous beans

An AsynchBeans work manager is used to start the includes. If the number of currently requested includes is greater than the work manager maximum thread pool size and this size is not growable, it starts the work on the current thread and skips the placeholder write. Utilizing AsynchBeans suppports propagation

of the J2EE context of the original thread including work area, internationalization, application profile, z/OS® operation system work load management, security, transaction, and connection context.

Timer

A single timer is used for ARD and timer tasks are created for all the timeout types of ARD requests. Tasks registered with the timer are not guaranteed to run at the exact time specified because the timer runs on a single thread, therefore one timeout might have to wait for the other timeout actions to complete. The timer is used as a last resort.

Remote request dispatcher

Optionally, ARD can be used in concert with the remote request dispatcher. The remote request dispatcher was introduced in WebSphere® Application Server Network Deployment 6.1. The remote request dispatcher runs the include on a different application server in a core group by serializing the request context into a SOAP message and using Web services to call the remote server. This is useful when the expense of creating and sending a SOAP message through Web services is outweighed by issuing the request locally. For more information, see this developerWorks article.

Exceptions

In the case of an exception in an included servlet, the Web container goes through the error page definitions mapped to exception types. So an error page defined in the deployment descriptor shows up as a portion of the aggregated page. Insert logic into the error page itself if behavior is different for an include. Because the include runs asynchronously, there is no guarantee that the top level servlet is still in service, therefore the exception is not propagated back from an asynchronous include like a normal include. Other includes finish so that partial pages can be displayed.

If the ARD work manager runs out of worker threads, the include is processed like a synchronous include. This is the default setting, but the work manager can also grow such that it does not result in this condition. This change in processing is invisible to the user during processing but is noted once in the system logs as a warning message and the rest of the time in the trace logs when enabled. Other states that can trigger the include to occur synchronously are reaching the maximum percentage of expired requests over a time interval and reaching the maximum size of the results store.

There are cases where exceptions happen outside of the scope of normal error page handling. For example, work can be rejected by the work manager. A timer can expire waiting for an include response to return. The ARD channel, acting as a generic service to retrieve the results, might receive an ID that is not valid. In these cases, there is no path to the error page handling because the context is missing, such as ServletRequest, ServletResponse, and ServletContext, for the request to work. To mitigate these issues, you can use the AsyncRequestDispatcherConfig interface to provide custom error messages. Defaults are provided and internationalized as needed.

Exceptions can also occur outside the scope of the request the custom configuration was set on, such as on the subsequent client-side XMLHttpRequests. In this case, the global configuration must be altered. This can be retrieved through com.ibm.wsspi.ard.AsyncRequestDispatcherConfigImpl.getRef().

Include start
: The work manager provides a timeout for how long to wait for an include to start. Since this typically happens immediately, there is not a programmatic way to enable this. However, this is configurable in the work manager settings. By default, you will not encounter this because of the maximum thread check before scheduling the work. Work can be retried if setRetriable(true) is called on the in use AsyncRequestDispatcherConfig.

Include finish
: The initiated timeout starts after the work is accepted. It can be configured through the console or programmatically through the AsyncRequestDispatcherConfig.setExecutionTimeoutOverride

method; The default value is 60000 ms, or one minute. In place of the include results, the message from the AsyncRequestDispatcherConfig.setExecutionTimeoutMessage is sent. If this intiated timeout is reached, but the actual include results are ready when the data can be flushed, preference is given to the actual results. Also, this does not apply to insertFragmentBlocking calls which always wait until the include is completed.

Expiration of results

Since the client-side has to hold the results in a service to send for the Ajax request, we want a way to expire the results if the client goes down and never retrieves the entry. The default of a minute is sufficient for a typical request because the Ajax request would come in immediately after sending the response. The timer can be configured programmatically via the setExpirationTimeoutOverride method the of AsyncRequestDispatcherConfig. The message from the getOutputRetrievalFailureMessage method of AsyncRequestDispatcherConfig is displayed when someone tries to access an entry that has expired and been removed from cache. This message is the same message that is sent to someone requesting a result with an ID that never existed.

Includes versus fragments

Consider which operations can be done asynchronously and when they can start. Ideally, all the includes are completed when the getFragment calls are made at the beginning of the request so that the includes can have more time to complete, and upon inserting the fragments, there would be less extra buffering and aggregating if they have completed. However, simply calling an asynchronous include is easier because it follows the same pattern as a normal request dispatcher include.

Web container

ServletContext

When doing cross-context includes, the context that is a target of the include must also have ARD enabled because the Web application must have been initialized for ARD for its servlet context to have valid methods to retrieve an AsyncRequestDispatcher. The aggregation type is determined by the original context's configuration because you cannot mix aggregation types.

ServletRequest

You must clone the request for each include. Otherwise, conflicts between threads might occur. Because applications can wrap the default request objects, your wrappers must implement the com.ibm.wsspi.webcontainer.servlet.IServletRequest interface, which has one method, the public Object clone method, which creates the CloneNotSupportedException.

Unwrapping occurs until a request wrapper that implements this interface is found. Non-implementing wrappers are lost; however, a servlet filter configured for the include can rewrap the response.

Changes made to the ServletRequest are not propagated back to the top level servlet unless transferState on the AsyncRequestDispatcherConfig is enabled and insertFragmentBlocking is called.

ServletResponse

A wrapped response extending com.ibm.websphere.servlet.response.StoredResponse is created by ARD and sent to the includes because the response output must be retrievable beyond the lifecycle of the original response.

Internal headers set in asynchronous includes are not supported due to lifecycle restrictions unless transferState on the AsyncRequestDispatcher config is enabled and insertFragmentBlocking is called. Normal headers are not supported in a synchronous include as specified by the servlet specification.

Include filters can rewrap the new response and must flush upon completion.

ServletInputStream
An application reading parameters using getParameter is not problematic.Parsing of parameters is forced before the first asynchronous include to prevent concurrent access to the input stream.

HttpSession
Initial getSession calls that result in a Set-Cookie header must be called from the top level servlet because it is unpredictable when the includes are started and if the headers have already been flushed. The exception is when transferState on the AsyncRequestDispatcherConfig is enabled and an insertFragmentBlocking is called. This normally creates an exception when you add the header.

Filters If there is a filter for an include, the filter is issued on the asynchronous thread.

Nested asynchronous includes
Nested asynchronous includes are not supported because they complicate aggregation. However, an asynchronous include can have nested synchronous includes. Any attempt to perform a nested asynchronous include reverts back to a synchronous include.

Transactions

Every asynchronous bean method is called using its own transaction, much like container-managed transactions in typical enterprise beans. The runtime starts a local transaction before invoking the method. The asynchronous bean method can start its own global transaction if this transaction is possible for the calling J2EE component.

If the asynchronous bean method creates an exception, any local transactions are rolled back. If the method returns normally, any incomplete local transactions are completed according to the unresolved action policy configured for the bean. If the asynchronous bean method starts its own global transaction and does not commit this global transaction, the transaction is rolled back when the method returns.

Connection management

An asynchronous bean method can use the connections that its creating servlet obtained using java:comp resource references. However, the bean method must access those connections using a get, use or close pattern. There is no connection caching between method calls on an asynchronous bean. The connection factories or data sources can be cached, but the connections must be retrieved on every method call, used, and then closed. While the asynchronous bean method can look up connection factories using a global Java Naming and Directory Interface (JNDI) name, this is not recommended for the following reasons:

- The JNDI name is hard coded in the application, for example, as a property or string literal.
- The connection factories are not shared because there is no way to specify a sharing scope.

Evaluate high load scenarios because asynchronous includes might increase the number of threads waiting on the connection.

Performance

Because includes are completed asynchronously, the total performance data for a request must take into consideration the performance of the asynchronous includes. The total time of the request could previously be understood by the time for the top level servlet to complete, but now that servlet is exiting before the includes are completed. The top level servlet still accounts for much of the additional setup time required for each include.

Therefore, a new ARD performance metric was added to the Performance Monitoring Infrastructure to measure the time for a complete request through the ARD channel. The granularity of these metrics is at the request URI level.

Since ARD is an optional feature that has to be enabled, no performance decline is seen when not utilizing ARD. However, non-ARD applications that reside on an ARD-enabled application server would suffer from the extra layer of the ARDChannel. The channel layer does not know to which application it is going so it is either on or off for all applications in a channel chain. These are defined per virtual host.

Security

Security is not invoked on synchronous include dispatches according to the servlet specification. However, security context is passed along through AsynchBeans to support programmatic usage of the isUserInRole and getUserPrincipal methods on the ServletRequest. This security context can also be propagated across to a remote request dispatch utilizing Web services security.

Related concepts

"Asynchronous request dispatcher" on page 2
Asynchronous request dispatcher (ARD) can improve Servlet response time when slow operations can be logically separated and performed concurrently with other operations required to complete the response. ARD enables Java™ servlet programmers to perform standard javax.servlet.RequestDispatcher include calls for the same request concurrently on separate threads. These javax.servlet.RequestDispatcher include calls are completed sequentially on the same thread. ARD is also useful in low CPU, long wait situations like waiting for a database connection.

Related tasks

Web modules can dispatch requests concurrently on separate threads. Requests can be dispatched by the server or client.

Asynchronous request dispatching settings

Use this page to enable the asynchronous request dispatcher (ARD), which enables servlets and JSP pages to make standard include calls concurrently on separate threads.

To view this administrative console page, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Web Container Settings** → **Web container** → **Asynchronous request dispatching**.

Additionally, the initiation and the insertion of the include contents can be separated so that the include has more time to execute before it needs to be written to the response. ARD requires aggregation of the include contents with the original response. The application server can aggregate the contents in memory or the client browser can aggregate the contents through AJAX. Aggregation type is configurable at the application level.

Allow Asynchronous Request Dispatching

Enables applications installed on this server to use asynchronous request dispatching.

Asynchronous include timeout
Specifies the default timeout in milliseconds to complete asynchronous includes.

Data type	Integer
Units	Milliseconds
Default	60000
Range	

Maximum expired requests per minute
Specifies the maximum percentage of expired response versus total response in one minute before switching to synchronous requests.

Data type	Integer
Units	Percentage
Default	15
Range	

Maximum memory size of results store
Specifies the maximum size of store for client side requests.

Data type	Integer
Units	Megabytes
Default	100
Range	

Task overview: Managing HTTP sessions

IBM® WebSphere Application Server provides a service for managing HTTP sessions, Session Manager. The key activities for session management are summarized in this topic.

About this task

Before you begin these steps, make sure you are familiar with the programming model for accessing HTTP session support in the applications following the Servlet 2.5 API.

1. Plan your session tracking approach for session management.
2. Create or modify your own applications to use session support to maintain sessions on behalf of Web applications.
3. Assemble your application.
4. Deploy your application.
5. Ensure the administrator appropriately configures session management in the administrative domain.
6. Adjust configuration settings and perform other tuning activities for optimal use of sessions in your environment.

Sessions

A session is a series of requests to a servlet, originating from the same user at the same browser.

Sessions allow applications running in a Web container to keep track of individual users.

For example, a servlet might use sessions to provide ″shopping carts″ to online shoppers. Suppose the servlet is designed to record the items each shopper indicates he or she wants to purchase from the Web site. It is important that the servlet be able to associate incoming requests with particular shoppers. Otherwise, the servlet might mistakenly add Shopper_1's choices to the cart of Shopper_2.

A servlet distinguishes users by their unique session IDs. The session ID arrives with each request. If the user's browser is cookie-enabled, the session ID is stored as a cookie. As an alternative, the session ID can be conveyed to the servlet by URL rewriting, in which the session ID is appended to the URL of the servlet or JavaServer Pages (JSP) file from which the user is making requests. For requests over HTTPS or Secure Sockets Layer (SSL), another alternative is to use SSL information to identify the session. Session tracking using the SSL ID is deprecated in WebSphere Application Server version 7.0. You can configure session tracking to use cookies or modify the application to use URL rewriting.

HTTP session migration

There are no programmatic changes required to migrate from version 5.x to version 6.x. This article describes features that are available after migration.

Migration from Version 5.x

Note: In Version 5 and later, default write frequency mode is TIME_BASED_WRITES, which is different from Version 4.0.x default mode of END_OF_SERVICE.

Session security support

You can integrate HTTP sessions and security in WebSphere Application Server. When security integration is enabled in the session management facility and a session is accessed in a protected resource, you can access that session only in protected resources from then on.

You cannot mix secured and unsecured resources accessing sessions when security integration is turned on. Security integration in the session management facility is not supported in form-based login with SWAM.

Note: SWAM is deprecated in WebSphere Application Server Version 7.0 and will be removed in a future release.

Security integration rules for HTTP sessions

Only authenticated users can access sessions created in secured pages and are created under the identity of the authenticated user. Only this authenticated user can access these sessions in other secured pages. To protect these sessions from unauthorized users, you cannot access them from an unsecured page.

Programmatic details and scenarios

WebSphere Application Server maintains the security of individual sessions.

An identity or user name, readable by the com.ibm.websphere.servlet.session.IBMSession interface, is associated with a session. An unauthenticated identity is denoted by the user name `anonymous`. WebSphere Application Server includes the com.ibm.websphere.servlet.session.UnauthorizedSessionRequestException class, which is used when a session is requested without the necessary credentials.

The session management facility uses the WebSphere Application Server security infrastructure to determine the authenticated identity associated with a client HTTP request that either retrieves or creates a session. WebSphere Application Server security determines identity using certificates, LPTA, and other methods.

After obtaining the identity of the current request, the session management facility determines whether to return the session requested using a getSession call.

The following table lists possible scenarios in which security integration is enabled with outcomes dependent on whether the HTTP request is authenticated and whether a valid session ID and user name was passed to the session management facility.

	Unauthenticated HTTP request is used to retrieve a session	**HTTP request is authenticated, with an identity of ″FRED″ used to retrieve a session**
No session ID was passed in for this request, or the ID is for a session that is no longer valid	A new session is created. The user name is `anonymous`	A new session is created. The user name is `FRED`
A session ID for a valid session is passed in. The current session user name is ″anonymous″	The session is returned.	The session is returned. session management changes the user name to `FRED`
A session ID for a valid session is passed in. The current session user name is `FRED`	The session is not returned. An UnauthorizedSessionRequestException error is created*	The session is returned.
A session ID for a valid session is passed in. The current session user name is `BOB`	The session is not returned. An UnauthorizedSessionRequestException error is created*	The session is not returned. An UnauthorizedSessionRequestException error is created*

* A com.ibm.websphere.servlet.session.UnauthorizedSessionRequestException error is created to the servlet.

Session management support

WebSphere Application Server provides facilities, grouped under the heading *Session Management*, that support the javax.servlet.http.HttpSession interface described in the Servlet API specification.

In accordance with the Servlet 2.3 API specification, the session management facility supports session scoping by Web modules. Only servlets in the same Web module can access the data associated with a particular session. Multiple requests from the same browser, each specifying a unique Web application, result in multiple sessions with a shared session ID. You can invalidate any of the sessions that share a session ID without affecting the other sessions.

You can configure a session timeout for each Web application. A Web application timeout value of 0 (the default value) means that the invalidation timeout value from the session management facility is used.

When an HTTP client interacts with a servlet, the state information associated with a series of client requests is represented as an HTTP session and identified by a session ID. Session management is responsible for managing HTTP sessions, providing storage for session data, allocating session IDs, and tracking the session ID associated with each client request through the use of cookies or URL rewriting techniques. Session management can store session-related information in several ways:

- In application server memory (the default). This information cannot be shared with other application servers.
- In a database. This storage option is known as *database persistent sessions*.

The last two options are referred to as *distributed sessions*. Distributed sessions are essential for using HTTP sessions for the failover facility. When an application server receives a request associated with a session ID that it currently does not have in memory, it can obtain the required session state by accessing the external store (database or memory-to-memory). If distributed session support is not enabled, an application server cannot access session information for HTTP requests that are sent to servers other than the one where the session was originally created. Session management implements caching optimizations to minimize the overhead of accessing the external store, especially when consecutive requests are routed to the same application server.

Storing session states in an external store also provides a degree of fault tolerance. If an application server goes offline, the state of its current sessions is still available in the external store. This availability enables other application servers to continue processing subsequent client requests associated with that session.

Saving session states to an external location does not completely guarantee their preservation in case of a server failure. For example, if a server fails while it is modifying the state of a session, some information is lost and subsequent processing using that session can be affected. However, this situation represents a very small period of time when there is a risk of losing session information.

The drawback to saving session states in an external store is that accessing the session state in an external location can use valuable system resources. session management can improve system performance by caching the session data at the server level. Multiple consecutive requests that are directed to the same server can find the required state data in the cache, reducing the number of times that the actual session state is accessed in external store and consequently reducing the overhead associated with external location access.

Session tracking options

HTTP session support also involves session tracking. You can use cookies, URL rewriting, or Secure Sockets Layer (SSL) information for session tracking.

the following tracking methods are available:
- Session tracking with cookies
- Session tracking with URL rewriting
- Session tracking with Secure Sockets Layer (SSL) information

Session tracking with cookies

Tracking sessions with cookies is the default. No special programming is required to track sessions with cookies.

Session tracking with URL rewriting

An application that uses URL rewriting to track sessions must adhere to certain programming guidelines. The application developer needs to do the following:
- Program servlets to encode URLs
- Supply a servlet or JavaServer Pages (JSP) file as an entry point to the application

Using URL rewriting also requires that you enable URL rewriting in the session management facility.

Note: In certain cases, clients cannot accept cookies. Therefore, you cannot use cookies as a session tracking mechanism. Applications can use URL rewriting as a substitute.

Program session servlets to encode URLs

Depending on whether the servlet is returning URLs to the browser or redirecting them, include either the encodeURL method or the encodeRedirectURL method in the servlet code. Examples demonstrating what to replace in your current servlet code follow.

Rewrite URLs to return to the browser

Suppose you currently have this statement:

```
out.println("<a href=\"/store/catalog\">catalog<a>");
```

Change the servlet to call the encodeURL method before sending the URL to the output stream:

```
out.println("<a href=\"");
out.println(response.encodeURL ("/store/catalog"));
out.println("\">catalog</a>");
```

Rewrite URLs to redirect

Suppose you currently have the following statement:

```
response.sendRedirect ("http://myhost/store/catalog");
```

Change the servlet to call the encodeRedirectURL method before sending the URL to the output stream:

```
response.sendRedirect (response.encodeRedirectURL ("http://myhost/store/catalog"));
```

The encodeURL method and encodeRedirectURL method are part of the HttpServletResponse object. These calls check to see if URL rewriting is configured before encoding the URL. If it is not configured, the calls return the original URL.

If both cookies and URL rewriting are enabled and the response.encodeURL method or encodeRedirectURL method is called, the URL is encoded, even if the browser making the HTTP request processed the session cookie.

You can also configure session support to enable protocol switch rewriting. When this option is enabled, the product encodes the URL with the session ID for switching between HTTP and HTTPS protocols.

Supply a servlet or JSP file as an entry point

The entry point to an application, such as the initial screen presented, may not require the use of sessions. However, if the application in general requires session support (meaning some part of it, such as a servlet, requires session support), then after a session is created, all URLs are encoded to perpetuate the session ID for the servlet (or other application component) requiring the session support.

The following example shows how you can embed Java code within a JSP file:

```
<%
response.encodeURL ("/store/catalog");
%>
```

Session tracking with SSL information (Deprecated)

Note: Session tracking using the SSL ID is deprecated in WebSphere Application Server version 7.0. You can configure session tracking to use cookies or URL rewriting.

No special programming is required to track sessions with Secure Sockets Layer (SSL) information.

To use SSL information, turn on **Enable SSL ID tracking** in the session management property page. Because the SSL session ID is negotiated between the Web browser and HTTP server, this ID cannot survive an HTTP server failure. However, the failure of an application server does not affect the SSL session ID if an external HTTP server is present between WebSphere Application Server and the browser.

SSL tracking is supported for the IBM HTTP Server and iPlanet Web servers only. You can control the lifetime of an SSL session ID by configuring options in the Web server. For example, in the IBM HTTP Server, set the configuration variable SSLV3TIMEOUT to provide an adequate lifetime for the SSL session ID. An interval that is too short can cause a premature termination of a session. Also, some Web browsers might have their own timers that affect the lifetime of the SSL session ID. These Web browsers may not leave the SSL session ID active long enough to serve as a useful mechanism for session tracking. The internal HTTP Server of WebSphere Application Server also supports SSL tracking.

When using the SSL session ID as the session tracking mechanism in a cloned environment, use either cookies or URL rewriting to maintain session affinity. The cookie or rewritten URL contains session affinity information that enables the Web server to properly route a session back to the same server for each request.

Session recovery support

For session recovery support, WebSphere Application Server provides distributed session support in the form of database sessions. You can use session recovery support when the user's session data must be maintained across a server restart or when the user's session data is too valuable to lose through an unexpected server failure.

All the attributes set in a session must implement java.io.Serializable if the session requires external storage. In general, consider making all objects held by a session serialized, even if immediate plans do not call for session recovery support. If the Web site grows, and session recovery support becomes necessary, the transition occurs transparently to the application if the sessions only hold serialized objects. If not, a switch to session recovery support requires coding changes to make the session contents serialized.

Session management tuning

WebSphere Application Server session support has features for tuning session performance and operating characteristics, particularly when sessions are configured in a distributed environment. These options support the administrator flexibility in determining the performance and failover characteristics for their environment.

The following table summarizes the features, including whether they apply to sessions tracked in memory, in a database, with memory-to-memory replication, or all. Some features are easily manipulated using administrative settings; others require code or database changes.

Feature or option	**Goal**	**Applies to sessions in memory, database, or memory-to-memory**
Write frequency	Minimize database write operations.	Database
Session affinity	Access the session in the same application server instance.	All
Multirow schema	Fully utilize database capacities.	Database
Base in-memory session pool size	Fully utilize system capacity without overburdening system.	All
Write contents	Allow flexibility in determining what session data to write	Database
Scheduled invalidation	Minimize contention between session requests and invalidation of sessions by the Session Management facility. Minimize write operations to database for updates to last access time only.	Database
Tablespace and row size	Increase efficiency of write operations to database.	Database (DB2® only)

HTTP sessions: Resources for learning

Use the following links to find relevant supplemental information about HTTP sessions. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks® that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Scheduled invalidation
Instead of relying on the periodic invalidation timer that runs on an interval based on the session timeout parameter, you can set specific times for the session management facility to scan for invalidated sessions in a distributed environment.

When used with distributed sessions, this feature has the following benefits:
- You can schedule the scan for invalidated sessions for times of low application server activity, avoiding contention between invalidation scans of database or another WebSphere Application Server instance and read and write operations to service HTTP session requests.
- Significantly fewer external write operations can occur when running with the End of Service Method Write mode because the last access time of the session does not need to be written out on each HTTP request. (Manual Update options and Time Based Write options already minimize the writing of the last access time.)

Usage considerations
- The session manager invalidates sessions only at the scheduled time, therefore sessions are available to an application if they are requested before the session is invalidated.
- With scheduled invalidation configured, HttpSession timeouts are not strictly enforced. Instead, all invalidation processing is handled at the configured invalidation times.
- HttpSessionBindingListener processing is handled at the configured invalidation times unless the HttpSession.invalidate method is explicitly called.
- The HttpSession.invalidate method immediately invalidates the session from both the session cache and the external store.
- The periodic invalidation thread still runs with scheduled invalidation. If the current hour of the day does not match one of the configured hours, sessions that have exceeded the invalidation interval are removed from cache, but not from the external store. Another request for that session results in returning that session back into the cache.
- When the periodic invalidation thread runs during one of the configured hours, all sessions that have exceeded the invalidation interval are invalidated by removal from both the cache and the external store.
- The periodic invalidation thread can run more than once during an hour and does not necessarily run exactly at the top of the hour.
- If you specify the interval for the periodic invalidation thread using the HttpSessionReaperPollInterval custom property, do not specify a value of more than 3600 seconds (1 hour) to ensure that invalidation processing happens at least once during each hour.

Base in-memory session pool size
The base in-memory session pool size number depends on the session support configuration.
- With in-memory sessions, session access is optimized for up to this number of sessions.

General memory requirements for the hardware system, and the usage characteristics of the e-business site, determines the optimum value.

Note that increasing the base in-memory session pool size can necessitate increasing the heap sizes of the Java processes for the corresponding WebSphere Application Servers.

Overflow in non-distributed sessions

By default, the number of sessions maintained in memory is specified by base in-memory session pool size. If you do not wish to place a limit on the number of sessions maintained in memory and allow overflow, set overflow to *true*.

Allowing an unlimited amount of sessions can potentially exhaust system memory and even allow for system sabotage. Someone could write a malicious program that continually hits your site and creates sessions, but ignores any cookies or encoded URLs and never utilizes the same session from one HTTP request to the next.

When overflow is disallowed, the Session Management facility still returns a session with the HttpServletRequest getSession(true) method when the memory limit is reached, and this is an invalid session that is not saved.

With the WebSphere Application Server extension to HttpSession, com.ibm.websphere.servlet.session.IBMSession, an isOverflow method returns *true* if the session is such an invalid session. An application can check this status and react accordingly.

HTTP session invalidation

HTTP sessions are invalidated by calling the invalidate method on the session object or by specifying a specific time interval using the MaxInactiveInterval property.

Sessions that are invalidated explicitly by application code are invalidated immediately. Sessions that are not invalidated by application code are invalidated by the session manager. Session invalidation occurs regardless of session persistence configuration.

A session is a candidate for invalidation if it has not been accessed for a period that is longer than the specified session timeout, specified by the MaxInactiveInterval value. The session manager has an invalidation process thread that runs every X seconds to invalidate sessions that are eligible for invalidation.

The session manager uses a formula to determine the value of X, specified by the ReaperInterval property. The value of X is calculated based on the MaxInactiveInterval value that is specified in the session manager.

For example, for a maximum inactive interval less than 15 minutes, the ReaperInterval value is approximately 60 to 90 seconds. For a maximum inactive interval greater than 15 minutes, the ReaperInterval value is approximately 300 to 360 seconds.

A session is invalidated when the MaxInactiveInterval is exceeded and the ReaperInterval passes. After a session is eligible for invalidation, the invalidation thread must run for the session to be invalidated. Therefore, a session might not be invalidated for the sum of the MaxInactiveInterval and ReaperInterval value in seconds.

A session that has exceeded the MaxInactiveInterval but is not yet removed by the invalidation thread is still available for use. If that session is requested then it is returned to the client.

You can specify whether the session is invalidated immediately or after a specified time interval. For immediate invalidation the application should call the invalidate method. To invalidate a session at a specific time, you can set the ReaperInterval Web container custom property in seconds to specify the frequency of the invalidation thread.

Write operations

You can manually control when modified session data is written out to the database or to another WebSphere Application Server instance by using the sync method in the com.ibm.websphere.servlet.session.IBMSession interface. The manual update, end of service servlet and the time based write frequency modes are available to tune write frequency of session data.

This interface extends the javax.servlet.http.HttpSession interface. By calling the sync method from the service method of a servlet, you send any changes in the session to the external location. When manual update is selected as the write frequency mode, session data changes are written to an external location only if the application calls the sync method. If the sync method is not called, session data changes are lost when a session object leaves the server cache. When end of service servlet or time based is the write frequency mode, the session data changes are written out whenever the sync method is called. If the sync method is not called, changes are written out at the end of service method or on a time interval basis based on the write frequency mode that is selected.

```
IBMSession iSession = (IBMSession) request.getSession();
iSession.setAttribute("name", "Bob");

//force write to external store
iSession.sync( )
```

If the database is down or is having difficulty connecting during an update to session values, the sync method always makes three attempts before it finally creates a BackedHashtable.getConnectionError error. For each connection attempt that fails, the BackedHashtable.StaleConnectionException is created and can be found in the sync method. If the database opens during any of these three attempts, the session data in the memory is then persisted and committed to the database.

However, if the database is still not up after the three attempts, then the session data in the memory is persisted only after the next check for session invalidation. Session invalidation is checked by a separate thread that is triggered every five minutes. The data in memory is consistent unless a request for session data is issued to the server between these events. For example, if the request for session data is issued within five minutes, then the previous persisted session data is sent.

Sessions are not transactional resources. Because the sync method is associated with a separate thread than the client, the exception that is created does not propagate to the client, which is running on the primary thread. Transactional integrity of data can be maintained through resources such as enterprise beans.

Related reference

“Session management tuning” on page 14
WebSphere Application Server session support has features for tuning session performance and operating characteristics, particularly when sessions are configured in a distributed environment. These options support the administrator flexibility in determining the performance and failover characteristics for their environment.

Tuning parameter settings

Use this page to set tuning parameters for distributed sessions.

To view this administrative console page, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Session management** → **Distributed environment settings** → **Custom tuning parameters**.

Tuning level

Specifies that the session management facility provides certain predefined settings that affect performance.

Select one of these predefined settings or customize a setting. To customize a setting, select one of the predefined settings that comes closest to the setting desired, click **Custom settings**, make your changes, and then click **OK**.

Very high (optimize for performance)

Write frequency	Time based
Write interval	300 seconds
Write contents	Only updated attributes
Schedule sessions cleanup	true
First time of day default	0
Second time of day default	2

High

Write frequency	Time based
Write interval	300 seconds
Write contents	All session attributes
Schedule sessions cleanup	false

Medium

Write frequency	End of servlet service
Write contents	Only updated attributes
Schedule sessions cleanup	false

Low (optimize for failover)

Write frequency	End of servlet service
Write contents	All session attributes
Schedule sessions cleanup	false

Custom settings

Write frequency default	Time based
Write interval default	10 seconds
Write contents default	All session attributes
Schedule sessions cleanup default	false

Tuning parameter custom settings

Use this page to customize tuning parameters for distributed sessions.

To view this administrative console page, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Session management** → **Distributed environment settings** → **Custom tuning parameters** → **Custom settings**.

Write frequency

Specifies when the session is written to the persistent store.

End of servlet service	A session writes to a database or another WebSphere Application Server instance after the servlet completes execution.

Manual update
A programmatic sync on the IBMSession object is required to write the session data to the database or another WebSphere Application Server instance.

Time based
Session data writes to the database or another WebSphere Application Server instance based on the specified Write interval value. Default: 10 seconds

Write contents
Specifies whether updated attributes are only written to the external location or all of the session attributes are written to the external location, regardless of whether or not they changed. The external location can be either a database or another application server instance.

Only updated attributes
Only updated attributes are written to the persistent store.

All session attribute
All attributes are written to the persistent store.

Schedule sessions cleanup
Specifies when to clean the invalid sessions from a database or another application server instance.

Specify distributed sessions cleanup schedule
Enables the scheduled invalidation process for cleaning up the invalidated HTTP sessions from the external location. Enable this option to reduce the number of updates to a database or another application server instance required to keep the HTTP sessions alive. When this option is not enabled, the invalidator process runs every few minutes to remove invalidated HTTP sessions.

When this option is enabled, specify the two hours of a day for the process to clean up the invalidated sessions in the external location. Specify the times when there is the least activity in the application servers. An external location can be either a database or another application server instance.

First Time of Day (0 - 23)
Indicates the first hour during which the invalidated sessions are cleared from the external location. Specify this value as a positive integer between 0 and 23. This value is valid only when schedule invalidation is enabled.

Second Time of Day (0 - 23)
Indicates the second hour during which the invalidated sessions are cleared from the external location. Specify this value as a positive integer between 0 and 23. This value is valid only when schedule invalidation is enabled.

Best practices for using HTTP sessions
This topic presents best practices for the implementation of HTTP sessions.

Note: Browse the following recommendations for implementing HTTP sessions.

- **Enable Security integration for securing HTTP sessions**

  HTTP sessions are identified by session IDs. A session ID is a pseudo-random number generated at the runtime. Session hijacking is a known attack HTTP sessions and can be prevented if all the requests going over the network are enforced to be over a secure connection (meaning, HTTPS). But not every configuration in a customer environment enforces this constraint because of the performance impact of SSL connections. Due to this relaxed mode, HTTP session is vulnerable to hijacking and because of this vulnerability, WebSphere Application Server has the option to tightly integrate HTTP sessions and WebSphere Application Server security. Enable security in WebSphere Application Server so that the sessions are protected in a manner that only users who created the sessions are allowed to access them.

- **Release HttpSession objects using `javax.servlet.http.HttpSession.invalidate()` when finished.**

  HttpSession objects live inside the Web container until:
  - The application explicitly and programmatically releases it using the javax.servlet.http.HttpSession.invalidate method; quite often, programmatic invalidation is part of an application logout function.
  - WebSphere Application Server destroys the allocated HttpSession when it expires (default = 1800 seconds or 30 minutes). The WebSphere Application Server can only maintain a certain number of HTTP sessions in memory based on session management settings. In case of distributed sessions, when maximum cache limit is reached in memory, the session management facility removes the least recently used (LRU) one from cache to make room for a session.

  .
- **Avoid trying to save and reuse the HttpSession object outside of each servlet or JSP file.**

  The HttpSession object is a function of the HttpRequest (you can get it only through the req.getSession method), and a copy of it is valid only for the life of the service method of the servlet or JSP file. You *cannot* cache the HttpSession object and refer to it outside the scope of a servlet or JSP file.
- **Implement the java.io.Serializable interface when developing new objects to be stored in the HTTP session.**

  Serializability of a class is enabled by the class implementing the java.io.Serializable interface. Implementing the java.io.Serializable interface allows the object to properly serialize when using distributed sessions. Classes that do not implement this interface will not have their states serialized or deserialized. Therefore, if a class does not implement the Serializable interface, the JVM cannot persist its state into a database or into another JVM. All subtypes of a serializable class are serializable. An example of this follows:

  ```
  public class MyObject implements java.io.Serializable {...}
  ```

  Make sure all instance variable objects that are not marked transient are serializable. You cannot cache a non-serializable object.

  In compliance with the Java Servlet specification, the distributed servlet container must create an IllegalArgumentException for objects when the container cannot support the mechanism necessary for migration of the session storing them. An exception is created only when you have selected distributable.
- **The HTTPSession API does not dictate transactional behavior for sessions.**

  Distributed HTTPSession support does not guarantee transactional integrity of an attribute in a failover scenario or when session affinity is broken. Use transactional aware resources like enterprise Java beans to guarantee the transaction integrity required by your application.
- **Ensure the Java objects you add to a session are in the correct class path.**

  If you add Java objects to a session, place the class files for those objects in the correct class path (the application class path if utilizing sharing across Web modules in an enterprise application, or the Web module class path if using the Servlet 2.2-complaint session sharing) or in the directory containing other servlets used in WebSphere Application Server.

  Because the HttpSession object is shared among servlets that the user might access, consider adopting a site-wide naming convention to avoid conflicts.
- **Avoid storing large object graphs in the HttpSession object.**

  In most applications each servlet only requires a fraction of the total session data. However, by storing the data in the HttpSession object as one large object, an application forces WebSphere Application Server to process all of it each time.
- **Utilize Session Affinity to help achieve higher cache hits in the WebSphere Application Server.**

  WebSphere Application Server has functionality in the HTTP Server plug-in to help with session affinity. The plug-in reads the cookie data (or encoded URL) from the browser and helps direct the request to the appropriate application or clone based on the assigned session key. This functionality increases use of the in-memory cache and reduces hits to the database or another WebSphere Application Server instance
- **Maximize use of session affinity and avoid breaking affinity.**

Using session affinity properly can enhance the performance of the WebSphere Application Server. Session affinity in the WebSphere Application Server environment is a way to maximize the in-memory cache of session objects and reduce the amount of reads to the database or another WebSphere Application Server instance. Session affinity works by caching the session objects in the server instance of the application with which a user is interacting. If the application is deployed in multiple servers of a server group, the application can direct the user to any one of the servers. If the users starts on server1 and then comes in on server2 a little later, the server must write all of the session information to the external location so that the server instance in which server2 is running can read the database. You can avoid this database read using session affinity. With session affinity, the user starts on server1 for the first request; then for every successive request, the user is directed back to server1. Server1 has to look only at the cache to get the session information; server1 never has to make a call to the session database to get the information.

You can improve performance by not breaking session affinity. Some suggestions to help avoid breaking session affinity are:

- Combine all Web applications into a single application server instance, if possible, and use modeling or cloning to provide failover support.
- Create the session for the frame page, but do not create sessions for the pages within the frame when using multi-frame JSP files. (See discussion later in this topic.)

- **When using multi-framed pages, follow these guidelines:**
  - Create a session in only one frame or before accessing any frame sets. For example, assuming there is no session already associated with the browser and a user accesses a multi-framed JSP file, the browser issues concurrent requests for the JSP files. Because the requests are not part of any session, the JSP files end up creating multiple sessions and all of the cookies are sent back to the browser. The browser honors only the last cookie that arrives. Therefore, only the client can retrieve the session associated with the last cookie. Creating a session before accessing multi-framed pages that utilize JSP files is recommended.
  - By default, JSP files get a HTTPSession using `request.getSession(true)` method. So by default JSP files create a new session if none exists for the client. Each JSP page in the browser is requesting a new session, but only one session is used per browser instance. A developer can use `<% @ page session="false" %>` to turn off the automatic session creation from the JSP files that do not access the session. Then if the page needs access to the session information, the developer can use `<%HttpSession session = javax.servlet.http.HttpServletRequest.getSession(false); %>` to get the already existing session that was created by the original session creating JSP file. This action helps prevent breaking session affinity on the initial loading of the frame pages.
  - Update session data using only one frame. When using framesets, requests come into the HTTP server concurrently. Modifying session data within only one frame so that session changes are not overwritten by session changes in concurrent frameset is recommended.
  - Avoid using multi-framed JSP files where the frames point to different Web applications. This action results in losing the session created by another Web application because the JSESSIONID cookie from the first Web application gets overwritten by the JSESSIONID created by the second Web application.
- **Secure all of the pages (not just some) when applying security to servlets or JSP files that use sessions with security integration enabled, .**

  When it comes to security and sessions, it is all or nothing. It does not make sense to protect access to session state only part of the time. When security integration is enabled in the session management facility, all resources from which a session is created or accessed must be either secured or unsecured. You cannot mix secured and unsecured resources.

  The problem with securing only a couple of pages is that sessions created in secured pages are created under the identity of the authenticated user. Only the same user can access sessions in other secured pages. To protect these sessions from use by unauthorized users, you cannot access these sessions from an unsecured page. When a request from an unsecured page occurs, access is denied and an `UnauthorizedSessionRequestException` error is created. (`UnauthorizedSessionRequestException` is a runtime exception; it is logged for you.)
- **Use manual update and either the sync() method or time-based write in applications that read session data, and update infrequently.**

With END_OF_SERVICE as write frequency, when an application uses sessions and anytime data is read from or written to that session, the LastAccess time field updates. If database sessions are used, a new write to the database is produced. This activity is a performance hit that you can avoid using the Manual Update option and having the record written back to the database only when data values update, not on every read or write of the record.

To use manual update, turn it on in the session management service. (See the tables above for location information.) Additionally, the application code must use the `com.ibm.websphere.servlet.session.IBMSession` class instead of the generic HttpSession. Within the IBMSession object there is a sync method. This method tells the WebSphere Application Server to write the data in the session object to the database. This activity helps the developer to improve overall performance by having the session information persist only when necessary.

Note: An alternative to using the manual updates is to utilize the timed updates to persist data at different time intervals. This action provides similar results as the manual update scheme.

- Implement the following suggestions to achieve high performance:
  - If your applications do not change the session data frequently, use Manual Update and the sync function (or timed interval update) to efficiently persist session information.
  - Keep the amount of data stored in the session as small as possible. With the ease of using sessions to hold data, sometimes too much data is stored in the session objects. Determine a proper balance of data storage and performance to effectively use sessions.
  - If using database sessions, use a dedicated database for the session database. Avoid using the application database. This helps to avoid contention for JDBC connections and allows for better database performance.
  - Verify that you have the latest fix packs for the WebSphere Application Server.
- Utilize the following tools to help monitor session performance.
  - Run the com.ibm.servlet.personalization.sessiontracking.IBMTrackerDebug servlet. - To run this servlet, you must have the servlet invoker running in the Web application you want to run this from. Or, you can explicitly configure this servlet in the application you want to run.
  - Use the WebSphere Application Server Resource Analyzer which comes with WebSphere Application Server to monitor active sessions and statistics for the WebSphere Application Server environment.
  - Use database tracking tools such as ″Monitoring″ in DB2. (See the respective documentation for the database system used.)

HTTP session manager troubleshooting tips

This article provides troubleshooting tips for problems creating or using HTTP sessions with your Web application hosted by WebSphere Application Server.

Here are some steps to take:

- See HTTP session aren't getting created or are getting dropped to see if your specific problem is discussed.
- View the JVM logs for the application server which hosts the problem application:
  - first, look at messages written while each application is starting. They will be written between the following two messages:

    ```
    Starting application: application
    ......................
    Application started: application
    ```

  - Within this block, look for any errors or exceptions containing a package name of com.ibm.ws.webcontainer.httpsession. If none are found, this is an indication that the session manager started successfully.
  - Error ″**SRVE0054E: An error occurred while loading session context and Web application**″ indicates that SessionManager didn't start properly for a given application.
  - Look within the logs for any Session Manager related messages. These messages will be in the format SESNxxxxE and SESNxxxxW for errors and warnings, respectively, where xxxx is a number identifying the precise error. Look up the extended error definitions in the Session Manager message table.

- See the Best practices for using HTTP Sessions section in the *Developing and deploying applications* PDF books for more details.
- To dynamically view the number of sessions as a Web application is running, enable performance monitoring for HTTP sessions. This will give you an indication as to whether sessions are actually being created.
- To learn how to view the HTTP session counters as the application runs, read the Monitoring performance with Tivoli® Performance Viewer chapter of the *Administering applications and their environment* PDF book.
- Alternatively, a special servlet can be invoked that displays the current configuration and statistics related to session tracking. This servlet has all the counters that are in performance monitor tool and has some additional counters.
  - Servlet name: **com.ibm.ws.webcontainer.httpsession.IBMTrackerDebug**.
  - It can be invoked from any Web module which is enabled to serve by class name. For example, using default_app, **http://localhost:9080/servlet/com.ibm.ws.webcontainer.httpsession.IBMTrackerDebug**.
  - If you are viewing the module via the serve-by-class-name feature, be aware that it may be viewable by anyone who can view the application. You may wish to map a specific, secured URL to the servlet instead and disable the serve-servlets-by-classname feature.
- Enable tracing for the HTTP Session Manager component:
  - Use the trace specification **com.ibm.ws.session.*=all=enabled**. Follow the instructions for dumping and browsing the trace output to narrow the origin of the problem.
  - If you are using persistent sessions based on memory replication, also enable trace for **com.ibm.ws.drs.***.
- If you are using **database-based persistent sessions**, look for problems related to the **data source** the Session Manager relies on to keep session state information. For details on diagnosing database related problems see the Errors accessing a datasource or connection pool in the *Administering applications and their environment* PDF book

Error message `SRVE0079E Servlet host not found` after you define a port

Error message SRVE0079E can occur after you define the port in WebContainer > HTTP Transports for a server, indicating that you do not have the port defined in your virtual host definitions. To define the port,

1. On the administrative console, go to Environment > Virtual Hosts > default_host> Host Aliases> New
2. Define the new port on host ″*″

The application server gets EC3 - 04130007 ABENDs

To prevent an EC3 - 04130007 abend from occuring on the application server, change the HTTP Output timeout value. The custom property *ConnectionResponseTimeout* specifies the maximum number of seconds the HTTP port for an individual server can wait when trying to read or write data. For instructions on how to set *ConnectionResponseTimeout*, see HTTP transport custom properties section of the *Administering applications and their environment* PDF book.

If none of these steps fixes your problem, check to see if the problem has been identified and documented by looking at the available online support (hints and tips, technotes, and fixes). If you don’t find your problem listed there contact IBM support.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

HTTP session problems

This article provides troubleshooting information related to creating or using Hypertext Transfer Protocol (HTTP) sessions.

To view and update the session manager settings discussed here, use the administrative console. Select the application server that hosts the problem application, then under **Additional properties**, select **Web Container**, then **Session manager**.

What kind of problem are you having?

- HTTP Sessions are not getting created, or are lost between requests.
- Session is shared across multiple browsers on same client machine.
- Session is not getting invalidated immediately after specified session timeout interval.
- Unwanted sessions are being created by JavaServer Pages.
- Session data intended for one client is seen by another client.
- A ClassCastException error occurs during failover of a session that contains an Enterprise JavaBeans™ (EJB) reference.
- Users are not logged out after HTTP session timer expires

If your problem is not described here, or none of these steps fixes the problem:

- Review “HTTP session manager troubleshooting tips” on page 22 for general steps on debugging session-manager related problems.
- Review Task overview: Managing HTTP sessions in the *Administering applications and their environment* PDF book for information on how to configure the session manager, and best practices for using it.
- Check to see if the problem has been identified and documented by looking at the available online support (hints and tips, technotes, and fixes).
- If you don’t find your problem listed there contact IBM support.

HTTP sessions are not getting created, or are lost between requests

By default, the session manager uses cookies to store the session ID on the client between requests. Unless you intend to avoid cookie-based session tracking, ensure that cookies are flowing between WebSphere Application Server and the browser:

- Make sure the **Enable cookies** check box is checked under the **Session tracking Mechanism** property.
- Make sure cookies are enabled on the browser you are testing from or from which your users are accessing the application.
- Check the Cookie domain specified on the SessionManager (to view the or update the cookie settings, in the **Session tracking mechanism->enable cookies** property, click **Modify**).
  - For example, if the cookie domain is set as ″.myCom.com″, resources should be accessed using that domain name. Example: http://www.myCom.com/myapp/servlet/sessionservlet.
  - If the domain property is set, make sure it begins with a dot (.). Certain versions of Netscape do not accept cookies if domain name doesn’t start with a dot. Internet Explorer honors the domain with or without a dot. For example, if the domain name is set to *mycom.com*, change it to *.mycom.com* so that both Netscape and Internet Explorer honor the cookie.

    Note: When the servers are on different hosts, ensure that session cookies flow to all the servers by configuring a front-end router such as a Web server with the plug-in or setting the Cookie domain.
- Check the **Cookie path** specified on the SessionManager. Check whether the problem URL is hierarchically below the Cookie path specified. If not correct the Cookie path.
- If the `Cookie maximum age` property is set, ensure that the client (browser) machine’s date and time is the same as the server’s, including the time zone. If the client and the server time difference is over the ″Cookie maximum age″ then every access would be a new session, since the cookie expires after the access.

- If you have multiple Web modules within an enterprise application that track sessions:
  - If you want to have different session settings among Web modules in an enterprise application, ensure that each Web module specifies a different cookie name or path, or
  - If Web modules within an enterprise application use a common cookie name and path, ensure that the HTTP session settings, such as Cookie maximum age, are the same for all Web modules. Otherwise cookie behavior is unpredictable, and depends upon which application creates the session. Note that this does not affect session data, which is maintained separately by Web module.
- Check the cookie flow between browser and server:
  1. On the browser, enable ″cookie prompt″. Hit the servlet and make sure cookie is being prompted.
  2. On the server, enable SessionManager trace. Enable tracing for the HTTP session manager component, by using the trace specification ″com.ibm.ws.session.*=all=enabled″. After trace is enabled, exercise your session-using servlet or JSP, then follow the instructions for dumping and browsing the trace output .
  3. Access the session servlet from the browser.
  4. The browser prompts for the cookie; note the jsessionid.
  5. Reload the servlet, note down the cookie if a new cookie is sent.
  6. Check the session trace and look for the session ID and trace the request by the thread. Verify that the session is stable across Web requests:
     - Look for **getIHttpsession(...)** which is start of session request.
     - Look for **releaseSession(..)** which is end of servlet request.
- If you are using URL rewriting instead of cookies:
  - Ensure there are no static HTML pages on your application's navigation path.
  - Ensure that your servlets and JSP files are implementing URL rewriting correctly. For details and an example see the Session tracking options section in the *Developing and deploying applications* PDF book.
-

  Note: Session tracking using the SSL ID is deprecated in WebSphere Application Server version 7.0. You can configure session tracking to use cookies or modify the application to use URL rewriting.

  If you are using SSL as your session tracking mechanism:
  - Ensure that you have SSL enabled on your IBM HTTP Server or iPlanet HTTP server.
  - Review the Session tracking options section in the *Developing and deploying applications* PDF book..

Session is shared across multiple browsers on same client machine

This behavior is browser-dependent. It varies between browser vendors, and also may change according to whether a browser is launched as a new process or as a subprocess of an existing browser session (for example by hitting Ctl-N on Windows®).

The Cookie maximum age property of the session manager also affects this behavior, if cookies are used as the session-tracking mechanism. If the maximum age is set to some positive value, all browser instances share the cookies, which are persisted to file on the client for the specified maximum age time.

Session is not getting invalidated immediately after specified session timeout interval

The SessionManager invalidation process thread runs every *x* seconds to invalidate any invalid sessions, where x is determined based on the session timeout interval specified in the session manager properties. For the default value of 30 minutes , *x* is around 300 seconds. In this case, it could take up to 5 minutes (300 seconds) beyond the timeout threshold of 30 minutes for a particular session to become invalidated.

Unwanted sessions are being created by JavaServer Pages

As required by the JavaServer Pages (JSP) specification, JSP pages by default perform a request.getSession(true), so that a session is created if none exists for the client. To prevent JSP pages from creating a new session, set the session scope to **false** in the .jsp file using the page directive as follows:

```
<% @page session="false" %>
```

Session data intended for one client is seen by another client

In rare situations, usually due to application errors, session data intended for one client might be seen by another client. This situation is referred to as session data crossover. When the *DebugSessionCrossover* custom property is set to true, code is enabled to detect and log instances of session data crossover. Checks are performed to verify that only the session associated with the request is accessed or referenced. Messages are logged if any discrepancies are detected. These messages provide a starting point for debugging this problem. This additional checking is only performed when running on the WebSphere-managed dispatch thread, not on any user-created threads.

For additional information on how to set this property, see article, Web container custom properties in the *Administering applications and their environment* PDF book.

Users are not logged out after the HTTP session timer expires

If users of WebSphere Application Server log onto an application and sit idle longer than the specified HTTP session timeout value, the user information is not invalidated and user credentials stay active until LTPA token timeout occurs.

After you apply PK25740, complete the following steps to log out users from the application after the HTTP session has expired.

1. In the administrative console, click **Security > Global security**.
2. Under Custom properties, click **New**.
3. In the Name field, enter com.ibm.ws.security.web.logoutOnHTTPSessionExpire.
4. In the Values field, enter true.
5. Click Apply and Save to save the changes to your configuration.
6. Resynchronize and restart the server.

IBM Support has documents and tools that can save you time gathering information needed to resolve problems as described in Troubleshooting help from IBM. Before opening a problem report, see the Support page:

- http://www.ibm.com/servers/eserver/support/iseries/allproducts/index.html

Modifying the default Web container configuration

About this task

A Web container handles requests for servlets, JavaServer Pages (JSP) files, and other types of files that include server-side code. The Web container creates servlet instances, loads and unloads servlets, creates and manages request and response objects, and performs other servlet management tasks. The Web server plug-ins, provided by the product, help supported Web servers to pass servlet requests to Web containers.

If the property to start servlets during application server startup is enabled, part of its startup process calls the Servlet.init method on its servlets when you start the Web container. Therefore, when the Web container starts and calls the init method, other components such as Naming and Work Load Management

might not be fully started yet. As a result, application server related calls may not work because all of the application server components might not be ready yet. Once the application server is 'ready for e-business', it is completely ready. If application server related calls fail during Servlet.init method, you can either:

- Start the servlet manually when the server is ready for e-business instead of starting the servlet upon startup or
- You can choose not to make application server related calls in the servlet's init method.

The Web container is created initially with default properties values suitable for simple Web applications. However, these values might not be appropriate for more complex Web applications.

Your application is considered complex if it requires any of the following features:
- Additional virtual host aliases
- Servlet caching
- Persistent HTTP session support
- Session tracking support with URL rewriting
- Special Web container transport chain settings
- Asynchronous or remote dispatching
- No request or response pooling

Make the following configuration changes if you have a complex application:

1. In the administrative console, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name***. Then under Web container settings, click on one of the following:
   a. **Web container**, if your Web application requires a virtual host, other than the default_host, or requires servlet caching.
   b. **Web container transport chains**, if you need to reconfigure your HTTP connections.
2. If your application handles special client request loads, in the administrative console, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name***. Then under Additional Properties, click **Thread pools** to modify your thread pool settings.
3. If your application requires global settings for internal servlets for Web archive (WAR) files packaged by third-party tools, in the administrative console, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Web Container Settings** → **Web container**. Then under Additional Properties, click **Custom properties** and enter the appropriate custom property.

Web container settings

Use this page to configure the Web container settings.

To view this administrative console page, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Web Container Settings** → **Web container**.

Default virtual host

Specifies a virtual host that enables a single host machine to resemble multiple host machines. Resources associated with one virtual host cannot share data with resources associated with another virtual host, even if the virtual hosts share the same physical machine.

Select a virtual host option:

default_host

The product provides a default virtual host with some common aliases such as the machine IP address, short host name, and fully qualified host name. The alias comprises the first part of the path for accessing a resource such as a servlet. For example, it is `localhost:9080` in the request `http://localhost:9080/myServlet`.

admin_host

This is another name for the application server; also known as *server1* in the base installation. This process supports the use of the administrative console.

proxy_host
The virtual host called proxy_host, includes default port definitions, port 80 and 443, which are typically initialized as part of the proxy server initialization. Use this proxy host as appropriate with routing rules associated with the proxy server.

Enable servlet caching
Specifies that if a servlet is invoked once and it generates output to be cached, a cache entry is created containing not only the output, but also side effects of the invocation. These side effects can include calls to other servlets or JavaServer Pages (JSP) files, as well as metadata about the entry, including timeout and entry priority information.

Portlet fragment caching requires that servlet caching is enabled. Therefore, enabling portlet fragment caching automatically enables servlet caching. Disabling servlet caching automatically disables portlet fragment caching.

Disable servlet request and response pooling
Specifies to disable the pooling of servlet request and servlet response objects that are pooled by the Web container. When you disable pooling of servlet request and servlet response objects, new servlet request and servlet response objects are created for each request.

When you disable pooling of servlet request and servlet response objects, new servlet request and servlet response objects are created for each request, which can negatively affect performance, but provides protection from any unforeseen pooling bugs.

Web container custom properties
You can configure name-value pairs of data, where the name is a property key and the value is a string value that you can use to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console. The following is a list of some of the available Web container custom properties.

To specify Web container custom properties:
1. In the administrative console click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Web Container Settings** → **Web container**.
2. Under **Additional Properties** select **Custom Properties**.
3. On the Custom Properties page, click **New**.
4. On the settings page, enter the name of the custom property that you want to configure in the **Name** field and the value that you want to set it to in the **Value** field.
5. Click **Apply** or **OK**.
6. Click **Save** on the console task bar to save your configuration changes.
7. Restart the server.

The following is a list of custom properties provided with the Application Server. “JavaServer Pages specific Web container custom properties” on page 75 and HTTP transport custom properties are listed in a separate topic.

com.ibm.ws.webcontainer.disallowAllFileServing
This property is for disabling file serving on all applications on a specific application server. You can enable file serving on a global level across a given application server by using the fileServingEnabled custom property. However, the fileServingEnabled property is overridden by the specific deployment information of each application. Therefore, the current fileServingEnabled custom property only applies as a backup in case an application does not define the fileServingEnabled setting itself. To globally override this setting on a specific application server to prevent the application server from serving static files regardless of their individual deployment settings, set the com.ibm.ws.webcontainer.disallowAllFileServing Web container custom property to `true` using the following name-value pair.

Name	Value
com.ibm.ws.webcontainer.disallowAllFileServing	true

Disallow the use of the serving servlets by class name

When the serveServletsByClassnameEnabled property is enabled, it is possible to access servlets directly, resulting in a possible security exposure. Define the following custom property to disallow the use of the serveServletsByClassnameEnabled property across the entire application server level.

Name	Value
com.ibm.ws.webcontainer.disallowserveservletsbyclassname	true

Defining classes that cannot be served by class name

The com.ibm.ws.webcontainer.donotservebyclassname custom property specifies a list of classes that cannot be served by the class name.

Name	Value
com.ibm.ws.webcontainer.donotservebyclassname	A semi-colon delimited list of classes to be completely disallowed from being served by class name.

Writing chunks of data using synchronous writes

By default, the Web container uses asynchronous writes to write response data in chunks up to the response buffer size. For larger responses that are greater than the response buffer size, the Web container continues to buffer response data into memory while waiting for an asynchronous write of a response data chunk to complete. This can result in part of a large response held in memory, which can lead to high memory usage and potentially an out of memory error. An application server hang may also occur when a server is simultaneously processing more requests than Web container defined threads.

If the com.ibm.ws.webcontainer.channelwritetype property is set to `sync`, synchronous writing is used, otherwise asynchronous writing is used by default. With synchronous writing, response data are written synchronously in chunks of up to the value of responsebuffersize and no response data are buffered into memory while waiting for a synchronous write of a response data chunk to complete. As a result, the approximate maximum amount of response data that is held in memory is equal to the responsebuffersize multiplied by the number of Web container threads. The maximum number of requests that can be processed simultaneously by the Web container is limited by the number of Web container threads. Additional requests are queued, waiting for a request that is in process to complete.

The responsebuffersize Web container custom property defines the maximum amount of response data written by the Web container in a single chunk, and is 32k by default. As a result, it is used to change the number of writes needed by the Web container to send complete response data. However, if an application flushes response data, any response data held by the Web container is immediately written irrespective of the responsebuffersize.

Use the following name-value pair to write chunks of data using synchronous writes.

Name	Value
com.ibm.ws.webcontainer.channelwritetype	sync

Recognizing filter mappings to ″*″ as a mapping to ″/*″

When processing a request, the Web container recognizes servlet mappings to ″*″ as the same as servlet mappings to ″/*″. To provide the same behavior with filter mapping, set the com.ibm.ws.webcontainer.mapFiltersToAsterisk custom property to `true`. Setting the com.ibm.ws.webcontainer.mapFiltersToAsterisk custom property to `true` causes the Web container to recognize filter mappings to ″*″ as a filter mapping to ″/*″ . This custom property is not case sensitive.

Name	Value
com.ibm.ws.webcontainer.mapFiltersToAsterisk	true

Suppressing the HTML output of error text

During a recursive error that an application specified error page cannot handle, the stack trace and error message are outputted as an HTML page. This information includes class names and program information that the application developer does not want expose to the user.

You can set the com.ibm.ws.webcontainer.suppressHtmlRecursiveErrorOutput Web container custom property to suppress the HTML output of the error text, without changing the internal logging of the message. Set the custom property com.ibm.ws. webcontainer.suppressHtmlRecursiveErrorOutput to `true` to disable the HTML output of the error message to the user and present the user with blank page with a 500 error code.

Name	Value
com.ibm.ws.webcontainer.suppressHtmlRecursiveErrorOutput	true

DebugSessionCrossover

The *DebugSessionCrossover* custom property enables code to perform additional checks to verify that only the session associated with the request is accessed or referenced. Messages are logged if any discrepancies are detected.

Note: The use of the *DebugSessionCrossover* property as a Web container custom property is deprecated. You can now define it as a session management custom property.

To enable session data crossover detection, use the following name-value pair:

Name	Value
DebugSessionCrossover	true

See article, “HTTP session problems” on page 24, for additional information.

DecodeUrlAsUTF8

The UTF-8 encoded URL feature, which provides UTF-8 encoded Uniform Resource Locators (URLs) to support the double-byte characters in URLs is enabled by default. You can prevent the Web container from explicitly decoding URLs in UTF-8 and have them use the ISO-8859 standard as per the current HTTP specification by using the following name-value pair.

Name	Value
DecodeUrlAsUTF8	false

enableInProcessConnections

Use the enableInProcessConnections custom property to reduce response times and to reduce the number of threads that are used to service a request, which reduces the potential for a deadlock. There is an optimized communication path between a Web services client application and a Web container that are located in the same application server process. Requests from the Web services client that are normally sent to the Web container using a network connection are delivered directly to the Web container using an optimized local path. The local path is available because the Web services client application and the Web container are running in the same process. This optimized communication path is disabled by default. Before enabling this property, make sure that wild cards are not specified for the Web container ports. Use specific ports for the Web container when the optimized communication path is enabled. To enable the optimized communication path, use the following name-value pair:

Name	Value
enableInProcessConnections	true

See article, Web services client to Web container optimized communication, for additional information.

fileServingEnabled

fileServingEnabled, directoryBrowsingEnabled, and similar properties are global settings for internal servlets. Web application archive (WAR) files that are packaged using third-party tools cannot specify behavior for the services that are exposed by the Web container internal servlets. You can globally enable and disable internal servlets for all Web applications at the Web container level by creating name-value pairs.

Name	Value
fileServingEnabled	true
directoryBrowsingEnabled	true
serveServletsByClassnameEnabled	true

Settings that are defined in an assembly tool take precedence over the global settings that are set through the custom properties at the Web container level.

Web application deployment extensions continue to hold configuration information for the services that are provided by the internal servlets, and take precedence over the global settings that are set through the custom properties at the Web container level.

Invalidating sessions after specified time has elapsed

The *ForceSessionInvalidationMultiple* custom property indicates whether the session manager should wait indefinitely for a request to complete before attempting to invalidate the session, or attempt to invalidate a session after the specified time limit has elapsed. The default value for this property is 1.

- If you specify 0 (zero) for this custom property, the session manager waits indefinitely until a request is complete before attempting to invalidate the session.

  If your requests normally are not bound by a response time limit, specify 0 for this property.
- If you specify a positive integer, such as 1, 2, or 3 for this custom property, even if a session is not known to have completed, the session manager attempts to invalidate the session if the indicated time period since the last access occurred has elapsed. This time period is the result of multiplying the value specified for this property and the value specified for the Session Timeout property. For example, if you specify 2 minutes for the Session Timeout property and 2 for the ForceSessionInvalidationMultiple property, the session manager attempts to invalidate the session after 4 minutes.

  If you want to invalidate your sessions after a certain amount of time has elapsed, specify the appropriate positive integer for this property.

Name	Value
ForceSessionInvalidationMultiple	1

httpsIndicatorHeader

The custom property *httpsIndicatorHeader* manages HTTPS requests that are forwarded to an application server from an SSL offloader that is used in front of WebSphere Application Server. When an HTTPS request is received by a SSL offloader it is redirected over HTTP to an application server using WebSphere Application Server. The SSL offloader adds a header indicating the original request was over HTTP. The *httpsIndicatorHeader* property specifies the header name added by the SSL box. The application server checks this indicator to determine if SSL is required. If it determines the request is SSL over HTTP, an HTTPS scheme is chosen.

Name	Value
httpsIndicatorHeader	*Request header key name*

HttpSessionIdReuse

The custom property *HttpSessionIdReuse* determines whether the session manager can use the session ID sent from a browser to preserve session data across Web applications that are running in an environment that is not configured for session persistence. In a multi-JVM environment that is not configured for session persistence setting this property to `true` enables the session manager to use the same session information for all of a user's requests even if the Web applications that are handling these requests are governed by different JVMs. The default value for this property is `false`.

Note: The use of the *HttpSessionIdReuse* property as a Web container custom property is deprecated. You can now define it as a session management custom property.

To enable the session manager ton use the session ID sent from a browser to preserve session data across Web applications that are running in an environment that is not configured for session persistence, use the following name-value pair:

Name	Value
HttpSessionIdReuse	true

Global configuration of servlet listeners

The servlet specification supports applications registering listeners for servlet-related events on an individual application basis through the `web.xml` descriptor. However, using the listeners custom property, a server can listen to servlet events across Web applications. To implement global listening, a listener is registered at the Web container level and is propagated to all of the installed and new Web applications. This global behavior of internal servlet listeners is controlled by the listeners custom property by using the following name-value pair format.

Name	Value
listeners	*listener_class*

The values for this property is a string specifying a comma separated list of listener classes. The listener supplied must implement standard listener classes from the Java Servlet API or IBM listener extension classes.

Using Uniform Resource Locators (URLs) without leading front slashes (/)

WebSphere Application Server 5.x supports Uniform Resource Locators (URLs) without leading front slashes (/) and to preserve compatibility, You can set the custom property, prependSlashToResource to `true`. To ignore the specification and consider URLs without the leading front slash, use the following name-value pair.

Name	Value
prependSlashToResource	true

UseOracleBLOB

The *UseOracleBLOB* custom property creates the HTTP session database table using the Binary Large Object (BLOB) data type for the medium column. This property increases performance of persistent sessions when Oracle databases are used. Due to an Oracle restriction, BLOB support requires use of the oci database driver for Oracle for more than 4000 bytes of data. You must also ensure that a new sessions table is created before the server is restarted by dropping your old sessions table or by changing the datasource definition to reference a database that does not contain a sessions table.

Note: The use of the *UseOracleBLOB* property as a Web container custom property is deprecated. You can now define it as a session management custom property.

To create a sessions table using the BLOB data type, use the following name-value pair:

Name	Value
UseOracleBLOB	true

Convert start and end attributes of the repeat tag to strings

Set the com.ibm.wsspi.jsp.convertAttrValueToString Web container custom property to `true` to convert start and end attributes of the repeat tag to strings before they are used.

Name	Value
com.ibm.wsspi.jsp.convertAttrValueToString	true

Disable the commons-el expression cache

Set the com.ibm.wsspi.jsp.disableElCache Web container custom property to `true` to disable the commons-el expression cache if you are experiencing out of memory conditions because the hash maps are held by the expression evaluator.

Name	Value
com.ibm.wsspi.jsp.disableElCache	true

Create a FileNotFoundException exception when a JSP file is not found

Set the com.ibm.ws.webcontainer.throwMissingJspException custom property to `true` to create a FileNotFoundException when a resource that is included by a JSP file is missing. If this property is not set to `true`, an error page is displayed.

Name	Value
com.ibm.ws.webcontainer.throwMissingJspException	true

com.ibm.ws.webcontainer.suppressServletExceptionLogging

If a servlet creates an exception, it is logged in the systemErr log file. For some applications, this is undesirable as it may fill up the log. In WebSphere Application Server Version 5, servlet exceptions are created but they are not logged in the systemErr log file. Beginning with WebSphere Application Server Version 6.0.2, all servlet exceptions are logged. You can use the following custom property to specify that the Web container does not log the servlet exceptions that are created in the systemErr file:

Name	Value
com.ibm.ws.webcontainer.suppressServletExceptionLogging	true

Invoke global session listeners

If a system application is the first to start, and the application attempts to load a global listener in a shared library that is associated with the server classloader, the application does not load that listener and prevents the listener from being loaded or invoked by a later non-system application. Set the com.ibm.ws.webcontainer.disableSystemAppGlobalListenerLoading custom property to true to prevent system applications from loading global listeners. When this property is set to `true`, the system application does not attempt to load the global listeners and later non-system applications can load them from a shared library associated with a server class loader.

Name	Value
com.ibm.ws.webcontainer.disableSystemAppGlobalListenerLoading	true

Controlling active request completion time
By default, when an application is stopped the Web container waits up to 60 seconds for each active request for a resource of that application to complete. You can now define the com.ibm.ws.webcontainer.ServletDestroyWaitTime Web container custom property to control the amount of time that the Web container waits for an active request to complete when the owning application is stopped.

Set the com.ibm.ws.webcontainer.ServletDestroyWaitTime custom property to an integer value, which specifies the number of seconds to wait for a request to complete. The default value is 60 seconds.

Name	Value
com.ibm.ws.webcontainer.ServletDestroyWaitTime	integer

Web module deployment settings
Use this page to configure an instance of Web module deployment.

To view this administrative console page, click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***application_name*** → **Manage Modules** → ***Web_module_instance***.

URI
Specifies the relative location of the module within the application enterprise archive (EAR) file.

Alternate deployment descriptor
Specifies the alternate deployment descriptor for the module as defined in the application deployment descriptor according to the Java Platform, Enterprise Edition (Java EE) specification.

Starting weight
Specifies the order that modules are started. Lower weighted modules are started before higher weighted modules.

Class loader order
Specifies whether the class loader searches in the parent class loader or in the application class loader first to load a class. The standard for development kit class loaders and product class loaders is `Classes loaded with parent class loader first`. By specifying `Classes loaded with application class loader first`, your application can override classes contained in the parent class loader, but this action can potentially result in ClassCastException or LinkageErrors if you have mixed use of overridden classes and non-overridden classes.

The options are `Classes loaded with parent class loader first` and `Classes loaded with local class loader first (parent last)` . The default is to search in the parent class loader before searching in the application class loader to load a class.

Data type String
Default Classes loaded with parent class loader first

Context root for Web modules settings
Use this page to specify the context root for Web modules during or after installation of an application onto a WebSphere Application Server deployment target.

To view this administrative console panel, click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***application_name*** → **Context root for Web modules**. This panel is the same as the Context root for Web modules panel on the application installation and update wizards.

Web module
Specifies the name of a Web module in the application that you are installing or that you are viewing after installation.

URI
Specifies the location of the module relative to the root of the application EAR file.

Context root
Specifies the context root of the Web application (WAR).

A context root for each Web module is defined in the application deployment descriptor during application assembly. Use this field to assign a different context root to a Web module. The context root is combined with the defined servlet mapping (from the WAR file) to compose the full URL that users type to access the servlet. For example, if the context root is `/gettingstarted` and the servlet mapping is `MySession`, then the URL is `http://host:port/gettingstarted/MySession`.

Environment entries for Web modules settings
Use this page to configure the environment entries of Web modules such as servlets and JavaServer Pages (JSP) files.

To view this administrative console panel, click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***application_name*** → **Environment entries for Web modules**. This page is the same as the Environment entries for Web modules panel on the application installation and update wizards.

Module
Specifies the name of a module in the `web.xml` Web application.

URI
Specifies the location of the module relative to the root of the application (EAR file).

Name
Specifies the name of the environment entry that you are editing or viewing. The environment entry is the `Env-entry` property in the module `web.xml` file.

Type
Specifies a data type for the environment entry defined by the `Env-entry` property in the module `web.xml` file.

Description
Specifies information on the environment entry.

Value
Specifies an editable value for the environment entry defined by the `Env-entry` property in the module `web.xml` file.

Web container troubleshooting tips

If you are having problems starting a Web module, or accessing resources within a particular Web module:
- View the JVM logs and process logs for the application server which hosts the problem Web modules, and look for messages in the JVM output file which indicate that the web module has started successfully. You should see messages similar to the following:

```
WebContainer  A SRVE0161I: IBM WebSphere Application Server - Web Container.
Copyright IBM Corp. 1998-2002
WebContainer  A SRVE0169I: Loading Web Module: [module_name]
```

```
ApplicationMg A WSVR0221I: Application started: [application_name]
HttpTransport A SRVE0171I: Transport http is listening on port [port_number]
[server_name] open for e-business in profile_root/logs/[server_name]/SystemOut.log
```

- For specific problems that can cause servlets, HTML files, and JavaServer Pages (JSP) files not to be served, see Web resource (JSP file, servlet, HTML file, image) does not display .
- For a detailed trace of the run-time behavior of the Web container, enable trace for the component com.ibm.ws.webcontainer using `com.ibm.ws.webcontainer*=all`.

If application server related calls fail during Servlet.init method, you can either:

- Initialize the servlet manually by making a single request to that servlet in your browser when the server is ready for e-business instead of starting the servlet upon startup or
- You can choose not to make application server related calls in the servlet's init method.

If the property to start servlets during application server startup is enabled, part of its startup process calls the Servlet.init method on its servlets when you start the Web container. Therefore, when the Web container is starts and calls the init method, other components such as Naming and Work Load Management may not be fully started yet. As a result, application server related calls may not work since all of the application server components may not be ready yet. Once the application server is 'ready for e-business', it is completely ready.

If none of these steps fixes your problem, check to see if the problem has been identified and documented by looking at the available online support (hints and tips, tech notes, and fixes). If you don't find your problem listed there contact IBM support.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

Disabling servlet pooling: Best practices and considerations

This topic provides usage examples of when you may want to disable servlet pooling. You may want to disable request and response pooling if your application is creating threads inside of the application or if you are concerned about the Web container reusing request and response objects.

Disabling request and response pooling

- Application is creating threads inside of the application.

  The Servlet 2.4 specification states the following:

  > **SRV.4.10 Lifetime of the Request Object** Each request object is valid only within the scope of a servlet's service method, or within the scope of a filter's doFilter method. Containers commonly recycle request objects in order to avoid the performance overhead of request object creation. The developer must be aware that maintaining references to request objects outside the scope described above is not recommended as it may have indeterminate results.
  >
  > **SRV.5.6 Lifetime of the Response Object** Each response object is valid only within the scope of a servlet's service method, or within the scope of a filter's doFilter method. Containers commonly recycle response objects in order to avoid the performance overhead of response object creation. The developer must be aware that maintaining references to response objects outside the scope described above may lead to non-deterministic behavior.

- If you are concerned about the Web container reuse of reusing request and response objects. Since these objects are reused, there is the potential for two requests in two separate applications to have access to the same request or response object as described in the Thread Safety section of Servlet 2.4.

SRV.2.3.3.3 Thread Safety Implementations of the request and response objects are not guaranteed to be thread safe. This means that they should only be used within the scope of the request handling thread.

References to the request and response objects should not be given to objects executing in other threads as the resulting behavior may be nondeterministic. If the thread created by the application uses the container-managed objects, such as the request or response object, those objects must be accessed only within the servlet's service life cycle and such thread itself should have a life cycle within the life cycle of the servlet's service method because accessing those objects after the service method ends may cause undeterministic problems. Be aware that the request and response objects are not thread safe. If those objects were accessed in the multiple threads, the access should be synchronized or be done through the wrapper to add the thread safety, for instance, synchronizing the call of the methods to access the request attribute, or using a local output stream for the response object within a thread.

It is important to note that disabling pooling prevents the Web container from recycling the servlet request and servlet response objects for subsequent requests. This creates additional overhead as a result of an increase in request and response object creation and the subsequent garbage collection of these discarded objects.

Task overview: Developing and deploying Web applications

About this task

A developer creates the files comprising a Web application, and then assembles the Web application components into a Web module. Next, the deployer (typically the developer in a unit-testing environment or the administrator in a production environment) installs the Web application on the server.

1. **(Optional)** Migrate existing Web applications to run in the new version of WebSphere Application Server.
2. Design the Web application and develop its code artifacts: Servlets, JavaServer Pages (JSP) files, and static files, as for example, images and Hyper Text Markup Language (HTML) files. See the "Web applications: Resources for learning" on page 80 topic for links to design documentation.

   JavaServer Pages programming tips:
   - Disable session state of JavaServer Pages files using `<%@ page language="java" contentType="text/html" session="false" %>` instead of `<%@ page language="java" contentType="text/html" %>`
   - Replace setProperties calls in your JavaServer Pages files with direct calls to the appropriate setxxx methods.
3. Develop the Web application, using WebSphere Application Server extensions to enhance its functionality.
4. Assemble the Web application into a Web module using an assembly tool. Web module assembly properties might include the ability to:
   - Configure servlet page lists.
   - Configure servlet filters.
   - Serve servlets by class name.

     Serving servlets by name or class name is triggered by setting the serveServletsbyclassnameEnabled property within IBM extensions. Use the invoker.patterns attribute to specify the patterns that trigger invocation of the server component and allows the serving of servlets by name or by class name. This value is a list separated by either a space, colon, or semicolon.
   - Enable file serving.

     In file serving, Web applications can serve static file types, such as HTML. File-serving attributes are used by the servlet that implements file-serving behavior.

5. Deploy the Web module or application module that contains the Web application.

   Following deployment, you might find it handy to use the tool that enables batch compiling of the JSP files for quicker initial response times.
6. **(Optional)** Troubleshoot your Web application.
7. **(Optional)** Modify the default Web container configuration in the application server in which you deployed the Web module or application module containing the Web application.
8. **(Optional)** Manage the deployed Web application.

Web applications

A Web application is comprised of one or more related servlets, JavaServer Pages technology (JSP files), and Hyper Text Markup Language (HTML) files that you can manage as a unit.

The files in a Web application are related in that they work together to perform a business logic function. The Web application is a concept supported by the Java Servlet Specification. Web applications are typically packaged as `.war` files.

Web modules

A Web module represents a Web application. A Web module is created by assembling servlets, JavaServer Pages (JSP) files, and static content such as Hypertext Markup Language (HTML) pages into a single deployable unit. Web modules are stored in Web archive (WAR) files, which are standard Java archive files.

A Web module contains:
- One or more servlets, JSP files, and HTML files.
- A deployment descriptor, stored in an Extensible Markup Language (XML) file.

  The file, named `web.xml`, declares the contents of the module. It contains information about the structure and external dependencies of Web components in the module and describes how the components are used at run time.

You can create Web modules as stand-alone applications, or you can combine Web modules with other modules to create Java Platform, Enterprise Edition (Java EE) applications. You can also install and run a Web module in the Web container of an application server.

web.xml file

The web.xml file provides configuration and deployment information for the Web components that comprise a Web application. Examples of Web components are servlet parameters, servlet and JavaServer Pages (JSP) definitions, and Uniform Resource Locators (URL) mappings.

The Java Servlet specification defines the web.xml deployment descriptor file in terms of an XML schema document. For backwards compatibility of applications written to the Java Servlet 2.2 Specification, Web containers are also required to support the Java Servlet 2.2 specification. For backwards compatibility of applications written to the Java Servlet 2.3 specification, Web containers are also required to support the Java Servlet 2.3 specification.

If you use Rational® Application Developer version 6 to create your portlets, you must remove the following reference to the std-portlet.tld from the web.xml file:

```
<taglib id="PortletTLD">
   <taglib-uri>http://java.sun.com/portlet</taglib-uri>
   <taglib-location>/WEB-INF/tld/std-portlet.tld</taglib-location>
  </taglib>
```

Location

The web.xml file must reside in the `WEB-INF` directory under the context of the hierarchy of directories that exist for a Web application.

For example, if the application is client.war, then the web.xml file is placed in the *profile_root*/`installedApps/cellName/client.ear/client.war/WEB-INF` directory (in a default installation), where the edition is either Base or Network Deployment, depending on which edition you are using.

Usage notes

- Is this file read-only?

  No
- Is this file updated by a product component?

  This file is updated by the assembly tool.
- If so, what triggers its update?

  The assembly tool updates the web.xml file when you assemble Web components into a Web module, or when you modify the properties of the Web components or the Web module.
- How and when are the contents of this file used?

  WebSphere Application Server functions use information in this file during the configuration and deployment phases of Web application development.

Default Application

WebSphere Application Server provides a default configuration that administrators can use to easily verify that the Application Server is running. When the product is installed, it includes an application server called *server1* and an enterprise application called *Default Application*.

Default Application contains a Web module called *DefaultWebApplication* and an enterprise bean Java archive (JAR) file called *Increment*. The *Default Application* provides a number of servlets, described below. These servlets are available in the product.

For additional code examples, visit the Samples Gallery. Learn how to locate and install the Samples Gallery by viewing the Samples Gallery reference page.

Snoop servlet

Use the Snoop servlet to retrieve information about a servlet request. This servlet returns the following information:

- Servlet initialization parameters
- Servlet context initialization parameters
- URL invocation request parameters
- Preferred client locale
- Context path
- User principal
- Request headers and their values
- Request parameter names and their values
- HTTPS protocol information

- Servlet request attributes and their values
- HTTP session information
- Session attributes and their values

The Snoop servlet includes security configuration so that when WebSphere Security is enabled, clients must supply a user ID and password to initiate the servlet.

The URL for the Snoop servlet is: `http://your.server.name:9080/HitCount.jsp`.

HelloHTML servlet

Use the HelloHTML pervasive servlet to exercise the PageList support provided by the WebSphere Web container. This servlet extends the PageListServlet, which provides APIs that allow servlets to call other Web resources by name or, when using the *Client Type detection* support, by type.

You can invoke the Hello servlet from an HTML browser, speech client, or most Wireless Application Protocol (WAP) enabled browsers using the URL: `http://your.server.name:9080/HitCount.jsp`.

Note: The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 7.0 and will be removed in a future release. Re-architect your legacy applications to use javax.servlet.filter classes instead of com.ibm.servlet classes. Starting from the Servlet 2.3 specification, javax.servlet.filter classes you can intercept requests and examine responses. You can also use javax.servlet.filter classes to achieve chaining functionality, as well as embellishing or truncating responses.

HitCount application

Use the HitCount demonstration application to demonstrate how to increment a counter using a variety of methods, including:
- A servlet instance variable
- An HTTP session
- An enterprise bean

You can instruct the servlet to execute any of these methods within a transaction that you can commit or roll back. If the transaction is committed, the counter is incremented. If the transaction is rolled back, the counter is not incremented.

The enterprise bean method uses a container-managed persistence enterprise bean that persists the counter value to an Apache Derby database. This enterprise bean is configured to use the Default Datasource, which is set to the DefaultDB database.

When using the enterprise bean method, you can instruct the servlet to look up the enterprise bean, either in the WebSphere global namespace, or in the namespace local to the application.

The URL for the HitCount application is: `http://your.server.name:9080/HitCount.jsp`.

Servlets

Servlets are Java programs that use the Java Servlet Application Programming Interface (API). You must package servlets in a Web archive (WAR) file or Web module for deployment to the application server. Servlets run on a Java-enabled Web server and extend the capabilities of a Web server, similar to the way applets run on a browser and extend the capabilities of a browser.

Servlets can support dynamic Web page content, provide database access, serve multiple clients at one time, and filter data.

In the application server, discussions of servlets focus on HTTP servlets, which serve Web-based clients.

You can define servlets as welcome files. Non-servlet resources are served only when the fileServingEnabled attribute is set to `true` in the IBM extensions XMI file, ibm-web-ext.xmi, located in each Web module WEB-INF directory or by using an assembly tool to set the property in the source .war file. Serving welcome files is connected to serving static content. Therefore the fileServingEnabled attribute is set in the Web module.

Context parameters

A servlet context defines the server view of the Web application within which the servlet is running. The context also supports a servlet to access its available resourcest. Using the servlet context, a servlet can log events, obtain URL references to resources, and set and store attributes for other servlets in the context to use. These properties declare the parameters for the context of a Web application. The properties convey setup information, such as the e-mail address for the Webmaster or the name of a system with critical data.

Servlet mappings

A servlet mapping is a correspondence between a client request and a servlet. Web containers use URL paths to map client requests to servlets, and follow the URL path-mapping rules as specified in the Java Servlet specification. The container uses the Uniform Resource Identifier (URI) from the request, minus the context path, as the path to map to a servlet. The container chooses the longest matching available context path from the list of Web applications that it hosts.

JavaServer Pages

JavaServer Pages (JSP) are application components coded to the JavaServer Pages Specification. JavaServer Pages enable the separation of the Hypertext Markup Language (HTML) code from the business logic in Web pages so that HTML programmers and Java programmers can more easily collaborate in creating and maintaining pages.

JSP files support a division of roles:

HTML authors
: Develop JSP files that access databases and reusable Java components, such as servlets and beans.

Java programmers
: Create the reusable Java components and provide the HTML authors with the component names and attributes.

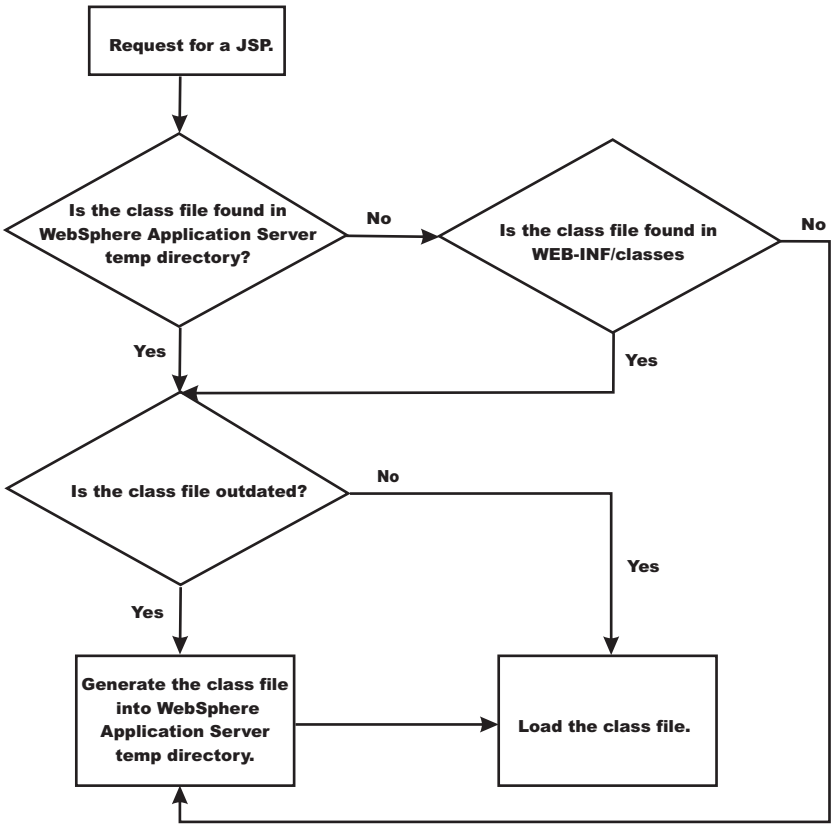
Database administrators
: Provide the HTML authors with the name of the database access and table information.

WebSphere Application Server Version 7.0 supports the JSP 2.1 specification.

JSP class file generation

At runtime, the WebSphere Application Server JavaServer Pages (JSP) engine loads JSP class files from either the WebSphere Application Server `temp` directory or a Web module's `WEB-INF/classes` directory. The JSP engine first searches for a class file in the `temp` directory and then it searches in the Web module's `WEB-INF/classes` directory.

In a default installation, the WebSphere Application Server `temp` directory is typically *`profile_root`*`/temp`. Figure 1 shows the processing logic of the JSP engine at runtime.



The batch compiler supports the generation of class files in both the WebSphere Application Server `temp` directory and a Web module's `WEB-INF/classes` directory, depending on the type of batch compiler target. In addition, the batch compiler enables the generation of class files into any directory on the filesystem, outside of the target application. Generating class files into a Web module's `WEB-INF/classes` directory enables you to deploy the Web module as a self-contained Web archive (WAR) file, or a WAR file inside an enterprise archive (EAR) file. The following table shows the batch compiler's behavior when compiling class files.

	ear.path or war.path supplied	enterpriseApp.name supplied
compileToDir not supplied; *compileToWebInf* not supplied, or is true	The class files are compiled into the Web module's `WEB-INF/classes` directory.	The class files are compiled into the Web module's `WEB-INF/classes` directory.
compileToDir not supplied; *compileToWebInf* is false	The class files are compiled into the Web module's `WEB-INF/classes` directory.	The class files are compiled into the WebSphere Application Server temp directory, usually *`profile_root`*`/temp`.
compileToDir is supplied; *compileToWebInf* not supplied, or is either true or false	The class files are compiled into the directory indicated by *compileToDir*.	The class files are compiled into the directory indicated by *compileToDir*.

Packages and directories for generated .java and .class files

By default, the .java files for all JavaServer Pages (JSP) files are generated with the package statement, `package com.ibm._jsp;`. The JSP engine's class loader knows how to load JSP classes when they are all in the same package. The .java files are located in the filesystem within a directory structure mirroring the JSP source directory structure.

If the JSP engine configuration parameter **useFullPackageNames** is set to true, the .java files are generated with the package statement

```
Package _ibmjsp.<directory structure in which the jsp is located>;
```

The usage of full package names enables the configuration of a JSP as a servlet in the `web.xml` file. See “JSP class loading settings” on page 45 for more information. The table below gives examples of packages and directory structures for generated .java and .class files.

	Java package		**Location of .java or .class files in file system**	
JSP file	**default**	**useFullPackageNames=true**	**default**	**useFullPackageNames=true**
/myJsp.jsp	com.ibm._jsp	_ibmjsp	/	/_ibmjsp
/jspFiles/ jspOne.jsp	com.ibm._jsp	_ibmjsp.jspFiles	/jspFiles	/_ibmjsp/jspFiles
/dir with spaces/jspTwo.jsp	com.ibm._jsp	_ibmjsp.dir_20_with_20_spaces	/dir with spaces	/_ibmjsp/ dir_20_with_20_spaces

Generated .java files:

When the JSP engine's **keepgenerated** configuration parameter is set to true, the `.java` file that is generated for JavaServer Pages (JSP) is retained. The `.java` file contains information that is useful in debugging.

Dependency information

In the `.java` file, immediately following the class declaration, an array of dependent files is defined, if the source JSP has any dependencies. There are three types of files that are tracked as dependencies:

1. Files that are statically included in the JSP
2. Tag files that are used by the JSP, but only tag files that are not in Java Archive (JAR) files
3. TLD files that are used by the JSP, but only TLDs that are not in JAR files

This array is always generated, but the JSP engine uses it, in determining whether a JSP needs to be recompiled, only when the trackDependencies parameter is set to true.

In the example below, three JSP fragments, one TLD and one tag file are dependencies of the JSP jsp1.jsp. There are three parts to each array entry:

1. The path to the dependency, relative to the Web module's context root. For example: `/dir1/frag1.jspf`
2. The long value representing the time the file was last modified. For example: 1082407108000
3. The String representation of the long value. For example: Mon Apr 19 16:38:28 EDT 2004

```
public final class _jsp1 extends com.ibm.ws.jsp.runtime.HttpJspBase
  implements com.ibm.ws.jsp.runtime.JspClassInformation {

  private static String[] _jspx_dependants;
  static {
  _jspx_dependants = new String[5];
  _jspx_dependants[0] = "/Banner.jspf^1082407108000^Mon Apr 19 16:38:28 EDT 2004";
  _jspx_dependants[1] = "/Footer.jspf^1077657462000^Tue Feb 24 16:17:42 EST 2004";
  _jspx_dependants[2] = "/dir1/frag1.jspf^1035396680000^Wed Oct 23 14:11:20 EDT 2002";
  _jspx_dependants[3] = "/utility.tld^1080069938000^Tue Mar 23 14:25:38 EST 2004";
  _jspx_dependants[4] = "/WEB-INF/tags/top.tag^1065440490000^Mon Oct 06 07:41:30 EDT 2003";
  }
```

Version, JSP engine options, and WEB.XML information

The generated .java source contains a comment that lists information about the file which is located at the bottom of the generated file. This information includes:

- The date and time the .java file was generated
- The version, build number and build date of the WebSphere Application Server on which the .java file was generated
- The values of the JSP engine configuration parameters that were in effect when the file was generated
- The values of any <jsp-config> elements in the web.xml file that pertained to the source JSP file.

```

JSP class loading settings

You can configure a JavaServer Pages (JSP) class to be loaded by either the JSP engine's class loader or by the Web module's class loader.

By default, a JSP class is loaded by a unique instance of the JSP engine's class loader. The JSP engine's class loader enables reloading at runtime of a JSP class when the JSP source or one of its dependents is modified. This allows you to reload a single JSP class when necessary, without affecting any other loaded JSP classes.

JSP classes are loaded by the Web module's class loader under either of the following scenarios.

1. The JSP engine configuration parameter useFullPackageNames is set to true, and the JSP file is configured as a servlet in the web.xml file using the <servlet-class> scenario in the table below.
2. The JSP engine configuration parameters useFullPackageNames and disableJspRuntimeCompilation are both set to true. In this case, you do not need to configure a JSP file does as a servlet in the web.xml file.

Configuring JSP files as Servlets

You can configure a JSP file as a servlet in the web.xml file. There are two ways to do this. They are described in the table below.

Before you configure a JSP file as a servlet, consider the following.

1. Reloading capability - If runtime reloading of JavaServer Pages files is desired, requests for JavaServer Pages files must be handled by the JSP engine. The <servlet-class> scenario in the table below disables runtime JSP file reloading, while the <jsp-file> scenario is compatible with reloading.
2. Reducing the number of class loaders - If you do not require runtime reloading of modified JSP pages and you want to reduce the number of class loader instances, then you can use the <servlet-class> scenario in the table below. Similarly, scenario 2 in section 1 above can be used without having to configure a JSP file as a servlet.

Scenario	Example	compatible with runtime reloading	multiple class loaders used?	useFullPackageNames
<jsp-file>	<servlet> <servlet-name>jspOne</servlet-name> <jsp-file>jspOne.jsp</jsp-file> </servlet>	Yes	Yes	Can be true or false
<servlet-class>	<servlet> <servlet-name>jspTwo</servlet-name> <servlet-class>_ibmjsp.jspTwo</servlet-class> </servlet>	No	No	Must be true

The JSP batch compiler tool helps you configure JavaServer Pages files as servlets. When useFullPackageNames is true, the JSP batch compiler generates <servlet> and <servlet-mapping> elements for each JSP file that it successfully translates and compiles. The elements are written to a web.xml fragment file named generated_web.xml which is located in the binaries WEB-INF directory of a Web module processed by the JSP file batch compiler (this directory is located within the deployed application's ear file). You can copy and paste all or some of these elements into the web.xml file to configure JavaServer Pages files as servlets.

Take note of the location of the web.xml that is used by the application server. The application specific configuration is obtained from either the application binaries (the application's ear file) or from the configuration repository. If an application is deployed into WebSphere Application Server with the flag Use Binary Configuration set to true, then the WEB-INF/web.xml file is looked for in a Web module's binaries directory, not in the configuration repository. Below are examples of these two locations.

- An example of a configuration repository directory is *profile_root*/config/cells/*cellName*/applications/*enterpriseAppName*/deployments/*deployedName*/*webModuleName*

- An example of an application binaries directory is: *profile_root*/installedApps/*nodeName*/*EnterpriseAppName*/*WebModuleName*/

If the JSP batch compiler is executed on a pre-deployed application then the `web.xml` file is in the Web module's `WEB-INF` directory.

JavaServer Pages (JSP) runtime reloading settings

JavaServer Pages files can be translated and compiled at run time when the JSP file or its dependencies are modified. This is known as JSP reloading.

JSP reloading is enabled through the **reloadEnabled** JSP engine parameter in the `WEB-INF/ibm-web-ext.xmi` file:

```
<jspAttributes xmi:id="JSPAttribute_1" name="reloadEnabled" value="true"/>
```

The following table contains reload settings for production and development environments.

	Settings	
Configuration Attribute	**Production Environment**	**Development Environment**
reloadEnabled	false	true
reloadInterval	n/a (ignored if reloadEnabled is false)	approximately 5 seconds
trackDependencies	n/a (ignored if reloadEnabled is false)	true Alternatively, set this to false to improve response time if dependencies are not changing
disableJspRuntimeCompilation	true - Alternatively, set this to false if JSP files are not pre-compiled and therefore need to be compiled on the first request.	false

If the **reloadEnabled** parameter is set to true, a JSP file is reloaded at run time if the JSP file and its class file do not have the same timestamp. In addition, if **trackDependencies** is set to true then the JSP file is reloaded if the timestamp of any of its dependencies has changed since the JSP class file was last generated. If the **reloadEnabled** parameter is set to false, a JSP file is still compiled if necessary on the first request to it unless the parameter **disableJspRuntimeCompilation** is true. For example, when **disableJspRuntimeCompilation** is false and **reloadEnabled** is false, a JSP file is compiled on the first request if the class file is outdated. It would not compiled on subsequent requests even if the JSP source file is modified or the class file is deleted unless **reloadEnabled** is true

Reload interval

The reload interval is set through the **reloadInterval** JSP engine parameter:

```
<jspAttributes xmi:id="JSPAttribute_1" name="reloadInterval" value="5"/>
```

If reloading is enabled, the **reloadInterval** parameter value determines the delay between checks to see if a JSP file is outdated. For example, if **reloadInterval** is 5, the JSP engine checks to see if a JSP file is outdated only when the last such check was done more than five seconds prior to the current request for the JSP file. Once the **reloadInterval** is exceeded, reload checking is performed and the reload interval timer is reset to 0 for that JSP file. The larger the **reloadInterval**, the less frequently the JSP engine checks for the need to reload a JSP file.

Dependency tracking

Dependency tracking is set through the **trackDependencies** JSP engine parameter:

```
<jspAttributes xmi:id="JSPAttribute_1" name="trackDependencies" value="true"/>
```

If reloading is enabled, the **trackDependencies** parameter value determines whether the JSP engine tracks modifications to the requested JSP file dependencies as well as to the JSP file itself. The three types of dependencies tracked by the JSP engine are:

- files statically included in the JSP file
- tag files that are referenced in the JSP file (excluding tag files that are in JAR files)
- TLDs that are referenced in the JSP file (excluding TLDs that are in JAR files)

Dependency tracking information is always included in the generated class file even if **trackDependencies** is false. The information is not used by the JSP engine or batch compiler unless the **trackDependencies** parameter is true. This means that you can enable dependency tracking without having to recompile JSP files.

For example, the `toplevel.jsp` file statically includes the `footer.jspf` file. When the `toplevel.jsp` file is compiled, the path to the `footer.jspf` file and its timestamp are stored in the `toplevel.jsp`'s class file. As a result, the `footer.jspf` file is modified and the `toplevel.jsp` file is requested. Now that the reload interval for the `toplevel.jsp` file has been exceeded, the JSP engine compares the timestamp stored in the class file with the `footer.jspf` file timestamp on disk. Because the timestamps are different, the `toplevel.jsp` file is compiled, picking up the modification to the `footer.jspf` file. In order for dependency tracking to work, the **trackDependencies** value must be set to true at the time a JSP file is requested at run time or is processed by the batch compiler.

Disabling compilation

Disablement of run time compilation of JavaServer Pages is set via the disableJspRuntimeCompilation JSP engine parameter:

```
<jspAttributes xmi:id="JSPAttribute_1" name="disableJspRuntimeCompilation" value="true"/>
```

If the **disableJspRuntimeCompilation** parameter is set to true, the JSP engine at run time does not translate and compile JSP files; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order for the class files to be loaded. With this option set to true, an application can be installed without JSP source, but must have precompiled class files. There is a Web container custom property of the same name that can be used to determine the behavior of all web modules installed in a server. If both the Web container custom property and the JSP engine option are set, the JSP engine option takes precedence. Setting the **disableJspRuntimeCompilation** parameter to true automatically sets **reloadEnabled** to false.

Reload processing sequence

The processing sequence pertaining to JSP file reloading when **trackDependencies** is false is shown in Figure 1.

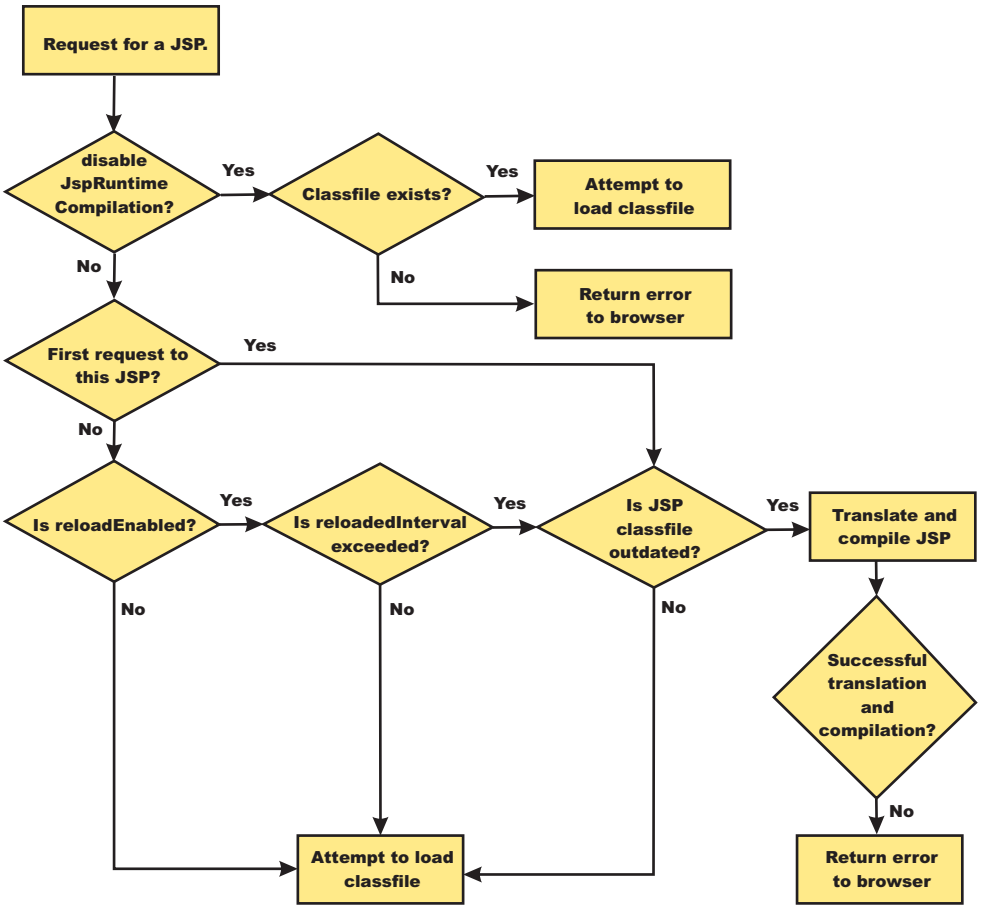

Figure 1. Reload processing sequence when **trackDependencies** *is false.*

When **trackDependencies** is true, the JSP engine does additional file system processing to determine if any of a JSP file's dependencies have changed since the JSP file was last translated and compiled. Figure 2 shows the additional processes that are performed on the 'No' path of flow chart labeled ″is JSP class file outdated?″. You can see that the path taken when disableJspRuntimeCompilation is true is the most efficient path.

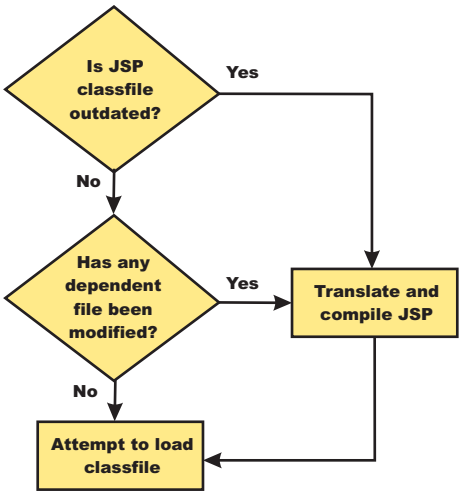

Figure 2. Additional reload processing performed when **trackDependencies** *is true.*

JSP and JSF option settings

Use this panel to configure the class reloading of Web modules such as JavaServer Pages (JSP) files and to select a JSF implementation to use with this application.

To view this administrative console panel, click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***application_name*** → **JSP and JSF options**. This panel is the same as the **Provide JSP reloading options for Web modules** panel on the application installation and update wizards.

Web module:

Specifies the name of a Web module in the installed or deployed application.

URI:

Specifies the location of the module relative to the root of the application (EAR file).

JSP enable class reloading:

Specifies whether to enable class reloading when JSP files are updated.

A Web container reloads JSP files only when the IBM extension reloadEnabled in the jspAttributes of the `ibm-web-ext.xmi` file is set to `true`.

J2EE 5 applications IBM extension files are in .xml file format. For applications versions earlier than J2EE 5, they are in the .xmi file format.

JSP reload interval in seconds:

Specifies the number of seconds to scan the application's file system for updated JSP files. The default is the value of the reloading interval attribute in the IBM extension (`META-INF/ibm-web-ext.xmi`) file of the Web module.

To enable reloading, specify a value greater than zero (for example, 1 to 2147483647). The default reload interval is 5. To disable reloading, specify zero (0). The range is from 0 to 2147483647.

The reloading interval attribute takes effect only if class reloading is enabled.

J2EE 5 applications IBM extension files are in .xml file format. For applications versions earlier than J2EE 5, they are in the .xmi file format.

Sun Reference Implementation 1.2:

Select this option to use the Sun Reference Implementation 1.2 JSF implementation. This is the default JSF implementation.

If you change the JSF implementation that you are using for your application, you must delete any previously compiled JSP files. If you precompiled your application, you must recompile. If you did not precompile, but have already requested JSP files from this application, you must delete the JSP files from the temp directory of your profile.

You can set the JSF engine configuration paramater, com.ibm.ws.jsf.JSF_IMPL_CHECK, to true to automatically mark the JSP files to recompile at application startup.

MyFaces 1.2:

Select this option to use the MyFaces 1.2 JSF implementation.

If you change the JSF implementation that you are using for your application, you must delete any previously compiled JSP files. If you precompiled your application, you must recompile. If you did not precompile, but have already requested JSP files from this application, you must delete the JSP files from the temp directory of your profile.

You can set the JSF engine configuration paramater, com.ibm.ws.jsf.JSF_IMPL_CHECK, to true to automatically mark the JSP files to recompile at application startup.

JSP run time compilation settings

By default, the JavaServer Pages (JSP) engine translates a requested JSP file, compiles the `.java` file, and loads the compiled servlet into the run time environment. You can change the JSP engine default behavior by indicating that a JSP file must not be translated or compiled at run time, even when a `.class` file does not exist.

If run time compilation is disabled, you must precompile the JSP files, which provides the following advantages:

- Reduces compilation related disk operations.
- Minimizes disk storage requirements necessary for handling temporary `.java` files generated during a run time compilation.
- Allows you to not include the JSP source files in the application.
- Allows verification that a JSP file compiled successfully before deploying and installing the application in the product

You can disable run time JSP file compilation on a global or an individual Web application basis:

- To disable the translation and compilation of JSP files for all Web applications, in the administrative console, click **Servers > Server Types > WebSphere application servers >** *server_name*. Then, in the Container Settings section, click **Web container settings > Web container > Custom properties**.

  If the disableJspRuntimeCompilation property appears in the list of defined custom properties, but is set to `false`, click the property name, and then set the property to `true`.

  If this property is not included in the list of defined custom properties, click **New**, and then specify `disableJspRuntimeCompilation` in the **Name** field and `true` in the **Value** field.

  Valid settings for this property are `true` or `false`. When this property is set to `true`, translation and compilation of the JSP files is disabled at run time for all Web applications.

- To disable the translation and compilation of JSP files for a specific Web application, set the JSP engine initialization parameter disableJspRuntimeCompilation to `true`. This setting, if enabled, determines the run time behavior of the JSP engine and overrides the Web container custom property setting.

  Set this parameter through the **JavaServer Pages attribute assembly settings** page in the Assembling applications.

  Valid values for this setting are `true` or `false`. If this parameter is set to `true`, then, for that specific Web application, translation and compilation of the JSP files is disabled at run time, and the JSP engine only loads precompiled files.
- If neither the Web container custom property nor the JSP parameter is set, the first request for a JSP file results in the translation and compilation of the JSP file when the `.class` file does not exist or is outdated. Subsequent requests for the file also result in translations and compilations, but only if the following conditions are met:
  - Translations are required because the `.class` file is outdated.
  - Reloading is enabled for the Web module.
  - Reload interval is exceeded.

If you disable run time compilation and a request arrives for a JSP file that does not have a matching .class file, the JSP engine returns the following 404 error to the browser:

```
Error 404: SRVE0200E: Servlet [org.apache.jsp._jsp1]: Could not find required servlet class - _jsp1.class
```

In this case, an exception is written to the System Out (SYSOUT) and First Failure Data Capture (FFDC) logs. .

If a JSP file has a matching .class file but that file is out of date, the JSP engine still loads the .class file into memory.

Provide options to compile JavaServer Pages settings

Use this panel to specify options to be used by the JavaServer Pages (JSP) compiler.

This administrative console panel is a step in the application installation and update wizards. To view this panel, you must select **Precompile JavaServer Pages files** on the **Select Installation options** panel. Thus, to view this panel, click **Applications** → **New application** *application_path* **> Show me all installation options and parameters > Next > Next > Precompile JavaServer Pages files > Next > Step: Provide options to compile JSPs**.

You can specify the JSP compiler options on this panel only when installing or updating an application that contains Web modules. After the application is installed, you must edit the JSP engine configuration parameters of a Web module's `WEB-INF/ibm-web-ext.xmi` file to change its JSP compiler options.

Web module:

Specifies the name of a module within the application.

URI:

Specifies the location of the module relative to the root of the application (EAR file).

JSP class path:

Specifies a temporary class path for the JSP compiler to use when compiling JSP files during application installation. This class path is not saved when the application installation is complete and is not used when the application is running. This class path is used only to identify resources outside of the application which are necessary for JSP compilation and which will be identified by other means (such as shared libraries) after the application is installed. In network deployment configurations, this class path is specific to the deployment manager machine.

To specify that multiple Web modules use the same class path:
1. In the list of Web modules, select the **Select** check box beside each Web module that you want to use a particular class path.
2. Expand **Apply Multiple Mappings**.
3. Specify the desired class path.
4. Click **Apply**.

Use full package names:

Specifies whether the JSP engine generates and loads JSP classes using full package names.

When full package names are used, precompiled JSP class files can be configured as servlets in the `web.xml` file, without having to use the `jsp-file` attribute. When full package names are not used, all JSP classes are generated in the same package, which has the benefit of smaller file-system paths.

When the options useFullPackageNames and disableJspRuntimeCompilation are both `true`, a single class loader is used to load all JSP classes, even if the JSP files are not configured as servlets in the `web.xml` file.

This option is the same as the useFullPackageNames JSP engine parameter.

JDK source level:

Specifies the source level at which the Java compiler compiles JSP Java sources. Valid values are `13`, `14`, and `15`. The default value is `13`, which specifies source level 1.3.

Disable JSP runtime compilation:

Specifies whether a JSP file should never be translated or compiled at run time, even when a `.class` file does not exist.

When this option is set to `true`, the JSP engine does not translate and compile JSP files at run time; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order to load class files. You can install an application without JSP source, but the application must have precompiled class files.

For a single Web application class loader to load all JSP classes, this compiler option and the **Use full package names** option both must be set to `true`.

This option is the same as the disableJspRuntimeCompilation JSP engine parameter.

JSP batch compilation

As an IBM enhancement to JavaServer Pages (JSP) support, IBM WebSphere Application Server provides a batch JSP compiler that allows JSP page compilation before application deployment. The batch compiler validates the syntax of JSP pages, translates the JSP pages into Java source files, and compiles the Java source files into Java servlet class files. The batch compiler also validates tag files and generates their Java implementation classes.

Batch compilation of JSP pages in a predeployed application simplifies the deployment process and improves the runtime performance of JSP page by eliminating first-request compilations. The batch compiler also operates on enterprise applications that have been deployed into WebSphere Application Server.

The JSP batch compiler works on Web modules that support Servlet 2.2 and later. The batch compiler works on JSP pages written to the JSP 2.1 specification or previous specifications back to JSP 1.0. It recognizes a Servlet 2.5 deployment descriptor, `web.xml`, and can use any jsp-config elements that it may

contain. In a Servlet 2.3 (JSP 1.2) or Servlet 2.2 (JSP 1.1) deployment descriptor the batch compiler recognizes and uses any taglib elements that the descriptor may contain.

Batch compiling makes the first request for a JSP page much faster because the JSP page is already translated and compiled into a servlet. Batch compiling is also useful as a fast way to resynchronize all of the JSP pages for an application.

The batch compiler supports the generation of class files in both the WebSphere Application Server `temp` directory and a Web module's `WEB-INF/classes` directory, depending on the type of batch compiler target. In addition, the batch compiler enables generation of class files into any directory on the filesystem, outside the target application. Generating class files into a Web module's `WEB-INF/classes` directory enables the Web module to be deployed as a self-contained WAR file, or a WAR inside an EAR.

Also, you can use shared libraries with the JSP batch complier. When you use the JSP batch compiler, you must either add the JAR to the WAR in the <WEB-INF>/lib directory, or add the JAR to the JVM class path to use shared libraries.

You can use the pre-touch tool for batch compilation, which can compile and load JSP class files into the application server JVM. This tool offers improved performance over the JSP batch compiler on iSeries® servers. See "Pre-touch tool for compiling and loading JSP files" on page 65 for more information.

JSPBatchCompiler command:

The batch compiler validates the syntax of JavaServer Pages, translates the JSP pages into Java source files, and compiles the Java source files into Java Servlet class files. The batch compiler also validates tag files and generates their Java implementation classes. Use this function to batch compile your JSP files and thereby enable faster responses to the initial client requests for the JSP files on your production Web server.

The batch compiler can be executed against compressed or expanded enterprise archive (EAR) files and Web application archive (WAR) files, as well as enterprise applications and Web modules that have been deployed into WebSphere Application Server. When the target is a deployed enterprise application, the server does not need to be running to execute the batch compiler. If the batch compiler is executed while the target sever is running, the server is not aware of an updated class file and does not load that class file unless the enterprise application is restarted. When the target is a compressed EAR file or WAR file, the batch compiler must expand it before executing.

Processing of Web modules

The batch compiler operates on one Web module at a time. If the target is either an EAR file or an installed enterprise application that contains more than one Web module, the batch compiler operates on each Web module individually. This is done because JSP pages are configured on a Web module basis, through the Web module's web.xml deployment descriptor file. Within a Web module, the batch compiler processes one directory at a time. It validates and translates each JSP page individually, and then invokes the Java compiler for the entire group of generated Java sources files in that directory. If one JSP page fails during the Java compilation phase, the Java compiler might not create class files for most or all of the JSP pages that successfully compiled in that directory.

JSP file extensions

The batch compiler uses four things to determine what file extensions it should process:

1. Standard JSP file extensions
   - *.jsp
   - *.jspx
   - *.jsw

- *.jsv

2. The url-pattern property of the jsp-property-group elements in the deployment descriptor file in Servlet 2.4 Web modules
3. The **jsp.file.extensions** JSP engine configuration parameter (for pre-Servlet 2.4 Web modules)
4. The batch compiler configuration parameter **jsp.file.extensions**

The standard extensions are always used by the batch compiler. If the Web module contains a Servlet 2.4 deployment descriptor, the batch compiler also processes any url-patterns found within the jsp-config element. If the batch compiler target contains the JSP engine configuration parameter **jsp.file.extensions**, then those extensions are also processed. If the batch compiler configuration parameter **jsp.file.extensions** is present, the extensions given are also processed and will override the JSP engine configuration parameter **jsp.file.extensions**.

It is a good idea to give JSP 'fragments' an extension that is not processed by the batch compiler. Statically-included fragments that do not stand alone generate translation or compilation errors if processed. The JSP 2.0 Specification suggests that you use the extension `.jspf` for such files.

Batch compiler command

The JspBatchCompiler script for running the batch compiler from the Qshell command line is found in the *app_server_root*/bin directory. An Ant task is also available for executing the batch compiler using Ant. See the topic, Batch Compiler Ant Task for additional information.

The batch compiler target is the only required parameter. The target is one of -ear.path, -war.path or -enterpriseapp.name.

```
JspBatchCompiler -ear.path | -war.path | -enterpriseapp.name <name>
   [-response.file <filename>]
   [-webmodule.name <name>]
   [-filename <jsp name | directory name>
   [-recurse <true | false>]
   [-config.root <path>]
   [-cell.name <name>]
   [-node.name <name>]
   [-server.name <name>]
   [-profileName <name>]
   [-extractToDir <path>]
   [-compileToDir <path>]
   [-compileToWebInf <true | false>]
   [-translate <true | false>]
   [-compile <true | false>]
   [-removeTempDir <true | false>]
   [-forceCompilation <true | false>]
   [-useFullPackageNames <true | false>]
   [-trackDependencies <true | false>]
   [-createDebugClassfiles <true | false>]
   [-keepgenerated <true | false>]
   [-keepGeneratedclassfiles <true | false>]
   [-usePageTagPool <true | false>]
   [-useThreadTagPool <true | false>]
   [-classloader.parentFirst <true | false>]
   [-classloader.singleWarClassloader <true | false>]
   [-additional.classpath <classpath to additional JAR files and classes>]

   [-verbose <true | false>]
   [-deprecation <true | false>]
   [-javaEncoding <encoding>
   [-jdkSourceLevel <13 | 14 | 15>]
   [-compilerOptions <space-separated list of java compiler options>]
   [-useJikes <true | false>]
   [-jsp.file.extensions <file extensions to process>]
   [-log.level <SEVERE | WARNING | INFO | CONFIG | FINE | FINER | FINEST | OFF>]
```

```
*** See batchcompiler.properties.default in app_server_root/bin for more information. ***
*** See JspCBuild.xml in app_server_root/bin for information about the public WebSphere Ant task JspC. ***
```

The batch compiler is aware of three groups of configuration parameters:

1. JSP engine configuration parameters for a Web module.

   See the topic, JSP engine configuration parameters.
2. Batch compiler response file configuration parameters.

   These are the parameters that are found in a batch compiler response file. See -response.file, below.
3. Batch compiler command line configuration parameters.

   These are the parameters entered on the command line when running the batch compiler.

The batch compiler looks at all three groups of configuration parameters in order to determine which value for a parameter is used when compiling JSP pages. When resolving the value for a given parameter, the precedence is:

1. If the parameter is found on the command line, its value is used.
2. If the parameter is not found on the command line, the batch compiler looks for the parameter in a response file named on the command line.
3. If no response file is named, or if the parameter is not found therein, the batch compiler looks for the parameter in the Web module's JSP engine configuration parameters.

If a configuration parameter is not found among these three groups, then a default value is used. The default values for the configuration parameters are given below along with the description of the parameters.

With one exception, these parameters are not case sensitive; -profileName is case sensitive. If the values specified for these arguments are comprised of two or more words separated by spaces, you must add quotation marks around the values.

The batch compiler does not create, or set the values of, equivalent JSP engine parameters. This means that if a JSP page in a deployed Web module is modified and is recompiled by the JSP engine at run time, the JSP engine's configuration parameters will determine the engine's behavior. For example, if you use the batch compiler to compile a Web module and you use the -useFullPackageNames true option, the JSP files will be compiled to support that option. But the JSP engine parameter useFullPackageNames must also be set to true in order for the JSP runtime to be able to load the compiled JSP pages. If JSP pages are modified in a deployed Web module, then the engine's parameters should be set to the same values used in batch compilation.

To use the JSP batch compiler, enter one of the following commands on a single line at an operating system command prompt.:

- **ear.path | war.path | enterpriseapp.name**

  Represents the full path to a single compressed or expanded enterprise application archive (EAR) file or Web application archive (WAR) file, or the name of the deployed enterprise application that you want to compile. For example:
  - `JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear`
  - `JspBatchCompiler -war.path /home/wasuser/wars/examples.war`
  - `JspBatchCompiler -enterpriseapp.name myEnterpriseApp -webmodule.name my.war -filename mydirectory/main.jsp`
- **response.file**

  Specifies the path to a file that contains configuration parameters used by the batch compiler. The *response.file* is used only if it is given on the command line; it is ignored if it is present in a response file.

  The template response file, batchcompiler.properties.default, is found in the *app_server_root*/`properties` directory. Copy this template to create your own response files containing defaults for the parameters in

which you are interested. You can configure all the required and optional parameters, except the response.file in a response file.**For example:** JspBatchCompiler -response.file /home/wasuser/myproject/batchc.props

Default : null

- **webmodule.name**

  Represents the name of the specific Web module that you want to batch compile. If this argument is not set, all Web modules in the enterprise application are compiled. This parameter is used only when *ear.path* or *enterpriseapp.name* is given. This parameter is useful when JSP pages in a specific Web module within a deployed enterprise application need to be regenerated, because all shared library dependencies are picked up.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -webmodule.name myWebModule.war

  Default: All Web modules in an EAR file or enterprise application are compiled if this parameter is not given.

- **filename**

  Represents the name of a single JSP file that you want to compile. If this argument is not set, all files in the Web module are compiled. Alternatively, if *filename* is set to the name of a directory, only the JSP files in that directory and that directory's child directories are complied. The name is relative to the context root of the Web module.

  Example 1: If you want to compile the file, `myTest.jsp`, and it is found in `/subdir/myJSPs`, you would enter `-filename /subdir/myJSPs/myTest.jsp`.

  Example 2: If you want to compile all JSP files in `/subdir/myJSPs` and its child directories, you would enter `-filename subdir/myJSPs`.

  Default: All JSP files in the Web module are compiled. Entering `-filename /` is equivalent to the default.

- **recurse**

  Determines whether subdirectories beneath the target directory are processed. This parameter is used only when the *filename* parameter is given. Set value to `false` to process only the directory named *filename* parameter; and not its subdirectories.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -filename /subdir1 -recurse false.

  Default: true; All directories beneath the target directory are processed.

- **config.root**

  Specifies the location of the WebSpehere Application Server configuration directory. This parameter is used only when *enterpriseapp.name* is given.

  Default: *profile_root*`/config`

- **cell.name**

  Specifies the name of the cell in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

  Default: The default is obtained from the profile script that is used. The symbolic name of this variable is WAS_CELL.

- **node.name**

  Specifies the name of the node in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

  Default: The default is obtained from the profile script that is used. The symbolic name of this variable is WAS_NODE.

- **server.name**

  Represents the name of the server in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

  Default: server1

- **profileName**

  Specifies the name of the profile you want to use. This parameter is used only when `enterpriseapp.name` is given.

Example: JspBatchCompiler -enterpriseApp.name sampleApp -profileName AppServer-3

Default: The default profile is used. This is obtained from the `setupCmdLine` script in the *app_server_root*`/bin` directory. The symbolic name is DEFAULT_PROFILE_SCRIPT.

- **extractToDir**

  Specifies the directory into which predeployed enterprise archive (EAR) files and Web application archive (WAR) files will be extracted before the batch compiler operates on them. This parameter is ignored when *enterpriseapp.name* is given. The extractToDir parameter is used as described in the table below.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -extractToDir /home/wasuser/mytempdir.

  Use-case: You must extract a compressed archive before it is batch compiled. You can also extract an expanded archive to a new directory as well. In both cases, extraction leaves the original archive untouched, which may be useful while development is underway.

  Default values:

	Expanded archive	**Compressed archive**
extractToDir supplied	The batch compiler extracts the archive to extractToDir before operating on it. If a file or directory of the same name as the archive already exists in the extractToDir, the batch compiler removes the archive completely before extracting that archive. If the batch compiler exits with no errors, it compresses the archive in place in the extractToDir, even if the original EAR file or WAR file was expanded. If errors are encountered during compilation, the EAR file or WAR file is left in the expanded state even if the original EAR file or WAR file was compressed.	
extractToDir not supplied	The batch compiler operates on the EAR file or WAR file in place (does not extract it to another directory) and the archive remains expanded after the batch compiler finishes.	The batch compiler extracts the archive to the directory returned by the JVM property ″java.io.tmpdir″. The rest of the behavior described above, when extractToDir is supplied, is the same in this case.

  The default is `server1`.

- **compileToDir**

  Specifies the directory into which JSP pages are translated into Java source files and compiled into class files. This directory can be anywhere on the filesystem, but the batch compiler's default behavior is usually adequate. The batch compiler's behavior when compiling class files is described in the table below

  Example:: JspBatchCompiler -enterpriseApp.name sampleApp -compileToDir /home/wasuser/myTargetDir

  Use-case: This parameter enables you to generate the Java and class files into a directory outside of the target, which may be useful if you want to compare the newly generated files with their previous versions which remain untouched within the target.

  Default values:

	ear.path or war.path supplied	**enterpriseApp.name supplied**
compileToDir not supplied; compileToWebInf not supplied, or is true	The class files are compiled into the Web module's `WEB-INF/classes` directory	The class files are compiled into the Web module's `WEB-INF/classes` directory.
compileToDir not supplied; compileToWebInf is false	The class files are compiled into the Web module's `WEB-INF/classes` directory.	The class files are compiled into the WebSphere Application Server temp directory (usually *profile_root*`/temp`).

compileToDir is supplied; compileToWebInf not supplied, or is either true or false	The class files are compiled into the directory indicated by compileToDir.	The class files are compiled into the directory indicated by compileToDir.

- **compileToWebInf**

  Specifies whether the target directory for the compiled JSP class files should be the Web module's `WEB-INF/classes directory`. This parameter is used only when *enterpriseApp.name* is given, and it is overridden by *compileToDir* if *compileToDir* is given.

  The batch compiler's default behavior is to compile to the Web module's `WEB-INF/classes` directory. The batch compiler's behavior when compiling class files is described in the table above.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -compileToWebInf false.

  Use-case: Set this parameter to false when enterpriseApp.name is supplied and you want the class files to be compiled to the WebSphere Application Server temp directory instead of the Web module's `WEB-INF/classes` directory. Recommendation: if this parameter is set to false, set forceCompilation to true if there are any JSP class files in the `WEB-INF/classes` directory.

  Default: true; see the table above.
- **forceCompilation**

  Specifies whether the batch compiler is forced to recompile all JSP resources regardless or whether the JSP page is outdated.

  Example: JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -forceCompilation true.

  Use-case: Especially useful when creating an archive for deployment, to make sure all JSP classes are up to date.

  Default: false
- **useFullPackageNames**

  Specifies whether the batch compiler generates full package names for JSP classes. The default is to generate all JSP classes in the same package. The JSP engine's class loader knows how to load JSP classes when they are all in the same package. The default has the benefit of generating smaller file-system paths. Full package names have the benefit of enabling the configuration of precompiled JSP class files as servlets in the `web.xml` file without use of the `jsp-file` attribute, resulting in a single class loader (the Web application's class loader) being used to load all such JSP classes. Similarly, when the JSP engine's configuration attributes **useFullPackageNames** and **disableJspRuntimeCompilation** are both true, a single class loader is used to load all JSP classes, even if the JSP pages are not configured as servlets in the `web.xml` file.

  When useFullPackageNames is set to true, the batch compiler generates a file called `generated_web.xml` in the Web module's `WEB-INF` directory. This file contains servlet configuration information for each JSP page that is successfully translated and compiled. The information can optionally be copied into the Web module's `web.xml` file so that the JSP pages are loaded as servlets by the Web container. Note that if a JSP page is configured as a servlet in this way, no reloading of the JSP page is done at run time if the JSP page is modified. This is because the JSP page is treated as a regular servlet and requests for it do not pass through the JSP engine.

  Example: JspBatchCompiler –enterpriseApp.name sampleApp –useFullPackageNames true

  Use-case: Enables JSP classes to be loaded by a single class loader.

  Default: false
- **removeTempDir**

  Specifies whether the Web module's temp directory is removed. The batch compiler by default generates JSP class files into a Web module's `WEB-INF/classes` directory. JSP class files are generated into the `temp` directory at run time if a JSP page is modified and JSP reloading is enabled. By batch compiling all the JSP pages in a Web module and also removing the `temp` directory, disk resources are preserved. You can only use the removeTempDir parameter when -enterpriseApp.name is given.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -removeTempDir true.

  Use-case: Free up disk space by clearing out a Web application's `temp` directory.

Default: false

- **translate**

  Specifies whether JSP pages are translated and compiled. Set translate to false if you do not want JSP pages to be translated and compiled. You must use this option in conjunction with `-removeTempDir` to tell the batch compiler to remove only the `temp` directory and to do no further processing.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -translate false -removeTempDir true.

  Use-case: Free up disk space by clearing out a Web application's `temp` directory, without invoking JSP processing.

  Default: true

- **compile**

  Specifies whether JSP pages go through the Java compilation phase. Set compile to `false` if you do not want JSP pages to go through the Java compilation phase.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -compile false

  Use-case: If you only want JSP pages to be syntax-checked, set -compile to false. You can set -keepgenerated to true if you want to see the `.java` files that are generated during the translation phase.

  Default: true

- **trackDependencies**

  Specifies whether the batch compiler recompiles a JSP page when any of its dependencies have changed, even if the JSP page itself has not changed. Tracking dependencies incurs a significant runtime performance penalty because the JSP Engine checks the filesystem on every request to a JSP page to see if any of its dependencies have changed. The dependencies tracked by WebSphere Application Server are :

  1. Files statically included in the JSP page
  2. Tag files used by the JSP page (excluding tag files that are in JAR files)
  3. TLD files used by the JSP page (excluding TLD files that are in JAR files)

  Example: JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -trackDependencies true.

  Use-case: Useful in a development environment.

  Default: false

- **createDebugClassfiles**

  Specifies whether the batch compiler generates class files that contain SMAP information, as per JSR 45, **Debugging support for Other Languages**.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -createDebugClassfiles true

  Use-case: Use this parameter when you want to be able to debug JSP pages in your JSR 45-compliant IDE.

  Default: false

- **keepgenerated**

  Specifies whether the batch compiler saves or erases the generated Java source files created during the translation phase.

  If set to `true`, WebSphere Application Server saves the generated `.java` files used for compilation on your server. By default, this argument is set to `false` and the `.java` files are erased after the class files have compiled.

  Example: JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -keepgenerated true

  Use-case: Use this parameter when you want to review the Java code generated by the batch compiler.

  Default: false

- **keepGeneratedclassfiles**

  Specifies whether the batch compiler saves or erases the class files generated during the compilation of Java source files.

Example: JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -keepGeneratedclassfiles false -keepgenerated false

Use-case: Set this parameter to false if you only want to see if there are any translation or compilation errors in your JSP pages. If paired with -keepgenerated false, this parameter results in all generated files being removed before the batch compiler completes.

Default: true

- **usePageTagPool**

  Enables or disables the reuse of custom tag handlers on an individual JSP page basis.

  Example: JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -usePageTagPool true

  Use-case: Use this parameter to enable JSP-page-based reuse of tag handlers.

  Default: false
- **useThreadTagPool**

  Enables or disables the reuse of custom tag handlers on a per request thread basis per Web module.

  Example: JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -useThreadTagPool true

  Use-case: Use this parameter to enable Web module-based reuse of tag handlers.

  Default: false
- **classloader.parentFirst**

  Specifies the search order for loading classes by instructing the batch compiler to search the parent class loader prior to application class loader. This parameter is only used when *ear.path* or *enterpriseApp.name* is given.

  Example: JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -classloader.parentFirst false

  Use-case: Set this parameter to false when your Web module contains a JAR file that is also found in the server lib directory, and you want your Web module's JAR file to be picked up first.

  Default: true
- **classloader.singleWarClassloader**

  Specifies whether to use one class loader per enterprise archive (EAR) file or one class loader per Web application archive (WAR) file. Used only when *ear.path* or *enterpriseApp.name* is given.

  Example: JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -classloader.singleWarClassloader true

  Use-case: Set this parameter to true when a Web module depends on JAR files and classes in another Web module in the same enterprise application.

  Default: false; One class loader is created per WAR file with no visibility of classes in other Web modules.
- **additional.classpath**

  Specifies additional class path entries to be used when parsing and compiling JSP pages. This parameter is used only when `war.path` is given. When `war.path` is the target, WebSphere Shared Libraries are not picked up by the batch compiler. Therefore, if your WAR file relies on, for example, a JAR file that is configured in WebSphere Application Server as a shared library, then use this option to point to that JAR file. In addition, if you give `war.path` and also use the `-extractToDir` parameter, then any JAR files that are in the WAR file's manifest class-path is not added to the class path (since the WAR file has now been extracted by itself outside the EAR file in which it resides). Use `-additional.classpath` in this case to point to the necessary JAR files. Add the full path to needed resources, separated by your system-dependent path separator.

  Example: JspBatchCompiler -war.path /home/wasuser/myproject/examples.war -additional.classpath /home/wasuser/myJars/someJar.jar:/home/wasuser/myClasses

  Use-case: Use this parameter to add to the class path JAR files and classes outside of your WAR file. At run time, these same JAR files and classes have to be made available through the standard WebSphere Application Server configuration mechanisms.

Default: null

- **verbose**

  Specifies whether the batch compiler should generate verbose output while compiling the generated sources.

  Example: JspBatchCompiler -war.path /home/wasuser/myproject/examples.war -verbose true

  Use-case: Set this parameter to true when you want to see Java compiler class loading and other messages.

  Default: false

- **deprecation**

  Indicates the compiler should generate deprecation warnings while compiling the generated sources.

  Example: JspBatchCompiler -war.path /home/wasuser/myproject/examples.war -deprecation true

  Use-case: Set this parameter to true when you want to see Java compiler deprecation messages.

  Default: false

- **javaEncoding**

  Specifies the encoding that will be used when the .java file is generated, and when it is compiled by the Java compiler. When -javaEncoding is set, that encoding is passed to the java compiler via the -encoding argument. Note that encoding is not supported by Jikes.

  Example: JspBatchCompiler -war.path/home/wasuser/myproject/examples.war -javaEncoding Shift-JIS

  Use-case: Set this parameter when the page encoding of your JSP pages is not UTF-8 compatible.

  Default value: UTF-8.

- **jdkSourceLevel**

  This is a new JSP engine parameter which was introduced in WebSphere Application Server version 6.1 to support JDK 5. This parameter should be used instead of the compileWithAssert parameter, although compile WithAssert still works in version 6.1.

  The default value for this parameter is 13. This parameter requires regeneration of Java source. The following are jdkSourceLevel paramater values:

  – **13 (default)** - This value will disable all new language features of JDK 1.4 and JDK 5.0.
  – **14** - This value will enable the use of the assertion facility and will disable all new language features of JDK 5.0.
  – **15** - This value will enable the use of the assertion facility and all new language features of JDK 5.0.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -jdkSourceLevel 14

  Use-case: Set this parameter when you want to enable or disable the language features of JDK 1.4 and JDK 5.0

  Default value: 13

- **compilerOptions**

  Specifies a list of strings to be passed on the Java compiler command. This is a space-separated list of the form ″arg1 arg2 argn″.

  Example: JspBatchCompiler -war.path /home/wasuser/myproject/examples.war -compilerOptions ″ -bootclasspath <path>″

  Use-case: Use this parameter if you need Java compiler arguments other than verbose, deprecation and Assert facility support.

  Default: null

- **useJikes**

  Specifies whether Jikes should be used for compiling Java sources. NOTE: Jikes is not shipped with WebSphere Application Server.

  Example: JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -useJikes true

  Use-case: Set this parameter to true in order for the batch compiler to use Jikes as the Java compiler.

Default value: false

- **jsp.file.extensions**

  Specifies the file extensions to be processed by the batch compiler. This is a semicolon- or colon-separated list of the form ″*.ext1;*.ext2:*.extn″. Note that this parameter is not necessary for Servlet 2.4 Web applications because the url-pattern property of the jsp-property-group elements in the deployment descriptor can be used to identify extensions that should be treated as JSP pages.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -jsp.file.extensions *jspz;*.jspt

  Use-case: Use this parameter to add additional extensions to the be processed by the batch compiler.

  Default: null. See section, ″JSP file extensions″, in this topic for additional information.

- **log.level**

  Specifies the level of logging that is directed to the console during batch compilation. Values are SEVERE | WARNING | INFO | CONFIG | FINE | FINER | FINEST | OFF

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -log.level FINEST

  Use-case: Set this parameter higher or lower to control logging output. FINEST generates the most output useful for debugging.

  Default: CONFIG

Batch compiler ant task:

The ant task **JspC** exposes all the batch compiler configuration options. It executes the batch compiler under the covers. It is backward compatible with the WebSphere Application Server 5.x version of the **JspC** ant task. The following table lists all the ant task attribute and their batch compiler equivalents.

JspC attribute	Equivalent batch complier parameter
earPath	-ear.path
warPath	-war.path
src Same as warPath, for backward compatiblity	-war.path
enterpriseAppName	-enterpriseapp.name
responseFile	-response.file
webmoduleName	-webmodule.name
fileName	-filename -config.root
configRoot	-config.root
cellName	-cell.name
nodeName	-node.name
serverName	-server.name
profileName	-profileName
extractToDir	-extractToDir
compileToDir same as compileToDir, for backward compatibility	-compileToDir -compileToDir
compileToWebInf	-compileToWebInf
compilerOptions	-compilerOptions
recurse	-recurse
removeTempDir	-removeTempDir
translate	-translate

compile	-compile
forceCompilation	-forceCompilation
useFullPackageNames	-useFullPackageNames
trackDependencies	-trackDependencies
createDebugClassfiles	-createDebugClassfiles
keepgenerated	-keepgenerated
keepGeneratedclassfiles	-keepGeneratedclassfiles
usePageTagPool	-usePageTagPool
useThreadTagPool	-useThreadTagPool
classloaderParentFirst	-classloader.parentFirst
classloaderSingleWarClassloader	-classloader.singleWarClassloader
additionalClasspath	-additional.classpath
classpath same as additionalClasspath, for backward compatibility	-additional.classpath
verbose	-verbose
deprecation	-deprecation
javaEncoding	-javaEncoding
compileWithAssert	-compileWithAssert
useJikes	-useJikes
jspFileExtensions	-jsp.file.extensions
logLevel	-log.level
wasHome	none
Classpathref	none
jdkSourceLevel	-jdkSourceLevel

Below is an example of a build script with multiple targets, each with different attributes. The following commands are used to execute the script:

On Windows:

```
ws_ant -Dwas.home=%WAS_HOME% -Dear.path=%EAR_PATH% -Dextract.dir=%EXTRACT_DIR%
ws_ant jspc2 -Dwas.home=%WAS_HOME% -Dapp.name=%APP_NAME% -Dwebmodule.name=%MOD_NAME%
ws_ant jspc3 -Dwas.home=%WAS_HOME% -Dapp.name=%APP_NAME% -Dwebmodule.name=%MOD_NAME% -Ddir.name=%DIR_NAME%
```

On UNIX® or i5/OS®:

```
ws_ant -Dwas.home=$WAS_HOME -Dear.path=$EAR_PATH -Dextract.dir=$EXTRACT_DIR
ws_ant jspc2 -Dwas.home=$WAS_HOME -Dapp.name=$APP_NAME -Dwebmodule.name=$MOD_NAME
ws_ant jspc3 -Dwas.home=$WAS_HOME -Dapp.name=$APP_NAME -Dwebmodule.name=$MOD_NAME -Ddir.name=$DIR_NAME
```

Example build.xml Using the JspC Task

```
<project name="JSP Precompile" default="jspc1" basedir=".">
 <taskdef name="wsjspc" classname="com.ibm.websphere.ant.tasks.JspC"/>
 <target name="jspc1" description="example using  a path to an EAR, and extracting the EAR to a directory">
  <wsjspc wasHome="${was.home}"
            earpath="${ear.path}"
            forcecompilation="true"
            extractToDir="${extract.dir}"
            useThreadTagPool="true"
            keepgenerated="true"
```

```
 />
</target>
<target name="jspc2" description="example using an enterprise app and webmodule">
 <wsjspc wasHome="${was.home}"
           enterpriseAppName="${app.name}"
           webmoduleName="${webmodule.name}"
           removeTempDir="true"
           forcecompilation="true"
           keepgenerated="true"

 />
</target>
<target name="jspc3" description="example using an enterprise app, webmodule and specific directory">
 <wsjspc wasHome="${was.home}"
           enterpriseAppName="${app.name}"
           webmoduleName="${webmodule.name}"
           fileName="${dir.name}"
           recurse="false"
           forcecompilation="true"
           keepgenerated="true"

 />
</target>
</project>
```

Pre-touch tool for compiling and loading JSP files:

When enabled, the pre-touch mechanism causes all JavaServer Pages (JSP) files to be compiled within the Web module for which they are configured. You can also configure some or all JSP files to be class loaded and JIT-compiled.

To enable the pre-touch mechanism, use Rational Application Developer to specify the following JSP attributes, which are Assembly Property Extensions for your Web module:

- **prepareJSPs (Required)**

  When this attribute is present, all JSP files are compiled at application server startup. This activity runs in a separate thread, allowing the application server to finish other startup actions in parallel. The numeric attribute value represents the minimum size in kilobytes that a JSP file must be in order to also be class loaded and JIT-compiled. The default is 0, which causes all JSP files to be class loaded and JIT-compiled.

  Note: JSP file compilation is different from JIT compilation. JSP compilation generates bytecodes, whereas JIT translates the bytecodes into machine code at run time.
- **prepareJSPAttribute (Optional)**

  The pre-touch mechanism compiles and JIT-compiles JSP files by directly invoking the JSP service method, thus making the JSP file susceptible to incurring exceptions because it is called out of context. Such exceptions are avoided by immediately checking the value of this attribute, causing a quick exit from the service method when the JSP was prepared by this tool. This attribute value is added as a request parameter and is composed of alphanumeric characters that your JSP files do not expect to use during normal initiation.
- **prepareJSPThreadCount (Optional)**

  Set this numeric attribute to the number of threads that you would like this mechanism to start up to compile your JSP files. Since a thread makes use of just one processor, multi-processor systems may better utilize this pre-touch mechanism by specifying a value greater than 1. The default setting for this attribute is 1, representing the number of threads that are created to perform pre-touch processing for this Web module.
- **prepareJSPClassload (Optional)**

Set this attribute to either a whole number or the word *changed*. By entering *changed*, only those JSP filess that have been updated or not previously touched, for example, those JSP files that need to be converted from a .jsp file to a .java file, are class loaded. By entering a numerical value, for example, 1000, the pre-touch tool starts class loading at the 1000th JSP that it processes and all subsequent JSP files. This is convenient in the event that the application server is stopped when starting the pre-touch tool. You can then check the server logs to see how many JSP files have been processed and update the prepareJSPClassload value accordingly to avoid duplicating work. If a JSP file is not class loaded, it cannot be JIT compiled. As a result, if a JSP file does not satisfy the requirements of the prepareJSPClassload attribute, but satisfies the requirements of the prepareJSPs attribute, the JSP file is compiled if it has been updated, but is not class loaded or JIT compiled.

Batch compiler class path:

The batch compiler builds its class path as shown in the table below. When the batch compiler target is a Web archive (WAR) file and `war.path` is supplied, the configuration *additional.classpath* parameter is used to give extra class path information.

	Batch compiler target		
Location added to class path	enterpriseapp.name	ear.path	war.path
WebSphere Application Server JAR files and classes	yes	yes	yes
JAR files listed in manifest class path for a Web module	yes	yes	yes, when the target WAR is inside an EAR and *–extractToDir* is not used; otherwise, no.
Shared libraries	yes	no	no
Web module JAR files and classes	yes	yes	yes
additional.classpath parameter to batch compiler	no	no	yes

Global tag libraries (deprecated)

JavaServer Pages (JSP) tag libraries contain classes for common tasks such as processing forms and accessing databases from JSP files.

Tag libraries encapsulate, as simple tags, core functionality common to many Web applications. The Java Standard Tag Library (JSTL) supports common programming tasks such as iteration and conditional processing, and provides tags for:

- manipulating XML documents
- supporting internationalization
- using Structured Query Language (SQL)

Tag libraries also introduce the concept of an expression language to simplify page development, and include a version of the JSP expression language.

A tag library has two parts - a Tag Library Descriptor (TLD) file and a Java archive (JAR) file.

tsx:dbconnect tag JavaServer Pages syntax (deprecated):

Use the <tsx:dbconnect> tag to specify information needed to make a connection to a database through Java DataBase Connectivity (JDBC) or Open Database Connectivity (ODBC) technology.

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The <tsx:dbconnect> syntax does not establish the connection. Use the <tsx:dbquery> and <tsx:dbmodify> syntax instead to reference a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file to establish the connection.

When the JSP file compiles into a servlet, the Java processor adds the Java coding for the <tsx:dbconnect> syntax to the servlet service() method, which means a new database connection is created for each request for the JSP file.

This section describes the syntax of the <tsx:dbconnect> tag.

```
<tsx:dbconnect id="connection_id"
    userid="db_user" passwd="user_password"
    url="jdbc:subprotocol:database"
    driver="database_driver_name"
    jndiname="JNDI_context/logical_name">
</tsx:dbconnect>
```

where:

- **id**

  Represents a required identifier. The scope is the JSP file. This identifier is referenced by the connection attribute of a <tsx:dbquery> tag.
- **userid**

  Represents an optional attribute that specifies a valid user ID for the database that you want to access. Specify this attribute to add the attribute and its value to the request object.

  Although the userid attribute is optional, you must provide the user ID. See <tsx:userid> and <tsx:passwd> for an alternative to hard coding this information in the JSP file.
- **passwd**

  Represents an optional attribute that specifies the user password for the userid attribute. (This attribute is not optional if the userid attribute is specified.) If you specify this attribute, the attribute and its value are added to the request object.

  Although the passwd attribute is optional, you must provide the password. See <tsx:userid> and <tsx:passwd> for an alternative to hard coding this attribute in the JSP file.
- **url** and **driver**

  Respresents a required attribute if you want to establish a database connection. You must provide the URL and driver.

  The application server supports connection to JDBC databases and ODBC databases.
  - For a JDBC database, the URL consists of the following colon-separated elements: jdbc, the subprotocol name, and the name of the database to access. An example for a connection to the Sample database included with IBM DB2 is:

    ```
    url="jdbc:db2:sample"
    driver="com.ibm.db2.jdbc.app.DB2Driver"
    ```
  - For an ODBC database, use the Sun JDBC-to-ODBC bridge driver included in their Java2 Software Developers Kit (SDK) or another vendor's ODBC driver.

    The url attribute specifies the location of the database. The driver attribute specifies the name of the driver to use in establishing the database connection.

    If the database is an ODBC database, you can use an ODBC driver or the Sun JDBC-to-ODBC bridge. If you want to use an ODBC driver, refer to the driver documentation for instructions on specifying the database location with the url attribute and the driver name.

    If you use the bridge, the url syntax is `jdbc:odbc:`*`database`*. An example follows:

    ```
    url="jdbc:odbc:autos"
    driver="sun.jdbc.odbc.JdbcOdbcDriver"
    ```

    Note: To enable the application server to access the ODBC database, use the ODBC Data Source Administrator to add the ODBC data source to the System DSN configuration. To access the ODBC Administrator, click the ODBC icon on the Windows NT® Control Panel.
- **jndiname**

Represents an optional attribute that identifies a valid context in the application server Java Naming and Directory Interface (JNDI) naming context and the logical name of the data source in that context. The Web administrator configures the context using an administrative client such as the WebSphere Administrative Console.

If you specify the jndiname attribute, the JSP processor ignores the driver and url attributes on the <tsx:dbconnect> tag.

An empty element (such as <url></url>) is valid.

dbquery tag JavaServer Pages syntax (deprecated):

Use the <tsx:dbquery> tag to establish a connection to a database, submit database queries, and return the results set.

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The <tsx:dbquery> tag does the following:
1. References a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file and uses the information the tag provides to determine the database URL and driver. You can also obtain the user ID and password from the <tsx:dbconnect> tag if those values are provided in the <tsx:dbconnect> tag.
2. Establishes a new connection
3. Retrieves and caches data in the results object.
4. Closes the connection and releases the connection resource.

This section describes the syntax of the <tsx:dbquery> tag.

```
<%-- SELECT commands and (optional) JSP syntax can be placed within the tsx:dbquery. --%>
<%-- Any other syntax, including HTML comments, are not valid. --%>
<tsx:dbquery id="query_id" connection="connection_id" limit="value" >
</tsx:dbquery>
```

where:
- **id**

  Represents the identifier of this query. The scope is the JSP file. Use `id` to reference the query. For example, from the <tsx:getProperty> tag, use `id` to display the query results.

  The `id` is a tsx reference to the bean and can be used to retrieve the bean from the page contect. For example, if id is named mySingleDBBean, instead of using:
  – if (mySingleDBBean.getValue(″UISEAM″,0).startsWith(″N″))

  use:
  – com.ibm.ws.webcontainer.jsp.tsx.db.QueryResults bean = (com.ibm.ws.webcontainer.jsp.tsx.db.QueryResults)pageContext. findAttribute(″mySingleDBBean″); if (bean.getValue(″UISEAM″,0).startsWith(″N″)). . .

  The bean properties are dynamic and the property names are the names of the columns in the results set. If you want different column names, use the SQL keyword for specifying an alias on the SELECT command. In the following example, the database table contains columns named FNAME and LNAME, but the SELECT statement uses the `AS` keyword to map those column names to FirstName and LastName in the results set:

  ```
  Select FNAME, LNAME AS FirstName, LastName from Employee where FNAME='Jim'
  ```
- **connection**

  Represents the identifier of a <tsx:dbconnect> tag in this JSP file. The <tsx:dbconnect> tag provides the database URL, driver name, and optionally, the user ID and password for the connection.
- **limit**

Represents an optional attribute that constrains the maximum number of records returned by a query. If this attribute is not specified, no limit is used. In such a case, the effective limit is determined by the number of records and the system caching capability.

- SELECT command and JSP syntax

  Represents the only valid SQL command, SELECT. The <tsx:dbquery> tag must return a results set. Refer to your database documentation for information about the SELECT command. See other articles in this section for a description of JSP syntax for variable data and inline Java code.

dbmodify tag JavaServer Pages syntax (deprecated):

The <tsx:dbmodify> tag establishes a connection to a database and then adds records to a database table.

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The <tsx:dbmodify> tag does the following:

1. References a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file and uses the information provided by that tag to determine the database URL and driver.

   Note: You can also obtain the user ID and password from the <tsx:dbconnect> tag if those values are provided in the <tsx:dbconnect> tag.
2. Establishes a new connection.
3. Updates a table in the database.
4. Closes the connection and releases the connection resource.

This section describes the syntax of the <tsx:dbmodify> tag.

```
<%-- Any valid database update commands can be placed within the DBMODIFY tag. -->
<%-- Any other syntax, including HTML comments, are not valid. -->
<tsx:dbmodify connection="connection_id">
</tsx:dbmodify>
```

where:

- **connection**

  Represents the identifier of a <tsx:dbconnect> tag in this JSP file. The <tsx:dbconnect> tag provides the database URL, driver name, and (optionally) the user ID and password for the connection.
- Database commands

  Represents valid database commands. Refer to your database documentation for details

In the following example, a new employee record is added to a database. The values of the fields are based on user input from this JavaServer Pages (JSP) file and referenced in the database commands using the <tsx:getProperty> tag.

```
<tsx:dbmodify connection="conn" >
insert into EMPLOYEE
    (EMPNO,FIRSTNME,MIDINIT,LASTNAME,WORKDEPT,EDLEVEL)
values
('<tsx:getProperty name="request" property=request.getParameter("EMPNO") />',
'<tsx:getProperty name="request" property=request.getParameter("FIRSTNME") />',
'<tsx:getProperty name="request" property=request.getParameter("MIDINIT") />',
'<tsx:getProperty name="request" property=request.getParameter("LASTNAME") />',
'<tsx:getProperty name="request" property=request.getParameter("WORKDEPT") />',
<tsx:getProperty name="request" property=request.getParameter("EDLEVEL") />)
</tsx:dbmodify>
```

tsx:getProperty tag JavaServer Pages syntax and examples (deprecated):

The <tsx:getProperty> tag gets the value of a bean to display in a JavaServer Pages (JSP) file.

Note: Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

This IBM extension of the Sun JSP <jsp:getProperty> tag implements all of the <jsp:getProperty> function and adds the ability to introspect a database bean created using the IBM extension <tsx:dbquery> or <tsx:dbmodify>.

Note: You cannot assign the value from this tag to a variable. The value, generated as output from this tag, displays in the browser window.

This section describes the syntax of the <tsx:getProperty> tag:

```
<tsx:getProperty name="bean_name"
  property="property_name" />
```

where:

- **name**

  Represents the name of the bean declared by the id attribute of a <tsx:dbquery> syntax within the JSP file. See <tsx:dbquery> for an explanation. The value of this attribute is case-sensitive.
- **property**

  Represents the property of the bean to access for substitution. The value of the attribute is case-sensitive and is the locale-independent name of the property.

Tag example:

```
<tsx:getProperty name="userProfile" property="username" />
```

tsx:userid and tsx:passwd tag JavaServer Pages syntax (deprecated):

With the <tsx:userid> and <tsx:passwd> tags, you do not have to hard code a user ID and password in the <tsx:dbconnect> tag.

Note: Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

Use the <tsx:userid> and <tsx:passwd> tags to accept user input for the values and then add that data to the request object. You can access the request object with a JavaServer Pages (JSP) file, such as the *JSPEmployee.jsp* example that requests the database connection.

You must use <tsx:userid> and <tsx:passwd> tags within a <tsx:dbconnect> tag.

This section describes the syntax of the <tsx:userid> and <tsx:passwd> tags.

```
<tsx:dbconnect id="connection_id"
    <font color="red"><userid></font>
    <tsx:getProperty name="request" property=request.getParameter("userid") />
    <font color="red"></userid></font>
    <font color="red"><passwd></font>
    <tsx:getProperty name="request" property=request.getParameter("passwd") />
    <font color="red"></passwd></font>
    url="protocol:database_name:database_table"
    driver="JDBC_driver_name">
</tsx:dbconnect>
```

where:

- **<tsx:getProperty>**

  Represents the syntax as a mechanism for embedding variable data.

- **userid**

  Represents a reference to the request parameter that contains the user ID. You must add the parameter to the request object that passes to this JSP file. You can set the attribute and its value in the request object, using an HTML form or a URL query string to pass the user-specified request parameters.
- **passwd**

  Represents a reference to the request parameter that contains the password. Add the parameter to the request object that passes to this JSP file. You can set the attribute and its value in the request object, using an HTML form or a URL query string, to pass user-specified values.

tsx:repeat tag JavaServer Pages syntax (deprecated):

The <tsx:repeat> tag repeats a block of HTML tagging.

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

Use the <tsx:repeat> syntax to iterate over a database query results set. The <tsx:repeat> syntax iterates from the start value to the end value until one of the following conditions is met:
- The end value is reached.
- An exception is thrown.

If an exception of the types **ArrayIndexOutOfBoundsException** or **NoSuchElementException** is created before a block completes, output is written only for the iterations up to and not including the iteration during which the exception was created. All other exceptions results in no output being written for that tag instance.

This section describes the syntax of the <tsx:repeat> tag:

```
<tsx:repeat index="name" start="starting_index" end="ending_index">
</tsx:repeat>
```

where:
- **index**

  Represents an optional name used to identify the index of this repeat block. The scope of the index is NESTED. Its type must be integer.
- **start**

  Represents an optional starting index value for this repeat block. The default is 0.
- **end**

  Represents an optional ending index value for this repeat block. The maximum value is 2,147,483,647.

  If the value of the end attribute is less than the value of the start attribute, the end attribute is ignored.

Combining tsx:repeat and tsx:getProperty JavaServer Pages tags (deprecated)

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The following code snippet shows you how to code these tags:

```
<tsx:repeat>
<tr>
    <td><tsx:getProperty name="empqs" property="EMPNO" />
    <tsx:getProperty name="empqs" property="FIRSTNME" />
    <tsx:getProperty name="empqs" property="WORKDEPT" />
```

```
    <tsx:getProperty name="empqs" property="EDLEVEL" />
    </td>
</tr>
</tsx:repeat>
```

Example: Using tsx:repeat JavaServer Pages tag to iterate over a results set (deprecated):

The <tsx:repeat> tag iterates over a results set. The results set is contained within a bean. The bean can be a static bean, for example, a bean created by using the IBM WebSphere Studio database wizard, or a dynamically generated bean, for example, a bean generated by the <tsx:dbquery> syntax.

Note: Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The following table is a graphic representation of the contents of a bean called, *myBean*:

	col1	col2	col3
row0	friends	Romans	countrymen
row1	bacon	lettuce	tomato
row2	May	June	July

Some observations about the bean:

- The column names in the database table become the property names of the bean. The <tsx:dbquery> section describes a technique for mapping the column names to different property names.
- The bean properties are indexed. For example, `myBean.get(Col1(row2))` returns `May`.
- The query results are in the rows. The <tsx:repeat> tag iterates over the rows, beginning at the start row.

The following table compares using the <tsx:repeat> tag to iterate over a static bean, versus a dynamically generated bean:

Static Bean Example	<tsx:repeat> Bean Example

myBean.class
`// Code to get a connection`
 	
`// Code to get the data`
`Select * from myTable;`
 	
`// Code to close the connection`
 	
JSP file
`<tsx:repeat index=abc>`
`<tsx:getProperty name="myBean"`
`property="col1(abc)" />`
`</tsx:repeat>`
 	
Notes®:
• The bean (myBean.class) is a static bean.
• The method to access the bean properties is myBean.get(*property*(*index*)).
• You can omit the property index, in which case the index of the enclosing <tsx:repeat> tag is used. You can also omit the index on the <tsx:repeat> tag.
• The <tsx:repeat> tag iterates over the bean properties row by row, beginning with the start row.
	JSP file
	`<tsx:dbconnect id="conn"`
	`userid="alice"passwd="test"`
	`url="jdbc:db2:sample"`
	`driver="COM.ibm.db2.jdbc.app.DB2Driver">`
	`</tsx:dbconnect >`
	
	`<tsx:dbquery id="dynamic"`
	`connection="conn" >`
	`Select * from myTable;`
	`</tsx:dbquery>`
	
	`<tsx:repeat index=abc>`
	`<tsx:getProperty name="dynamic"`
	`property="col1(abc)" />`
	`</tsx:repeat>`
	
	Notes:
	• The bean (dynamic) is generated by the <tsx:dbquery> tag and does not exist until the syntax executes.
	• The method to access the bean properties is dynamic.getValue(*"property"*, *index*).
	• You can omit the property index, in which case the index of the enclosing <tsx:repeat> tag is used. You can also omit the index on the <tsx:repeat> tag.
	• The <tsx:repeat> tag syntax iterates over the bean properties row by row, beginning with the start row.

Implicit and explicit indexing

Examples 1, 2, and 3 show how to use the <tsx:repeat> tag. The examples produce the same output if all indexed properties have 300 or fewer elements. If there are more than 300 elements, Examples 1 and 2 display all elements, while Example 3 shows only the first 300 elements.

Example 1 shows *implicit indexing* with the default start and default end index. The bean with the smallest number of indexed properties restricts the number of times the loop repeats.

```
<table>
<tsx:repeat>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="city" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="address" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="telephone" />
  </tr></td>
</tsx:repeat>
</table>
```

Example 2 shows indexing, starting index, and ending index:

```
<table>
<tsx:repeat index=myIndex start=0 end=2147483647>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=city(myIndex) />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=address(myIndex) />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=telephone(myIndex) />
</tr></td>
</tsx:repeat>
</table>
```

Example 3 shows *explicit indexing* and ending index with implicit starting index. Although the index attribute is specified, you can still implicitly index the indexed property city because the (`myIndex`) tag is not required.

```
<table>
<tsx:repeat index=myIndex end=299>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="city" /t>
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="address(myIndex)" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="telephone(myIndex)" />
  </tr></td>
</tsx:repeat>
</table>
```

Nesting <tsx:repeat> blocks

You can nest <tsx:repeat> blocks. Each block is separately indexed. This capability is useful for interleaving properties on two beans, or properties that have subproperties. In the example, two <tsx:repeat> blocks are nested to display the list of songs on each compact disc in the user's shopping cart.

```
<tsx:repeat index=cdindex>
  <h1><tsx:getProperty name="shoppingCart" property=cds.title /></h1>
  <table>
  <tsx:repeat>
    <tr><td><tsx:getProperty name="shoppingCart" property=cds(cdindex).playlist />
    </td></tr>
  </tsx:repeat>
  </table>
 </tsx:repeat>
```

JavaServer Pages migration best practices and considerations

The standard JavaServer Pages (JSP) tags from JSP 1.1 such as jsp:include, jsp:useBean, and <%@ page %>, a will migrate successfully to JSP 2.0. However, there are several areas that must be considered when migrating JavaServer Pages. This topic discusses the areas that you must consider when migrating JavaServer Pages.

Classes from the unnamed or default package

As of JSP 2.0, referring to any classes from the unnamed or default package is not allowed. This can result in a translation error on some containers, specifically those that run in a JDK 1.4 or greater environment which will also break compatibility with some older JSP applications. However, as of JDK 1.4, importing classes from the unnamed package is not valid. See Java 2 Platform, Standard Edition Version 1.4.2 Compatibility with Previous Releases for details. Therefore, for forwards compatibility, applications must not rely on the unnamed package. This restriction also applies for all other cases where classes are referenced, such as when specifying the class name for a tag in a Tag Library Descriptor (TLD) file.

Page encoding for JSP documents

There have been noticeable differences in internationalization behavior on some containers as a result of ambiguity in the JSP 1.2 specification. However, steps were taken to minimize the impact on backwards compatibility and overall, the internationalization abilities of JSP files have been greatly improved.

In JSP specification versions prior to JSP 2.0, JSP pages in XML syntax, JSP documents, and those in standard syntax determined their page encoding in the same fashion, by examining the pageEncoding or contentType attributes of their page directive, defaulting to ISO-8859-1 if neither was present.

As of JSP 2.0, the page encoding for JSP documents is determined as described in section 4.3.3 and appendix F.1 of the XML specification, and the pageEncoding attribute of those pages is only checked to make sure it is consistent with the page encoding determined as per the XML specification. As a result of

this change, JSP documents that rely on their page encoding to be determined from their pageEncoding attribute are no longer decoded correctly. These JSP documents must be changed to include an appropriate XML encoding declaration.

Additionally, in JSP 1.2, page encodings are determined on translation unit basis whereas in JSP 2.0, page encodings are determined on the basis of each file. Therefore, if the a.jsp file statically includes the b.jsp file, and a page encoding is specified in the a.jsp file but not in the b.jsp file, in JSP 1.2 the encoding for the a.jsp file is used for the b.jsp file, but in JSP 2.0, the default encoding is used for the b.jsp file.

web.xml file version

The JSP container uses the version of the web.xml file to determine whether you are running a JSP 1.2 application or a JSP 2.0 application. Various features can behave differently depending on the version of the web.xml file. The following is a list of things JSP developers should be aware of when upgrading their web.xml file from version Servlet 2.3 to version Servlet 2.4:

1. EL expressions are ignored by default in JSP 1.2 applications. When you upgrade a Web application to JSP 2.0, EL expressions are interpreted by default. You can use the escape sequence \$ to escape EL expressions that should not be interpreted by the container. Alternatively, you can use the isELIgnored page directive attribute, or the <el-ignored> configuration element to deactivate EL for entire translation units. Users of JSTL 1.0 must upgrade their taglib imports to the JSTL 1.1 uris or use the _rt versions of the tags, for example, use c_rt instead of c or fmt_rt instead of fmt.
2. Web applications that contain files with an extension of .jspx will have those files interpreted as JSP documents, by default. You can use the JSP configuration element <is-xml> to treat .jspx files as regular JSP pages, but there is no way to disassociate .jspx from the JSP container.
3. The escape sequence \$ was not reserved in JSP 1.2. The output for any template text or attribute value that appeared as \$ in JSP 1.2 was \$, however, the output now is just $.

jsp:useBean tag

WebSphere Application Server version 5.1 and later enforces more strict adherence to the specification for the jsp:useBean tag: with type and class attributes. Specifically, you should use the type attribute should be used to specify a Java type that cannot be instantiated as a JavaBean. For example, a Java type that is an abstract class, interface, or a class with no public no-args constructor. If the class attribute is used for a Java type that cannot be instantiated as a JavaBean, the WebSphere Application Server JSP container produces a unrecoverable translation error at translation time.

Generated packages for JSP classes

Any reliance on generated packages for JSP classes will result in non-portable JSP files. Packages for generated classes are implementation-specific and therefore you should not rely on these packages.

JspServlet class

Any reliance on the existence of a JspServlet class will cause unrecoverable error problems. WebSphere Application Server version 6.0 and later no longer uses a JspServlet class.

JavaServer Pages specific Web container custom properties

You can configure name-value pairs of data, where the name is a property key and the value is a string value that you can use to set internal system configuration properties. Defining a new property enables you to configure a setting beyond what is available in the administrative console. The following is a list of the available JavaServer Pages custom properties. The JavaServer Pages custom properties are case sensitive.

com.ibm.wsspi.jsp.allowjspoutputelementmismatch:

CTS requirements in previous releases was not applicable to the product, therefore the JSP container supported multiple occurrences of properties in the jsp:output element. In the current release, CTS compliance requires that the JSP container strictly enforces rules about multiple occurrences of properties in the jsp:output element. You can use the *com.ibm.wsspi.jsp.allowjspoutputelementmismatch* custom property to relax the enforcement of the rule for backward compatibility.

Name	Value
com.ibm.wsspi.jsp.allowjspoutputelementmismatch	*true*

com.ibm.wsspi.jsp.allowtaglibprefixusebeforedefinition:

CTS compliance requires that a tag library directive that defines a prefix must occur before that prefix is used in a custom tag. Because CTS requirements in previous releases were not required, this rule was not enforced; however, you can use the *com.ibm.wsspi.jsp.allowtaglibprefixusebeforedefinition* custom property to relax the enforcement of the rule for backward compatibility.

Name	Value
com.ibm.wsspi.jsp.allowtaglibprefixusebeforedefinition	*true*

com.ibm.wsspi.jsp.allowtaglibprefixredefinition:

CTS compliance requires that if a tag library prefix is already defined with a different URI within a JSP, the product must create a translation error. Because CTS requirements in previous releases were not required, this rule was not enforced; however, you can use the *com.ibm.wsspi.jsp.allowtaglibprefixredefinition* custom property to relax the enforcement of the rule for backward compatibility.

Name	Value
com.ibm.wsspi.jsp.allowtaglibprefixredefinition	*true*

com.ibm.wsspi.jsp.allowunmatchedendtag:

In version 5 of the product, improper termination of end tags was ignored whereas in version 6, a translation exception is created. This change of behavior in version 6 causes problems to users who are migrating their applications, which had improperly terminated end tags, to version 6. In version 6, to facilitate migration, a WebContainer property, com.ibm.wsspi.jsp.allowunmatchedendtag, and a JSPAttribute, allowUnmatchedEndTag),are provided. Enabling these properties provides the version 5 behavior.

Name	Value
com.ibm.wsspi.jsp.allowunmatchedendtag	*true*

com.ibm.wsspi.jsp.userepeatint:

The custom property *com.ibm.wsspi.jsp.userepeatint* ....

Name	Value
com.ibm.wsspi.jsp.userepeatint	*true*

com.ibm.wsspi.jsp.usescriptvardupinit:

The code generated for a JSP file assumed that the same tag variables to be declared twice in an If-Else condition even if the variable had a 'page' scope. The custom property *com.ibm.wsspi.jsp.usescriptvardupinit* is used to enable this feature for all the applications deployed on a particular server. If the compatibility feature is required only for a specific application then the JSPAttribute useScriptVarDupInit needs to be enabled. If both the options are set then the JSPAttribute takes preference over the webcontainer property.

Name	Value
com.ibm.wsspi.jsp.usescriptvardupinit	*true*

com.ibm.wsspi.jsp.usestringcast:

The *com.ibm.wsspi.jsp.usestringcast* property explicitly adds a 'String cast' to the relative path before inclusion when you migrate version 5.1 applications. In version 6.0.x, the generated Java source for the JSP file did not add the ″implicit″ cast, for return types of type String when the request.getAttribute method is called. When a JSP file includes a resource whose relative path does not evaluate to a String, then the include fails as the include takes only a String as a relative path of the resource. You can set the com.ibm.wsspi.jsp.usestringcast custom property, which would affect all the deployed applications or you can set the property as a JSPAttribute, useStringCast, in the extensions file, which affects only the application for which the property is set.

Name	Value
com.ibm.wsspi.jsp.usestringcast	*true*

com.ibm.wsspi.jsp.usecdatatrim:

You can use the *com.ibm.wsspi.jsp.usecdatatrim* custom property to trim the text before creating CDATA section which eliminates the extra whitespaces addedUsers Affected: WebSphere Application server version 6 users who are migrating their applications from version 5 to version 6 and whose JSPs make use of nesting tags in separate lines. Problem Description: JSP files that make use of nesting tags have extra lines in the code generated for this section. In version 6, you could eliminate the extra spaces by appending all the lines into one as in: '' The extra line is added in the Java code generated because the text is not trimmed before creating the CDATA section. Therefore, a switch is provided to enable the trimming of the text before creating the CDATA section. You can set the JSP attribute, useCDataTrim, at the Web module level or set the *com.ibm.wsspi.jsp.usecdatatrim* Web container property at the Web container level using the following name-value pair.

Name	Value
com.ibm.wsspi.jsp.usecdatatrim	

com.ibm.ws.jsp.getparameterreturnemptystring:

This property is for returning an empty string for actions not set in a JSP file. If a JSP file contains an action and that property has not been set, the JSP engine returns null on WebSphere Application Server versions 6.0 and 6.1. However, in WebSphere Application Server version 5.1 an empty string is returned. This custom property was added to provide backwards compatibility. When it is set to true, the value returned on a call to jsp:getProperty is an empty string instead of null for versions 6.0 and 6.1.

Name	Value
com.ibm.ws.jsp.getparameterreturnemptystring	true

com.ibm.wsspi.jsp.evalquotedandescapedexpression:

This property is for compiling functions that contain an expression. The JSP translation code was modified to handle escape characters and quotations properly when determining whether to evaluate an expression or to treat it as a literal string. To apply this behavior globally across all Web applications, add the following name-value pair as a Web container custom property.

Name	Value
com.ibm.wsspi.jsp.evalquotedandescapedexpression	true

To enable this new behavior for a single application, you must also add the evalquotedandescapedexpression JSP attribute to the ibm-web-ext.xmi file of the failing application and set the value to `true`. An example entry is:

```
<jspAttributes xmi:id="JSPAttribute_1" name="evalquotedandescapedexpression" value="true"/>
```

The attribute id value must be unique.

com.ibm.ws.jsp.jdksourcelevel:

This property is for setting the JDK source level through the administrative console. A JSP engine parameter can be configured for different levels of JDK, but this requires that you set the jdksourcelevel JSP attribute in the Web extension file for each Web module. However, you can use the com.ibm.ws.jsp.jdkjdksourcelevel custom property to set the JSP attribute globally using the Web container custom property. If this attribute is also defined in the Web extension file, the property defined in the Web extension file supersedes the custom property for that particular application. This custom property is not case sensitive. The default value is 13.

Name	Value
com.ibm.ws.jsp.jdksourcelevel	13, 14, or 15

com.ibm.wsspi.jsp.recompilejsponrestart:

This property forces JSP files that were compiled at runtime to be recompiled every time the application is restarted. This is helpful if you switch the underlying JSF implementation. This property is best used on development environments.

Name	Value
com.ibm.wsspi.jsp.recompilejsponrestart	true

com.ibm.wsspi.jsp.modifyPageContextVariable:

During the translation phase of a tag file that is compiled, the JSP container implicitly uses the pageContext variable for the PageContext object. The use of the pageContext variable as an implicit variable name in tag files does not comply with the JSP Specification.

If compilation errors occur for applications that use a local pageContext variable in their tag file, set the com.ibm.wsspi.jsp.modifyPageContextVariable custom property to`true` to remove the use of the pageContext variable name in the generated Java code for tag files.

Name	Value
com.ibm.wsspi.jsp.modifyPageContextVariable	true

User profiles and authorities

WebSphere Application Server uses two OS/400® user profiles by default, QEJB and QEJBSVR.

The QEJB user profile is shipped as part of the operating system. This user profile is used only when accessing validation list objects used for storing the encoded passwords used with WebSphere Application Server. For more information on using validation list objects to store encoded passwords, see Restoring or replacing damaged validation list objects

The QEJBSVR user profile is created on your iSeries server when you install WebSphere Application Server. This profile is the default profile under which all application servers run. Directories and files used by WebSphere Application Server are normally owned by user profile QEJBSVR. The WebSphere Application Server runtime, administration tools, and Qshell scripts sets the ownership and authorities correctly on any objects created. If you create objects manually outside of the WebSphere Application Server tools, or if you modify the authorities on objects used by WebSphere Application Server, you must ensure QEJBSVR has the correct authorities to these objects.

You can also use the grtwasaut script and the rvkwasaut script to modify authorities on integrated file system objects. When you create new directories for WebSphere Application Server, the QEJBSVR user profile must have read and execute authorities (*RX) to those directories.

If you have specified another user profile to run your application servers, it is recommended that you specify QEJBSVR for its group profile. See Running application servers under specific user profiles for more information.

Web application deployment troubleshooting tips

Deployment of a Web application is successful if you can access the application by typing a Uniform Resource Locator (URL) in a browser or if you can access the application by following a link. If you cannot access your application, follow these steps to eliminate some common errors that can occur during migration or deployment.

Web module does not run in WebSphere Application Server Version 5.x or 6.x

Symptom Your Web module does not run when you migrate it to Version 5.x or 6.x

Problem In Version 4.x, the classpath setting that affected visibility was *Module Visibility Mode*. In Versions 5.x and 6.x, you must use class loader policies to set visibility.

Recommended response Reassemble an existing module, or change the visibility settings in the class loader policies.

See Class loaders and Class loading for more information.

Web module does not run in WebSphere Application Server Version 6.1

Symptom Your Web module does not run when you migrate it to Version 6.1.

Problem In Version 4.x, the classpath setting that affected visibility was *Module Visibility Mode*. In Version 6.1, you must use class loader policies to set visibility.

Recommended response Reassemble an existing module, or change the visibility settings in the class loader policies.

See Class loaders and Class loading for more information.

Welcome page is not visible.

Symptom You cannot access an application with a Web path of:

```
/webapp/myapp
```

Problem The default welcome page for a Web application is assumed to be *index.html*. You cannot access the default page of the *myapp* application unless it is named *index.html*.

Recommended response To identify a different welcome page, modify the properties of the Web module during assembly, see the topic, Assembling Web applications for more information in the *Developing and deploying applications* PDF book.

HTML files are not found.

Symptom — Your Web application ran successfully on prior versions, but now you encounter errors that the welcome page (typically *index.html*), or referenced HTML files are not found:

```
Error 404: File not found: Banner.html
Error 404: File not found: HomeContent.html
```

Problem — For security and consistency reasons, Web application URLs are now case-sensitive on all operating systems.

Suppose the content of the index page is as follows:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 5.0 Frameset//EN">
<HTML>
<TITLE>
Insurance Home Page
</TITLE>
    <frameset   rows="18,80">
    <frame      src="Banner.html"           name="BannerFrame"  SCROLLING=NO>
    <frame      src="HomeContent.html"      name="HomeContentFrame">
    </frameset>
</HTML>
```

However the actual file names in the `\WebSphere\AppServer\installedApps\...` directory where the application is deployed are:

```
banner.html
homecontent.html
```

Recommended response — To correct this problem, modify the *index.html* file to change the names *Banner.html* and *HomeContent.html* to *banner.html* and *homecontent.html* to match the names of the files in the deployed application.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

Web applications: Resources for learning

Use the following links to find relevant supplemental information about Web applications. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Configuring session management by level

When you configure session management at the Web container level, all applications and the respective Web modules in the Web container normally inherit that configuration, setting up a basic default configuration for the applications and Web modules below it. However, you can set up different configurations individually for specific applications and Web modules that vary from the Web container default. These different configurations override the default for these applications and Web modules only.

About this task

Note: When you overwrite the default session management settings on the application level, all the Web modules below that application inherit this new setting unless they too are set to overwrite these settings.

1. Open the administrative console.
2. Select the level that this configuration applies to:
   - For the Web container level:
     a. Click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Web Container Settings** → **Web container** → **Session management**.
   - For the enterprise application level:
     a. Click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***application_name*** → **Session management**.
   - For the Web module level:
     a. Click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***application_name*** → **Manage Modules**.
     b. Select a Web module from the list of Web modules defined for this application.
     c. Click **> Session Management**.
3. Manage sessions by configuring session tracking, session timeouts and serializing access.
4. If you are working on the Web module or application level and want these settings to override the inherited Session Management settings, under **General Properties**, select **Override session management**.
5. Click **Apply** and **Save**.

Session management settings

Use this page to manage HTTP session support. This support includes specifying a session tracking mechanism, setting maximum in-memory session count, controlling overflow, and configuring session timeout.

To view this administrative console page at the Web container level, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Session management** .

Note that the session management settings can be overridden at the application level.

Session tracking mechanism
Specifies a mechanism for HTTP session management.

Mechanism	Function	Default
Enable SSL ID Tracking	**Note:** This feature is deprecated in WebSphere Application Server version 7.0. You can reconfigure session tracking to use cookies or modify the application to use URL rewriting. Specifies that session tracking uses Secure Sockets Layer (SSL) information as a session ID. Enabling SSL tracking takes precedence over cookie-based session tracking and URL rewriting. There are two parameters available if you enable SSL ID tracking: SSLV3Timeout and Secure Authentication Service (SAS). SSLV3Timeout specifies the time interval after which SSL sessions are renegotiated. This is a high setting and modification does not provide any significant impact on performance. The SAS parameter establishes an SSL connection only if it goes out of the Java Virtual Machine (JVM) to another JVM. If all the beans are co-located within the same JVM, the SSL used by SAS does not hinder performance. These are set by editing the `sas.server.properties` and `sas.client.props` files located in the *product_installation_root*\properties directory, where *product_installation_root* is the directory where WebSphere Application Server is installed. **Note:** SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.	9600 seconds

Enable cookies	Specifies that session tracking uses cookies to carry session IDs. If cookies are enabled, session tracking recognizes session IDs that arrive as cookies and tries to use cookies for sending session IDs. If cookies are not enabled, session tracking uses Uniform Resource Identifier (URL) rewriting instead of cookies (if URL rewriting is enabled). Enabling cookies takes precedence over URL rewriting. Click **Enable cookies** to change these settings. Application level session management settings override the server level session management settings. Because session management is defined at the application level, enabling cookies for the administration console is handled in the deployment.xml file.
Enable URL rewriting	Specifies that the session management facility uses rewritten URLs to carry the session IDs. If URL rewriting is enabled, the session management facility recognizes session IDs that arrive in the URL if the encodeURL method is called in the servlet.
Enable protocol switch rewriting	This option is only available when **Enable URL rewriting** is selected. This option specifies that the session ID is added to a URL when the URL requires a switch from HTTP to HTTPS or from HTTPS to HTTP. If rewriting is enabled, the session ID is required to go between HTTP and HTTPS.

Maximum in-memory session count

Specifies the maximum number of sessions to maintain in memory.

The meaning differs depending on whether you are using in-memory or distributed sessions. For in-memory sessions, this value specifies the number of sessions in the base session table. Use the Allow overflow property to specify whether to limit sessions to this number for the entire session management facility or to allow additional sessions to be stored in secondary tables. For distributed sessions, this value specifies the size of the memory cache for sessions. When the session cache has reached its maximum size and a new session is requested, the session management facility removes the least recently used session from the cache to make room for the new one.

Note: Do not set this value to a number less than the maximum thread pool size for your server.

Allow overflow

Specifies that the number of sessions in memory can exceed the value specified by the Max in-memory session count property. This option is valid only in non-distributed sessions mode.

Session timeout
Specifies how long a session can go unused before it is no longer valid. Specify either `Set timeout` or `No timeout`. Specify the value in minutes greater than or equal to two.

The value specified in a Web module deployment descriptor file takes precedence over the administrative console settings. However, the value of this setting is used as a default when the session timeout is not specified in a Web module deployment descriptor. Note that to preserve performance, the invalidation timer is not accurate to the second. When the write frequency is time based, ensure that this value is least twice as large as the write interval.

Security integration
Specifies that when security integration is enabled, the session management facility associates the identity of users with their HTTP sessions

Serialize session access
Specifies that concurrent session access in a given server is not allowed.

Maximum wait time	Specifies the maximum amount of time a servlet request waits on an HTTP session before continuing execution. This parameter is optional and expressed in seconds. The default is 5 seconds. Under normal conditions, a servlet request waiting for access to an HTTP session gets notified by the request that currently owns the given HTTP session when the request finishes.
Allow access on timeout	Specifies whether the servlet is started normally or aborted in the event of a timeout. If this box is checked, the servlet is started normally. If this box is not checked, the servlet execution aborts and error logs are generated.

Configuring session tracking

About this task

Review the Session tracking options to plan your approach to session management. To configure session tracking, complete the following:

1. Go to the appropriate level of Session Management.
2. Specify the session tracking mechanism that you want to pass the session ID between the browser and the servlet:
   - To track sessions with cookies, click **Enable Cookies**.

     To change the cookie settings, click **Modify**.
   - To track sessions with URL rewriting, click **Enable URL Rewriting**.

     If you want to enable protocol switch rewriting, click **Enable protocol switch rewriting.**
   - To track sessions with SSL information, click **Enable SSL ID tracking**.

     Note: Session tracking using the SSL ID is deprecated in WebSphere Application Server version 7.0. You can reconfigure session tracking to use cookies or modify the application to use URL rewriting.
3. Click **Apply**.
4. Click **Save**.

Serializing access to session data

The Servlet API supports concurrent access to a session in a given server instance. WebSphere Application Server provides an option to prevent the concurrent access to a session in a given server instance so that concurrent modification of a session does not occur in a given server instance.

About this task

Preventing concurrent access to a session is achieved by synchronizing the requests based on session. When this feature is turned on, a session is obtained for the request before invoking the servlet and requests are synchronized by locking the session for the servlet initiation time. Note that synchronization is based on the memory copy of session. So this feature cannot serialize requests across servers based on session when session affinity fails.

You can also use the serializing access to session data feature to synchronize session objects inside of servlets or JavaServer pages. Applications cannot synchronize session objects inside of their servlets or JavaServer Pages because a deadlock with the session manager may occur. The deadlock occurs because the session manager does not expect the use of more than one locking mechanism. You can ensure that only one request can access the session at a time through the use of the configuration option, Allow serial access.

Use this feature only when concurrent modification of the same session data is possible and is not desirable by the application. This feature has overhead of serializing the requests based on a session.

Do the following to synchronize session access:

1. Select the level of Session Management on which you want to serialize session access.
2. Under Serialize Session access, click **Allow serial access**.
3. In the Maximum wait time box, type the amount of time, in milliseconds, a servlet waits on a session before continuing execution. The default is 120000 milliseconds or two minutes.
4. Select **Allow access on timeout** if you want the servlet to gain access to the session and continue normal execution even if the session is still locked by another servlet. If you do not select this box, the servlet execution will abort when the session request times out.
5. Click **Apply**.
6. Click **Save**.

Cookie settings

Use this page to configure cookie settings for session management.

To view this administrative console page, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Session management** → **Enable cookies**.

Cookie name

Specifies a unique name for the session management cookie. The servlet specification requires the name JSESSIONID. However, for flexibility, you can configure this value.

Restrict cookies to HTTPS sessions

Specifies that the session cookies include the secure field. Enabling this feature restricts the exchange of cookies to HTTPS sessions only.

Cookie domain

Specifies the domain field of a session tracking cookie. This value controls whether or not a browser sends a cookie to particular servers. For example, if you specify a particular domain, session cookies are sent to hosts in that domain. The default domain is the server.

Cookie path
Specifies that a cookie is sent to the URL designated in the path. Specify any string representing a path on the server. ″/″ indicates root directory. Specify a value to restrict the paths to which the cookie is sent. By restricting paths, you prevent the cookie from going to certain URLs on the server. If you specify the root directory, the cookie is sent no matter which path on the given server is accessed.

Cookie maximum age
Specifies the amount of time that the cookie lives on the client browser. Specify that the cookie lives only as long as the current browser session, or to a maximum age. If you choose the maximum age option, specify the age in seconds. This value corresponds to the Time to Live (TTL) value described in the Cookie specification.

Default is the current browser session which is equivalent to setting the value to -1.

Session management custom properties
You can specify additional settings for session management through setting custom properties.

Session management properties, like the session management configuration, can be configured at the server, application, or Web module level. The following steps are for setting the custom properties for session management at the server level.

1. In the administrative console click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Session management**.
2. Under **Additional Properties** select **Custom Properties**.
3. On the Custom Properties page, click **New**.
4. On the settings page, enter the property that you want to configure in the **Name** field and the value that you want to set it to in the **Value** field.
5. Click **Apply** or **OK**.
6. Click **Save** on the console task bar to save your configuration changes.
7. Restart the server.

CloneSeparatorChange
Use this property to maintain session affinity. The clone ID of the server is appended to session identifier separated by colon. On some Wireless Application Protocol (WAP) devices, a colon is not allowed. Set this property to ″true″ to change clone separator to a plus sign (+).

HttpSessionCloneId
Use this property to change the clone ID of the cluster member. Within a cluster, this name must be unique to maintain session affinity. When set, this name overwrites the default name generated by WebSphere Application Server.

Default clone ID length: 40

HttpSessionIdLength
Use this property to configure the session identifier length. Do not use an extremely low value; using a low value results in reduced number of combinations possible, thereby increasing risk of guessing the session identifier. In a cluster, all cluster members should be configured with same ID length. Allowed range: 8 to 128. Default length: 23.

HttpSessionReaperPollInterval
Use this property to set a wake-up interval for the process that removes invalid sessions. Setting this property overrides the default installation value, which is between 30 and 360 seconds. If the maximum inactive interval is less than 2 minutes, the reaper poll interval may be as short as 30 seconds. If the maximum inactive interval is more than 15 minutes, the reaper poll interval can be as long as 6 minutes. Because the default timeout and maximum inactive interval is 30 minutes, the reaper interval is usually

between 5 and 6 minutes. Set this property if you want to ensure that the reaper process runs at a specific interval. Use this property when you want the installation timed out sessions invalidated more frequently than 5 to 6 minutes. For example, setting HttpSessionReaperPollInterval=120 ensures that sessions are invalidated within 2 minutes of timing out. The minimum value for this property is 30 seconds. If a value less than the minimum is entered, the specified property is ignored and an appropriate value is automatically determined and used. The maximum inactive interval is the session timeout. The default is based on maximum inactive interval set in session management.

Data type	Integer
Units	Seconds

NoAdditionalSessionInfo
Set this value to ″true″ to force removal of information that is not needed in session identifiers.

SessionIdentifierMaxLength
Use this value to set maximum length that a session identifier can grow.

This property helps to find out the condition and take appropriate action to address servers fail-over. When this is specified, message is logged when specified maximum length is reached. Allowed value: integer.

SessionRewriteIdentifier
Use this property to change the key used with URL rewriting. Default key: jsessionid.

Servlet21SessionCompatibility
Set this custom property to true to enable global session behavior. In Servlet 2.2 and later, sessions are scoped at the Web module level. The default is false.

Note: This property is deprecated. The IBMApplicationSession method replaces the function of the Servlet21SessionCompatibility custom property.

SessionTableName
Use this custom property to set the database table name. Allowed value: String. The default value is SESSIONS.

Some applications may rely on method ejbCreate(...) to have created the entity bean in the database. For such a requirement, setting the JVM property *com.ibm.websphere.ejbcontainer.allowEarlyInsert* to **true** overrides the default behavior.

UseInvalidatedId
Set this custom property to true to reuse the incoming ID if the session with that ID was recently invalidated. This is a performance optimization because it prevents checking the persistent store. The default value is true.

UseOracleBLOB
The *UseOracleBLOB* custom property creates the HTTP session database table using the Binary Large Object (BLOB) data type for the medium column. This property increases performance of persistent sessions when Oracle databases are used. Due to an Oracle restriction, BLOB support requires use of the Oracle's oci database driver for more than 4000 bytes of data. You must also ensure that a new sessions table is created before the server is restarted by dropping your old sessions table or by changing the datasource definition to reference a database that does not contain a sessions table.

To create a sessions table using the BLOB data type, use the following name-vaule pair:

Name	Value
UseOracleBLOB	true

DebugSessionCrossover

The *DebugSessionCrossover* custom property enables code to perform additional checks to verify that only the session associated with the request is accessed or referenced. Messages are logged if any discrepancies are detected.

To enable session data crossover detection, use the following name-vaule pair:

Name	Value
DebugSessionCrossover	true

See article, "HTTP session problems" on page 24, for additional information.

HttpSessionIdReuse

The custom property *HttpSessionIdReuse* determines whether the session manager can use the session ID sent from a browser to preserve session data across Web applications that are running in an environment that is not configured for session persistence.

In a multi-JVM environment that is not configured for session persistence setting this property to `true` enables the session manager to use the same session information for all of a user's requests even if the Web applications that are handling these requests are governed by different JVMs. The default value for this property is `false`. To enable the session manager ton use the session ID sent from a browser to preserve session data across Web applications that are running in an environment that is not configured for session persistence, use the following name-value pair:

Name	Value
HttpSessionIdReuse	true

OptimizeCacheIdIncrements

Set the *OptimizeCacheIdIncrements* custom property to true to make the session manager assess whether the in-memory session is older than the copy in persistent store. Setting this property resolves the continually increasing cache ID.

If HTTP session management is configured to use session persistence and the user's browser session is moving back and forth across multiple Web applications you might see extra persistent store activity as the in-memory sessions are refreshed from the persistent store. As a result, the cache IDs are continually increasing and the in-memory session attributes are overwritten by those of the persistent copy. To prevent the cache IDs from continually increasing, use the following name-value pair:

Name	Value
OptimizeCacheIdIncrements	true

If the configuration is a cluster, ensure that the system times of each cluster member is identical as possible.

AlwaysEncodeURL

The Servlet 2.5 specification specifies to not encode the URL on a response.encodeURL call if it is not necessary. To support backward compatibility when URL encoding is enabled, set the *AlwaysEncodeURL* custom property to `true` to call the encodeURL method. The URL is always encoded, even if the browser supports cookies. Use the following name-value pair to encode all URLs:

Name	Value
AlwaysEncodeURL	true

UsingApplicationSessionsAndInvalidateAll

When the invalidateAllSet method is called, not all IBMApplicationSessions objects are checked. If you are using both the IBMApplicationSessions object and the invalidateAll call, use the following name-value pair:

Name	Value
UsingApplicationSessionsAndInvalidateAll	true

ForceSessionInvalidationMultiple

The *ForceSessionInvalidationMultiple* custom property indicates whether the session manager should wait indefinitely for a request to complete before attempting to invalidate the session, or should attempt to invalidate a session after the specified time limit has elapsed. The default value for this property is 1.

- If you specify 0 (zero) for this custom property, the session manager waits indefinitely until a request is complete before attempting to invalidate the session.

  If your requests normally are not bound by a response time limit, pecify 0 for this property.
- If you specify a positive integer, such as 1, 2, or 3, for this custom property, even if a session is not known to have completed, the session manager attempts to invalidate the session, if the indicated time period since the last access occurred has elapsed. This time period is the result of multiplying the value specified for this property and the value specified for the Session Timeout property. For example, if you specify 2 minutes for the Session Timeout property and 2 for the ForceSessionInvalidationMultiple property, the session manager attempts to invalidate the session after 4 minutes.

  If you want to invalidate your sessions after a certain amount of time has elapsed, specify the appropriate positive integer for this property.

Name	Value
ForceSessionInvalidationMultiple	1

Configuring session tracking for Wireless Application Protocol (WAP) devices

Applications that run in a Web container use sessions to keep track of individual users. Because most Wireless Application Protocol (WAP) devices do not support cookies, you can configure WAP devices to use URL rewriting to track sessions.

About this task

On most WAP devices, the maximum URL length is 128 characters. With URL rewriting, a session identifier is added to the URL itself, effectively decreasing the space available for the actual URL and the number of parameters that can be sent on a request.

To reduce the length of session identifier, you can configure key (jsessionid), session ID length and clone ID. To make these configuration changes, complete the following steps.

1. Open the administrative console.
2. Click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Web Container Settings** → **Web container**.
3. Under Additional Properties, click **Custom properties**.
4. Add the appropriate properties from the following list:
   - HttpSessionIdLength
   - SessionRewriteIdentifier
   - HttpSessionCloneId
   - CloneSeparatorChange
   - NoAdditionalSessionInfo

- SessionIdentifierMaxLength

5. Click **Apply** and **Save**.

Configuring for database session persistence

You can configure a database to collect session data for database session persistence.

About this task

To configure the session management facility for database session persistence, complete the following steps.

1. Create and configure a JDBC provider.
2. Create a data source pointing to a database.

   Use the JDBC provider that you defined: **Resources > JDBC > JDBC Providers >** *JDBC_provider* **> Data Sources > New**. The data source should be non-JTA, for example, non-XA enabled. Note the JNDI name of the data source.

   Point to an existing database.
3. Verify that the correct database is listed under **Resources > JDBC Providers >** *JDBC_provider* **> Data Sources >** *datasource_name*. If necessary, contact your database administrator to verify the correct database name.
4. Go to the appropriate level of Session Management.
5. Under Additional Properties, click **Distributed Environment Settings**
6. Select and click **Database**.
7. Specify the Data Source JNDI name from a previous step. The database user ID and password are case-sensitive.
8. Specify the database user ID and password that is used to access the database and for table creation. When you created your data source, you might have specified a Container Managed Authentication Alias or a Component Managed Authentication Alias; however, these two settings are not used by the session manager for session persistence. The session manager uses the userId and password specified in this step for session persistence.
9. Optional: Append the schema name in the session User ID field if you want to have more than one instance of the session table. The session manager uses the schema name to qualify the session table name for all database operations. If only the userid is specified without the schema name, the schema name defaults to NULL and therefore a table name with NULL as the schema name, for example, NULL.SESSIONS, is created. You can pass the create multiple session tables with different schema names, other than NULL, and access them separately by modifying the user name to contain the appropriate schema name. Use the following format to pass the schema name: userid::schemaName.
10. Retype the password for confirmation.
11. Configure a table space and page sizes for DB2 session databases.
12. Switch to a multirow schema.
13. Click **OK**.
14. If you want to change the tuning parameters, click **Custom Tuning Parameters** under Additional properties and select a setting or customize a setting.
15. Click **Apply**.
16. Click **Save**.

Switching to a multirow schema

The multirow schema configuration supports storing an unlimited amount of data that is only bounded by the database capacities in an application. The application can read individual fields instead of the whole record, which can help to improve performance by avoiding unnecessary Java object serialization.

Configure the session management facility to store each attribute in a session object in its own row in the database by using the multirow schema configuration.

About this task

The only practical limit that remains is the size of the session attribute object. The multirow schema potentially has performance benefits in certain usage scenarios, such as when larger amounts of data are stored in the session but only small amounts are specifically accessed during a given servlet processing of an HTTP request. In such a scenario, avoiding unneeded Java object serialization is beneficial to performance.

In addition to allowing larger session records, using multirow schema can yield performance benefits. However, it requires a little work to switch from single-row to multirow schema, as shown in the following table.

By default, a single session maps to a single row in the database table used to hold sessions. With this setup, there are hard limits to the amount of user-defined, application-specific data that WebSphere Application Server can access.

Consider configuring direct single-row usage to one database and multirow usage to another database while you verify which option suits your application needs. Do this in code by switching the data source used; then monitor performance.

Programming issue	**Application scenario**
Reasons to use single-row	• You can read or write all values with just one record read and write. • This takes up less space in a database because you are guaranteed that each session is only one record long.
Reasons **not** to use single-row	2-megabyte limit of stored data per session.
Reasons to use multirow	• The application can store an unlimited amount of data; that is, you are limited only by the size of the database and a 2-megabyte-per-record limit. • The application can read individual fields instead of the whole record. When large amounts of data are stored in the session but only small amounts are specifically accessed during servlet processing of an HTTP request, multirow sessions can improve performance by avoiding unneeded Java object serialization.
Reasons **not** to use multirow	If data is small in size, you probably do not want the extra overhead of multiple row reads when you can store everything in one row.

In the case of multirow usage, design your application data objects not to have references to each other, to prevent circular references. For example, suppose you are storing two objects A and B in the session using HttpSession.put(..) method, and A contains a reference to B. In the multirow case, because objects are stored in different rows of the database, when objects A and B are retrieved later, the object graph between A and B is different than stored. A and B behave as independent objects.

1. Modify the Session Management facility properties to switch from single to multirow schema.
2. Manually drop the table.

   To drop the table:
   a. Determine which data source configuration Session Management is using.
   b. In the data source configuration, look up the database name.
   c. Use the database facilities to connect to the database.

d. Drop the SESSIONS table.

Configuring tablespace and page sizes for DB2 session databases

If you are using DB2 for session persistence, you can increase the page size to optimize performance for writing large amounts of data to the database. Page sizes of 8K, 16K, and 32K are supported.

About this task

To use a page size other than the default (4K), complete the following steps.

1. If the SESSIONS table already exists, drop it from the DB2 database.
2. Create a new DB2 buffer pool and table space, specifying the same page size (8K, 16K or 32K) for both, and assign the new buffer pool to this table space.

```
DB2 Connect to session
DB2 CREATE BUFFERPOOL sessionBP SIZE 1000 PAGESIZE 8K
DB2 Connect reset
DB2 Connect to session
DB2 CREATE TABLESPACE sessionTS PAGESIZE 8K MANAGED BY SYSTEM
    USING ('D:\DB2\NODE0000\SQL00005\sessionTS.0') BUFFERPOOL sessionBP
DB2 Connect reset
```

   Refer to DB2 product documentation for details.
3. Configure the correct table space name and page size in the Session Management facility. Page size is referred to as *row size* on the Session Management page.)

Results

When the product is restarted, the Session Management facility creates the new SESSIONS table in the specified tablespace based on the indicated page size.

Creating a table for session persistence

You can use a database table to collect and store session data. If you are using a database table for session persistence, you must create and define a database table that is associated with the application server.

About this task

Whenever the session manager is set for database persistence, the session manager creates a table for its use. If you want to expand the column size limits to make it more appropriate for your Web site, you can create the table externally. If the external table is specified as the target table in the session manger database persistence configuration, then during the session manager start up, the external table is used. In most cases it is better to let the session manager create the table during startup.

To create a table for collecting session data, do the following:

1. Have your administrator create a database table for storing your session data using one of the following data definition language (DDL): For DB2:

```
CREATE TABLE <SchemaName>.sessions  (
  ID               VARCHAR(128) NOT NULL ,
  PROPID           VARCHAR(128) NOT NULL ,
  APPNAME          VARCHAR(128) NOT NULL,
  LISTENERCNT      SMALLINT ,
  LASTACCESS       BIGINT,
  CREATIONTIME     BIGINT,
  MAXINACTIVETIME  INTEGER ,
  USERNAME         VARCHAR(256) ,
```

```
  SMALL            VARCHAR(3122)  FOR BIT DATA ,
  MEDIUM           LONG VARCHAR FOR BIT DATA ,
  LARGE            BLOB(2M)
    )
```

For Oracle:

```
CREATE TABLE SESSIONS  (
  ID               VARCHAR(128) NOT NULL ,
  PROPID           VARCHAR(128) NOT NULL ,
  APPNAME          VARCHAR(128) NOT NULL,
  LISTENERCNT      SMALLINT ,
  LASTACCESS       INTEGER,
  CREATIONTIME     INTEGER,
  MAXINACTIVETIME  INTEGER ,
  USERNAME         VARCHAR(256) ,
  SMALL            RAW(2000),
  MEDIUM           LONG RAW ,
  LARGE            RAW(1)
  )
```

If the Web container custom property UseOracleBLOB is set to true then:

```
CREATE TABLE SESSIONS  (
  ID               VARCHAR(128) NOT NULL ,
  PROPID           VARCHAR(128) NOT NULL ,
  APPNAME          VARCHAR(128) NOT NULL,
  LISTENERCNT      SMALLINT ,
  LASTACCESS       INTEGER,
  CREATIONTIME     INTEGER,
  MAXINACTIVETIME  INTEGER ,
  USERNAME         VARCHAR(256) ,
  SMALL            RAW(2000),
  MEDIUM           BLOB,
  LARGE            RAW(1)
  )
```

Note:

a. At run time, the session manager accesses the target table using the identity of the J2EE server in which the owning Web application is deployed. Any Web container that is configured to use persistent sessions must have both read and update access to the subject database table.

b. HTTP session processing uses the index defined using the `CREATE INDEX` statement to avoid database deadlocks. In some situations, such as when a relatively small table size is defined for the database, DB2 may decide not to use this index. When the index is not used, database deadlocks can occur. If database deadlocks occur, see the DB2 Administration Guide for the version of DB2 you are using for recommendations on how to calculate the space required for an index and adjust the size of the tables that you are using accordingly.

c. It might be necessary to tune DB2 to make efficient use of the sessions database table and to avoid deadlocks when accessing it. Your DB2 administrator should refer to the DB2 Administration Guide for specific information about tuning the version of DB2 that you are using.

2. .

Database settings

Use this page to specify the settings for database session support.

To view this administrative console page, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Session management** → **Distributed environment settings** → **Database**.

Datasource JNDI name
Specifies the datasource description.

The JNDI name of the non-XA enabled datasource from which session management obtains database connections. For example, if the JNDI name of the datasource is ″jdbc/sessions″, specify ″jdbc/sessions.″ The datasource represents a pool of database connections and a configuration for that pool (such as the pool size). The datasource must already exist as a configured resource in the environment.

User ID
Specifies the user ID for database access.

Password
Specifies the password for database access.

DB2 row size
Specifies the table space page size configured for the sessions table, if using a DB2 database. Possible values are 4, 8, 16, and 32 kilobytes (KB). The default row size is 4KB.

The default row size is 4KB. In DB2, it can be updated to a larger value. This can help database performance in some environments. When this value is other than 4, you must specify table space name to use this property. For 4KB pages, the table space name is optional.

Table space name
Specifies that table space to be used for the sessions table.

This value is required when the DB2 page size is other than 4KB.

Use multi row schema
Specifies that each session data attribute is placed in a separate row in the database, allowing larger amounts of data to be stored for each session. This action can yield better performance when session attributes are very large and few changes are required to the session attributes. If use multi row schema is not enabled, instances of application data can be placed in the same row.

Configuring Web module class loaders

You can set values that control the class-loading behavior of an installed Web module.

Before you begin

This topic assumes that you installed a Web module on an application server.

About this task

Configure the class loader order value of an installed Web module. By default, a Web module has its own Web application archive (WAR) class loader to load the contents of the Web module, which are in the WEB-INF/classes and WEB-INF/lib directories.

An application class loader is the parent of a WAR class loader. The WAR class-loader policy value of an application class loader determines whether the WAR class loader or the application class loader is used to load the contents of the Web module.

The default WAR class loader policy value is `Class loader for each WAR file in application`. If the policy is set to `Class loader for each WAR file in application`, then each Web module receives its own class loader whose parent is the application class loader. If the policy is set to `Single class loader for application` on the settings page of an application class loader, then the application class loader loads the Web module contents as well as the enterprise bean (EJB) modules, shared libraries, resource adapter

archives (RAR files), and dependency Java archive (JAR) files associated to an application. Thus, the configuration of the parent application class loader affects the WAR class loader.

Use the administrative console to configure the application and WAR class loaders.

Note: If an application is running, changing an application setting causes the application to restart. On stand-alone servers, the application restarts after you save the change. On multiple-server products, the application restarts after you save the change and files synchronize on the node where the application is installed. To control when synchronization occurs on multiple-server products, deselect **Synchronize changes with nodes** on the Console preferences page.

1. If you have not done so already, configure the application class loader.

   Settings such as **Override class reloading settings for Web and EJB modules**, **Polling interval for updated files** and **WAR class loader policy** can affect Web module class loading.

   If **WAR class loader policy** is set to `Class loader for each WAR file in application`, then the Web module receives its own class loader and the WAR class-loader policy of the Web module defines the mode for a WAR class loader. If the policy is set to `Single class loader for application`, then the application class loader loads the Web module contents.

2. Specify the class loader order for the installed Web module.

   The Web module class-loader mode specifies whether the class loader searches in the parent application class loader or in the WAR class loader first to load a class. The default is to search in the parent application class loader before searching in the WAR class loader to load a class.

   Select either of the following values for **Class loader order**:

Option	Description
Classes loaded with parent class loader first	Causes the class loader to search in the parent application class loader first to load a class. This is the standard for Development Kit class loaders and WebSphere Application Server class loaders. **Note:** If classes and resources needed by the Web module cannot be accessed by the application class loader, but can be accessed by the WAR class loader, specify `Classes loaded with local class loader first (parent last)`. If the application class loader cannot find a class, the class loader delegates the request to find the class to its parent, the WebSphere Application Server extensions class loader. If the WebSphere Application Server extensions class loader cannot find the class, the class loader delegates the request to its parent, the bootstrap, extensions, and CLASSPATH class loaders created by the Java virtual machine. Requests can only go to a parent class loader; they cannot go to a child class loader. Thus, if `Classes loaded with parent class loader first` is specified, the WAR class loader never receives a request to load a class.
Classes loaded with local class loader first (parent last)	Causes the class loader to search in the WAR class loader first to load a class. By specifying `Classes loaded with local class loader first (parent last)`, your WAR class loader can override classes contained in the parent application class loader. **Note:** Specifying the `Classes loaded with local class loader first (parent last)` value might result in LinkageErrors or ClassCastException messages if you have mixed use of overridden classes and non-overridden classes.

3. Click **OK**.

What to do next

Save the changes to the administrative configuration.

Backing up and recovering servlets

Servlet source and class files, user profile data, Hypertext Transfer Protocol (HTTP) configuration, and administrative configuration should be considered for backup when using servlets. You should consider saving your HTTP configuration because changes to the HTTP configuration are often made to enable WebSphere Application Server to serve servlets and JSP requests, and to enable WebSphere Application Server security. You should consider backing up the user proifle data if you use the User Profile function of WebSphere Application Server.

- Backup servlet source and class files. Application code and configuration such as bindings, is located by default in the *profile_root*/installedApps directory. By saving this directory, you save your installed applications, including HTML, servlets, JavaServer Pages (JSP) files, and enterprise beans. Normally, each application is located in a separate subdirectory, so you can choose to save all applications or a subset.
  1. Save all installed applications. The commands below have been wrapped for display purposes. Enter each as a single command.

     ```
     SAV DEV('/QSYS.lib/wsalib.lib/wsasavf.file')
      OBJ(('/profile_root/installedApps'))
     ```

  2. Saves the sampleApp application only. The commands below have been wrapped for display purposes. Enter each as a single command.

     ```
     SAV DEV('/QSYS.lib/wsalib.lib/wsasavf.file')
      OBJ(('/profile_root/installedApps/cellName/sampleApp.ear'))
     ```

  If you have located utility or general purpose classes in other directories, such as *profile_root*/lib/app or *profile_root*/lib/ext, be sure to include those locations in your backup plan as well.
- Save your HTTP configuration.

  Note: The following information applies to IBM HTTP Server for iSeries (powered by Apache). If you are using Lotus® Domino® HTTP Server, see the Notes.net Documentation Library.

  1. Save the HTTP server instances for IBM HTTP Server for iSeries (powered by Apache). The HTTP server instances for IBM HTTP Server for iSeries (powered by Apache) are members of the QATMHINSTC file in the library QUSRSYS. An example save command for this file could be the following: SAVOBJ OBJ(QATMHINSTC) LIB(QUSRSYS) DEV(*SAVF) OBJTYPE(*FILE) SAVF(WSALIB/WSASAVF)
  2. Save the HTTP configurations for IBM HTTP Server for iSeries (powered by Apache). The HTTP configurations for IBM HTTP Server for iSeries (powered by Apache) are stored in the integrated file system in a subdirectory, chosen when the configuration was created. The recommended location is within the WebSphere instance directory. You can determine this file location by inspecting HTTP server instance member in the QATMHINSTC file in library QUSRSYS. An example save command for this file could be the following: SAV DEV('/QSYS.lib/wsalib.lib/wsasavf.file') OBJ(('*profile_root*/profile/apache/conf') ('*profile_root*/profile/htdocs')) where profile is the name of your instance. The default instance name is default.

Backing up and recovering JavaServer Pages files

JavaServer Pages source and generated servlet classes, Hypertext Transfer Protocol (HTTP) configuration, and administrative configuration should be considered for backup when using JavaServer Pages files.

- Save installed applications. Application code and configuration such as bindings, is located by default in the *profile_root*/installedApps directory. By saving this directory, you save your installed applications, including HTML, servlets, JavaServer Pages (JSP) files, and enterprise beans. Normally, each application is located in a separate subdirectory, so you can choose to save all applications or a subset.

1. Save all installed applications. The command below has been wrapped for display purposes. Enter the following as a single command, with a space between the end of DEV parameter and OBJ.

   ```
   SAV DEV('/QSYS.lib/wsalib.lib/wsasavf.file')
      OBJ(('/profile_root/installedApps'))
   ```

2. Save the sampleApp application only. The command below has been wrapped for display purposes. Enter the following as a single command with a space between the end of DEV parameter and OBJ.

   ```
   SAV DEV('/QSYS.lib/wsalib.lib/wsasavf.file')
      OBJ(('/profile_root/installedApps/cellName/sampleApp.ear'))
   ```

- Save and restore your JSP files. When JSP files are run, a servlet class is generated, compiled, and then run. When saving and restoring your JSP files, you can elect to save only the JSP source or the generated files as well.
  - If you save and restore only the JSP source, the servlet source and class files are regenerated when they are invoked. This is a simpler, smaller save and restore operation. Note that regeneration slows the first requests, and default optimization is done on the generated Java programs.
  - If you save and restore the source and generated files, no regeneration is done. If you have optimized Java programs to levels other than the default, this optimization is preserved.

Example

WebSphere Application Server places the generated files (*.class, .java*, and optionally, *.dat*) in a temporary directory under the WebSphere Application Server instance. For example, the default instance stores the generated files in this directory:

/profile_root/temp/*node_name*/*application_server*/*enterprise_app*/*web_module*

In this example:

- *profile* is the name of your instance. The default instance name is default.
- *node_name* is the name of the iSeries server or partition on which your WebSphere Application Server instance is running
- *application_server* is the name of your WebSphere Application Server
- *enterprise_app* is the name of the enterprise application to which the JSP file belongs
- *web_module* is the Web module that contains your JSP file.

Note: A .dat file is a helper file used by the generated servlet.

Chapter 2. Portlet applications

Task overview: Managing portlets

You can use this task to manage deployed portlet applications.

Before you begin

Before you begin this task, you must have a portlet application installed. See Installing enterprise application files for additional information.

About this task

You can complete the following steps to manage portlets.

- Render a portlet.
  - Access a single portlet using “Portlet Uniform Resource Locator (URL) addressability” on page 106.
  - Access multiple portlets using “Portlet aggregation using JavaServer Pages” on page 100.
- Change the location of “Portlet preferences” on page 108. By default, portlet preferences for each portlet window are stored in a cookie. However, you can change the location of where to store portlet preferences.
- Disable URL addressability. By default, you can access a portlet through an Uniform Resource Locator (URL), however, you can disable this feature.
- Enable portlet fragment caching. Portlet fragment caching is disabled by default.

Portlets

Portlets are reusable Web modules that provide access to Web-based content, applications, and other resources. Portlets can run on WebSphere Application Server because it has an embedded JSR 286 Portlet container. The JSR 286 API provides backwards compatibility. You can assemble portlets into a larger portal page, with multiple instances of the same portlet displaying different data for each user.

From a user’s perspective, a portlet is a window on a portal site that provides a specific service or information, for example, a calendar or news feed. From an application development perspective, portlets are pluggable Web modules that are designed to run inside a portlet container of any portal framework. You can either create your own portlets or select portlets from a catalog of third-party portlets.

Each portlet on the page is responsible for providing its output in the form of markup fragments to be integrated into the portal page. The portal is responsible for providing the markup surrounding each portlet. In HTML, for example, the portal can provide markup that gives each portlet a title bar with minimize, maximize, help, and edit icons.

You can also include portlets as fragments into servlets or JavaServer Pages files. This provides better communication between portlets and the Java Platform, Enterprise Edition (Java EE) Web technologies provided by the application server.

If you use Rational Application Developer version 6 (RAD) to create your portlets, you must remove the following reference to the std-portlet.tld from the web.xml file to run the portlets outside of RAD:

```
<taglib id="PortletTLD">
 <taglib-uri>http://java.sun.com/portlet</taglib-uri>
 <taglib-location>/WEB-INF/tld/std-portlet.tld</taglib-location>
</taglib>
```

Also if you use RAD version 6 to create portlets, note that portlets created by using the Struts Portlet Framework are not supported on WebSphere Application Server.

Portlet applications

If the portlet application is a valid Web application written to the Java Portlet API, the portlet application can operate on both the Portal Server and the WebSphere Application Server without requiring any changes. JSR 168 and JSR 286 compliant portlet applications must not use extended services provided by WebSphere Portal to operate on the WebSphere Application Server.

Portlet container

The *portlet container* is the runtime environment for portlets using the JSR 286 Portlet specification, in which portlets are instantiated, used, and finally destroyed. The JSR 286 Portlet API provides standard interfaces for portlets and backwards compatibility for JSR 168 portlets. Portlets based on this JSR 286 Portlet Specification are referred to as standard portlets.

A simple portal framework is provided by the PortletServingServlet servlet. The PortletServingServlet servlet registers itself for each Web application that contains portlets. You can use the PortletServingServlet servlet to directly render a portlet into a full browser page by a URL request and invoke each portlet by its context root and name. See “Portlet Uniform Resource Locator (URL) addressability” on page 106 for additional information. If you want to aggregate multiple portlets on the page, you need to use the aggregation tag library. See the article “Portlet aggregation using JavaServer Pages” for additional information. The PortletServingServlet servlet can be disabled in an extended portlet deployment descriptor called the ibm-portlet-ext.xmi file.

Remote request dispatcher support for portlets

The remote request dispatcher (RRD) support allows the invocation of portlets outside of the current Java virtual machine (JVM) within an Network Deployment single core group environment. The request related data is passed to the remote JVM where the portlet is invoked. The response is transmitted back and processed on the local JVM. Thus it guarantees that URLs contained in the portlet markup are created according to the local portal context. The remote request dispatcher support is only provided for JSR 168 compliant portlets.

Portlet container settings

Use this page to configure and manage the portlet container of this application server.

To view this administrative console page, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Portlet Container Settings** → **Portlet container**.

Enable portlet fragment cache

Specifies whether to create a cached entry when a portlet is invoked, similar to servlet caching of the Web container settings.

Portlet fragment caching requires that servlet caching is enabled. Therefore, enabling portlet fragment caching automatically enables servlet caching. Disabling servlet caching automatically disables portlet fragment caching.

Portlet aggregation using JavaServer Pages

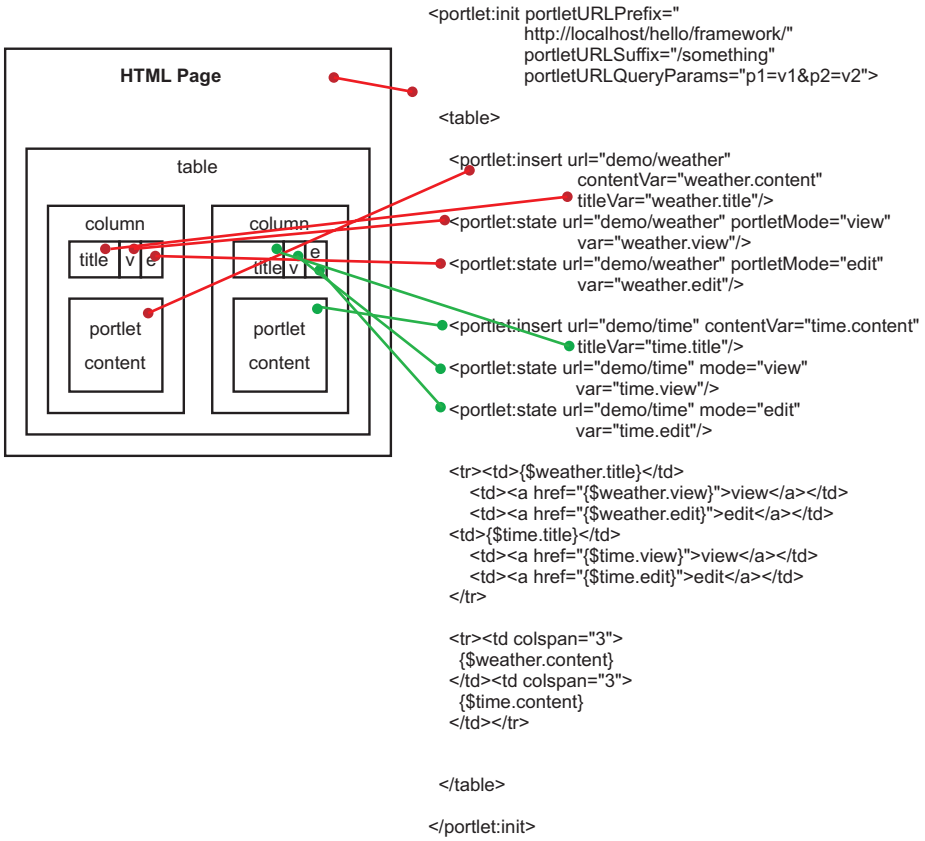
The aggregation tag library generates a portlet aggregation framework to address one or more portlets on one page If you write JavaServer Pages, you can aggregate multiple portlets on one page using the aggregation tag library. This tag library does not provide full featured portal aggregation implementation, but provides a good migration scenario if you already have aggregating servlets and JavaServer Pages and want to switch to portlets.

To allow the customer to create a simple portal aggregation, the aggregation tag library also provides the following features.

- Invoke a portlet's action method
- Render multiple portlets on one page
- Provide links to change the portlet's mode or window state
- Display the portlet's title
- Retain the portlet cookie state

The aggregation tag library and JavaServer Pages that use the aggregation tag library will only work with the WebSphere Application Server portlet container implementation because the protocol between the tags and the container is not standardized.

The following diagram depicts how an HTML page would look like and what tags are used in order to create the page. See "Aggregation tag library attributes" on page 102 for information on the aggregation tag library attributes.



When you use the aggregation tag library, you must set the portletUrlPrefix attribute of the init tag to the aggregating application. You need to:

- Ensure that the portletUrlPrefix attribute is set to the following in the aggregator page.

  `"http://" + <server_address> + ":" + <server_port> + "/" + <aggregator context> + "/" <aggregator mapping>`
- Reference the aggregation JSP page within the web.xml file through a servlet mapping ending with `/*`. For example, `/aggregation/*`

When aggregating multiple portlets on a single page, special care must be used with the naming conventions of form attribute names in your portlets. Because your portlets are all on the same page, they all share the same HttpServletRequest. When one portlet is viewed the entire page is refreshed and form data is re-posted. Therefore, if there are multiple portlets that are aggregated on a single page with the same form attribute names, there could be logic corruption when form data is re-posted.

Aggregation tag library attributes

The aggregation tag library is used to aggregate multiple portlets on one page. This topic describes the attributes within the aggregation tag library.

Supported arguments include:

init

This tag initializes the portlet framework and has to be used in the beginning of the JSP. All other tags described in this section are only valid in the body of this tag, therefore the init tag usually encloses the whole body of a JSP. In case the current URL contains an action flag the action method of the corresponding portlet is called. The state and insert tags are sub-tags of the init tag.

The init tag has the following attributes:

- portletURLPrefix = ”<any string>”

  This URL defines the prefix used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet’s render method, which is called by using the insert tag. This is a required attribute.
- portletURLSuffix = ”<any string>”

  This URL defines the suffix used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet’s render method, which is called by using the insert tag. This is attribute optional.
- portletURLQueryParams = ”<any string>”

  This URL defines the query parameters used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet’s render method, which is called by using the insert tag. This is attribute optional.

scope, portlet

The scope tag and portlet tag are used to provide information that is necessary when a portlet application is installed under a multiple part context root, for example, /context1/context2. These tags add a render parameter to the newly created URL.

The urlParam tag has the following attributes:

- context = ″/<context1>/<context2>″

  Specifies the context root of the portlet application in which the portlet is deployed. This attribute is required.
- portletname = ″<portlet-name>″

  Specifies the portlet-name. This attribute is required.
- windowId = ”<any string>”

  Defines the window ID for the concrete portlet instance. This attribute is required.

The following is an example of how to use the scope and portlet tags:

```
<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>

<portlet:scope>
        <portlet:portlet context="/myportletcontext1/myportletcontext2" portletname="MyPortlet" windowId="sample"/>
</portlet:scope>

<portlet:init portletURLPrefix="/myportalcontext/ ">
....
</portlet:init>
```

state

The state tag creates a URL pointing to the given portlet using the given state. You can place this URL either into a variable specified by the var attribute or you can write it directly to the output stream. This tag is useful to create URLs for HTML buttons, images, and other items such that when the URL is invoked, the state changes defined in the URL are applied to the given portlet.

The state tag has the following attributes:

- url = ”<context>/<portlet-name>”

  Identifies the portlet for this tag by using the context and portlet-name to address the portlet. This attribute is required.
- windowId = ”<any string>”

  Defines the window ID for the portlet URL created by this tag. This is attribute optional.
- var = ”<any string>”

  If defined the URL is written into a variable with the given scope and name, not to the output stream. This is attribute optional.
- scope = ”page|request|session|application”

  This attribute is only valid if the var attribute is specified. If defined, the URL is not written to the output stream but a variable is created in the given scope with the given name. The default is page. This is attribute optional.
- portletMode = ”view|help|edit|<custom>”

  This attribute sets the portlet mode.
- portletWindowState = ”maximized|minimized|normal|<custom>”

  This attribute sets the window state.
- action = ”true/false”

  This attribute defines whether this is an action URL. This is attribute optional. The default is false.

urlParam

Adds a render parameter to the newly created URL.

The urlParam tag has the following attributes:

- name = ”<any string>”

  Indicates the name of the parameter. This is attribute required.
- value = ”<any string>”

  Indicates the value of the parameter. This is attribute required.

insert

This tag calls the render method of the portlet and retrieves the content as well as the title. You can optionally place the content and title of the specified portlet into variables using the contentVar and titleVar attributes.

The insert tag has the following attributes:

- url = ”<context>/<portlet-name>” (mandatory) Identifies the portlet for this tag by using the context and portlet-name to address the portlet

  This is attribute required.
- windowId = ”<any string>”

  Defines the window ID of the portlet. This is attribute optional.
- contentVar = ”<any string>”

  If defined, the portlet’s content is not written to the output stream but written into a variable with the given scope and name. This is attribute optional.
- contentScope = ”page|request|session|application”

  This attribute is only valid if the contentVar tag is used. If defined, the portlet’s content is written into a variable with the given scope and name, not to the output stream. The default is page. This is attribute optional.
- titleVar = ”<any string>”

  If defined the portlet’s title is written into a variable with the given scope and name. If it is not defined, the title is ignored and not written to the output stream. This is attribute optional.
- titleScope = ”page|request|session|application”

This attribute is only valid if titleVar tag is used. If defined, the portlet's title is written into a variable with the given scope and name, not to the output stream. The default is page. This is attribute optional.

Example: Using the portlet aggregation tag library

You can use the aggregation tag library to aggregate multiple portlets to have multiple and different content on one page. The library can be used by every JavaServer Pages (JSP) file that has been included by a servlet.

To use the portlet aggregation tag library, you must declare the tag-lib at the top of the JSP file using, `<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>`, as in the following example. The following JSP file example shows how to aggregate portlets on one page.

```
<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>
<%@ page isELIgnored="false" import="java.util.Enumeration"%>

<portlet:init portletURLPrefix="/dummy/portletTagTest/" portletURLSuffix="/more" portletURLQueryParams="p1=v1&p2=v2">

   <portlet:insert url="worldclock/StdWorldClock" contentVar="worldclockcontent" titleVar="worldclocktitle"/>
    <portlet:state url="worldclock/StdWorldClock" portletMode="view" var="worldclockview"
       portletWindowState="maximized">
        <portlet:urlParam name="namea" value="valuea"/>
        <portlet:urlParam name="nameb" value="valueb"/>
    </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" portletMode="edit" var="worldclockedit" portletWindowState="normal">
        <portlet:urlParam name="name1" value="value1"/>
        <portlet:urlParam name="name2" value="value2"/>
    </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" portletMode="view" var="worldclockmin"
       portletWindowState="minimized">
        <portlet:urlParam name="namemin" value="valuemin"/>
        <portlet:urlParam name="namemin" value="valuemin"/>
    </portlet:state>

    <portlet:insert url="worldclock/StdWorldClock" windowId="min" contentVar="simplecontent" titleVar="simpletitle"/>
    <portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="view" var="simpleview"
  portletWindowState="maximized">
        <portlet:urlParam name="name3" value="value3"/>
        <portlet:urlParam name="name4" value="value4"/>
        <portlet:urlParam name="name5" value="value5"/>
        <portlet:urlParam name="name5" value="value5a"/>
        <portlet:urlParam name="name5" value="value5b"/>
        <portlet:urlParam name="name5" value="value5c"/>
    </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="edit" var="simpleedit"
  action="true" portletWindowState="normal">
        <portlet:urlParam name="name6" value="value6"/>
        <portlet:urlParam name="name6" value="value6z"/>
            </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="view" var="simplemin"
  portletWindowState="minimized">
        <portlet:urlParam name="name1" value="value1"/>
        <portlet:urlParam name="name2" value="value2"/>
    </portlet:state>

    <portlet:insert url="test/TestPortlet1" contentVar="testcontent" titleVar="testtitle"/>
    <portlet:state url="test/TestPortlet1" portletMode="view" var="testview" portletWindowState="maximized"/>
    <portlet:state url="test/TestPortlet1" portletMode="edit" var="testedit" portletWindowState="maximized"/>

<!--  This table is the outtermost table for creating two-column portal layout  -->

```

Portlet Uniform Resource Locator (URL) addressability

You can request a portlet directly through a Uniform Resource Locator (URL) to display its content without portal aggregation. The PortletServingServlet servlet registers each Web application that contains portlets. It is similar to the FileServingServlet servlet of the Web container that serves resources. The PortletServingServlet servlet supports direct rendering of portlets into a full browser page by a URL request.

You can invoke each portlet by its context root and name with the URL mapping /<portlet-name> that is created for each portlet. The context root and name has the following format:

```
http://<host>:<port>/<context-root>/<portlet-name> For example,
 http://localhost:9080/portlets/TestPortlet1
```

The context root identifies the Web archive (WAR) file that contains the portlet. The portlet name uniquely identifies the portlet with a portlet application of a WAR file. The DefaultDocumentFilter servlet only supports HTML, UTF8 encoding and an extended URL form based on the basic URL form as shown above.

You can only display one portlet at a time using the PortletServingServlet servlet. If you want to aggregate multiple portlets on the page, you need to use the aggregation tag library. See the article “Portlet aggregation using JavaServer Pages” on page 100 for additional information.

Because a portlet only delivers fragment output whereas a servlet usually delivers document output, a mechanism is introduced to convert the fragment into a document, called the PortletDocumentFilter filter. By default, the PortletDocumentFilter filter only supports converting HTML. The conversion is implemented using a servlet filter before the PortletServingServlet servlet is initiated to return the portlet's content inside of a document. This default document servlet filter only applies to URL requests, not for includes or forwards using the RequestDispatcher method. You can create servlet filters to support other markups additional document servlet filters. See the article, Converting portlet fragments to an HTML document, for additional information.

The PortletServingServlet servlet does not persist portlet preferences in a XML file or database. It places the portlet preferences directly into a cookie to store the preferences persistently. See the article, "Portlet preferences" on page 108, for additional information on how to change this behavior.

Portlet URL syntax

You can add additional portal context such as portlet mode or window state. You can access the PortletServingServlet servlet by using a URL mapping that has the following structure:

```
http://host:port/context/portlet-name [/portletwindow[/ver [/action |
 /resource[/id=custom-id][/cacheability]] [/mode] [/state] [rparam][/?name]]]
```

Any differing URL structure results in a com.ibm.wsspi.portletcontainer.InvalidURLException exception. Empty strings are not permitted as parameter values and creates an InvalidURLException exception. The following is a list of valid parameters:

http:// host:port/context/*portlet-name*
: This is the minimum URL required to access a portlet. A default portlet window called 'default' is created. The *portlet-name* variable is case-sensitive.

/portletwindow
: This parameter identifies the portlet window. You must set this parameter if you choose to add more portal context information to the URL.

/ver=*major.minor*
: This optional parameter is used to define the version of the portlet API that is used. You must set this parameter if you choose to add more portal context information to the URL. Only versions '1.0' and '2.0' are supported. Any other version creates an InvalidURLException exception.

/action
: This is a required parameter if you call the action method of the portlet. The action parameter causes the action process of the portlet to be called. After the action has been completed, a redirect is automatically issued to call the render process. To control the subsequent render process, a document servlet filter can set a request attribute with name 'com.ibm.websphere.portlet.action' and value 'redirect' to specify that the portlet serving servlet directly returns after action without calling the render process.

/mode=view | edit | help | *custom-mode*
: This optional parameter defines the portlet mode that is used to render the portlet. The default mode is 'view'. The value is not case-sensitive. For example, 'View', 'view' or 'VIEW' results in the same mode.

/state=normal | maximized | minimized | *custom-state*
: This optional parameter defines the window state that is used to render the portlet. The default state is 'normal'. The value is not case-sensitive, for example, 'Normal', 'normal', or 'NORMAL' results in the same state.

*** [/rparam=***name* ***[=***value***]]**
: This optional parameter specifies render parameters for the portlet. Repeat this parameter chain to provide more than one render parameter. For example, /rparam=invitation/ rparam=days=Monday=Tuesday.

?name=*value***&***name2***=***value2* **...**
Query parameters may follow optionally. They are not explicitly supported by the portlet container, but they do not invalidate the URL format.

/action | /resource
This parameter defines the methods of the portlet that is called. Valid values are no, action or resource parameter. No specific method defined calls the render method. The resource parameter is only supported for JSR 286 portlets.

/resource [/id=custom-id] [/cacheability=cacheLevelFull | cacheLevelPortlet | cacheLevelPage]
Set this parameter to define the method of the portlet to be called. No redirection occurs. No other method of the portlet is called. To control the resource parameter, you can add an additional ID parameter to provide a resource serving identifier that is passed through to the portlet. The cacheability parameter defines the cache level of this resource URL. This parameter is only supported with JSR 286 portlets .

The following list includes examples of valid JSR 168 and JSR 286 URLs:

- http:// your.server.name:9080/sample/WorldClock
- http:// your.server.name:9080/sample/WorldClock/myPortlet/ver=1.0/mode=edit/rparam=timezone=UTC
- http:// your.server.name:9080/sample/WorldClock/myPortlet/ver=1.0/action/state=maximized?timezone=UTC
- http://your.server.name:9080/sample/WorldClock/myPortlet/ver=2.0/resource/id=somePicture.jpg

Portlet preferences

Preferences are set by portlets to store customized information. By default, the PortletServingServlet servlet stores the portlet preferences for each portlet window in a cookie. However, you can change the location to store them in either a session, an .xml file, or a database.

Storing portlet preferences in cookies

The attributes of the cookie are defined as follows:

Path
context/*portlet-name*/*portletwindow*

Name:
The name of the cookie has the fixed value of **PortletPreferenceCookie**.

Value
The value of the cookie contains a list of preferences by mapping to the following structure:

```
*['/' pref-name *['=' pref-value]]
```

All preferences start with '/' followed by the name of the preference. If the preference has one or more values, the values follow the name separated by the '=' character. A null value is represented by the string '#*!0_NULL_0!*#'. As an example, the cookie value may look like, /locations=raleigh=boeblingen/regions=nc=bw

Customizing the portlet preferences storage

You can override how the cookie is handled to store preferences in a session, an .xml file or database. To customize the storage, you must create a filter, servlet or JavaServer Pages file as new entry point that wraps the request and response before calling the portlet. Examine the following example wrappers to understand how to change the behavior of the PortletServingServlet to store the preferences in a session instead of cookies.

The following is an example of how the main servlet manages the portlet invocation.

```
public class DispatchServlet extends HttpServlet
{
    ...
    public void service(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException
    {
 response.setContentType("text/html");

 // create wrappers to change preference storage
 RequestProxy req = new RequestProxy(request);
 ResponseProxy resp = new ResponseProxy(request, response);

 // create url prefix to always return to this servlet
                ...
                req.setAttribute("com.ibm.wsspi.portlet.url.prefix", urlPrefix);

 // prepare portlet url
 String portletPath = request.getPathInfo();
                ...

 // include portlet using wrappers
 RequestDispatcher rd = getServletContext().getRequestDispatcher(modifiedPortletPath);
                rd.include(req, resp);
    }
}
```

In the following example, the request wrapper changes the cookie handling to retrieve the preferences out of the session.

```
public class RequestWrapper extends HttpServletRequestWrapper
{
    ...
    public Cookie[] getCookies() {
        Cookie[] cookies = (Cookie[]) session.getAttribute("SessionPreferences");
        return cookies;
    }
}
```

In the following example, the response wrapper changes the cookie handling to store the preferences in the session:

```
public class ResponseProxy extends HttpServletResponseWrapper
{
   ...
    public void addCookie(Cookie cookie) {
        Cookie[] oldCookies = (Cookie[]) session.getAttribute("SessionPreferences");
        int newPos = (oldCookies == null) ? 0 : oldCookies.length;
        Cookie[] newCookies = new Cookie[newPos+1];
        session.setAttribute("SessionPreferences", newCookies);

        if (oldCookies != null) {
        System.arraycopy(oldCookies, 0, newCookies, 0, oldCookies.length);
        }
        newCookies[newPos] = cookie;
    }
}
```

Example: Configuring the extended portlet deployment descriptor to disable PortletServingServlet

Portlet URL serving supports direct access to all functions and states of a portlet by creating the appropriate URLs. In a production setup where the portlet is served through an enterprise portal application that applies its own access control, is considered a security risk. By setting the portletServingEnabled property to false, an administrator can ensure that a sensitive portlet is never accessed by direct URL serving.

Extensions for the portlet deployment descriptor are defined within a file called ibm-portlet-ext.xmi. This deployment descriptor is an optional descriptor that you can use to configure WebSphere extensions for the portlet application and its portlets. For example, you can disable the PortletServingServlet servlet for the portlet application in the extended portlet deployment descriptor.

The ibm-portlet-ext.xmi extension file is loaded during application startup. If there are no extension files specified with this setting, the default values of the portlet container are used.

The default for the portletServingEnabled attribute is true. The following is an example of how to configure the application so that a PortletServingServlet servlet is not created for any portlet on the portlet application.

```
<?xml version="1.0" encoding="UTF-8"?>
<portletappext:PortletApplicationExtension xmi:version="1.0"
    xmlns:xmi="http://www.omg.org/XMI"
    xmlns:portletappext="portletapplicationext.xmi"
    xmlns:portletapplication="portletapplication.xmi"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmi:id="PortletApp_ID_Ext"
    portletServingEnabled="false">
  <portletappext:portletApplication href="WEB-INF/portlet.xml#myPortletApp"/>
</portletappext:PortletApplicationExtension>
```

Portlet container custom properties

You can configure name-value pairs of data, where the name is a property key and the value is a string value that you can use to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console. The following is a list of the available Portlet container custom properties.

To specify Portlet container custom properties:

1. In the administrative console click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Portlet Container Settings** → **Portlet container**.
2. Under **Additional Properties** select **Custom Properties**.
3. On the Custom Properties page, click **New**.
4. On the settings page, enter the name of the custom property that you want to configure in the **Name** field and the value that you want to set it to in the **Value** field.
5. Click **Apply** or **OK**.
6. Click **Save** on the console task bar to save your configuration changes.
7. Restart the server.

Following is a list of custom properties provided with the Application Server.

Using short names for Portlet and PortletApplication MBeans

Portlet MBeans are registered by both their short name and full name. To enable the use of short MBean names, create the following name-value pair:

Name	Value
useShortMBeanNames	true

The default is false.

MBeans registered by the full identifiable name, have the following format:

```
<ApplicationName>#<WARfilename.war>_portlet.<portlet_name> for the Portlet MBean
<ApplicationName>#<WARfilename.war>_portlet for the PortletApplication MBean
```

where <..> is replaced by the corresponding application data. For example, `SampleApplication#SamplePortlet.war_portlet.SamplePortlet`.

Portlet and PortletApplication MBeans

The MBeans of type portlet and portletapplication provide information about a given portlet application and its portlets. Through the MBean of type portletapplication, you can retrieve a list of names of all portlets that belong to a portlet application. By querying the MBean of type portlet with a given portlet name, you can retrieve portlet specific information from the MBean of type portlet.

Each MBean that corresponds to a portlet or portlet application is uniquely identifiable by its name. Portlet applications are not required to have a name set within the portlet.xml. The MBean name for MBeans of the portletapplication type is the enterprise archive (EAR) file name followed by ″#″ and the Web module name concatenated with the string ″_portlet″. For example, portletapplication type MBeans have the following format:

```
<EarFileName>#<WarFileName>_portlet
```

The name chosen for the MBean of type portlet is the name of the MBean of type portletapplication that the portlet belongs to, concatenated with the portlet name:

```
<EarFileName>#<WarFileName>_portlet.<portletname>
```

The following is an example of the resulting PortletApplication MBean name and portlet names:

```
EarName            SampleEar
WebModule            SampleWar.war

PortletApplication MBean name:   SampleEar#SampleWar_portlet
Portlet:            SampleEar#SampleWar_portlet.BookmarkPortlet
```

The MBean names have been changed compared to version 6.1, because the old naming patterns are not unique and can lead to problems under certain circumstances. If you rely on the old naming pattern, you can set the portlet container custom property, `useShortMBeanNames`, to true to activate the previous known MBean names. Because this is a performance impact, you might not want to activate the old naming pattern if it is not necessary.

A full stop separates the preceding Web module name from the portlet name. Review the Portlet and PortletApplication MBean type API documentation for additional information. The generated API documentation is available in the information center table of contents from the path, **Reference** > **Administrator** > **API documentation** > **MBean interfaces**.

The following code is an example of how to invoke the MBean of type portletapplication for an application with the name, SampleWar.

```
String myPortletApplicationName = "SampleEar#SampleWar_portlet";
This name is composed by the Ear file name followed by "#" and
the Web module name concatenated with the substring "_portlet"

com.ibm.websphere.management.AdminService adminService =
  com.ibm.websphere.management.AdminServiceFactory.getAdminService();
javax.management.ObjectName on =
  new ObjectName("WebSphere:type=PortletApplication,name=" + myPortletApplicationName + ",*");

Iterator onIter = adminService.queryNames(on, null).iterator();
while(onIter.hasNext())
{
 on = (ObjectName)onIter.next();
}

String ctxRoot = (java.lang.String)adminService.getAttribute(on, "webApplicationContextRoot");
```

In the previous example, the MBeanServer is first queried for an MBean of type portletapplication. If this query is successful, the webApplicationContextRoot attribute is retrieved on that MBean or the first MBean that is found. The result is stored in the ctxRoot variable. This variable now contains the context root of the Web application that contains the portlet application that was searched. The variable is similar to ″/bookmark″.

The next code example demonstrates how to invoke the MBean of type portlet for a portlet with the name, BookmarkPortlet.

```
String myPortletName = "SampleEar#SampleWar_portlet.BookmarkPortlet";
This name is composed by the name of the MBean of type portletapplication and
the portlet name, separated by a full stop because the same portlet name may
be used within different Web modules, but must be unique within the system.

com.ibm.websphere.management.AdminService adminService =
  com.ibm.websphere.management.AdminServiceFactory.getAdminService();
javax.management.ObjectName on =
  new ObjectName("WebSphere:type=Portlet,name=" + myPortletName + ",*");
Iterator iter = adminService.queryNames(on, null).iterator();

while(iter.hasNext())
{
 on = (ObjectName)iter.next;
}

java.util.Locale locale = (java.util.Locale) adminService.getAttribute(on, "defaultLocale");
```

The locale returned by the method getAttribute method for the MBean is the default locale defined for this portlet.

Full names for Portlet and PortletApplication MBeans

MBeans are also registered by the full identifiable name:

```
<ApplicationName>#<WARfilename.war>_portlet.<portlet_name> for the Portlet MBean
<ApplicationName>#<WARfilename.war>_portlet for the PortletApplication MBean
```

where <..> is replaced by the corresponding application data. For example, `SampleApplication#SamplePortlet.war_portlet.SamplePortlet`. You can enable the short MBean names by setting the `useShortMBeanNames` portlet container custom property to true.

Portlet URL security

WebSphere Application Server enables direct access to portlet Uniform Resource Locators (URLs), just like servlets. This section describes security considerations when accessing portlets using URLs.

For security purposes, portlets are treated similar to servlets. Most portlet security uses the underlying servlet security mechanism. However, portlet security information resides in the `portlet.xml` file, while the servlet and JavaServer Pages files reside in the `web.xml` file. Also, when you make access decisions for portlets, the security information, if any, in the `web.xml` file is combined with the security information in the `portlet.xml` file.

Portlet security must support both programmatic security, that is `isUserInRole`, and declarative security. The programmatic security is exactly the same as for servlets. However, for portlets, the `isUserInRole` method uses the information from the security-role-ref element in `portlet.xml`. The other two methods used by programmatic security, `getRemoteUser` and `getUserPrincipal`, behave the same way as they do when accessing a servlet. Both of these methods return the authenticated user information accessing the portlet.

The declarative security aspect of the portlets is defined by the security-constraint information in the portlet.xml file. This is similar to the security-constraint information used for the servlets in the web.xml file with the following differences:

- The auth-constraint element, which lists the names of the roles that can access the resources, does not exist in the portlet.xml file. The portlet.xml file contains only the user-data-constraint element, which indicates what type of transport layer security (HTTP or HTTPS) is required to access the portlet.
- The security-constraint information in the portlet.xml file contains the portlet-collection element, while the web.xml file contains the web-resource-collection element. The portlet-collection element contains only a list of simple portlet names, while the web-resource-collection contains the url-patterns as well as the HTTP methods that need protection.

The portlet container does not deal with the user authentication directly. For example, it does not prompt you to collect the credential information. The portlet container must, instead, use the underlying servlet container for the user authentication mechanism. As a result, there is no auth-constraint element in the security-constraint information in the portlet.xml file.

In WebSphere Application Server, when a portlet is accessed using a URL, the user authentication is processed based on the security-constraint information for that portlet in the web.xml file. This implies that to authenticate a user for a portlet, the web.xml file must contain the security-constraint information for that portlet with the relevant auth-constraints contained in it. If a corresponding auth-constraint for the portlet does not exist in the web.xml file, it indicates that the portlet is not required to have authentication. In this case, unauthenticated access is permitted just like a URL pattern for a servlet that does not contain any auth-constraints in the web.xml file. An auth-constraint for a portlet can be specified directly by using the portlet name in the url-pattern element, or indirectly by a url-pattern that implies the portlet.

Note: You cannot have a servlet or JSP with the same name as a portlet for WebSphere Application Server security to work with portlet.

The following examples demonstrate how the security-constraint information contained in the portlet.xml and web.xml files in a portlet application are used to make security decisions for portlets. The security-role-ref element, which is used for isUserInRole calls, is not discussed here because it is used the same way for servlets.

In the examples below (unless otherwise noted), there are four portlets (MyPortlet1, MyPortlet2, MyPortlet3, MyPortlet4) defined in portlet.xml. The portlets are secured by combining the information, if any, in the web.xml file when they are accessed directly through URLs.

All of the examples show the contents of the web.xml and portlet.xml files. Use the correct tools when creating these deployment descriptor files as you normally would when assembling a portlet application.

Example 1: The web.xml file does not contain any security-constraint data

In the following example, the security-constraint information is contained in portlet.xml:

```
<security-constraint>
   <display-name>Secure Portlets</display-name>
   <portlet-collection>
   <portlet-name>MyPortlet1</portlet-name>
   <portlet-name>MyPortlet3</portlet-name>
   </portlet-collection>
   <user-data-constraint>
   <transport-guarantee>CONFIDENTIAL</transport-guarantee>
   </user-data-constraint>
</security-constraint>
```

In this example, when you access anything under MyPortlet1 and MyPortlet3, and these portlets are accessed using the unsecured HTTP protocol, you are redirected through the secure HTTPS protocol. The transport-guarantee is set to use secure connections. For MyPortlet2 and MyPortlet4, unsecured (HTTP)

access is permitted because the transport-guarantee is not set. There is no corresponding security-constraint information for all four portlets in the web.xml file. Therefore, all of the portlets can be accessed without any user authentication and role authorization. The only security involved in this instance is the transport-layer security using Secure Sockets Layer (SSL) for MyPortlet1 and MyPortlet3.

The following table lists the security constraints that are applicable to the individual portlets.

URL	Transport Protection	User Authentication	Role Based Authorization
/MyPortlet1/*	HTTPS	None	None
/MyPortlet2/*	None	None	None
/MyPortlet3/*	HTTPS	None	None
/MyPortlet4/*	None	None	None

Example 2: The web.xml file contains portlet specific security-constraint data

In the following example, the security-constraint information that corresponds to the portlet is contained in web.xml. The portlet.xml file is the same as that shown in the previous example.

```
<security-constraint id="SecurityConstraint_1">
    <web-resource-collection id="WebResourceCollection_1">
      <web-resource-name>Protected Area</web-resource-name>
      <url-pattern>/MyPortlet1/*</url-pattern>
      <url-pattern>/MyPortlet2/*</url-pattern>
      </web-resource-collection>
    <auth-constraint id="AuthConstraint_1">
      <role-name>Employee</role-name>
    </auth-constraint>
</security-constraint>
```

The security-constraint information contained in the web.xml file in this example indicates that the user authentication must be performed when accessing anything under the MyPortlet1 and MyPortlet2 portlets. When you attempt to access these portlets directly using URLs, and there is no authentication information available, you are prompted to enter their credentials. After you are authenticated, the authorization check is performed to see if you are listed in the Employee role. The user/group to role mapping is assigned during the portlet application deployment. In the web.xml file listed above, note the following:

- Because the web.xml file uses url-pattern, the portlet names have been modified slightly. MyPortlet1 is now /MyPortlet1/*, which indicates that everything under the MyPortlet1 URL is protected. This matches the information in the portlet.xml file because the security runtime code converts the portlet-name element in the portlet.xml file to url-pattern (for example, MyPortlet1 to /MyPortlet1/*), even for the transport-guarantee.
- The http-method element in the web.xml file is not used in the example because all HTTP methods must be protected.

The following table lists the new security constraints that are applicable to the individual portlets.

URL	Transport Protection	User Authentication	Role Based Authorization
MyPortlet1/*	HTTPS	Yes	Yes (Employee)
MyPortlet2/*	None	Yes	Yes (Employee)
MyPortlet3/*	HTTPS	None	None
MyPortlet4/*	None	None	None

Example 3: The web.xml file contains generic security-constraint data implying all portlets.

In the following example, the security-constraint information is contained in the web.xml file that corresponds to the portlet. The portlet.xml file is the same as that shown in the first example.

```
<security-constraint id="SecurityConstraint_1">
    <web-resource-collection id="WebResourceCollection_1">
      <web-resource-name>Protected Area</web-resource-name>
      <url-pattern>/*</url-pattern>
      </web-resource-collection>
    <auth-constraint id="AuthConstraint_1">
      <role-name>Manager</role-name>
    </auth-constraint>
    </security-constraint>
```

In this example, /* implies that all resources that do not contain their own explicit security-constraints should be protected by the Manager role as per the URL pattern matching rules. Because the portlet.xml file contains explicit security-constraint information for MyPortlet1 and MyPortlet3, these two portlets are not protected by the Manager role, only by the HTTPS transport. Because the portlet.xml file cannot contain the auth-constraint information, any portlets that contain security-contraints in it are rendered unprotected when an implying URL (/* for example) is listed in the web.xml file because of the URL matching rules.

In the case above, both MyPortlet1 and MyPortlet3 can be accessed without user authentication. However, because MyPortlet2 and MyPortlet4 do not have security-constraints in the portlet.xml file, the /* pattern is used to match these portlets and are protected by the Manager role, which requires user authentication.

The following table lists the new security constraints that are applicable to the individual portlets with this setup.

URL	Transport Protection	User Authentication	Role Based Authorization
MyPortlet1/*	HTTPS	None	None
MyPortlet2/*	None	Yes	Yes (Manager)
MyPortlet3/*	HTTPS	None	None
MyPortlet4/*	None	Yes	Yes (Manager)

If in the example above, if you must also protect a portlet contained in the portlet.xml file (for example, MyPortlet1), the web.xml file should contain an explicit security-constraint entry in addition to /* as shown in the following example:

```
<security-constraint id="SecurityConstraint_1">
         <web-resource-collection id="WebResourceCollection_1">
            <web-resource-name>Protected Area</web-resource-name>
            <url-pattern>/*</url-pattern>
            </web-resource-collection>
         <auth-constraint id="AuthConstraint_1">
            <role-name>Manager</role-name>
          </auth-constraint>
      </security-constraint>
      <security-constraint id="SecurityConstraint_2">
         <web-resource-collection id="WebResourceCollection_2">
            <web-resource-name>Protection for MyPortlet1</web-resource-name>
            <url-pattern>/MyPortlet1/*</url-pattern>
            </web-resource-collection>
         <auth-constraint id="AuthConstraint_1">
            <role-name>Manager</role-name>
          </auth-constraint>
      </security-constraint>
```

In this case, MyPortlet1 is protected by the Manager role and requires authentication. The data-constraint of CONFIDENTIAL is also applied to it because the information in the web.xml file and the portlet.xml file

are combined. Because MyPortlet3 is not explicitly listed in the `web.xml` file, it is still not protected by the Manager role and does not require user authentication.

The following table shows the effect of this change.

URL	Transport Protection	User Authentication	Role Based Authorization
MyPortlet1/*	HTTPS	Yes	Yes (Manager)
MyPortlet2/*	None	Yes	Yes (Manager)
MyPortlet3/*	HTTPS	None	None
MyPortlet4/*	None	Yes	Yes (Manager)

Developing console modules

Console modules are Web applications that are accessed from Integrated Solutions Console. Console modules provide the business logic and transaction processes that enable administration functions.

About this task

The following skills are essential for developing and testing console modules.

- Java Platform, Enterprise Edition (Java EE)
- XML
- Portlet development using the Java Portlet Specification (JSR 168)

The console also supports existing modules that have been developed using Struts and Tiles APIs. This is only for legacy support. New console modules are supported only if they are developed using standard portlet APIs.

- Review the console module samples. The sample console modules provide examples of portal application archives and how to use the APIs and other features.
- Set up the development environment. You need an integrated development environment (IDE) that supports Java development to quickly develop, test, and deploy your portlet applications.
- Develop your first console module. This topic is for developers new to console module development. It is assumed that you already have an IDE prepared. The topics in this section take you through the process of creating a simple console module. The console module in this exercise consists of a single portlet which is deployed to a single page as a member of the sample console modules provided by IBM. Be sure you have successfully deployed the sample console modules before starting.
- Adding advanced API features. The class files for console modules are developed using the portlet API of the Java Portlet Specification (JSR 168). Integrated Solutions Console includes additional APIs for launching pages, passing properties to other console modules, and launching Eclipse-based help. This topic provides information about the APIs available to console modules.

Overview of Integrated Solutions Console

Integrated Solutions Console offers several advantages for implementing administration functions, as described in this topic.

Integrated Solutions Console provides a single, common interface for system administration. It provides the main platform on which IBM and non-IBM products can build administrative user interfaces as individual plug-ins to a common console framework. Standardizing product administration functions to run on the Integrated Solutions Console platform gives them a more common look and feel and a more consistent behavior, thereby reducing the learning curve and adoption as new management components are introduced. Administrators can interact with multiple IBM and non-IBM products from a single browser-based console.

Consistency across administrative interfaces

Integrated Solutions Console provides a common appearance (for example, theme, layout and banner) and behavior (for example, navigation and authentication) to enable consistent user interaction for administering software products.

A standards-based architecture

Integrated Solutions Console provides a standards-based architecture for Web administration. Each Integrated Solutions Console module consists of one or more Web applications that have access to services within the Java Platform, Enterprise Edition (Java EE) environment provided by WebSphere Application Server. The help interface is implemented using the Eclipse open standard. Console modules are developed using the Java Portlet Specification.

Easy deployment of product administration consoles

The Integrated Solutions Console framework provides an XML-based interface for deploying console modules to a console installation. XML descriptors provide the information needed to deploy the portlet, resources, and setup the page layout and navigation in the console. A console module can be easily removed without impact to the remaining console modules.

Accelerated development of solutions

Using Integrated Solutions Console enables products to reduce the time required to develop solutions that require administration functions. The standards-based architecture, common framework, and support for existing investment help reduce the time required to implement solutions.

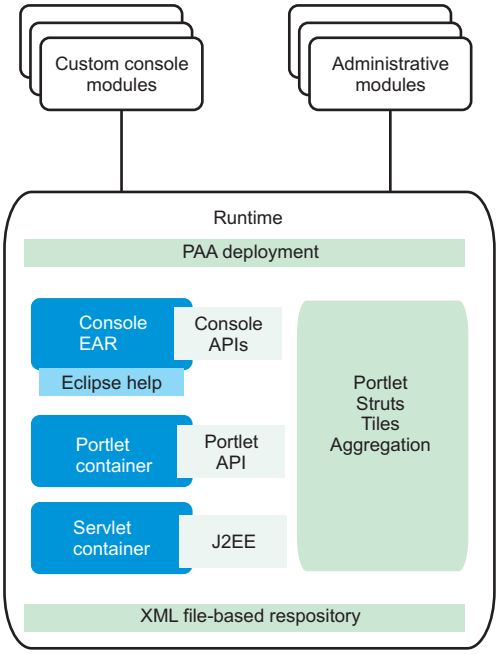
Improved administration efficiency

Customers invest significant resources in training administrative personnel. Providing a common interface across IBM products enables customers to reduce training time and expense.

Integrated Solutions Console components

This topic describes the components of the administrative console.

This figure illustrates the Integrated Solutions Console platform.



The following components and features support console modules running in Integrated Solutions Console.

- A common console

  Provides a common appearance and navigation behavior for console modules. For example, each portlet is rendered using a common skin, rendering the same title bar icons for actions such as editing preferences, maximizing, or requesting help for the portlet.
- Built-in administration console modules

  Provide security, log and trace, and other functions that apply to the entire the Integrated Solutions Console installation.
- A portlet container

  Supports portlets developed using the Java Portlet Specification. The current specification as of this writing is JSR 168.
- PAA deployment

  XML descriptors are provided for the developer to specify pages, navigation nodes, and access control for the console module, which are created at deployment. The descriptor can also register the following information about the console module.
  - Custom roles for the application in addition to the roles provided by the application server
  - An about page with links to useful information and resources for a product
  - A pointer to another console module that is the lead application for the product
  - Prerequisite applications and console modules that should be already deployed
  - Portlets that are already deployed on the server that should be reused for the console module
  - Multiple entities of a single portlet definition that can be used on different pages
  - External URLs that can be launched from the console navigation
  - Row and column layout of a page
  - Windows that contain portlets on the page
  - Empty windows on a page that are filled at runtime depending on the user's navigation selection
  - The order and nesting of navigation nodes used by the console module
  - Parent navigation nodes under which the navigation tree for the current console module are placed
  - Navigation nodes from other products that should be included under the current console module's navigation

- An application server

  Provides a complete Java runtime environment for console modules.
- APIs for console modules

  Supports the following actions:
  - Passing properties between portlets
  - Launching a page from a portlet
  - Invoking Eclipse-based help
- Eclipse Help

  Eclipse Help is provided as a Web application running on the same server as Integrated Solutions Console. Eclipse Help serves help documents for a single module as well as for the entire console.

What is new in Integrated Solutions Console

Learn about changes to the administrative console since the last release of WebSphere Application Server.

Customizing the banner

You can change the console banner to display custom text in the greeting. This could be useful, for example, in environments where you have multiple application servers and you want to make sure console users can determine which server they are administering. The same text is also displayed in the title bar of the browser window.

Administrative agent console

In environments that use the administrative agent to administer multiple application server nodes, you have a choice to select when logging in to the console. You can choose to log into the administrative agent or one of its registered profiles.

Example: Console module samples

The sample console modules provide examples of portal application archives and how to use the APIs and other features. These samples are available from the *Samples for WebSphere Application Server* page at the following location

http://www.ibm.com/developerworks/websphere/library/samples/index.html

These samples help understand the structure of a console module WAR package and the portal application descriptors that distinguish the application as a console module. After downloading the samples, follow the instructions in “Deploying a console module” on page 126. The following table lists the samples that are ready for deployment.

Sample	Description
Page layout (pagelayout.war)	Demonstrates how to specify the layout of console modules on a page using the elements of the portal topology descriptor. This sample shows how the lead application of a product provides an about page, which contains helpful information and resources about the product. The about page can be accessed from the console Welcome page. This module also demonstrates how to reuse a portlet from another module (Tree merge).
Tree merge (TreeMerge.war)	Demonstrates how a subordinate application deploys into the lead application for a product. The <PAA-ref/> element indicates the page layout sample as the lead application. Also, the <requires/> element indicates the page layout sample as a prerequisite that must already be deployed. The <parent-tree/> element merges the navigation nodes for the tree merge sample into the page layout navigation tree.

Sample	Description
Portlet context (PortletContext.war)	Demonstrates how to use the Dynamic UI Manager APIs to launch a page and how to pass properties to other console modules. The module receiving these properties can be on the same page or on another page.
Modes (Modes.war)	Demonstrates how to implement the Edit and Help modes in a module and how to invoke Eclipse-based help.
Basic module (Basicmodule.war)	Demonstrates how to implement basic module components.

Setting up the development environment

Set up your integrated development environment (IDE) for developing and debugging console modules.

You can use the Integrated Solutions Console Visual Designer feature to create the portal topology and security deployment descriptors needed to enable portlet applications to run in the administrative console environment. Visual Designer is available for download at http://www.ibm.com/support/docview.wss?rs=180&uid=swg24011666. This feature is supported using one of the following IDEs.

- IBM Application Server Toolkit, Version 6.1.1
- IBM Rational Application Developer, Version 7.0

After you download Visual Designer, you can install it to your development environment like any other feature. Refer to the documentation for your IDE for more information.

As you test your console modules, you might discover that changes that you make to the JSP files are not rendered when you log in to the application server. If so, you probably need to check the **reloadingEnabled** attribute in the extended deployment descriptor for the module (ibm-web-ext.xmi) Make sure this value is set to `true` to enable the JSP file to reload each time you deploy a new change. See the ″Hot deployment and dynamic reloading″ topic in the *Developing and deploying applications* PDF for more information.

Developing your first console module

Follow these steps if you are new to console module development.

Before you begin

You should have an integrated development environment (IDE) that supports Java programming setup. See “Setting up the development environment” for more information.

The topics in this section take you through the process of creating a simple console module. The sample console module consists of a single portlet which is deployed to a single page as part of the set of sample console modules provided by IBM. Be sure you have successfully deployed the sample console modules before starting.

- “Developing the portlet” on page 121
- “Creating the descriptors for the console module” on page 122
- “Packaging a console module” on page 125
- “Deploying a console module” on page 126
- “Testing a console module” on page 128
- “Removing a console module” on page 128

Developing the portlet

This topic is intended for developers who are unfamiliar with portlet development. A simple Java class and JSP are provided.

Developing the source Java class file

The following example shows the Java code for a portlet in its simplest form.

```
package com.ibm.isclite.samples.basicmodule;

import java.io.*;
import javax.portlet.*;

public class BasicModule extends GenericPortlet {

 public void doView(RenderRequest request, RenderResponse response)
             throws PortletException, IOException {
  // Set the MIME type for the render response
  response.setContentType("text/html");

        // Invoke the JSP to render
  PortletRequestDispatcher rd = getPortletContext().getRequestDispatcher("/jsp/basicView.jsp");
  rd.include(request,response);
 }

}
```

The portlet code must extend the GenericPortlet class and output for the response in the doView() method. Portlets are rendered in different modes. The initial mode when a portlet is called to render is the view mode. The response output is provided by a JSP, which provides markup that can be aggregated into a larger HTML page. The package name in this example is consistent with the console module samples.

Developing the JSP

The following shows a portlet JSP for view mode in its simplest form.

```
<%@ page language="java" contentType="text/html; charset=ISO-8859-1"
 pageEncoding="ISO-8859-1" session="false" buffer="none"%>
<%@ page import="javax.portlet.*" %>
<%@ taglib uri="http://java.sun.com/portlet" prefix="portletAPI" %>

<portletAPI:defineObjects />

<%
  PortletPreferences prefs = renderRequest.getPreferences();
  String URL = prefs.getValue("website","");
%>

<p><a name="<portletAPI:namespace/>basicAnchor">Basic contents</a></p>

<p>
  <a href="<%=URL%>" target="_blank">
    <img src='<%=renderResponse.encodeURL(renderRequest.getContextPath() + "/images/logo.gif")%>'
         alt="logo" />
      </a>
</p>
<p><em>Company logo with link.</em></p>
```

The taglib directive specifies the portlet tags from the Java Portlet Specification. The following tags are used in this example.

namespace
: Uniquely qualifies named HTML tags or JavaScript functions to prevent clashes with other portlets on the page using the same name.

defineObjects
Makes the RenderRequest, RenderResponse, and PortletConfig objects available to the JSP. This tag is used in this example so that the image can be rendered using the encodeURL() method of the render response, and to allow the JSP to read preferences in the portlet descriptor.

Creating the descriptors for the console module

Before you begin

The following descriptors are required for the console module.

- Web application descriptor (web.xml). This descriptor is required and described by the Java Servlet Specification.
- Portlet application descriptor (portlet.xml). This descriptor is required and described by the Java Portlet Specification. Refer to the console module samples for examples of how to create the portlet.xml.
- Portal topology descriptor (ibm-portal-topology.xml). This descriptor is unique to console modules and defines the portlets and resources in the module, how it is laid out on the page, and how it is accessed from the navigation.
- Portal security descriptor (ibm-portal-security.xml). This descriptor is unique to console modules and defines roles and access to navigation nodes and portlets.

About this task

The topology and security descriptors are the main component of console module packages that distinguish them from other portal application WAR files. The console module samples include these descriptors and demonstrate their features. The sample descriptors provide inline comments that explain the elements and how they are used.

For your first console module, you should use the Visual Designer plugin to the Application Server Toolkit to develop the descriptors. If you prefer to create them manually to become familiar with the structure of the XML, the steps in this topic show how to create simple descriptors that can be used to deploy an application into the samples provided by IBM. After following these steps, you should refer to the samples and the reference topics for the console module schemas for more complete information.

Portal topology descriptor

About this task

To follow these steps, open a file with the name ibm-portal-topology.xml in a text or XML editor and save each change at the end of each step.

1. Copy the following elements into ibm-portal-topology.xml. Some information is split on multiple lines for printing purposes.

```
<?xml version="1.0" encoding="UTF-8"?>

<ibm-portal-topology
    xmlns="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-topology.xsd"
    xmlns:base="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-base.xsd"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"

    xsi:schemaLocation="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-topology.xsd
ibm-portal-topology.xsd">

   <application-definition appID="com.ibm.isclite.samples.basicModule" version="6.1">

   </application-definition>
   <PAA-ref>com.ibm.isclite.samples.PageLayout</PAA-ref>

</ibm-portal-topology>
```

   - The elements in this step provide the top level content of the topology descriptor.

- Most of the content for this descriptor will be placed inside the <application-definition/> element.
- The value of the **appID** attribute is consistent with the naming convention used by the sample console modules. The **version** attribute matches the version used by the sample console modules.
- The <PAA-ref/> element specifies the **appID** of the page layout sample, which is the lead application to which this application will be deployed.
- The following convention is used for unique name for all of the elements in the descriptor.

  ```
  namespace + element_type + identifier
  ```

2. Create a title for your application. The title is the first element in the application definition element.

   ```
   <title>
         <base:nls-string lang="en">My basic module</base:nls-string>
   </title>
   ```

3. Place the component tree after the <requires/> element as shown.

   ```
   <component-tree uniqueName="com.ibm.isclite.samples.basicModule.appTree">
      <portlet-definition uniqueName="com.ibm.isclite.samples.basicModule.portletDefinition.A">
         <title>
            <base:nls-string lang="en">My basic module</base:nls-string>
         </title>
         <resource-link name="basicModule"
                        portletApplication="com.ibm.isclite.samples.basicmodule.BasicModule.01a"
                        type="static"/>
      </portlet-definition>
      <portlet-entity   uniqueName="com.ibm.isclite.samples.basicModule.portletEntity.A"
                        portletDefinitionRef="com.ibm.isclite.samples.basicModule.portletDefinition.A">
         <title>
            <base:nls-string lang="en">My basic module</base:nls-string>
         </title>
      </portlet-entity>
   </component-tree>
   ```

   - The **name** attribute of the <resource-link/> element must specify the <portlet-name/> from the portlet deployment descriptor.
   - The **portletApplication** attribute of the <resource-link/> element must specify the **id** attribute of the <portlet-app/> element from the portlet deployment descriptor.
   - The **portletDefinitionRef** attribute of the <portlet-entity/> element references the unique name of the <portlet-definition/>. Subsequent elements in this descriptor use the unique name of the <portlet-entity/> to invoke the portlet. Multiple portlet entities can point to the same portlet definition. For the purpose of this exercise, a single portlet definition is provided with a single portlet entity.
   - The portlet title that is rendered in this example is derived from the title in the portlet entity. If that value is not provided, the portlet title is rendered by the title provided by the <window/> element in the layout tree. If that value is also not provided, the title is obtained from the <portlet-name/> element in the portlet.xml for the portlet indicated by the <resource-link/>.

4. Place the layout tree after the component tree as shown.

   ```
   <layout-tree>
      <layout-element uniqueName="com.ibm.isclite.samples.basicModule.layoutElement.A">
         <title>
            <base:nls-string lang="en">My basic module</base:nls-string>
         </title>
         <simple-container orientation="row"
                           uniqueName="com.ibm.isclite.samples.basicModule.container.A">
            <window uniqueName="com.ibm.isclite.samples.basicModule.window.A">
               <title>
                  <base:nls-string lang="en">My basic module</base:nls-string>
               </title>
               <component-definition-ref>
                  com.ibm.isclite.samples.basicModule.portletEntity.A
               </component-definition-ref>
   ```

```
            </window>
         </simple-container>
      </layout-element>
   </layout-tree>
```

- Each layout element in the layout tree defines the layout of a page in the console.
- Each page can have nested containers, and each simple container can have multiple windows. Each simple container has either a row or column orientation. The nesting of these containers can create a complex table structure for the page layout.
- The <component-definition-ref/> element specifies the unique name of the portlet entity that provides the content of this window.

5. Create the navigation element after the layout tree as shown.

```
<navigation-element uniqueName="com.ibm.isclite.samples.navigationElement.basicModule"
                    layoutElementRef="com.ibm.isclite.samples.basicModule.layoutElement.A">
   <title>
      <base:nls-string lang="en">Basic Module Sample</base:nls-string>
   </title>
   <preference name="ProductFilter">
      <base:value>
         <base:string>com.ibm.isclite.samples.PageLayout</base:string>
      </base:value>
   </preference>
   <parent-tree parentTreeRef="com.ibm.isclite.samples.navigationElement.Samples"/>
</navigation-element>
```

- Each navigation element defines a node in the console navigation. If you nest the navigation elements, it creates a hierarchical tree structure that is reflected in the console navigation. For the purpose of this exercise, only a single navigation element is provided. The **layoutElementRef** attribute indicates the unique name of the layout element that is rendered on the page that is displayed when this element is selected by the console user.
- The content of the `ProductFilter` preference indicates the **appID** of the lead application. This is used to render this navigation element when the lead product is selected by the console user for filtering the navigation.
- The content of the **parentTreeRef** element indicates the unique name of the parent navigation element for this element.

The following figure shows how this navigation element is rendered with the page layout sample. In this figure, the user has selected `Integrated Solutions Console Sample` from the **View** selection list to filter the navigation.

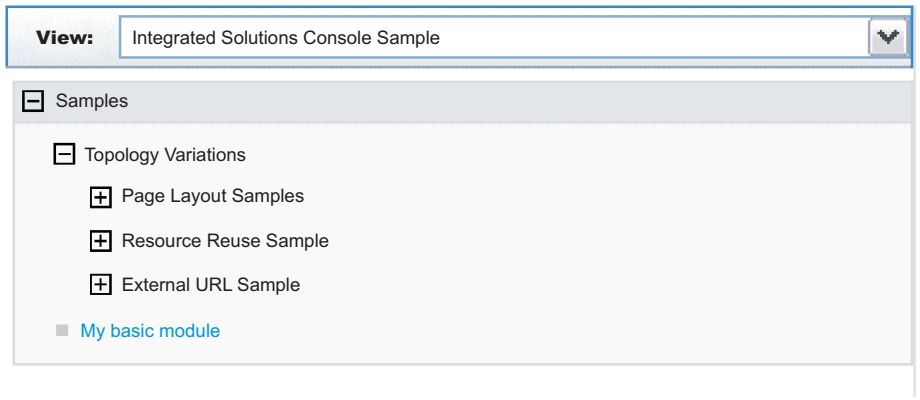


Figure 3. Sample console module navigation

What to do next

When you have finished, save and close the file and store in the /WEB-INF directory of your console module project.

Portal security descriptor
Before you begin

To follow these steps, open a file with the name ibm-portal-security.xml in a text or XML editor and save each change at the end of each step.

1. Copy the following elements into ibm-portal-security.xml. Some information is split on multiple lines for printing purposes.

```
<?xml version="1.0" encoding="UTF-8"?>

<ibm-portal-security
     xmlns="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-security.xsd"
     xmlns:base="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-base.xsd"
     xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"

xsi:schemaLocation="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-topology.xsd
ibm-portal-topology.xsd
         http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-base.xsd ibm-portal-base.xsd
         http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-security.xsd ibm-portal-security.xsd">

  </ibm-portal-security>
```

2. Add the <application-role/> element as the content of the <ibm-portal-security/> element.

```
<application-role uniqueName="monitor">

</application-role>
```

   This sample identifies the administrative role, `monitor`, for access rights. See Portal security schema for a complete description of this element and the uniqueName attribute.

3. Add the following <portal-role/> elements as the content of the application role.

```
<portal-role object-ref="com.ibm.isclite.samples.navigationElement.basicModule"/>
<portal-role object-ref="com.ibm.isclite.samples.basicModule.navigationElement.A"/>
<portal-role object-ref="com.ibm.isclite.samples.basicModule.portletEntity.A"
             role-type="Privileged User"/>
```

   This sample assigns permission to a user with monitor access to view two navigation elements and to view, edit, and access help for one portlet. See Portal security schema for a complete description of this element and its attributes.

What to do next

When you have finished, save and close the file and store in the /WEB-INF directory of your console module project.

Packaging a console module
Before you begin

Before you start this task, be sure your Java sources compiles without errors and the XML descriptors have been validated against the corresponding schemas.

About this task

An Integrated Solutions Console module must be packaged as a WAR file for deployment. For best results, use a comprehensive development tool such as Rational Application Developer. Otherwise, you can follow these steps to package your console module resources into the WAR file.

1. Create a working directory to collect all of the files that need to be packaged in the WAR file.
2. Organize your portlets and other resource files in the prescribed directory structure for portlet WAR files using the following steps:
   a. Place the following deployment descriptors in the directory /WEB-INF directory:
      - ibm-portal-topology.xml (topology descriptor)
      - ibm-portal-security.xml (security descriptor)
      - portlet.xml (portlet descriptor)
      - web.xml (Web application descriptor)
   b. Place individual Java classes for your portlets in the directory /WEB-INF/classes. Use a directory structure that reflects the fully-qualified class name of your portlet, for example, /com/ibm/isclite/samples/basicModule.
   c. Put JAR files in the directory /WEB-INF/lib.
   d. If the console module supports multiple languages, place the properties file that contains the translated strings (the resource bundles) in the directory /WEB-INF/classes/nls.
   e. Put any JavaServer Pages that must be served directly by the client in a directory that is not under the /WEB-INF directory (such /jsp). Resources in the /WEB-INF directory are protected and are not URL-addressable. JavaServer Pages that are accessed only by the portlets in the console module can be placed in the /WEB-INF path.
   f. If the console module has help files, copy the Eclipse help plug-in files to the directory /help/*plugin_name*, where *plugin_name* is the name of the Eclipse help plug-in, such as com.ibm.myprod.help.doc.
3. Use the Java JAR utility to create the WAR file. For instructions, see the Java Tutorial at http://java.sun.com/docs/books/tutorial/jar/basics/index.html . You can also use an assembly tool like Rational Application Developer to create the WAR file for the console module.

Deploying a console module

After you create the WAR file for a console module, you can deploy the console module to a system where the runtime for Integrated Solutions Console is installed and then test that the console module works correctly. Only one instance of a console module can be deployed on an Integrated Solutions Console installation. This rule applies even if the versions of the console module are different.

About this task

If you need to update the version of a console module, you must perform these steps.

1. Remove the console module.
2. Update the module with the required changes.
3. Reissue the deploy command.

To deploy a console module on a system where the runtime for Integrated Solutions Console is installed, perform the following procedure:

1. Go to the machine where the Integrated Solutions Console runtime is installed. You can also use a machine that has remote access to the drive where the runtime is installed.
2. Copy the console module WAR file to the *app_server_root*/systemApps/isclite.ear directory. As an alternative, you can extract the WAR file into a subdirectory of this location using the WAR file name for the subdirectory. For example, you would extract pagelayout.war to the *app_server_root*/systemApps/isclite.ear/pagelayout.war directory.
3. Grant the QEJBSVR profile the authority needed to complete the task. From an i5/OS command prompt, issue this command:

   ```
   CHGAUT OBJ('path_to_war') USER(QEJBSVR) DTAAUT(*RWX) OBJAUT(*ALL)
   ```

4. Start the wsadmin scripting client. If the server is not running, use the -conntype NONE option to run in local mode.

5. At the **wsadmin** command prompt, enter the command syntax. The following example presents the syntax:

```
$AdminApp update isclite modulefile {
-operation add
-contents path_to_war
-contenturi war_filename
-custom paavalidation=true
-custom containWebServices=true|false
-usedefaultbindings -contextroot /context
-MapWebModToVH {{.* .* admin_host}}
-MapModulesToServers {{.*  .*.war,.*  WebSphere:cell=cellname,node=nodename,server=servername}}}
```

Note:

- The values of the -contents and -contenturi options are case sensitive and should match the war file name that you are ready to deploy.
- Specifying `-custom paavalidation=true` causes the deployment to validate the XML descriptors for the console module package before deployment. This is optional.
- Set the option `-custom containWebServices=true` only if the package contains a Web service. This setting invokes more deployment processing to locate and setup the Web service. The default for this option is true. If the package does not contain any Web services, be sure to set this option to false for more efficient deployment.
- Use the -MapModulesToServers option when deploying to an agent profile.

For example:

```
$AdminApp update isclite modulefile {
-operation add
-contents app_server_root/systemApps/isclite.ear/pagelayout.war
-contenturi pagelayout.war
-custom paavalidation=true
-custom containWebServices=false
-usedefaultbindings  -contextroot /ibm/pagelayout
-contextroot /pagelayout
-MapWebModToVH {{.* .* admin_host}}
-MapModulesToServers {{.*  .*.war,.*  WebSphere:cell=cell_A,node=node_B,server=server_C}}}
```

The following messages are displayed if the deployment is successful.

```
Update of isclite has started.
ADMA5009I: An application archive is extracted at profile_root/wstemp/wstemp/app_10793d84b8e/ext/pagelayout.war
ADMA5064I: FileMergeTask completed successfully for isclite.
ADMA5005I: The application isclite is configured in the WebSphere Application Se
rver repository.
ADMA5005I: The application isclite is configured in the WebSphere Application Se
rver repository.
ADMA5110I: The application isclite is installed as a hidden application and will
 not be exposed via administrative interfaces such as GUI client, wsadmin or MBe
an Java API.  In order to perform management operations on this application, the
 application name must be known.
CWLAA10001I: The Integrated Solutions Console module was deployed successfully.
ADMA5005I: The application isclite is configured in the WebSphere Application Se
rver repository.
ADMA5011I: The cleanup of the temp directory for application isclite is complete
.
Update of isclite has ended.
```

6. After the deployment has completed successfully, save your work by issuing the following command:

```
$AdminConfig save
```

Results

If the deployment is successful, the WAR file contents are extracted to the /systemApps/isclite.war directory and the module metadata is copied to the following directory:

profile_root/config/cells/*cellname*/applications/isclite.ear/deployments/isclite

To view your console module, you must log back in to the console. Make sure the navigation is updated correctly. If so, select the new navigation nodes verify that the new pages and console modules are rendered correctly.

Testing a console module
About this task

Use the following checklist to test your console module after it has been deployed.

1. Log in to Integrated Solutions Console as an administrator.
2. If the module includes an <about-page/> element in the topology descriptor, verify that your suite and its version are listed in the table on the Welcome page. Also confirm that the product is listed in the **View** selection list for the navigation.
3. Verify that the console navigation tree contains all of the organizational nodes and pages that were defined. Verify that each node is at the correct level in the tree.
4. For each page, verify that the portlets on the page work correctly. If a portlet on the page launches a new page in work area, verify that the launching works correctly.
5. To test the access permissions specified in the console module descriptor, logout and then log in as a different user to verify that the correct pages are accessible.
6. If the console module included a help plug-in, make sure you can launch the help.
7. If the console module contains errors, refer to the SystemOut.log and SystemErr.log for any errors or messages. These logs are located in the following directory:

   profile_root/logs/server1

Removing a console module
About this task

Follow these steps to delete a console module.

1. Ensure that the server is started. You do not need to log in to the console.
2. Start the wsadmin scripting client.
3. Enter the following command from the wsadmin command prompt.

   ```
   $AdminApp update isclite modulefile {-operation delete -contenturi module_file_name.war}
   ```
4. Save your configuration changes.

   ```
   $AdminConfig save
   ```
5. Exit the wsadmin command environment.

   ```
   quit
   ```

Adding advanced API features

The class files for console modules are developed using the Java Portlet Specification. Integrated Solutions Console includes additional APIs for launching pages, passing properties to other portlets, and launching Eclipse-based help. This section provides information about the APIs available to console modules.

Developing portlets

Console modules are portlets that run in the portlet container of WebSphere Application Server.

Integrated Solutions Console supports console modules written to the Java Portlet Specification. A packaged console module WAR file contains one or more portlets or reuses portlets from other modules. According to the JSR 168 specification, a *portlet* is a Java technology based Web component, managed

by a portlet container, that processes requests and generates content that contributes to the overall portal page. Portlets share many of the same characteristics as servlets. However, portlets also exhibit differences. For example, portlets cannot set HTTP headers and can contribute only markup fragments to the portal page. The portlet specification leverages the functionality of the servlet specification as much as possible, and many parts of the Java Portlet Specification have been modeled after the servlet specification.

The application server includes a JSR 168-compliant portlet container to support deploying and running console modules in Integrated Solutions Console. The JSR 168 portlet container relies on the Java Platform, Enterprise Edition (Java EE) architecture implemented by the application server. Consequently, an Integrated Solutions Console module and its portlets are packaged and deployed similar to Java EE Web applications. In addition to the Web application descriptor and the portlet descriptor, the WAR file for an Integrated Solutions Console module includes additional descriptors needed to deploy the application to a console installation.

The following Web resources can useful for learning more about portlet development.

Resource	Web site URL

Launching pages

Typically, users of the console launch pages using the links in the console navigation. However, portlets in a console module also launch pages directly using the Dynamic UI Manager API.

The DynamicUI Manager APIs are provided by 3 services: PropertyFactory, DynamicUIManagerFactoryService, and URLGeneratorFactoryService. To use these services the portlet must first perform a JNDI lookup to get the PortletServiceHome object which you then can use to get the actual service interface object. This is demonstrated in the GetApps portlet of the PortletContext sample.. The following code is placed in a `try` block of the portlet's init() method.

Some information is split on multiple lines for printing purposes.

```
Context ctx = new InitialContext(com.ibm.portal.jndi.Constants.ENV);
// get propertyfactory service

propertyFactoryServiceHome = (PortletServiceHome)ctx.lookup("iscportletservice/com.ibm.portal.
propertybroker.service.PropertyBrokerService");
if (propertyFactoryServiceHome == null)
   logger.log(Level.FINE, "no PropertyBrokerService propertyFactoryServiceHome");
else
   propertyFactoryService =

      (PropertyFactory)propertyFactoryServiceHome.getPortletService(com.ibm.portal.
propertybroker.service.PropertyBrokerService.class);
logger.log(Level.FINE, "propertyBrokerService="+propertyFactoryService);
```

```
// get dynamicUIManagerFactory service
dynamicUIManagerFactoryServiceHome =
   (PortletServiceHome)ctx.lookup("iscportletservice/com.ibm.portal.portlet.service.DynamicUIManagerFactoryService");
if (dynamicUIManagerFactoryServiceHome == null)
   logger.log(Level.FINE, "no dynamicUIManagerFactoryService propertyFactoryServiceHome");
else
   dynamicUIManagerFactoryService =

      (DynamicUIManagerFactoryService)dynamicUIManagerFactoryServiceHome.getPortletService
(com.ibm.portal.portlet.service.DynamicUIManagerFactoryService.class);
logger.log(Level.FINE, "dynamicUIManagerFactoryService="+dynamicUIManagerFactoryService);
// get urlGeneratorFactory service
urlGeneratorFactoryServiceHome =
   (PortletServiceHome)ctx.lookup("iscportletservice/com.ibm.portal.portlet.service.URLGeneratorFactoryService");
if (urlGeneratorFactoryServiceHome == null)
   logger.log(Level.FINE, "no urlGeneratorFactoryService propertyFactoryServiceHome");
else
   urlGeneratorFactoryService =

      (URLGeneratorFactoryService) urlGeneratorFactoryServiceHome.getPortletService
(com.ibm.portal.portlet.service.URLGeneratorFactoryService.class);
logger.log(Level.FINE, "urlGeneratorFactoryService="+urlGeneratorFactoryService);
```

A portlet can launch a new page using the dynamicUICtrl interface, passing the object ID of the page definition for the new page. The object ID is determined by performing a JNDI lookup on the unique name of the navigation element that launches the page. If you are planning to launch a navigation element, the navigation node must point to a layout element. In other words the navigation element must contain the l**ayoutElementRef** attribute. The addPage() method returns the object ID of the page instance, which should be saved by the portlet to create a URL and launch the page. The following excerpt from the PortletContext sample demonstrates how this works. The portlet GetApps.java includes a launchPage() method with this code.

```
Context ctx;
ObjectID pageDefinitionID = null;
String pagename="com.ibm.isclite.portletcontext.navigationElement.B";
logger.log(Level.FINE, "launch page=" + pagename);

PortletSession ps  = request.getPortletSession(false);
try {
    ctx = new InitialContext();
    pageDefinitionID =(ObjectID)ctx.lookup("portal:uniquename/"+pagename);
} catch (NamingException ne) {
    return;
}
try {
    PropertyController cproperty = propertyFactoryService.createProperty(myconfig);
    PropertyController cproperty2 = propertyFactoryService.createProperty(myconfig);

    cproperty.setType("String");
    cproperty.setName("servername");
    cproperty2.setType("String");
    cproperty2.setName("appDeployed");
    PropertyValue[] propertyValues = new PropertyValue[2];
    propertyValues[0] =
        propertyFactoryService.createPropertyValue(request, cproperty, serverName);
    propertyValues[1] =
        propertyFactoryService.createPropertyValue(request, cproperty2, appDeployed);

    DynamicUICtrl dmanagerCtrl =
       dynamicUIManagerFactoryService.getDynamicUICtrl(request, response, "isc.tasklaunch");

    ObjectID newPageID =
        dmanagerCtrl.addPage(pageDefinitionID, null, propertyValues);

    RedirectURLGenerator urlGenerator =
        urlGeneratorFactoryService.getURLGenerator(request, response);
```

```
    EngineURL redirectURL = urlGenerator.createPageURL(newPageID);

    response.sendRedirect(redirectURL.toString());
} catch  ...
```

- The `pagename` String is created with the unique name of the navigation element (from the topology descriptor) that launches the page.
- The object ID is found by performing a JNDI lookup on this Context instance using this String:

  ```
  "portal:uniquename/"+pagename
  ```

  The String `portal:uniquename/` is required to obtain the object ID for the navigation element.
- Properties are created to be passed to the portlets on the page. The property names are `servername` and `appDeployed`.
- In addition to the request and response, you must include the String `isc.tasklaunch` as the configuration name on the getDynamicUICtrl() method.
- Use the addPage() method of the new DynamicUICtrl instance to create and instance of the page. Any properties that need to be passed to portlets on the new page must be provided in this method. The addPage() method does not launch the page, but it returns the object ID of the page instance. The next two methods, getURLGenerator() and createPageURL(), are used to construct the URL that opens the page. The URL contains property names and values if they have been provided.
- The URL to open the page is provided on the sendRedirect() method of the response.

Passing properties to other portlets

This topic describes how portlets can exchange properties. You should be familiar with the concepts for launching console pages before reading this topic.

Information can be provided to portlets on the same page using the addSharedPortlet() method. Property values are of the type com.ibm.portal.propertybroker.property.PropertyValue. The example in “Launching pages” on page 129 shows these properties passed to the page using an instance of the PropertyValue interface (`propertyValues`) and shows how that object was created using the PropertyFactory interface.

The SetServer.java source from the PortletContext sample shows how to pass properties to a portlet on the same page. It is assumed that the portlet has already performed a JNDI lookup to determine that the PropertyFactory, DynamicUIManagerFactoryService, and URLGeneratorFactoryService services are available. This is described in “Launching pages” on page 129

- In this example, the portlet that is the source of the properties needs the object ID of the target portlet. The object ID is determined by performing a JNDI lookup using the values from the portlet’s <resource-link/> element in the topology descriptor.
- The property, `cproperty`, is created using the PropertyController interface and the createProperty() method of the PropertyFactory interface. The data type for the property must be a String.
- Prior to sending the property, the source portlet creates an instance of the DynamicUICtrl interface, passing the string ″isc.tasklaunch″ as the configuration name.
- The addSharedPortlet() method sends the properties to the target portlet on the request. After the action phase, the target portlet updates the output for the response.

```
Context ctx = null;
ObjectID portletDefinitionID1 = null;
ObjectID portletDefinitionID2 = null;

String portletname1="com.ibm.isclite.samples.PortletContext/PortletGetPerformance";
String portletname2="com.ibm.isclite.samples.PortletContext/PortletGetApps";

PortletSession ps  = request.getPortletSession(false);

try
   {
```

```
      ctx = new InitialContext(com.ibm.portal.jndi.Constants.ENV);
      portletDefinitionID1 =
         (ObjectID)ctx.lookup("portal:config/portletdefinition/"+portletname1);
      portletDefinitionID2 =
         (ObjectID)ctx.lookup("portal:config/portletdefinition/"+portletname2);
   } catch (NamingException ne)
     {
        logger.log(Level.FINE, "portletdefinitionID not found - Naming exception:"+ne.getMessage());
        return;
     }
logger.log(Level.FINE, "portletdefinitionID="+portletDefinitionID1.toString());

try
{
   PropertyController cproperty =
      propertyFactoryService.createProperty(myconfig);
   cproperty.setType("String");

   PropertyValue[] propertyValues = new PropertyValue[1];
   propertyValues[0] =
      propertyFactoryService.createPropertyValue(request, cproperty, serverName);

   DynamicUICtrl dmanagerCtrl =
      dynamicUIManagerFactoryService.getDynamicUICtrl(request, response, "isc.tasklaunch");

   ObjectID newPortletID1 =
      dmanagerCtrl.addSharedPortlet(portletDefinitionID1, null, propertyValues);
   ObjectID newPortletID2 =
      dmanagerCtrl.addSharedPortlet(portletDefinitionID2, null, propertyValues);

      logger.log(Level.FINE, "portlet ID created:"+newPortletID1.getOID());
    } catch ...
```

In some cases, the target portlet might be on a separate page. In this case, the properties are passed using the addPage() method. The target portlet receives the properties only when the page is launched that contains the portlet. If a property value is set multiple times before the page is launched, the value that was set last for the property is passed to the portlets on the page. You can use the URLGeneratorFactoryService interface to redirect the console to the page for the target portlet. This is demonstrated in the GetApps portlet of the PortletContext sample.

```
ObjectID newPageID = dmanagerCtrl.addPage(pageDefinitionID, null, propertyValues);
RedirectURLGenerator urlGenerator = urlGeneratorFactoryService.getURLGenerator(request, response);
EngineURL redirectURL = urlGenerator.createPageURL(newPageID);
response.sendRedirect(redirectURL.toString());
```

To use the URLGeneratorFactoryService, the portlet must first perform a JNDI lookup for this portlet service. Refer to the GetApps.java source to see how to obtain a reference to the portlet service.

Receiving properties

To receive properties, the target portlet must provide the `com.ibm.portal.pagecontext.enable` preference parameter in the portlet.xml with a value of true. If the portlet should receive any subsequent updates, the `com.ibm.portal.context.enable` read-only preference should also be set to true. Only String property types are supported and the context is passed as parameters of the action request. The following example shows how the GetApps portlet receives properties passed by the SetServer portlet.

```
public void processAction(ActionRequest request, ActionResponse response)
       throws PortletException, IOException {

        PortletSession ps = request.getPortletSession(true);
        appDeployed = request.getParameter("appDeployed");
        serverName=request.getParameter("servername");

        ps.setAttribute("servername",serverName);
```

```
        ps.setAttribute("appDeployed",appDeployed);
        launchPage(request, response);

    }
```

A target portlet can check `com.ibm.portal.action` parameter of the request during action processing to determine if any properties have been passed. If properties are being passed to the portlet, the value of this parameter is `com.ibm.portal.pagecontext.receive`. For example:

```
String action = req.getParameter(com.ibm.portal.action.name);
if (action!=null && action.equalsIgnoreCase("com.ibm.portal.pagecontext.receive")) {

  // code to get the properties as a parameter on the request

}
```

Launching Eclipse-based help

If your console module contains a portlet that requires a help page, follow the instructions in this topic to implement help for the portlet.

About this task

To implement portlet help, you use the portlet's doHelp() method, the EclipseHelp class, and the help setting in the portlet.xml file. Inside the doHelp() method, link to the target help topic in your Eclipse help plug-in by using the portletHelp() method of the EclipseHelp class. By including a doHelp() method in your portlet and adding the help setting to the portlet.xml file, you enable the portlet help mode. When portlet help mode is enabled, the ? icon is displayed on the portlet title bar. When a user clicks the icon, a separate browser window opens and displays only that help topic.

The Modes sample (modes.war) demonstrates how a console module can provide user assistance or help. This sample is described in "Example: Console module samples" on page 119.

1. Add the doHelp() method to your portlet.
   a. In the portlet Java file, include the following import statement:
      ```
      import com.ibm.portal.help.EclipseHelp;
      ```
   b. Implement the doHelp() method in the portlet.
      ```
      public void doHelp(RenderRequest request, RenderResponse response)
             throws PortletException, IOException {

      }
      ```
   c. Create a String in the deHelp() method to contain the help topic. The syntax for specifying a help topic is *pluginID*/*file_path*/*file_name*, where *pluginID* is the Eclipse help plug-in ID as specified in its plugin.xml file, *file_path* is the sub-directory path (if any), and *file_name* is the filename and extension of the help content file.
      ```
      public void doHelp(RenderRequest request, RenderResponse response)
             throws PortletException, IOException {

         String topic = "com.ibm.isc.help.modes/help_mode.html";
      }
      ```
   d. Call the method EclipseHelp.portletHelp() passing in the request, response, and topic as shown in the code snippet below.
      ```
      public void doHelp(RenderRequest request, RenderResponse response)
             throws PortletException, IOException{

         String topic = "com.ibm.isc.help.modes/help_mode.html";
        EclipseHelp.portletHelp(request, response, topic);

      }
      ```

2. Set help mode in the portlet.xml file.
   a. Use a text editor to open the portlet deployment descriptor (the portlet.xml file). See topics under Developing portlets for more information about creating a portlet.xml file.
   b. Inside the <portlet-app> element, locate the <portlet> element for the portlet that implements the doHelp() method.
3. Inside the <supports> sub-element, add a <portlet-mode> element like the one shown in the following example.

```
<?xml version="1.0" encoding="UTF-8"?>
<portlet-app xmlns="http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd"
             version="1.0" id="com.ibm.isclite.samples.Modes"
             xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
             xsi:schemaLocation="http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd
                                 http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd">
   <portlet id="Modes_Portlet" >
      <portlet-name>ModesPortlet</portlet-name>
      <display-name>Modes portlet1 (JSR 168)</display-name>
      <display-name xml:lang="en">Modes portlet1 (JSR 168)</display-name>
      <portlet-class>com.ibm.isclite.samples.Modes</portlet-class>
      <expiration-cache>0</expiration-cache>
      <supports>
         <mime-type>text/html</mime-type>
         <portlet-mode>VIEW</portlet-mode>
         <portlet-mode>EDIT</portlet-mode>
         <portlet-mode>HELP</portlet-mode>
      </supports>
      <supported-locale>en</supported-locale>
      <resource-bundle>nls.HTML</resource-bundle>
   </portlet>

</portlet-app>
```

4. When packaging the console module, place the Eclipse help plugin in the /help directory of the WAR file. See “Packaging a console module” on page 125 for more information.

Support for bidirectional characters

Integrated Solutions Console supports bidirectional text. If your console module provides support for Hebrew, it must provide two identical resource bundles for the translated Strings. The file name for one resource bundle must be appended with the `_iw` suffix and the other resource bundle must be appended with the `_he` suffix. For example:

```
portlet_iw.properties
portlet_he.properties
```

Developing your first console module

Follow these steps if you are new to console module development.

Before you begin

You should have an integrated development environment (IDE) that supports Java programming setup. See “Setting up the development environment” on page 120 for more information.

The topics in this section take you through the process of creating a simple console module. The sample console module consists of a single portlet which is deployed to a single page as part of the set of sample console modules provided by IBM. Be sure you have successfully deployed the sample console modules before starting.

Developing the portlet

This topic is intended for developers who are unfamiliar with portlet development. A simple Java class and JSP are provided.

Developing the source Java class file

The following example shows the Java code for a portlet in its simplest form.

```
package com.ibm.isclite.samples.basicmodule;

import java.io.*;
import javax.portlet.*;

public class BasicModule extends GenericPortlet {

 public void doView(RenderRequest request, RenderResponse response)
             throws PortletException, IOException {
  // Set the MIME type for the render response
  response.setContentType("text/html");

        // Invoke the JSP to render
  PortletRequestDispatcher rd = getPortletContext().getRequestDispatcher("/jsp/basicView.jsp");
  rd.include(request,response);
 }

}
```

The portlet code must extend the GenericPortlet class and output for the response in the doView() method. Portlets are rendered in different modes. The initial mode when a portlet is called to render is the view mode. The response output is provided by a JSP, which provides markup that can be aggregated into a larger HTML page. The package name in this example is consistent with the console module samples.

Developing the JSP

The following shows a portlet JSP for view mode in its simplest form.

```
<%@ page language="java" contentType="text/html; charset=ISO-8859-1"
 pageEncoding="ISO-8859-1" session="false" buffer="none"%>
<%@ page import="javax.portlet.*" %>
<%@ taglib uri="http://java.sun.com/portlet" prefix="portletAPI" %>

<portletAPI:defineObjects />

<%
  PortletPreferences prefs = renderRequest.getPreferences();
  String URL = prefs.getValue("website","");
%>

<p><a name="<portletAPI:namespace/>basicAnchor">Basic contents</a></p>

<p>
  <a href="<%=URL%>" target="_blank">
    <img src='<%=renderResponse.encodeURL(renderRequest.getContextPath() + "/images/logo.gif")%>'
         alt="logo" />
      </a>
</p>
<p><em>Company logo with link.</em></p>
```

The taglib directive specifies the portlet tags from the Java Portlet Specification. The following tags are used in this example.

namespace
Uniquely qualifies named HTML tags or JavaScript functions to prevent clashes with other portlets on the page using the same name.

defineObjects
Makes the RenderRequest, RenderResponse, and PortletConfig objects available to the JSP. This tag is used in this example so that the image can be rendered using the encodeURL() method of the render response, and to allow the JSP to read preferences in the portlet descriptor.

Creating the descriptors for the console module
Before you begin

The following descriptors are required for the console module.

- Web application descriptor (web.xml). This descriptor is required and described by the Java Servlet Specification.
- Portlet application descriptor (portlet.xml). This descriptor is required and described by the Java Portlet Specification. Refer to the console module samples for examples of how to create the portlet.xml.
- Portal topology descriptor (ibm-portal-topology.xml). This descriptor is unique to console modules and defines the portlets and resources in the module, how it is laid out on the page, and how it is accessed from the navigation.
- Portal security descriptor (ibm-portal-security.xml). This descriptor is unique to console modules and defines roles and access to navigation nodes and portlets.

About this task

The topology and security descriptors are the main component of console module packages that distinguish them from other portal application WAR files. The console module samples include these descriptors and demonstrate their features. The sample descriptors provide inline comments that explain the elements and how they are used.

For your first console module, you should use the Visual Designer plugin to the Application Server Toolkit to develop the descriptors. If you prefer to create them manually to become familiar with the structure of the XML, the steps in this topic show how to create simple descriptors that can be used to deploy an application into the samples provided by IBM. After following these steps, you should refer to the samples and the reference topics for the console module schemas for more complete information.

Portal topology descriptor
About this task

To follow these steps, open a file with the name ibm-portal-topology.xml in a text or XML editor and save each change at the end of each step.

1. Copy the following elements into ibm-portal-topology.xml. Some information is split on multiple lines for printing purposes.

```
<?xml version="1.0" encoding="UTF-8"?>

<ibm-portal-topology
    xmlns="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-topology.xsd"
    xmlns:base="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-base.xsd"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"

    xsi:schemaLocation="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-topology.xsd
ibm-portal-topology.xsd">

   <application-definition appID="com.ibm.isclite.samples.basicModule" version="6.1">
```

```
   </application-definition>
   <PAA-ref>com.ibm.isclite.samples.PageLayout</PAA-ref>

</ibm-portal-topology>
```

- The elements in this step provide the top level content of the topology descriptor.
- Most of the content for this descriptor will be placed inside the <application-definition/> element.
- The value of the **appID** attribute is consistent with the naming convention used by the sample console modules. The **version** attribute matches the version used by the sample console modules.
- The <PAA-ref/> element specifies the **appID** of the page layout sample, which is the lead application to which this application will be deployed.
- The following convention is used for unique name for all of the elements in the descriptor.

```
namespace + element_type + identifier
```

2. Create a title for your application. The title is the first element in the application definition element.

```
<title>
      <base:nls-string lang="en">My basic module</base:nls-string>
</title>
```

3. Place the component tree after the <requires/> element as shown.

```
<component-tree uniqueName="com.ibm.isclite.samples.basicModule.appTree">
   <portlet-definition uniqueName="com.ibm.isclite.samples.basicModule.portletDefinition.A">
      <title>
         <base:nls-string lang="en">My basic module</base:nls-string>
      </title>
      <resource-link name="basicModule"
                     portletApplication="com.ibm.isclite.samples.basicmodule.BasicModule.01a"
                     type="static"/>
   </portlet-definition>
   <portlet-entity   uniqueName="com.ibm.isclite.samples.basicModule.portletEntity.A"
                     portletDefinitionRef="com.ibm.isclite.samples.basicModule.portletDefinition.A">
      <title>
         <base:nls-string lang="en">My basic module</base:nls-string>
      </title>
   </portlet-entity>
</component-tree>
```

- The **name** attribute of the <resource-link/> element must specify the <portlet-name/> from the portlet deployment descriptor.
- The **portletApplication** attribute of the <resource-link/> element must specify the **id** attribute of the <portlet-app/> element from the portlet deployment descriptor.
- The **portletDefinitionRef** attribute of the <portlet-entity/> element references the unique name of the <portlet-definition/>. Subsequent elements in this descriptor use the unique name of the <portlet-entity/> to invoke the portlet. Multiple portlet entities can point to the same portlet definition. For the purpose of this exercise, a single portlet definition is provided with a single portlet entity.
- The portlet title that is rendered in this example is derived from the title in the portlet entity. If that value is not provided, the portlet title is rendered by the title provided by the <window/> element in the layout tree. If that value is also not provided, the title is obtained from the <portlet-name/> element in the portlet.xml for the portlet indicated by the <resource-link/>.

4. Place the layout tree after the component tree as shown.

```
<layout-tree>
   <layout-element uniqueName="com.ibm.isclite.samples.basicModule.layoutElement.A">
      <title>
         <base:nls-string lang="en">My basic module</base:nls-string>
      </title>
      <simple-container orientation="row"
                        uniqueName="com.ibm.isclite.samples.basicModule.container.A">
         <window uniqueName="com.ibm.isclite.samples.basicModule.window.A">
            <title>
               <base:nls-string lang="en">My basic module</base:nls-string>
```

```
            </title>
            <component-definition-ref>
               com.ibm.isclite.samples.basicModule.portletEntity.A
            </component-definition-ref>
         </window>
      </simple-container>
   </layout-element>
</layout-tree>
```

- Each layout element in the layout tree defines the layout of a page in the console.
- Each page can have nested containers, and each simple container can have multiple windows. Each simple container has either a row or column orientation. The nesting of these containers can create a complex table structure for the page layout.
- The <component-definition-ref/> element specifies the unique name of the portlet entity that provides the content of this window.

5. Create the navigation element after the layout tree as shown.

```
<navigation-element uniqueName="com.ibm.isclite.samples.navigationElement.basicModule"
            layoutElementRef="com.ibm.isclite.samples.basicModule.layoutElement.A">
   <title>
      <base:nls-string lang="en">Basic Module Sample</base:nls-string>
   </title>
   <preference name="ProductFilter">
      <base:value>
         <base:string>com.ibm.isclite.samples.PageLayout</base:string>
      </base:value>
   </preference>
   <parent-tree parentTreeRef="com.ibm.isclite.samples.navigationElement.Samples"/>
</navigation-element>
```

- Each navigation element defines a node in the console navigation. If you nest the navigation elements, it creates a hierarchical tree structure that is reflected in the console navigation. For the purpose of this exercise, only a single navigation element is provided. The **layoutElementRef** attribute indicates the unique name of the layout element that is rendered on the page that is displayed when this element is selected by the console user.
- The content of the `ProductFilter` preference indicates the **appID** of the lead application. This is used to render this navigation element when the lead product is selected by the console user for filtering the navigation.
- The content of the **parentTreeRef** element indicates the unique name of the parent navigation element for this element.

The following figure shows how this navigation element is rendered with the page layout sample. In this figure, the user has selected `Integrated Solutions Console Sample` from the **View** selection list to filter the navigation.

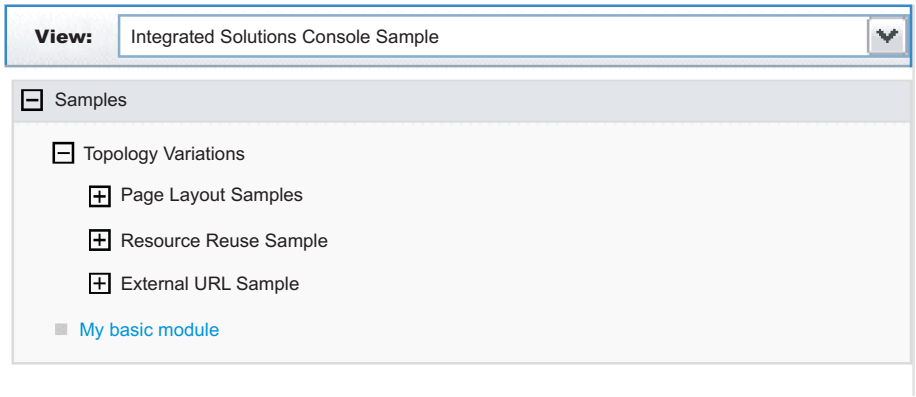

Figure 4. Sample console module navigation

What to do next

When you have finished, save and close the file and store in the /WEB-INF directory of your console module project.

Portal security descriptor

Before you begin

To follow these steps, open a file with the name ibm-portal-security.xml in a text or XML editor and save each change at the end of each step.

1. Copy the following elements into ibm-portal-security.xml. Some information is split on multiple lines for printing purposes.

```
<?xml version="1.0" encoding="UTF-8"?>

<ibm-portal-security
     xmlns="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-security.xsd"
     xmlns:base="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-base.xsd"
     xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"

xsi:schemaLocation="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-topology.xsd
ibm-portal-topology.xsd
         http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-base.xsd ibm-portal-base.xsd
         http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-security.xsd ibm-portal-security.xsd">

  </ibm-portal-security>
```

2. Add the <application-role/> element as the content of the <ibm-portal-security/> element.

```
<application-role uniqueName="monitor">

</application-role>
```

   This sample identifies the administrative role, `monitor`, for access rights. See Portal security schema for a complete description of this element and the uniqueName attribute.

3. Add the following <portal-role/> elements as the content of the application role.

```
<portal-role object-ref="com.ibm.isclite.samples.navigationElement.basicModule"/>
<portal-role object-ref="com.ibm.isclite.samples.basicModule.navigationElement.A"/>
<portal-role object-ref="com.ibm.isclite.samples.basicModule.portletEntity.A"
             role-type="Privileged User"/>
```

   This sample assigns permission to a user with monitor access to view two navigation elements and to view, edit, and access help for one portlet. See Portal security schema for a complete description of this element and its attributes.

What to do next

When you have finished, save and close the file and store in the /WEB-INF directory of your console module project.

Packaging a console module

Before you begin

Before you start this task, be sure your Java sources compiles without errors and the XML descriptors have been validated against the corresponding schemas.

About this task

An Integrated Solutions Console module must be packaged as a WAR file for deployment. For best results, use a comprehensive development tool such as Rational Application Developer. Otherwise, you can follow these steps to package your console module resources into the WAR file.

1. Create a working directory to collect all of the files that need to be packaged in the WAR file.
2. Organize your portlets and other resource files in the prescribed directory structure for portlet WAR files using the following steps:
   a. Place the following deployment descriptors in the directory /WEB-INF directory:
      - ibm-portal-topology.xml (topology descriptor)
      - ibm-portal-security.xml (security descriptor)
      - portlet.xml (portlet descriptor)
      - web.xml (Web application descriptor)

   b. Place individual Java classes for your portlets in the directory /WEB-INF/classes. Use a directory structure that reflects the fully-qualified class name of your portlet, for example, /com/ibm/isclite/samples/basicModule.
   c. Put JAR files in the directory /WEB-INF/lib.
   d. If the console module supports multiple languages, place the properties file that contains the translated strings (the resource bundles) in the directory /WEB-INF/classes/nls.
   e. Put any JavaServer Pages that must be served directly by the client in a directory that is not under the /WEB-INF directory (such /jsp). Resources in the /WEB-INF directory are protected and are not URL-addressable. JavaServer Pages that are accessed only by the portlets in the console module can be placed in the /WEB-INF path.
   f. If the console module has help files, copy the Eclipse help plug-in files to the directory /help/*plugin_name*, where *plugin_name* is the name of the Eclipse help plug-in, such as com.ibm.myprod.help.doc.
3. Use the Java JAR utility to create the WAR file. For instructions, see the Java Tutorial at http://java.sun.com/docs/books/tutorial/jar/basics/index.html . You can also use an assembly tool like Rational Application Developer to create the WAR file for the console module.

Deploying a console module

After you create the WAR file for a console module, you can deploy the console module to a system where the runtime for Integrated Solutions Console is installed and then test that the console module works correctly. Only one instance of a console module can be deployed on an Integrated Solutions Console installation. This rule applies even if the versions of the console module are different.

About this task

If you need to update the version of a console module, you must perform these steps.

1. Remove the console module.

2. Update the module with the required changes.
3. Reissue the deploy command.

To deploy a console module on a system where the runtime for Integrated Solutions Console is installed, perform the following procedure:

1. Go to the machine where the Integrated Solutions Console runtime is installed. You can also use a machine that has remote access to the drive where the runtime is installed.
2. Copy the console module WAR file to the *app_server_root*/systemApps/isclite.ear directory. As an alternative, you can extract the WAR file into a subdirectory of this location using the WAR file name for the subdirectory. For example, you would extract pagelayout.war to the *app_server_root*/systemApps/isclite.ear/pagelayout.war directory.
3. Grant the QEJBSVR profile the authority needed to complete the task. From an i5/OS command prompt, issue this command:

   ```
   CHGAUT OBJ('path_to_war') USER(QEJBSVR) DTAAUT(*RWX) OBJAUT(*ALL)
   ```
4. Start the wsadmin scripting client. If the server is not running, use the -conntype NONE option to run in local mode.
5. At the **wsadmin** command prompt, enter the command syntax. The following example presents the syntax:

   ```
   $AdminApp update isclite modulefile {
   -operation add
   -contents path_to_war
   -contenturi war_filename
   -custom paavalidation=true
   -custom containWebServices=true|false
   -usedefaultbindings -contextroot /context
   -MapWebModToVH {{.* .* admin_host}}
   -MapModulesToServers {{.*  .*.war,.*  WebSphere:cell=cellname,node=nodename,server=servername}}}
   ```

   Note:

   - The values of the -contents and -contenturi options are case sensitive and should match the war file name that you are ready to deploy.
   - Specifying `-custom paavalidation=true` causes the deployment to validate the XML descriptors for the console module package before deployment. This is optional.
   - Set the option `-custom containWebServices=true` only if the package contains a Web service. This setting invokes more deployment processing to locate and setup the Web service. The default for this option is true. If the package does not contain any Web services, be sure to set this option to false for more efficient deployment.
   - Use the -MapModulesToServers option when deploying to an agent profile.

   For example:

   ```
   $AdminApp update isclite modulefile {
   -operation add
   -contents app_server_root/systemApps/isclite.ear/pagelayout.war
   -contenturi pagelayout.war
   -custom paavalidation=true
   -custom containWebServices=false
   -usedefaultbindings  -contextroot /ibm/pagelayout
   -contextroot /pagelayout
   -MapWebModToVH {{.* .* admin_host}}
   -MapModulesToServers {{.*  .*.war,.*  WebSphere:cell=cell_A,node=node_B,server=server_C}}}
   ```

   The following messages are displayed if the deployment is successful.

   ```
   Update of isclite has started.
   ADMA5009I: An application archive is extracted at profile_root/wstemp/wstemp/app_10793d84b8e/ext/pagelayout.war
   ADMA5064I: FileMergeTask completed successfully for isclite.
   ADMA5005I: The application isclite is configured in the WebSphere Application Se
   rver repository.
   ```

```
ADMA5005I: The application isclite is configured in the WebSphere Application Se
rver repository.
ADMA5110I: The application isclite is installed as a hidden application and will
 not be exposed via administrative interfaces such as GUI client, wsadmin or MBe
an Java API.  In order to perform management operations on this application, the
 application name must be known.
CWLAA10001I: The Integrated Solutions Console module was deployed successfully.
ADMA5005I: The application isclite is configured in the WebSphere Application Se
rver repository.
ADMA5011I: The cleanup of the temp directory for application isclite is complete
.
Update of isclite has ended.
```

6. After the deployment has completed successfully, save your work by issuing the following command:

```
$AdminConfig save
```

Results

If the deployment is successful, the WAR file contents are extracted to the /systemApps/isclite.war directory and the module metadata is copied to the following directory:

profile_root/config/cells/*cellname*/applications/isclite.ear/deployments/isclite

To view your console module, you must log back in to the console. Make sure the navigation is updated correctly. If so, select the new navigation nodes verify that the new pages and console modules are rendered correctly.

Testing a console module

About this task

Use the following checklist to test your console module after it has been deployed.

1. Log in to Integrated Solutions Console as an administrator.
2. If the module includes an <about-page/> element in the topology descriptor, verify that your suite and its version are listed in the table on the Welcome page. Also confirm that the product is listed in the **View** selection list for the navigation.
3. Verify that the console navigation tree contains all of the organizational nodes and pages that were defined. Verify that each node is at the correct level in the tree.
4. For each page, verify that the portlets on the page work correctly. If a portlet on the page launches a new page in work area, verify that the launching works correctly.
5. To test the access permissions specified in the console module descriptor, logout and then log in as a different user to verify that the correct pages are accessible.
6. If the console module included a help plug-in, make sure you can launch the help.
7. If the console module contains errors, refer to the SystemOut.log and SystemErr.log for any errors or messages. These logs are located in the following directory:

   profile_root/logs/server1

Removing a console module

About this task

Follow these steps to delete a console module.

1. Ensure that the server is started. You do not need to log in to the console.
2. Start the wsadmin scripting client.
3. Enter the following command from the wsadmin command prompt.

```
$AdminApp update isclite modulefile {-operation delete -contenturi module_file_name.war}
```

4. Save your configuration changes.

```
$AdminConfig save
```

5. Exit the wsadmin command environment.

```
quit
```

Adding advanced API features

The class files for console modules are developed using the Java Portlet Specification. Integrated Solutions Console includes additional APIs for launching pages, passing properties to other portlets, and launching Eclipse-based help. This section provides information about the APIs available to console modules.

Developing portlets

Console modules are portlets that run in the portlet container of WebSphere Application Server.

Integrated Solutions Console supports console modules written to the Java Portlet Specification. A packaged console module WAR file contains one or more portlets or reuses portlets from other modules. According to the JSR 168 specification, a *portlet* is a Java technology based Web component, managed by a portlet container, that processes requests and generates content that contributes to the overall portal page. Portlets share many of the same characteristics as servlets. However, portlets also exhibit differences. For example, portlets cannot set HTTP headers and can contribute only markup fragments to the portal page. The portlet specification leverages the functionality of the servlet specification as much as possible, and many parts of the Java Portlet Specification have been modeled after the servlet specification.

The application server includes a JSR 168-compliant portlet container to support deploying and running console modules in Integrated Solutions Console. The JSR 168 portlet container relies on the Java Platform, Enterprise Edition (Java EE) architecture implemented by the application server. Consequently, an Integrated Solutions Console module and its portlets are packaged and deployed similar to Java EE Web applications. In addition to the Web application descriptor and the portlet descriptor, the WAR file for an Integrated Solutions Console module includes additional descriptors needed to deploy the application to a console installation.

The following Web resources can useful for learning more about portlet development.

Resource	Web site URL

Launching pages

Typically, users of the console launch pages using the links in the console navigation. However, portlets in a console module also launch pages directly using the Dynamic UI Manager API.

The DynamicUI Manager APIs are provided by 3 services: PropertyFactory, DynamicUIManagerFactoryService, and URLGeneratorFactoryService. To use these services the portlet must first perform a JNDI lookup to get the PortletServiceHome object which you then can use to get the actual service interface object. This is demonstrated in the GetApps portlet of the PortletContext sample.. The following code is placed in a `try` block of the portlet's init() method.

Some information is split on multiple lines for printing purposes.

```
Context ctx = new InitialContext(com.ibm.portal.jndi.Constants.ENV);
// get propertyfactory service

propertyFactoryServiceHome = (PortletServiceHome)ctx.lookup("iscportletservice/com.ibm.portal.
propertybroker.service.PropertyBrokerService");
if (propertyFactoryServiceHome == null)
   logger.log(Level.FINE, "no PropertyBrokerService propertyFactoryServiceHome");
else
   propertyFactoryService =

      (PropertyFactory)propertyFactoryServiceHome.getPortletService(com.ibm.portal.
propertybroker.service.PropertyBrokerService.class);
logger.log(Level.FINE, "propertyBrokerService="+propertyFactoryService);
// get dynamicUIManagerFactory service
dynamicUIManagerFactoryServiceHome =
   (PortletServiceHome)ctx.lookup("iscportletservice/com.ibm.portal.portlet.service.DynamicUIManagerFactoryService");
if (dynamicUIManagerFactoryServiceHome == null)
   logger.log(Level.FINE, "no dynamicUIManagerFactoryService propertyFactoryServiceHome");
else
   dynamicUIManagerFactoryService =

      (DynamicUIManagerFactoryService)dynamicUIManagerFactoryServiceHome.getPortletService
(com.ibm.portal.portlet.service.DynamicUIManagerFactoryService.class);
logger.log(Level.FINE, "dynamicUIManagerFactoryService="+dynamicUIManagerFactoryService);
// get urlGeneratorFactory service
urlGeneratorFactoryServiceHome =
   (PortletServiceHome)ctx.lookup("iscportletservice/com.ibm.portal.portlet.service.URLGeneratorFactoryService");
if (urlGeneratorFactoryServiceHome == null)
   logger.log(Level.FINE, "no urlGeneratorFactoryService propertyFactoryServiceHome");
else
   urlGeneratorFactoryService =

      (URLGeneratorFactoryService) urlGeneratorFactoryServiceHome.getPortletService
(com.ibm.portal.portlet.service.URLGeneratorFactoryService.class);
logger.log(Level.FINE, "urlGeneratorFactoryService="+urlGeneratorFactoryService);
```

A portlet can launch a new page using the dynamicUICtrl interface, passing the object ID of the page definition for the new page. The object ID is determined by performing a JNDI lookup on the unique name of the navigation element that launches the page. If you are planning to launch a navigation element, the navigation node must point to a layout element. In other words the navigation element must contain the l**ayoutElementRef** attribute. The addPage() method returns the object ID of the page instance, which should be saved by the portlet to create a URL and launch the page. The following excerpt from the PortletContext sample demonstrates how this works. The portlet GetApps.java includes a launchPage() method with this code.

```
Context ctx;
ObjectID pageDefinitionID = null;
String pagename="com.ibm.isclite.portletcontext.navigationElement.B";
logger.log(Level.FINE, "launch page=" + pagename);

PortletSession ps  = request.getPortletSession(false);
try {
    ctx = new InitialContext();
    pageDefinitionID =(ObjectID)ctx.lookup("portal:uniquename/"+pagename);
} catch (NamingException ne) {
    return;
}
```

```
try {
    PropertyController cproperty = propertyFactoryService.createProperty(myconfig);
    PropertyController cproperty2 = propertyFactoryService.createProperty(myconfig);

    cproperty.setType("String");
    cproperty.setName("servername");
    cproperty2.setType("String");
    cproperty2.setName("appDeployed");
    PropertyValue[] propertyValues = new PropertyValue[2];
    propertyValues[0] =
        propertyFactoryService.createPropertyValue(request, cproperty, serverName);
    propertyValues[1] =
        propertyFactoryService.createPropertyValue(request, cproperty2, appDeployed);

    DynamicUICtrl dmanagerCtrl =
       dynamicUIManagerFactoryService.getDynamicUICtrl(request, response, "isc.tasklaunch");

    ObjectID newPageID =
        dmanagerCtrl.addPage(pageDefinitionID, null, propertyValues);

    RedirectURLGenerator urlGenerator =
        urlGeneratorFactoryService.getURLGenerator(request, response);

    EngineURL redirectURL = urlGenerator.createPageURL(newPageID);

    response.sendRedirect(redirectURL.toString());
} catch  ...
```

- The `pagename` String is created with the unique name of the navigation element (from the topology descriptor) that launches the page.
- The object ID is found by performing a JNDI lookup on this Context instance using this String:

  ```
  "portal:uniquename/"+pagename
  ```

  The String `portal:uniquename/` is required to obtain the object ID for the navigation element.
- Properties are created to be passed to the portlets on the page. The property names are `servername` and `appDeployed`.
- In addition to the request and response, you must include the String `isc.tasklaunch` as the configuration name on the getDynamicUICtrl() method.
- Use the addPage() method of the new DynamicUICtrl instance to create and instance of the page. Any properties that need to be passed to portlets on the new page must be provided in this method. The addPage() method does not launch the page, but it returns the object ID of the page instance. The next two methods, getURLGenerator() and createPageURL(), are used to construct the URL that opens the page. The URL contains property names and values if they have been provided.
- The URL to open the page is provided on the sendRedirect() method of the response.

Passing properties to other portlets

This topic describes how portlets can exchange properties. You should be familiar with the concepts for launching console pages before reading this topic.

Information can be provided to portlets on the same page using the addSharedPortlet() method. Property values are of the type com.ibm.portal.propertybroker.property.PropertyValue. The example in “Launching pages” on page 129 shows these properties passed to the page using an instance of the PropertyValue interface (`propertyValues`) and shows how that object was created using the PropertyFactory interface.

The SetServer.java source from the PortletContext sample shows how to pass properties to a portlet on the same page. It is assumed that the portlet has already performed a JNDI lookup to determine that the PropertyFactory, DynamicUIManagerFactoryService, and URLGeneratorFactoryService services are available. This is described in “Launching pages” on page 129

- In this example, the portlet that is the source of the properties needs the object ID of the target portlet. The object ID is determined by performing a JNDI lookup using the values from the portlet's <resource-link/> element in the topology descriptor.
- The property, cproperty, is created using the PropertyController interface and the createProperty() method of the PropertyFactory interface. The data type for the property must be a String.
- Prior to sending the property, the source portlet creates an instance of the DynamicUICtrl interface, passing the string ″isc.tasklaunch″ as the configuration name.
- The addSharedPortlet() method sends the properties to the target portlet on the request. After the action phase, the target portlet updates the output for the response.

```
Context ctx = null;
ObjectID portletDefinitionID1 = null;
ObjectID portletDefinitionID2 = null;

String portletname1="com.ibm.isclite.samples.PortletContext/PortletGetPerformance";
String portletname2="com.ibm.isclite.samples.PortletContext/PortletGetApps";

PortletSession ps  = request.getPortletSession(false);

try
   {
      ctx = new InitialContext(com.ibm.portal.jndi.Constants.ENV);
      portletDefinitionID1 =
         (ObjectID)ctx.lookup("portal:config/portletdefinition/"+portletname1);
      portletDefinitionID2 =
         (ObjectID)ctx.lookup("portal:config/portletdefinition/"+portletname2);
   } catch (NamingException ne)
     {
        logger.log(Level.FINE, "portletdefinitionID not found - Naming exception:"+ne.getMessage());
        return;
     }
logger.log(Level.FINE, "portletdefinitionID="+portletDefinitionID1.toString());

try
{
   PropertyController cproperty =
      propertyFactoryService.createProperty(myconfig);
   cproperty.setType("String");

   PropertyValue[] propertyValues = new PropertyValue[1];
   propertyValues[0] =
      propertyFactoryService.createPropertyValue(request, cproperty, serverName);

   DynamicUICtrl dmanagerCtrl =
      dynamicUIManagerFactoryService.getDynamicUICtrl(request, response, "isc.tasklaunch");

   ObjectID newPortletID1 =
      dmanagerCtrl.addSharedPortlet(portletDefinitionID1, null, propertyValues);
   ObjectID newPortletID2 =
      dmanagerCtrl.addSharedPortlet(portletDefinitionID2, null, propertyValues);

      logger.log(Level.FINE, "portlet ID created:"+newPortletID1.getOID());
    } catch ...
```

In some cases, the target portlet might be on a separate page. In this case, the properties are passed using the addPage() method. The target portlet receives the properties only when the page is launched that contains the portlet. If a property value is set multiple times before the page is launched, the value that was set last for the property is passed to the portlets on the page. You can use the URLGeneratorFactoryService interface to redirect the console to the page for the target portlet. This is demonstrated in the GetApps portlet of the PortletContext sample.

```
ObjectID newPageID = dmanagerCtrl.addPage(pageDefinitionID, null, propertyValues);
RedirectURLGenerator urlGenerator = urlGeneratorFactoryService.getURLGenerator(request, response);
EngineURL redirectURL = urlGenerator.createPageURL(newPageID);
response.sendRedirect(redirectURL.toString());
```

To use the URLGeneratorFactoryService, the portlet must first perform a JNDI lookup for this portlet service. Refer to the GetApps.java source to see how to obtain a reference to the portlet service.

Receiving properties

To receive properties, the target portlet must provide the `com.ibm.portal.pagecontext.enable` preference parameter in the portlet.xml with a value of true. If the portlet should receive any subsequent updates, the `com.ibm.portal.context.enable` read-only preference should also be set to true. Only String property types are supported and the context is passed as parameters of the action request. The following example shows how the GetApps portlet receives properties passed by the SetServer portlet.

```
public void processAction(ActionRequest request, ActionResponse response)
       throws PortletException, IOException {

        PortletSession ps = request.getPortletSession(true);
        appDeployed = request.getParameter("appDeployed");
        serverName=request.getParameter("servername");

        ps.setAttribute("servername",serverName);
        ps.setAttribute("appDeployed",appDeployed);
        launchPage(request, response);

    }
```

A target portlet can check `com.ibm.portal.action` parameter of the request during action processing to determine if any properties have been passed. If properties are being passed to the portlet, the value of this parameter is `com.ibm.portal.pagecontext.receive`. For example:

```
String action = req.getParameter(com.ibm.portal.action.name);
if (action!=null && action.equalsIgnoreCase("com.ibm.portal.pagecontext.receive")) {

  // code to get the properties as a parameter on the request

}
```

Launching Eclipse-based help

If your console module contains a portlet that requires a help page, follow the instructions in this topic to implement help for the portlet.

About this task

To implement portlet help, you use the portlet's doHelp() method, the EclipseHelp class, and the help setting in the portlet.xml file. Inside the doHelp() method, link to the target help topic in your Eclipse help plug-in by using the portletHelp() method of the EclipseHelp class. By including a doHelp() method in your portlet and adding the help setting to the portlet.xml file, you enable the portlet help mode. When portlet help mode is enabled, the ? icon is displayed on the portlet title bar. When a user clicks the icon, a separate browser window opens and displays only that help topic.

The Modes sample (modes.war) demonstrates how a console module can provide user assistance or help. This sample is described in "Example: Console module samples" on page 119.

1. Add the doHelp() method to your portlet.
   a. In the portlet Java file, include the following import statement:
      ```
      import com.ibm.portal.help.EclipseHelp;
      ```
   b. Implement the doHelp() method in the portlet.

```
public void doHelp(RenderRequest request, RenderResponse response)
       throws PortletException, IOException {

}
```

c. Create a String in the deHelp() method to contain the help topic. The syntax for specifying a help topic is *pluginID*/*file_path*/*file_name*, where *pluginID* is the Eclipse help plug-in ID as specified in its plugin.xml file, *file_path* is the sub-directory path (if any), and *file_name* is the filename and extension of the help content file.

```
public void doHelp(RenderRequest request, RenderResponse response)
       throws PortletException, IOException {

   String topic = "com.ibm.isc.help.modes/help_mode.html";
}
```

d. Call the method EclipseHelp.portletHelp() passing in the request, response, and topic as shown in the code snippet below.

```
public void doHelp(RenderRequest request, RenderResponse response)
       throws PortletException, IOException{

   String topic = "com.ibm.isc.help.modes/help_mode.html";
  EclipseHelp.portletHelp(request, response, topic);

}
```

2. Set help mode in the portlet.xml file.
   a. Use a text editor to open the portlet deployment descriptor (the portlet.xml file). See topics under Developing portlets for more information about creating a portlet.xml file.
   b. Inside the <portlet-app> element, locate the <portlet> element for the portlet that implements the doHelp() method.
3. Inside the <supports> sub-element, add a <portlet-mode> element like the one shown in the following example.

```
<?xml version="1.0" encoding="UTF-8"?>
<portlet-app xmlns="http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd"
             version="1.0" id="com.ibm.isclite.samples.Modes"
             xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
             xsi:schemaLocation="http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd
                                 http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd">
   <portlet id="Modes_Portlet" >
      <portlet-name>ModesPortlet</portlet-name>
      <display-name>Modes portlet1 (JSR 168)</display-name>
      <display-name xml:lang="en">Modes portlet1 (JSR 168)</display-name>
      <portlet-class>com.ibm.isclite.samples.Modes</portlet-class>
      <expiration-cache>0</expiration-cache>
      <supports>
         <mime-type>text/html</mime-type>
         <portlet-mode>VIEW</portlet-mode>
         <portlet-mode>EDIT</portlet-mode>
         <portlet-mode>HELP</portlet-mode>
      </supports>
      <supported-locale>en</supported-locale>
      <resource-bundle>nls.HTML</resource-bundle>
   </portlet>

</portlet-app>
```

4. When packaging the console module, place the Eclipse help plugin in the /help directory of the WAR file. See “Packaging a console module” on page 125 for more information.

Support for bidirectional characters

Integrated Solutions Console supports bidirectional text. If your console module provides support for Hebrew, it must provide two identical resource bundles for the translated Strings. The file name for one resource bundle must be appended with the `_iw` suffix and the other resource bundle must be appended with the `_he` suffix. For example:

```
portlet_iw.properties
portlet_he.properties
```

Chapter 3. EJB applications

Task overview: Using enterprise beans in applications

This article provides an overview of the tasks you must perform to use enterprise beans in a Java-based application.

About this task

Use the following steps to develop an Enterprise JavaBeans (EJB) application:

1. **EJB 3.0 beans:** Design a Java Platform, Enterprise Edition (Java EE) application and the enterprise beans that it needs.
2. **EJB 2.x beans:** Design a Java 2 Platform, Enterprise Edition (J2EE) application and the enterprise beans that it needs.
3. Develop any enterprise beans that your application uses.
4. Prepare for assembly. For your EJB 2.x-compliant entity beans, decide on an appropriate access intent policy.
5. Assemble the beans into one or more EJB modules using one of the assembly tools. This process includes setting security. For your EJB 2.x-compliant entity beans, you might also want to designate container-managed persistence (CMP) sequence groups.
6. **EJB 3.0 beans:** Assemble the beans into one or more EJB 3.0 modules using one of the assembly tools.
7. Assemble the modules into a J2EE application using the assembly tool.
8. For a given application server, update the EJB container configuration if needed for the application to be deployed.
9. For a given application server, update the EJB container configuration if needed for the application to be deployed, and determine if you want to batch commands or defer commands for container-managed persistence.
10. Deploy the application in an application server.
11. Test the modules.
    - As needed, debug problems with the container.
    - Debug access problems.
12. Assemble the production application using one of the assembly tools
13. Deploy the application to a production environment.
14. Manage the application:
    a. Manage installed EJB modules. After an application has been installed, you can manage its EJB modules individually through assembly tools.
    b. Manage other aspects of the Java application.
15. Update the module and redeploy it using one of the assembly tools.
16. Tune the performance of the application. See Best practices for developing enterprise beans.

Enterprise beans

An enterprise bean is a Java component that can be combined with other resources to create Java applications. There are three types of enterprise beans, *entity* beans, *session* beans, and *message-driven* beans.

All beans reside in Enterprise JavaBeans (EJB) containers, which provide an interface between the beans and the application server on which they reside.

EJB 2.1 and earlier versions of the specification define entity beans as a means to store permanent data, so they require connections to a form of persistent storage. This storage might be a database, an existing legacy application, a file, or another type of persistent storage.

The EJB 3.0 specification deprecates EJB 1.1-style entity beans. The Java Persistence API (JPA) specification is intended to replace the deprecated enterprise beans. While the JPA replacement is called an entity class, it should not be confused with entity enterprise beans. A JPA entity is not an enterprise bean and is not required to run in an EJB container.

Session beans typically contain the high-level and mid-level business logic for an application. Each method on a session bean performs a particular high-level operation. For example, submitting an order or transferring money between accounts. Session beans often invoke methods on entity beans in the course of their business logic.

Session beans can be either *stateful* or *stateless*. A stateful bean instance is intended for use by a single client during its lifetime, where the client performs a series of method calls that are related to each other in time for that client. One example is a *shopping cart* where the client adds items to the cart over the course of an online shopping session. In contrast, a stateless bean instance is typically used by many clients during its lifetime, so stateless beans are appropriate for business logic operations that can be completed in the span of a single method invocation. Stateful beans should be used only where absolutely necessary. Using stateless beans improves the ability to debug, maintain, and scale the application.

The EJB 3.0 specification supports stateless and stateful session beans. They follow a simple pattern such as:

- Define the business interface.
- Define the class that implements it.
- Add metadata with annotations or with XML deployment descriptors.

The end result of a simple EJB 3.0 stateful session bean looks like the following:

```
package ejb3demo;

@Stateful
public class Cart3Bean implements ShoppingCart {
    private ArrayList contents = new ArrayList();

public void addToCart (Object o) {
  contents.add(o);
    }

public Collection getContents() {
    return contents;

    }
}
```

EJB components can use annotations such as @EJB and other injectable @Resource references if the module is an EJB 3.0 module.

Web application clients and application clients can use deployment descriptor-defined EJB references. If the reference is for an EJB 3.0 session bean without a home interface, the reference should be defined with a null <home> or <local-home> setting in the deployment descriptor.

Web application clients and application clients can also use @EJB injections for references to EJB session beans within the same enterprise archive (EAR) file, but the binding must either use the AutoLink support within the container or the annotation must use the name of the reference that is defined by the deployment descriptor and bound when the application is installed. For more information about AutoLink, see the topic, ″EJB 3.0 application bindings support.″

Message-driven beans enable asynchronous message servicing.

- The EJB container and a Java Message Service (JMS) provider work together to process messages. When a message arrives from another application component through JMS, the EJB container forwards it through an onMessage method call to a message-driven bean instance, which then processes the message. In other respects, message-driven beans are similar to stateless session beans.
- The EJB container and a Java Connector Architecture (JCA) resource adapter work together to process messages from an enterprise information system (EIS). When a message arrives from an EIS, the resource adapter receives the message and forwards it to a message-driven bean, which then processes the message. The message-driven bean is provided services such as transaction support by the EJB container in the same way that other enterprise beans are provided service.

Beans that require data access use *data sources*, which are administrative resources that define pools of connections to persistent storage mechanisms.

EJB modules

An Enterprise JavaBeans (EJB) module is used to assemble one or more enterprise beans into a single deployable unit. An EJB module is stored in a standard Java archive (JAR) file.

An EJB module contains the following:

- One or more deployable enterprise beans.
- A deployment descriptor, stored in an Extensible Markup Language (XML) file. This file declares the contents of the module, defines the structure and external dependencies of the beans in the module, and describes how the beans are to be used at run time.

  It is not necessary to use XML deployment descriptors in EJB 3.0 modules, although XML descriptors are supported. Instead of deployment descriptors, you can use annotations to provide component metadata.

You can deploy an EJB module as a stand alone application, or combine it with other EJB modules or with Web modules to create a Java application. An EJB module is installed and run in an enterprise bean container.

If you want to package an EJB 3.0 module with a deployment descriptor, there are several ways to do it. You can package an EJB 3.0 module with an EJB 3.0 style session and/or message-driven beans exclusively; with an EJB 2.1 style session and/or message-driven beans exclusively, or a combination of 2.1 and 3.0 style beans. The XML deployment descriptor must be a Version 3.0 deployment descriptor. It is required that 2.1 entity beans are packaged in modules with 2.1 deployment descriptors.

EJB modules that contain EJB 3.0 beans must be at the EJB 3.0 specification level when running on the product. To set the EJB module to support EJB 3.0 beans, you can set the ejb-jar.xml deployment descriptor level to 3.0, or you can make sure that the module does not contain an ejb-jar.xml deployment descriptor. If the module level is EJB 2.1 or earlier, no EJB 3.0 functions, including annotation scanning or resource injection is performed at runtime.

For more information about packaging and deployment of EJB 3.0 beans, see the topic EJB 3.0 module packaging overview.

EJB containers

An Enterprise JavaBeans (EJB) container provides a run-time environment for enterprise beans within the application server. The container handles all aspects of an enterprise bean's operation within the application server and acts as an intermediary between the user-written business logic within the bean and the rest of the application server environment.

One or more EJB modules, each containing one or more enterprise beans, can be installed in a single container.

The EJB container provides many services to the enterprise bean, including the following:
- Beginning, committing, and rolling back transactions as necessary.
- Maintaining pools of enterprise bean instances ready for incoming requests and moving these instances between the inactive pools and an active state, ensuring that threading conditions within the bean are satisfied.
- Most importantly, automatically synchronizing data in an entity bean's instance variables with corresponding data items stored in persistent storage.

By dynamically maintaining a set of active bean instances and synchronizing bean state with persistent storage when beans are moved into and out of active state, the container makes it possible for an application to manage many more bean instances than could otherwise simultaneously be held in the application server's memory. In this respect, an EJB container provides services similar to virtual memory within an operating system.

WebSphere Application Server provides significant flexibility in the management of database data with entity beans. The Entity EJBs Activate at and Load at configuration settings specify how and when to load and cache data from the corresponding database row data of an enterprise bean. These configuration settings provide the capability to specify enterprise bean caching Options A, B or C, as specified in the EJB 1.1 specifications. You can configure these settings with assembly tools. To read more about how to use the assembly tools see the assembly tool information center.

Option A provides maximum enterprise bean performance by caching database data outside of the transaction scope. Generally, Option A is only applicable where the EJB container has exclusive access to the given database. Otherwise, data integrity is compromised. Option B provides more aggressive caching of Entity EJB object instances, which can result in improved performance over Option C, but also results in greater memory usage. Option C is the most common real-world configuration for Entity EJBs and is the default setting.

The Activate at setting specifies the point at which an enterprise bean is activated and placed in the cache. Removal from the cache and passivation are also governed by this setting. Valid values are Once and Transaction. The Once setting indicates that the bean is activated when it is first accessed in the server process, and passivated (and removed from the cache) at the discretion of the container, for example when the cache becomes full. The Transaction setting indicates that the bean is activated at the start of a transaction and passivated (and removed from the cache) at the end of the transaction. The default value is Transaction.

The Load at setting specifies when the bean loads its state from the database. The value of this property implies whether the container has exclusive or shared access to the database. Valid values are Activation and Transaction. Activation indicates the bean is loaded when it is activated and implies that the container has exclusive access to the database. Transaction indicates that the bean is loaded at the start of a transaction and implies that the container has shared access to the database. The default is Transaction. The settings of the Activate at and Load at properties govern which commit options are used. For Option A (exclusive database access), use Activate at = Once and Load at = Activation. This option reduces database input/output by avoiding calls to the ejbLoad function, but serializes all transactions accessing the bean instance. Option A can increase memory usage by maintaining more objects in the cache, but can provide better response time if bean instances are not generally accessed concurrently by multiple transactions.

Note: When using WebSphere Network Deployment and workload management is enabled, Option A cannot be used.

You must use settings that result in the use of Options B or C. For Option B (shared database access), use Activate at = Once and Load at = Transaction. Option B can increase memory usage by maintaining more objects in the cache. However, because each transaction creates its own copy of an object, there can be multiple copies of an instance in memory at any given time (one per transaction), requiring the database be accessed at each transaction. If an enterprise bean contains a significant number of calls to

the ejbActivate function, using Option B can be beneficial because the required object is already in the cache. Otherwise, this option does not provide significant benefit over Option A. For Option C (shared database access), use Activate at = Transaction and Load at = Transaction. Load at = Transaction. This option can reduce memory usage by maintaining fewer objects in the cache. However, there can be multiple copies of an instance in memory at any given time (one per transaction). This option can reduce transaction contention for enterprise bean instances that are accessed concurrently but not updated.

By default, an EJB container runs in the **quick start** mode. The EJB container startup logic delays the loading and processing of all EJB types *except* Message Driven Beans, because message driven beans must exist before messages are posted for them; Startup Beans, which must be processed when the server starts; and EJB types that you specify to initialize when the server starts. .

All other EJB initialization is delayed until the first use of the EJB type. When using local interfaces, the first use is when you perform an InitialContext.lookup method for the type. For remote interfaces, it is when you call the first method on an EJB or its Home.

Enterprise beans back up and recovery best practices

The following items should be considered for backup when using enterprise beans.

Database data

Enterprise beans often use a database for back-end persistence. Container-managed persistence (CMP) entity beans always use a database for back-end persistence. This data should be backed up the same as any of your business data.

The collection for container-managed entity beans persistence is determined by either the schema name specified during deployment, or the schema specified on the data source associated with the enterprise bean. Any persistent store used by session and bean-managed beans is defined by the bean implementation. For database tables, you can choose to save the entire collection or an individual table as shown with the following commands, respectively:

```
SAVLIB LIB(EJB) DEV(*SAVF) SAVF(WSALIB/WSASAVF)
SAVOBJ OBJ(MYBEANTBL) LIB(EJB) DEV(*SAVF) OBJTYPE(*FILE) SAVF(WSALIB/WSASAVF)
```

It might be possible to save database objects while the product is active, if the save operation can obtain a snapshot of the data store. You may have to shut down if a snapshot cannot be obtained. This occurs if there are requests that obtain locks or have open transactions against the database being saved.

Enterprise JavaBeans (EJB) source code, class files, and deployed code

When you deploy enterprise beans, a WebSphere Application Server-specific implementation of the enterprise beans is generated. Save these deployed Java(TM) Archive (JAR) files to avoid redeploying, and to preserve any binding information that was specified during the application installation. The JAR files, application code and configuration, such as bindings, are located by default in the *profile_root*/installedApps directory. By saving this directory, you save your installed applications, including HTML, servlets, JavaServer Pages(TM) (JSP(TM)) files, and enterprise beans. Normally, each application is located in a separate subdirectory, so you can choose to save all applications or a subset.

Note: The commands below have been wrapped for display purposes. Enter each as a single command.

This command saves all installed applications:

```
SAV DEV('/QSYS.lib/wsalib.lib/wsasavf.file')
 OBJ(('/profile_root/installedApps'))
```

This command saves the sampleApp application only:

```
SAV DEV('/QSYS.lib/wsalib.lib/wsasavf.file')
 OBJ(('/profile_root/installedApps/cellName/sampleApp.ear'))
```

If you have located utility or general purpose classes in other directories, such as /*profile_root*/lib/app or /*profile_root*/lib/ext, be sure to include those locations in your backup plan as well.

Administrative configuration

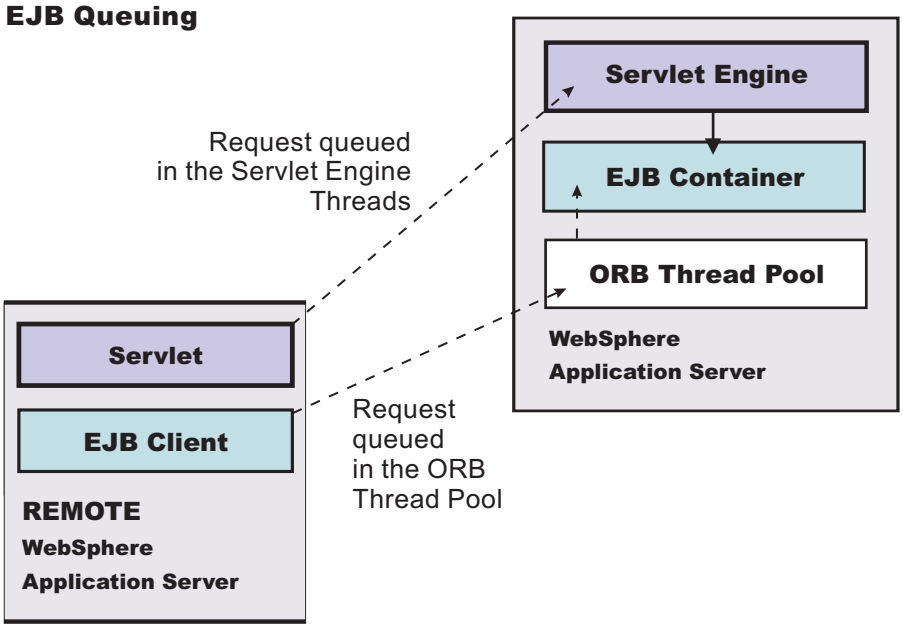
For more information, see Introduction: Administrative configuration data.

EJB method Invocation Queuing

Method invocations to enterprise beans are only queued for remote clients making the method call. An example of a remote client is an Enterprise JavaBeans (EJB) client running in a separate Java virtual machine (JVM) (another address space) from the enterprise bean. In contrast, no queuing occurs if the EJB client, either a servlet or another enterprise bean, is installed in the same JVM on which the EJB method runs, and on the same thread of execution as the EJB client.

Remote enterprise beans communicate by using the Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP). Method invocations initiated over RMI-IIOP are processed by a server-side object request broker (ORB). The thread pool acts as a queue for incoming requests. However, if a remote method request is issued and there are no more available threads in the thread pool, a new thread is created. After the method request completes the thread is destroyed. Therefore, when the ORB is used to process remote method requests, the EJB container is an open or closed queue, due to the use of unbounded threads.

The following illustration depicts the two queuing options of enterprise beans.



Enterprise bean and EJB container troubleshooting tips

If you are having problems starting an Enterprise JavaBeans (EJB) container, or encounter error messages or exceptions that appear to be generated on by an EJB container, follow these steps to resolve the problem:

- Use the administrative console to verify that the application server which hosts the container is running.

- Browse the JVM log files for the application server which hosts the container. Look for the message **server *server_name* open for e-business** in the `SystemOut.log` . If it does not appear, or if you see the message **problems occurred during startup**, browse the `SystemErr.log` for details.
- Browse the system log files for the application server which hosts the container.
- Enable tracing for the EJB container component, by using the following trace specification `EJBContainer=all=enabled`. Follow the instructions for dumping and browsing the trace output to narrow the origin of the problem.

If none of these steps solves the problem, check to see if the problem is identified and documented using the links in Diagnosing and fixing problems: Resources for learning. If you do not see a problem that resembles yours, or if the information provided does not solve your problem, contact IBM support for further assistance.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

Application client log error indicates missing JAR file

The following error message appears in the client log file because a Java archive (JAR) file is missing from the classpath on the client machine. The Object Request Broker (ORB) needs this file to unmarshal the nested exception that is part of the EJB exception, returned by the server to the client application. For example, if the EJB returns a DB2® JCC SQL exception nested inside of the EJB exception that it returns to the client, the ORB is not able to unmarshal the nested exception if the db2jcc.jar file that contains the DB2 SQL exception is not in the client classpath.

```
java.rmi.MarshalException: CORBA MARSHAL 0x4942f89a No; nested exception is:
org.omg.CORBA.MARSHAL: Unable to read value
from underlying bridge : Custom marshaling (4) Sender's class does not match
local class  vmcid: 0x4942f000  minor  code: 2202  completed: No*
```

To avoid this error, include the JAR file that contains the class for the nested exception that is returned in the EJB exception.

Enterprise bean cannot be accessed from a servlet, a JSP file, a stand-alone program, or another client

Use these troubleshooting tips for problems related to accessing enterprise beans.

What kind of error are you seeing?

- **javax.naming.NameNotFoundException: Name *name* not found in context ″local″ message** when access is attempted
- **BeanNotReentrantException** is thrown
- **CSITransactionRolledbackException / TransactionRolledbackException** is thrown
- Call fails, Stack trace beginning **EJSContainer E Bean method threw exception [exception_name]** found in JVM log file.
- Call fails, **ObjectNotFoundException or ObjectNotFoundLocalException** when accessing stateful session EJB found in JVM log file.
- Attempt to start container managed persistence (CMP) Enterprise JavaBeans (EJB) module fails with **javax.naming.NameNotFoundException: *dataSourceName***
- **Transaction [tran ID] has timed out after 120 seconds** error accessing EJB.
-
- Symptom: **CNTR0001W: A Stateful SessionBean could not be passivated**
- Symptom: **org.omg.CORBA.BAD_PARAM: Servant is not of the expected type. minor code: 4942F21E completed: No** returned to client program when attempting to execute an EJB method

If the client is remote to the enterprise bean, which means, running in a different application server or as a stand-alone client, browse the JVM logs of the application server hosting the enterprise bean, as well as log files of the client.

If you do not see a problem that resembles yours, or if the information provided does not solve your problem, perform these steps:

1. If the problem appears to be name-service related, which means that you see a NameNotFoundException error, or a message ID beginning with NMSV, see these topics for more information:
   - Application access problems
   - Naming service troubleshooting tips
2. Check to see if the problem is identified and documented using the links in Diagnosing and fixing problems: Resources for learning.

If you still cannot fix your problem, seeTroubleshooting help from IBM for further assistance.

ObjectNotFoundException or ObjectNotFoundLocalException when accessing stateful session EJB

A possible cause of this problem is that the stateful session bean timed out and was removed by the container. This event must be addressed in the code, according to the EJB 2.1 and later specification. You can review the EJB 2.1 and 3.0 specifications at `http://java.sun.com/products/ejb/docs.html`.

Stack trace beginning ″EJSContainer E Bean method threw exception [exception_name]″ found in JVM log file

If the exception name indicates an exception thrown by an IBM class that begins with ″com.ibm...″, then search for the exception name within the information center, and in the online help as described below. If ″exception name″ indicates an exception thrown by your application, contact the application developer to determine the cause.

javax.naming.NameNotFoundException: Name name not found in context ″local″

A possible reason for this exception is that the enterprise bean is not local (not running in the same Java virtual machine [JVM] or application server) to the client JSP, servlet, Java application, or other enterprise bean, yet the call is to a ″local″ interface method of the enterprise bean . If access worked in a development environment but not when deployed to WebSphere Application Server, for example, it might be that the enterprise bean and its client were in the same JVM in development, but are in separate processes after deployment.

To resolve this problem, contact the developer of the enterprise bean and determine whether the client call is to a method in the local interface for the enterprise bean. If so, have the client code changed to call a remote interface method, or to promote the local method into the remote interface.

References to enterprise beans with local interfaces are bound in a name space local to the server process with the URL scheme of `local:`. To obtain a dump of a server `local:` name space, use the name space dump utility described in the article ″Namespace dump utility for `java:`, `local:` and `server` namespaces.″

BeanNotReentrantException is thrown

This problem can occur because client code, typically a servlet or JSP file, is attempting to call the same stateful SessionBean from two different client threads. This situation often results when an application stores the reference to the stateful session bean in a static variable, uses a global (static) JSP variable to

refer to the stateful SessionBean reference, or stores the stateful SessionBean reference in the HTTP session object. The application then has the client browser issue a new request to the servlet or JSP file before the previous request has completed.

To resolve this problem, ask the developer of the client code to review the code for these conditions.

CSITransactionRolledbackException / TransactionRolledbackException is thrown

An enterprise bean container creates these high-level exceptions to indicate that an enterprise bean call did not complete. When this exception is thrown, browse the JVM logs to determine the underlying cause.

Some possible causes include:
- The enterprise bean might throw an exception that was not declared as part of its method signature. The container is required to roll back the transaction in this case. Common causes of this situation are where the enterprise bean or code that it calls creates a NullPointerException, ArrayIndexOutOfBoundsException, or other Java runtime exception, or where a BMP bean encounters a JDBC error. The resolution is to investigate the enterprise bean code and resolve the underlying exception, or to add the exception to the problem method signature.
- A transaction might attempt to do additional work after being placed in a ″Marked Rollback″, ″RollingBack″, or ″RolledBack″ state. Transactions cannot continue to do work after they are set to one of these states. This situation occurs because the transaction has timed out which, often occurs because of a database deadlock. Work with the application database management tools or administrator to determine whether database transactions called by the enterprise bean are timing out.
- A transaction might fail on commit due to dangling work from local transactions. The local transaction encounters some ″dangling work″ during commit. When a local transactions encounters an ″unresolved action″ the default action is to ″rollback″. You can adjust this action to ″commit″ in an assembly tool. See the assembly tool information center on how to adjust

Attempt to start EJB module fails with ″javax.naming.NameNotFoundException dataSourceName_CMP″exception

This problem can occur because:
- When the DataSource resource was configured, container managed persistence was not selected.
  - To confirm this problem, in the administrative console, browse the properties of the data source given in the NameNotFoundException. On the Configuration panel, look for a check box labeled **Container Managed Persistence**.
  - To correct this problem, select the check box for **Container Managed Persistence**.
- If container managed persistence is selected, it is possible that the CMP DataSource was not bound into the namespace.
  - Look for additional naming warnings or errors in the status bar, and in the hosting application server JVM logs. Check any further naming-exception problems that you find by looking at the topic Application access problems.

Transaction [tran ID] has timed out after 120 seconds accessing an enterprise bean

This error can occur when a client executes a transaction on a CMP or BMP enterprise bean.
- The default timeout value for enterprise bean transactions is 120 seconds. After this time, the transaction times out and the connection closes.
- If the transaction legitimately takes longer than the specified timeout period, go to **Manage Application Servers > *server_name***, select the **Transaction Service properties** page, and look at the property **Total transaction lifetime timeout**. Increase this value if necessary and save the configuration.

Symptom:CNTR0001W: A Stateful SessionBean could not be passivated

This error can occur when a Connection object used in the bean is not closed or nulled out.

To confirm this is the problem, look for an exception stack in the JVM log for the EJB container that hosts the enterprise bean, and looks similar to:

```
[time EDT] <ThreadID> StatefulPassi W CNTR0001W:
A Stateful SessionBean could not be passivated: StatefulBean0
(BeanId(XXX#YYY.jar#ZZZZ, <ThreadID>),
state = PASSIVATING) com.ibm.ejs.container.passivator.StatefulPassivator@<ThreadID>

```

where *XXX,YYY,ZZZ* is the Bean's name, and *<ThreadID>* is the thread ID for that run.

To correct this problem, the application must close all connections and set the reference to null for all connections. Typically this activity is done in the `ejbPassivate()` method of the bean. Also, note that the bean must have code to reacquire these connections when the bean is reactivated. Otherwise, there are NullPointerExceptions when the application tries to reuse the connections.

Symptom: org.omg.CORBA.BAD_PARAM: Servant is not of the expected type. minor code: 4942F21E completed: No

This error can be returned to a client program when the program attempts to execute an EJB method.

Typically this problem is caused by a mismatch between the interface definition and implementation of the client and server installations, respectively.

Another possible cause is when an application server is set up to use a single class loading scheme. If an application is uninstalled while the application server remains active, the classes of the uninstalled application are still loaded in the application server. If you change the application, redeploy and reinstall it on the application server, the previously loaded classes become back level. The back level classes cause a code version mismatch between the client and the server.

To correct this problem:
1. Change the application server class loading scheme to multiple.
2. Stop and restart the application server and try the operation again.
3. Make sure the client and server code version are the same.

Using access intent policies

You can use access intent policies to help the product runtime environment manage various aspects of Enterprise JavaBeans (EJB) persistence.

About this task

You apply access intent policies to EJB Version 2.0 and 2.1 entity beans, and their methods, by using an assembly tool. A set of default access intent policies comes with the assembly tool. The Rational Application Developer product provides supported assembly tools. Entity beans are not supported in EJB 3.0 modules.

1. Apply default access intent to CMP entity beans. For more information, see the online help available with the assembly tools.
2. Apply access intent policies to methods of container managed persistence entity beans.

Access intent policies

An access intent policy is a named set of properties or access intents that govern data access for Enterprise JavaBeans (EJB) persistence. You can assign policies to an entity bean and to individual methods on an entity bean's home, remote, or local interfaces during assembly. You can set access intents only within EJB Version 2.x-compliant and later modules for entity beans with CMP Version 2.x.

This product supplies a number of access intent policies that specify permutations of read intent and concurrency control; the pessimistic and update policy can be qualified further. The selected policy determines the appropriate isolation level and locking strategy used by the run time environment.

Note: Access intent policies are specifically designed to supplemant the use of isolation level and access intent method-level modifiers found in the extended deployment descriptor for EJB version 1.1 enterprise beans. You cannot specify isolation level and read-only modifiers for EJB version 2.x and later enterprise beans.

Access intent policies configured on an entity basis define the default access intent for that entity. The default access intent controls the entity unless you specify a different access intent policy based on either method-level configuration or application profiling.

Note: Method level access intents were deprecated in Version 6.x.

You can use application profiling or method level access intent policies to control access intent more precisely. Method-level access intent policies are named and defined at the module level. A module can have one or many policies. Policies are assigned, and apply, to individual methods of the declared interfaces of entity beans and their associated home interfaces. A method-based policy is acted upon by the combination of the EJB container and persistence manager when the method causes the entity to load.

For entity beans that are backed by tables with nullable columns, use an optimistic policy with caution. The top down default mapping excludes nullable fields. You can override this when doing a meet-in-the-middle mapping. The fields used in overqualified updates are specified in the ejb-rdb mapping. If nullable columns are selected as overqualified columns, partial update should also be selected.

An entity that is configured with a read-only policy that causes a bean to be activated can cause problems if updates are attempted within the same transaction. Those changes are not committed, and the process displays an exception because data integrity might be compromised.

Concurrency control

Concurrency control is the management of contention for data resources. A concurrency control scheme is considered *pessimistic* when it locks a given resource early in the data-access transaction and does not release it until the transaction is closed. A concurrency control scheme is considered *optimistic* when locks are acquired and released over a very short period of time at the end of a transaction.

The objective of optimistic concurrency is to minimize the time that a given resource is unavailable for use by other transactions. This is especially important with long-running transactions, which under a pessimistic scheme would lock up a resource for unacceptably long periods of time.

Under an optimistic scheme, locks are obtained immediately before a read operation and released immediately after. Update locks are obtained immediately before an update operation and held until the end of the transaction.

To enable optimistic concurrency, this product uses an *overqualified update scheme* to test if the underlying data source has been updated by another transaction since the beginning of the current transaction. With this scheme, the columns marked for update and their original values are added explicitly through a WHERE clause in the UPDATE statement so that the statement fails if the underlying column values have been changed. As a result, this scheme can provide column-level concurrency control; pessimistic schemes can control concurrency at the row level only.

Optimistic schemes typically perform this type of test only at the end of a transaction. If the underlying columns have not been updated since the beginning of the transaction, pending updates to container-managed persistence fields are committed and the locks are released. If locks cannot be acquired or if some other transaction has updated the columns since the beginning of the current transaction, the transaction is rolled back: All work performed within the transaction is lost.

Pessimistic and optimistic concurrency schemes require different transaction isolation levels. Enterprise beans that participate in the same transaction and require different concurrency control schemes cannot operate on the same underlying data connection.

Note: Whether to use optimistic concurrency depends on the type of transaction. Transactions with a high penalty for failure might be better managed with a pessimistic scheme. A high-penalty transaction is one for which recovery is risky or resource-intensive. For low-penalty transactions, it is often worth the risk of failure to gain efficiency through the use of an optimistic scheme. In general, optimistic concurrency is more efficient when update collisions are expected to be infrequent; pessimistic concurrency is more efficient when update collisions are expected to occur often.

Read-ahead hints

Read-ahead schemes enable applications to minimize the number of database round trips by retrieving a working set of container-managed persistence (CMP) beans for the transaction within one query. Read-ahead involves activating the requested CMP beans and caching the data for their related beans, which ensures that data is present for the beans that an application most likely needs next. A *read-ahead hint* is a representation of the related beans to read. The hint is associated with the *findByPrimaryKey* method for the requested bean type, which must be an EJB 2.x-compliant CMP entity bean.

A read-ahead hint takes the form of a character string. You do not have to provide the string; the wizard generates it for you based on the container-managed relationships (CMRs) that are defined for the bean. The following example is provided as supplemental information only. Suppose a CMP bean type A has a finder method that returns instances of bean A. A read-ahead hint for this method is specified using the following notation: `RelB.RelC; RelD`

Interpret the preceding notation as follows:
- Bean type A has a CMR with bean types B and D.
- Bean type B has a CMR with bean type C.

For each bean of type A that is retrieved from the database, its directly-related B and D beans and its indirectly-related C beans are also retrieved. The order of the retrieved bean data columns in each row of the result set is the same as the order in the read-ahead hint: an A bean, a B bean (or null), a C bean (or null), a D bean (or null). For hints in which the same relationship is mentioned more than once, for example, `RelB.RelC;RelB.RelE`, the data columns for a bean occur only once in the result set, at the position the bean first occupies in the hint.

The tokens shown in the notation, like *RelB*, must be CMR field names for the relationships, as defined in the deployment descriptor for the bean. In indirect relationships such as `RelB.RelC`, *RelC* is a CMR field name that is defined in the deployment descriptor for bean type B.

A single read-ahead hint cannot refer to the same bean type in more than one relationship. For example, if a Department bean has an *employees* relationship with the Employee bean and also has a *manager* relationship with the Employee bean, the read-ahead hint cannot specify both *employees* and *manager*.

For more information about how to set read-ahead hints, see the documentation for the Rational Application Developer product.

Run-time behaviors of read-ahead hints

When developing your read-ahead hints, consider the following tips and limitations:

- Read-ahead hints on long or complex paths can result in a query that is too complex to be useful. Read-ahead hints on root or leaf inheritance mappings need particular care. Add up the number of tables that potentially comprise a read-ahead preload to gauge the complexity of the join operations that are required. Consider if the resulting statement constitutes a reasonable query on your target database.
- Read-ahead hints do not work in the following cases:
  - Preload paths across M:N relationships
  - Preload paths across recursive enterprise bean relationships or recursive fk relationships
  - When a read-head hint applies to a SELECT FOR UPDATE statement that requires a table join in a database that does not support the combination of those two operations.

    Generally, the persistence manager issues a SELECT FOR UPDATE statement for a bean only if the bean has an access intent that enforces strict locking policies. Strict locking policies require SELECT FOR UPDATE statements for database select queries. If the database table design requires a join operation to fulfill the statement, many databases issue exceptions because these databases do not support table joins with SELECT FOR UPDATE statements. In those cases, WebSphere Application Server does not implement a read-ahead hint. If the database does provide that support, Application Server implements the read-ahead hints that you configure.

Database deadlocks caused by lock upgrades

To avoid databse deadlocks caused by lock upgrades, you can change the access intent policy for entity beans from the default of wsPessimisticUpdate-WeakestLockAtLoad to wsPessimisticUpdate, or you can use an optimistic locking approach.

When concurrently accessing data, ensure that the application is prepared for database locking that must occur to secure the integrity of the data.

If an entity bean performs a findByPrimaryKey method, which by default obtains a *Read* lock in the database, and the entity bean is updated within the same transaction, a lock upgrade to *Exclusive*.

If this scenario occurs concurrently on multiple threads, a deadlock can happen. This is because multiple read locks can be obtained at the same time but one exclusive lock can only be obtained when the other locks are dropped. Since all transactions are attempting the lock upgrade in this scenario, the one exclusive lock cannot be obtained.

To avoid this problem, you can change the access intent policy for the entity bean from the default of wsPessimisticUpdate-WeakestLockAtLoad method to wsPessimisticUpdate method. This change enables the application to inform the product and the database that the transaction has updated the enterprise bean. The *Update* lock is immediately obtained on the findByPrimaryKey method. This avoids the lock upgrade when the update is performed at a later time.

The preferred technique to define access intent policies is to change the access intent for the entire entity bean. You can change the access intent for the findByPrimaryKey method, but this was deprecated in Version 6. You might want to change the access intent for an individual method if, for example, the entity bean is involved in some transactions that are read only.

An alternative technique is to use an optimistic approach, where the findByPrimaryKey method does not hold a read lock, so there is no lock upgrade. However, this requires that the application is coded for this in order to handle rollbacks. Optimistic locking is intended for applications that do not expect database contention on a regular basis.

To change the access intent policy for an entity bean, you can use the assembly tool to set the bean level, as described in “Applying access intent policies to beans” on page 165.

Access intent assembly settings

Access intent policies contain data-access settings for use by the persistence manager. Default access intent policies are configured on the entity bean.

These settings are applicable only for EJB 2.x and EJB 3.0-compliant entity beans that are packaged in EJB 2.x and EJB 3.0-compliant modules. Connection sharing between beans with bean-managed persistence and those with container-managed persistence is possible if they all use the same access intent policy.

Name:

Specifies a name for a mapping between an access intent policy and one or more methods.

Description:

Contains text that describes the mapping.

Methods - name:

Specifies the name of an enterprise bean method, or the asterisk character (*). The asterisk is used to denote all of the methods of an enterprise bean’s remote and home interfaces.

Methods - enterprise bean:

Specifies which enterprise bean contains the methods indicated in the Name setting.

Methods - type:

Used to distinguish between a method with the same signature that is defined in both the home and remote interface. Use `Unspecified` if an access intent policy applies to all methods of the bean.

Data type	String
Range	Valid values are `Home`, `Remote`,`Local`, `LocalHome` or `Unspecified`

Methods - parameters:

Contains a list of fully qualified Java type names of the method parameters. This setting is used to identify a single method among multiple methods with an overloaded method name.

Applied access intent:

Specifies how the container must manage data access for persistence. Configurable both as a default access intent for an entity and as part of a method-level access intent policy.

Data type	String
Default	`wsPessimisticUpdate-WeakestLockAtLoad`. With Oracle, this is the same as wsPessimisticUpdate.

Range

Valid settings are `wsPessimisticUpdate`, `wsPessimisticUpdate-NoCollision`, `wsPessimisticUpdate-Exclusive`, `wsPessimisticUpdate-WeakestLockAtLoad`, `wsPessimisticRead`, `wsOptimisticUpdate`, or `wsOptimisticRead`. Only `wsPessimisticRead` and `wsOptimisticRead` are valid when class-level caching is enabled in the EJB container.

This product supports lazy collections. For each segment of a collection, iterating through the collection (*next()*) does not trigger a remote method call to retrieve the next remote reference. Two policies (`wsPessimisticUpdate` and `wsPessimisticUpdate-Exclusive`) are extremely lazy; the collection increment size is set to 1 to avoid overlocking the application. The other policies have a collection increment size of 25.

If an entity is not configured with an access intent policy, the run-time environment typically uses `wsPessimisticUpdate-WeakestLockAtLoad` by default. If, however, the **Lifetime in cache** property is set on the bean, the default value of **Applied access intent** is `wsOptimisticRead`; updates are not permitted.

Additional information about valid settings follows:

Profile name	Concurrency control	Access type	Transaction isolation
wsPessimisticRead (Note 1)	pessimistic	read	For Oracle, read committed. Otherwise, repeatable read
wsPessimisticUpdate (Note 2)	pessimistic	update	For Oracle, read committed. Otherwise, repeatable read
wsPessimisticUpdate-Exclusive (Note 3)	pessimistic	update	serializable
wsPessimisticUpdate-NoCollision (Note 4)	pessimistic	update	read committed
wsPessimisticUpdate-WeakestLockAtLoad (Note 5)	pessimistic	update	Repeatable read
wsOptimisticRead	optimistic	read	read committed
wsOptimisticUpdate (Note 6)	optimistic	update	read committed

Notes:

1. Read locks are held for the duration of the transaction.
2. The generated SELECT FOR UPDATE query grabs locks at the beginning of the transaction.
3. SELECT FOR UPDATE is generated; locks are held for the duration of the transaction.
4. A plain SELECT query is generated. No locks are held, but updates are permitted. Use cautiously. This intent enables execution without concurrency control.
5. Where supported by the backend, the generated SELECT query does not include `FOR UPDATE`; locks are escalated by the persistent store at storage time if updates were made. Otherwise, the same as wsPessimisticUpdate.
6. Generated overqualified-update query forces failure if CMP column values have changed since the beginning of the transaction.

   Be sure to review the rules for forming overqualified-update query predicates. Certain column types (for example, BLOB) are ineligible for inclusion in the overqualified-update query predicate and might affect your design.

Applying access intent policies to beans

You can apply an access intent policy to an application's entity beans through the assembly tool.

About this task

Container-managed persistence (CMP) developers can use *access intent* to provide hints on how the application server run time should manage the details of persistence without having to explicitly manage any of the persistence logic from within their application.

Using the access intent service is also an option for programmers who develop bean-managed persistence (BMP) entity beans. Because the only meaningful difference between BMP and CMP components is the mechanism that provides the persistence logic, BMP beans leverage access intent hints in the same manner as the EJB container manages accent intent for CMP beans. This ability becomes especially important when BMP entities and CMP entities want to share connections. BMP beans configured with the same concurrency as the CMP beans and implemented to the same isolation level mapping as the CMP can share connections.

Developers can apply access intent policies to BMP entity beans as well as to CMP entity beans. It is expected that BMP developers use only those access intent attributes that are important to a particular BMP bean. The access intent service interface is bound into the *java:comp namespace* for each particular BMP bean. The access intent policy retrieved from the access intent service is current from the time that the *ejbLoad* process is called until the time that the *ejbStore* process completes its invocation.

Note: This is the preferred technique to define access intent policies. Method-level access intent is deprecated in Version 6.0.

1. Start an assembly tool.
2. Optional: Open the Java EE perspective to work with Java EE projects. Click **Window > Open Perspective > Other > Java EE**.
3. Optional: Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

   a. Select **File > Import > EAR file > Next**
   b. Select the EAR file.
   c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.
   d. In the *Target server* field, select *WebSphere Application Server v6.0* type of Server Runtime.
   e. Select **Finish**
5. In the Project Explorer view of the J2EE perspective, right-click **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
6. Select the **Access** tab.
7. In the **Access Intent for Entities 2.x (Bean Level)** panel, select the name of the bean.
8. On the right side of the **Access Intent for Entities 2.x (Method Level)** panel, select **Add**. The **Add Access Intent** panel displays.
9. In the **Access intent name** field, select wsPessimisticUpdate from the drop-down list.
10. Optional: Enter a **Description** to help you remember what this policy does.
11. Optional: Change the **Persistence Option** setting
12. Click **Finish**. The access intent policy for the entity bean is shown in the **Access Intent for Entities 2.x (Bean Level)** panel

Configuring read-read consistency checking with an assembly tool

Read-read consistency checking only applies to LifeTimeInCache beans whose data is read from another transaction. For the Access Intents that are for *repeatable read* (RR), this means the product checks that the data is consistent with that in the data store, and ensures that no one updates it after the checking.

About this task

For the access intents that are for *read committed* (RC), this means the product checks that the data is consistent at the point of checking, it does **not** guarantee that the data does not change after the checking. This makes the behavior of the LifeTimeInCache bean the same as non-LifeTimeInCache beans.

To perform this checking, you need to configure CMP entity beans with read-read consistency checking. You can do this using an assembly tool. To learn how to complete this task see the topic, ″Adding bean-level access intent for entity beans 2.x″ in the assembly tool documentation at http://publib.boulder.ibm.com/infocenter/radhelp/v7r5mbeta/topic/com.ibm.jee5.doc/topics/cejb3.html

Example: Read-read consistency checking

Read-read consistency checking only applies to LifeTimeInCache beans whose data is read from another transaction.

Usage scenario

For the access intents that are for *repeatable read* (RR), this means the product checks that the data is consistent with that in the data store and ensures that no one updates it after the checking. For the Access Intents that are for *read committed* (RC), this means the product checks that the data is consistent at the point of checking, but it does **not** guarantee that the data does not change after the checking. This makes the behavior of the LifeTimeInCache bean the same as non-LifeTimeInCache beans.

You have three options for setting consistency checking, as shown in the following scenarios concerning the calculation of interest in ″Ann's″ bank account. In each case, the data store is shared by this Enterprise JavaBeans (EJB) container managed persistence (CMP) application to calculate the interest and other applications, such as EJB bean managed persistence (BMP) , Java Database Connectivity (JDBC), or legacy applications. Also in each case, the EJB account is configured as a *long-lifetime* bean.

NONE

- The server is started.
- User 1 in Transaction 1 calls Account.findByPrimaryKey(″10001″), account data for Ann is read from the database, with a balance of $100.
- Ann's record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.
- User 3 in Transaction 2 calls Account.findByPrimaryKey() for account ″10001″, Ann's data is read from cache, with a balance of $100.
- Calculate Ann's interest, but the result might not be correct because of the data integrity issue.

Read-read checking AT_TRAN_BEGIN

- The server is started.
- User 1 in Transaction 1 calls Account.findByPrimaryKey(″10001″), account data for Ann is read from the database, with a balance of $100.
- Ann's record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.
- User 3 in Transaction 2 calls Account.findByPrimaryKey() for account ″10001″, Ann's data is read from cache, with a balance of $100.

- PM performs read-read check on Ann's account and finds that the balance of 100 is changed. It issues a database query to retrieve balance of $120, and Ann's data in the cache is refreshed.
- Calculate Ann's interest, proceed with the transaction because data integrity is protected.

Read-read checking AT_TRAN_END

- The server is started.
- User 1 in Transaction 1 calls Account.findByPrimaryKey(″10001″), account data for Ann is read from the database, with a balance of $100.
- Ann's record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.
- User 3 in Transaction 2 calls Account.findByPrimaryKey() for account ″10001″, Ann's data is read from database, with balance of $100.
- Calculate Ann's interest.
- During end of transaction 2, PM performs read-read check on Ann's account and finds that the balance of 100 is changed.
- PM rolls back the transaction and invalidates the cache. The transaction fails and again data integrity is protected.

Access intent service

Access intent is a WebSphere Application Server runtime service that enables you to precisely manage an application's persistence.

The access intent service defines a set of declarative annotations used by the Enterprise JavaBeans (EJB) container and its agents to make performance optimizations for entity bean access. These annotations are organized into sets called *access intent policies*.

Access intent policies contain a set of annotations considered as hints by the EJB container and its agents. Most access intent policies are hints representing high-level abstractions that can be mapped to a specific back end resource manager. It is the responsibility of the EJB persistence machinery to ensure the necessary concurrency control, connection, and cache management when carrying out the persistence details. The EJB persistence manager can use access intent hints to make better performance decisions when carrying out its assigned task. A smaller number of access intents are hints to the EJB container, influencing the management of EJB collections.

Typically, you configure *bean level* access intent for your applications. You can also apply access intent policies to beans within the scope of *application profiles*. Consequently, you can configure beans with multiple and opposing access intent policies. The application profiling documentation explains in more detail how to configure an application to apply a particular access intent policy to a bean for one request, then apply another access intent policy to the same bean for a different request.

Support for applying access intent policies at the method level is deprecated in WebSphere Application Server Version 6.0. In this practice of configuring access intent, you apply a policy to methods within the scope of an EJB module so that the policy becomes the default access intent for all requests upon those methods.

Access intent design considerations

Note: Refrain from over-tuning an application. You can introduce errors by incorrectly using the access intent service. For example, misuse of the wsPessimisticUpdate-NoCollision policy can result in lost updates; inappropriately setting the collection increment value can introduce performance issues; and problem determination is more difficult when an application is configured with multiple access intent policies.

Note: Clarity and simplicity should be your guiding principles when using the access intent service. This is even more important when applying access intent polices within the scope of application profiles.

Even though access intent policies can be configured on any method of an entity bean, some attributes of a policy can only be leveraged by the runtime environment under certain conditions. For example, concurrency and access intent are only used for CMP entity beans when the ejbLoad method is driven to open a connection and read data from a given resource; that data is cached and used to drive the proper queries during invocation of the ejbStore method. Read-ahead hints are only used during the execution of a finder for a bean. The collection increment and resource manager prefetch increment are only used on multi-object finders. Configuring policies on methods that do not use the policy is not an error. Only certain attributes of any policy are used, even when the policy is appropriately applied to a method. However, configuring policies unnecessarily throughout an application obscures the design of the application and complicates the maintenance of the application.

Access intent with BMP entity beans

Access intent's declarative functionality provides great power to you as a CMP entity bean developer. You can provide hints on how the product should manage the details of persistence without having to explicitly manage any of the persistence logic in the application. There are situations, however, in which you might need to develop BMP entity beans. Since the only meaningful difference between BMP and CMP components is who provides the persistence logic, BMP entity beans should be able to leverage access intent hints just as the product does on behalf of CMP entity beans. BMP entity beans that use the access intent service participate in application profiling; that is, the value of the access intent attributes can differ from request to request, allowing the BMP entity bean to seamlessly modify its persistence strategy.

You can apply access intent policies to BMP entity bean methods as well as CMP entity bean methods. Because access intent hints are not contractual in nature, there is no obligation for a BMP entity bean to exploit them. BMP entity beans are expected to use only those access intent attributes that are important to that particular bean.

The current access intent policy is bound into the java:comp namespace for a particular BMP entity bean. That policy is current only for the duration of the method call during which the access intent policy was retrieved. In a typical scenario, you would cache the access type during invocation of the ejbLoad method so that appropriate actions can be taken during invocation of the ejbStore method.

Access intent best practices

When applying access intent policies to EJB methods, consider the following issues.

- **Start by configuring the default access intent policy for an entity.** After your application is built and started, you can tune certain access paths in your application using application profiling or method-level access intent.
- **Don't mix access types.** Avoid using both pessimistic and optimistic policies in the same transaction. For most databases, pessimistic and optimistic policies use different isolation levels. This can result in multiple database connections, which prevents you from taking advantage of the performance benefits possible through connection sharing.
- **Take care when applying the `wsPessimisticUpdate-NoCollision` policy.** This policy does not ensure data integrity. No database locks are held, so concurrent transactions can overwrite each other's updates. Use this policy only if you can be sure that only one transaction attempts to update persistent store at any time.

For further information on Java Persistence API (JPA) Access intent, see the topic on JPA Access intent.

Applying access intent policies to methods

You apply an access intent policy to a method, or set of methods, in an application's entity beans through the assembly tool.

About this task

Note: Method-level access intent is deprecated in Version 6.0.

1. Start an assembly tool.
2. Optional: Open the Java EE perspective to work with Java EE projects. Click **Window > Open Perspective > Other > Java EE**.
3. Optional: Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

   a. Select **File > Import > EAR file > Next**
   b. Select the EAR file.
   c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.
   d. In the *Target server* field, select *WebSphere Application Server v6.0* type of Server Runtime.
   e. Select **Finish**
5. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
6. Select the **Access** tab.
7. On the right side of the **Access Intent for Entities 2.x (Method Level)** panel, select **Add**. The **Add Access Intent** panel displays.
8. Specify the **Name** for your new intent policy.
9. Select the **Access intent name** from the drop-down list.
10. Enter a **Description** to help you remember what this policy does.
11. Optional: Select **Read Ahead Hint**. A single access intent read ahead hint might not refer to the same bean type in more than one relationship. For example, if a **Department** enterprise bean has a relationship *employees* with the **Employee** enterprise bean, and also has a relationship *manager* with the **Employee** enterprise bean, then a read ahead hint cannot specify both *employees* and *manager*.
12. Click **Next**. The next **Add Access Intent** panel displays, with optional attributes.
13. Optional: Decide whether or not to overwrite these optional access intent attributes. Click on those you want to change.
14. Click **Next**. The next **Add Access Intent** panel, with a list of Enterprise Beans, displays.
15. Select one or more Enterprise Beans from the list.

    Note: If you selected **Read Ahead Hint** in an earlier step, you can only select **ONE** bean at this step.
16. Click **Next**. The next **Add Access Intent** panel, with a list of methods, displays.
17. Select the methods you want to use.
18. If you *DID NOT* select **Read Ahead Hint** in an earlier step, click **Finish**. If you *DID* select the Read Ahead Hint option, you can click **Next** to specify your Read Ahead Hint for the specified bean. The next **Add Access Intent** panel, with a list of EJB preload paths, displays.
19. Edit the EJB preload path by selecting relationship roles from the **Relationship roles:** window.
20. Click **Finish**. A new entry is created in the **Access Intent for Entities 2.x (Method Level)** panel

Using the AccessIntent API

This task describes how to programmatically retrieve and call the AccessIntent API during the execution of bean managed persistence (BMP) entity bean methods.

1. Look up the access intent service from the namespace. For example:

```
InitialContext ic = new InitialContext();
AccessIntentService aiService = ic.lookup("java:comp/websphere/AppProfile/AccessIntentService");
```

2. From a method of the remote or local component interface of the BMP, get the current AccessIntent object using the javax.ejb.EntityContext. This is passed to the BMP when the container calls the setEntityContext method. Assume the EntityContext was stored in a variable named myEntityCtx. For example:

```
AccessIntent ai = aiService.getAccessIntent (myEntityCtx);
```

3. Use the get() methods of AccessIntent interface to obtain the desired information. For example:

```
int concurrency = ai.getConcurrencyControl();
int accessType = ai.getAccessType();
if ( (concurrency == AccessIntent.CONCURRENCY_CONTROL_PESSIMISTIC)
   && (accessType == AccessIntent.ACCESS_TYPE_UPDATE) ) {
     int exclusive = ai.getPessimisticUpdateLockHint();
     // . . .
}
// . . .
```

   For a detailed example of the use of the AccessIntent API, see Example: Using IBM extended APIs to share connections between CMP beans and BMP beans.

Results

Note: The access intent object reference retrieved from the java:comp lookup is current for the duration of the method in which the reference was looked up. Depending on how you configured the application profile, subsequent calls of the same method might not retrieve the same access intent reference. You can only look up the object reference during the call of a BMP entity bean's method; the reference does not exist during a request on a container managed persistence (CMP) entity bean. Therefore, access intent object references should not be cached beyond, or used outside of, the scope of the execution of any given BMP method.

AccessIntent interface

The AccessIntent interface is available to bean-managed persistence (BMP) entity beans.

A BMP entity bean can get and use an instance of the AccessIntent interface. For more information see "Using the AccessIntent API" on page 170.

AccessIntent interface

```
package com.ibm.websphere.appprofile.accessintent;

/**
* This interface defines the essential access intents
* available at run time.
*/
public interface AccessIntent {

/**
* Returns the concurrency control intent, which indicates
* the application prefers either pessimistic or optimistic
* concurrency control when accessing the current component
* in the context of the current transaction.
*/
public int getConcurrencyControl();
public final int CONCURRENCY_CONTROL_PESSIMISTIC = 1;
public final int CONCURRENCY_CONTROL_OPTIMISTIC = 2;

/**
* Returns access type intent, which indicates the application
* intends either update or read access of the current component
* in the context of the current transaction.
```

```
*/
public int getAccessType();
public final int ACCESS_TYPE_UPDATE= 1;
public final int ACCESS_TYPE_READ = 2;

/**
* Returns an integer value that indicates that the run time should
* assume that there will be no collision on retrieved rows.
*/
public int getPessimisticUpdateLockHint();
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_NOCOLLISION = 1;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_WEAKEST_LOCK_AT_LOAD = 2;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_NONE = 3;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_EXCLUSIVE = 4;

/*
* Returns an integer value that indicates that the run time should
* assume that there will be collisions on retrieved rows.
*/
public int getPessimisticUpdateLockHint();
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_NOCOLLISION = 1;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_WEAKEST_LOCK_AT_LOAD = 2;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_NONE = 3;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_EXCLUSIVE = 4;

/**
* Returns the collection access intent, which indicates the
* application intends to access the objects returned by the
* currently executing finder in either serial or random fashion.
*/
public int getCollectionAccess();
public final int COLLECTION_ACCESS_RANDOM = 1;
public final int COLLECTION_ACCESS_SERIAL = 2;

/**
* Returns the collection scope, which indicates the maximum
* lifespan of a lazy collection.
*/
public int getCollectionScope();
public final int COLLECTION_SCOPE_TRANSACTION = 1;
public final int COLLECTION_SCOPE_ACTIVITYSESSION = 2;
public final int COLLECTION_SCOPE_TIMEOUT = 3;

/**
* Returns the timeout value in seconds when collectionScope is Timeout.
*/
public int getCollectionTimeout();

/**
* Returns the number of elements the application requests be contained
* in each segment of the element collection returned by the currently
* executing finder.
*/
public int getCollectionIncrement();

/**
* Returns the ReadAheadHint requested by the application for the currently
* executing finder.
*/
public ReadAheadHint getReadAheadHint();

/**
* Returns the number of elements the application requests be contained in
* each segment of a query made on a database.
```

```
*/
public int getResourceManagerPreFetchIncrement();

}
```

Access intent exceptions

The exceptions thrown in response to the application of access intent policies are listed.

com.ibm.ws.ejbpersistence.utilpm.PersistenceManagerException

If the method that drives the ejbLoad() method is configured to be read-only but updates are then made within the transaction that loaded the bean's state, an exception is thrown during invocation of the ejbStore() method, and the transaction is rolled back. Likewise, the ejbRemove() method cannot succeed in a transaction that is set as read-only. If an update hint is applied to methods of entity beans with bean-managed persistence, the same behavior and exception results. The forwarded exception object contains the message string `PMGR1103E: update instance level read only bean` *beanName*

This exception is also thrown if the applied access intent policy cannot be honored because a finder, ejbSelect, or container-managed relationship (CMR) accessor method returns an inherently read-only result. The forwarded exception object contains the message string `PMGR1001: No such DataAccessSpec -` *methodName*

The most common occurrence of this error is when a custom finder that contains a read-only EJB Query Language (EJB QL) statement is called with an applied access intent of `wsPessimisticUpdate` or `wsPessimisticUpdate-Exclusive`. These policies require the use of a USE AND KEEP UPDATE LOCKS clause on the SQL SELECT statement to be executed, but a read-only query cannot support USE AND KEEP UPDATE LOCKS. Other examples of read-only queries include joins; the use of ORDER BY, GROUP BY, and DISTINCT keywords.

To eliminate the exception, edit the EJB query so that it does not return an inherently read-only result or change the access intent policy being applied.

- If an update access is required, change the applied access intent setting to `wsPessimisticUpdate-WeakestLockAtLoad` or `wsOptimisticUpdate`.
- If update access is not truly required, use `wsPessimisticRead` or `wsOptimisticRead`.
- If connection sharing between entity beans is required, use `wsPessimisticUpdate-WeakestLockAtLoad` or `wsPessimisticRead`.

com.ibm.websphere.ejb.container.CollectionCannotBeFurtherAccessed

If a lazy collection is driven after it is no longer in scope, and beyond what has already been locally buffered, a CollectionCannotBeFurtherAccessed exception is thrown.

com.ibm.ws.exception.RuntimeWarning

If an application is configured incorrectly, a run-time warning exception is thrown as the application starts; startup is ended. You can validate an application's configuration by choosing the verify function. Some examples of misconfiguration include:

- A method configured with two different access intent policies
- A method configured with an undefined access intent policy

Access intent troubleshooting tips

The following frequently asked questions involving access intent are answered.

Oracle database fails when no access policies are applied

No access intent policies have been applied and the application runs with a DB2 database, but it fails with an Oracle database with the following message:

```
com.ibm.ws.ejbpersistence.utilpm.PersistenceManagerException: PMGR1001E: No such DataAccessSpec
:FindAllCustomers. The backend datastore does not support the SQLStatement needed by this
AccessIntent: (pessimistic update-weakestLockAtLoad)(collections: transaction/25) (resource
manager prefetch: 0) (AccessIntentImpl@d23690a).
```

If you have not configured access intent, all of your data is accessed under the default access intent policy (`wsPessimisticUpdate-WeakestLockAtLoad`). On DB2 the weakest lock is share. On Oracle databases, however, the weakest lock is update; this means that the SQL query must contain a FOR UPDATE clause. To avoid this problem, try to apply an access intent policy that supports optimistic concurrency.

Calling a finder method displays an InconsistentAccessIntentException at run time

This can occur when you use method-level access intent policies to apply more control over how a bean instance is loaded. This exception indicates that the entity bean was previously loaded in the same transaction. This could happen if you called a multifinder method that returned the bean instance with access intent policy X applied; you are now trying to load the second bean again by calling its findByPrimaryKey method with access intent Y applied. Both methods must have the same access intent policy applied.

Likewise, if the entity was loaded once in the transaction using an access intent policy configured on a finder, you might have called a container-managed relationship (CMR) accessor method that returned the entity bean configured to load using that entity's default access intent.

To avoid this problem, ensure that your code does not load the same bean instance twice within the same transaction with different access intent policies applied. Avoid the use of method-level access intent unless absolutely necessary.

An InconsistentAccessIntentException displays in a container-managed relationship with two beans

There are two beans in a container-managed relationship. The findByPrimaryKey method is called on the first bean and then the getBean2 method is called and a CMR accessor method is called, on the returned instance and an InconsistentAccessIntentException displays.

You are probably using read-ahead. When you loaded the first bean, you caused the second bean to be loaded under the access intent policy applied to the finder method for the first bean. However, you have configured your CMR accessor method from the first bean to the second with a different access intent policy. CMR accessor methods are really finder methods in disguise; the run-time environment behaves as if you were trying to change the access intent for an instance you have already read from persistent store.

To avoid this problem, beans configured in a read-ahead hint are all driven to load with the same access intent policy as the bean to which the read-ahead hint is applied.

A bean with a one-to-many relationship to a second bean displays an UpdateCannotProceedWithIntegrityException error when an instance of the second bean is added to the first bean's collection

A bean with a one-to-many relationship to a second bean displays an UpdateCannotProceedWithIntegrityException error when an instance of the second bean is added to the first bean's collection. The first bean has a pessimistic-update intent policy applied.

The second bean probably has a read intent policy applied. When you add the second bean to the first bean's collection, you are not updating the first bean's state, you are implicitly modifying the second bean's state. The second bean contains a foreign key to the first bean, which is modified.

To avoid this problem, ensure that both ends of the relationship have an update intent policy applied if you expect to change the relationship at run time.

Managing EJB containers

Each application server can have a single Enterprise JavaBeans (EJB) container; one is created automatically for you when the application server is created. The following steps are to be performed only as needed to improve performance after the EJB application has been deployed.

1. Adjust EJB container settings.
2. Adjust EJB cache settings.

What to do next

If adjustments do not improve performance, consider adjusting access intent policies for entity beans, reassembling the module, and redeploying the module in the application.

EJB container settings

Use this page to configure and manage the EJB container of this application server.

To view this administrative console page, click **Servers** → **WebSphere application servers** → **server** → **EJB Container Settings** → **EJB container**.

Passivation directory

Specifies the directory into which the container saves the persistent state of passivated stateful session beans. This directory must already exist. It is not automatically created.

Stateful session beans with an activation policy of TRANSACTION are passivated at the end of the transaction in which they are enlisted, and stateful session beans with an activation policy of ONCE (default) are passivated when the number of active bean instances becomes greater than the cache size specified in the container configuration. When a stateful bean is passivated, the container serializes the bean instance to a file in the passivation directory and discards the instance from the bean cache. If, at a later time, a request arrives for the passivated bean instance, the container retrieves it from the passivation directory, deserializes it, returns it to the cache, and dispatches the request to it. If any step fails (for example, if the bean instance is no longer in the passivation directory), the method invocation fails.

Inactive pool cleanup interval

Specifies the interval at which the container examines the pools of available bean instances to determine if some instances can be deleted to reduce memory usage. This setting is for all bean pools. **Attention:** Stateful session beans are NOT pooled, so this applies to stateless session and entity bean pools.

Data type	Integer
Default	30000
Units	Milliseconds
Range	0 to 2 147 483 647

Default data source JNDI name

Specifies the JNDI name of a data source to use if no data source is specified during application deployment. This setting is not applicable for EJB 2.x-compliant CMP beans.

Servlets and enterprise beans use *data sources* to obtain these connections. When configuring a container, you can specify a default data source for the container. This data source becomes the default data source used by any entity beans installed in the container that use container-managed persistence (CMP).

The default data source for a container is secure. When specifying it, you must provide a user ID and password for accessing the data source.

Specifying a default data source is optional if each CMP entity bean in the container has a data source specified in its configuration. If a default data source is not specified and a CMP entity bean is installed in the container without specifying a data source for that bean, applications cannot use that CMP entity bean.

Enable stateful session bean failover using memory-to-memory replication

Specifies that failover is enabled for *all* stateful session beans installed in this EJB container.

This checkbox is disabled until you define a replication domain. This selection has a hyperlink to help you configure the replication settings. If no replication domains are configured, the link takes you to a panel where you can create one. If at least one domain is configured, the link takes you to a panel where you can select the replication settings to be used by the EJB container.

Data type	Checkbox
Default	Unselected
Range	Selected or unselected.

Initial state

Specifies the execution state requested when the server first starts.

Data type	String
Default	Started
Range	Valid values are `Started` and `Stopped`

EJB container system properties

In addition to the settings accessible from the administrative console, you can set the following system property by command-line scripting.

com.ibm.websphere.ejbcontainer.poolSize

Specifies the size of the pool for the specified bean type. This property applies to stateless, message-driven and entity beans. If you do not specify a default value, the container defaults of 50 and 500 are used.

Set the pool size for a given entity bean as follows:

```
beantype= [H]
min,[H]
max [:beantype=
[H]min,
[H]max...]
```

beantype is the Java EE name of the bean, formed by concatenating the application name, the **#** character, the module name, the **#** character, and the name of the bean, that is, the string assigned to the `<ejb-name>` field in the bean's deployment descriptor. *min* and *max* are the minimum and maximum pool sizes, respectively, for that bean type. Do not specify the square brackets shown in the previous prototype; they denote optional additional bean types that you can specify after the first. Each bean-type specification is delimited by a colon (:).

Use an asterisk (*) as the value of *beantype* to indicate that all bean types are to use those values unless overridden by an exact bean-type specification somewhere else in the string, as follows:

```
*=30,100
```

To specify that a default value be used, omit either *min* or *max* but retain the comma (,) between the two values, as follows (split for publication):

```
SMApp#PerfModule#TunerBean=54,
   :SMApp#SMModule#TypeBean=100,200
```

You can specify the bean types in any order within the string.

You can designate the maximum configured EJB pool size as a *hard limit* by inserting the character *H* directly in front of the *max* value. Without the *H*, the maximum value indicates how many EJB instances can be pooled, and does not limit the number of EJB instances that can be created or in use. Inserting the *H* before the max value indicates that it is a hard limit, and the EJB Container blocks creation of more instances when that limit is reached. Further threads must wait until an instance becomes available or until the transaction times out.

You can designate the minimum configured EJB pool size as a *hard limit* by inserting the character *H* directly in front of the *min* value. Without the *H*, the minimum value indicates how many EJB instances are maintained in the pool when the EJB type is not actively in use, but does not pre-load the pool when the application is started. Normally, the minimum pool size is not reached until the minimum number of EJB instances has been accessed concurrently by the application. Inserting the *H* before the min value indicates that it is a hard limit, and the EJB Container pre-loads the pool with the minimum number of EJB instances when the application is started.

As an example, if you want to indicate that no more than 200 EJB instances are created, and that additional requests must wait for an instance and might time out while waiting, you enter:

```
SMApp#SMModule#TypeBean=100,H200
```

If you want to indicate that the EJB Container pre-load the pool with a minimum of 100 EJB instances when the application is started, you enter:

```
SMApp#SMModule#TypeBean=H100,200
```

Note: The hard limit indicator is only available to EJB Version 2.0 or later Stateless Session beans.

com.ibm.websphere.ejbcontainer.allowEarlyInsert

This property is applicable to CMP 1.1 beans only. By default, the EJB Container creates the entity bean representation in the database only after the method ejbPostCreate(...) is called.

Note: CMP beans are not supported in EJB 3.0 modules.

Some applications may rely on method ejbCreate(...) to have created the entity bean in the database. For such a requirement, setting the JVM property *com.ibm.websphere.ejbcontainer.allowEarlyInsert* to **true** overrides the default behavior.

Changing enterprise bean types to initialize at application start time using the administrative console

All Enterprise JavaBeans (EJB) types within a server can be forced to initialize at application start time by setting a system property within the administrative console.

About this task

If the value of this property is set to **true**, then all beans within the server are initialized at each application's start time.

However, by default, the product's EJB container delays the initialization (loading of classes and processing of deployment descriptor metadata) of most EJB types until they are needed during run time. This delay helps to speed up the application start time.

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.

5. In the Server Infrastructure area, select **Java and Process Management**.
6. In the Server Infrastructure area, select **Process Definition**.
7. In the Additional Properties area, select **Java Virtual Machine**.
8. In the Additional Properties area, select **Custom Properties**.
9. Select the **New** box.
10. In the **Name** entry field, type *com.ibm.websphere.ejbcontainer.initializeEJBsAtStartup*.
11. In the **Value** entry field, type *true*. Entering *true* causes all Enterprise JavaBeans to initialize when your application starts. Entering *false* causes initialization of all beans to be delayed.

    Note: Setting com.ibm.websphere.ejbcontainer.initializeEJBsAtStartup to either true or false takes precedence over any *Start EJB at Application Start* settings made on individual EJB types.
12. Select **OK**.

What to do next

This task can also be done by using an assembly tool.

Tuning the EJB cache using the trace service

About this task

The size of your Enterprise JavaBeans (EJB) cache can effect the performance of the application server. One of the steps in tuning your EJB container to optimum performance levels is to fine tune the EJB cache. The following describes how to use the diagnostic trace service to help you determine the best cache size for you.

1. Enable the EJB cache trace. To learn about working with the trace service, see Working with trace. For information about the trace service settings, see Diagnostic trace service settings.

   Set up your trace to use this trace string:

```
com.ibm.ejs.util.cache.BackgroundLruEvictionStrategy=all=enabled:com.ibm.ejs.util.cache.CacheElementEnumerator=
all=enabled
```

   Set **Maximum File Size** to *200MB* or more. If you leave the default value of 20MB, you could fill up the single 20MB trace log and lose some data because of trace wrapping.

   Set **Maximum Number of Historical Files** to *5*. Five files should be sufficient, but if you see that all five files are full and trace wrapping occurs, increase this value.
2. Stop your server, delete existing logs, then start your server.
3. Run typical scenarios to capture cache trace data. By running a typical scenario with the trace enabled, you will get the EJB cache trace data to analyze in the following steps.
4. View and analyze the trace output.
   a. Open your trace log. Look for either or both of the following trace strings to appear:

      BackgroundLru 3 EJB Cache: Sweep (1,40) - Cache limit not reached : 489/2053
      BackgroundLru > EJB Cache: Sweep (16,40) - Cache limit exceeded : 3997/2053 Entry

      In the trace strings that include the words **Cache limit** you find a ratio. For example, 3997/2053. The first number is the number of enterprise beans currently in the EJB cache (called the *capacity*). The second number is the EJB cache setting (more about this in later steps). You will use this ratio, particularly the capacity, in your analysis.

      Also look for the statements *Cache limit not reached* and *Cache limit exceeded*.

      Cache limit not reached
      Your cache is equal to or larger than what is appropriate. If it is larger, you are wasting memory, and should reduce the cache size to a more appropriate value, as described below.

      Cache limit exceeded
      The number of beans currently being used is greater than the capacity you have specified,

indicating that your cache is not properly tuned. The capacity can exceed the EJB Cache setting because the setting is not a hard limit. The EJB Container does not stop adding beans to the cache when the limit is reached. Doing so could mean that when the cache is full, a request for a bean would not be fulfilled, or would at least be delayed until the cache fell below the limit. Instead, the cache limit can be exceeded, but the EJB Container attempts to clean up the cache and keep it below the EJB Cache size.

In the case where the cache limit is exceeded, you might see a trace point similar to this:

BackgroundLru < EJB Cache: Sweep (64,38) - Evicted = 50 : 3589/2053 Exit

Notice the *Evicted =* string. If you see this string, you are using either Stateful Session Beans or Entity Beans configured for Option A or B caching. Evicted objects mean you are not taking full advantage of the caching option that you have chosen. Your first step is to try increasing the EJB Cache size. If continued running of your application results in more evictions, it means that the application is accessing or creating more new beans between EJB Cache sweeps than the cache can hold, and *NOT* re-using existing beans. At this point, you might want to consider using Option C caching for your entity beans, or checking your application to see if it is not removing Stateful Session Beans after they are no longer needed.

Note: Entity beans configured with Option C caching are only in the cache while in a transaction, and are required to be held in the cache for the entire transaction. Therefore, they are never evicted during a cache sweep, but are removed from the cache when the transaction completes. In addition, if you are using only Stateless Session Beans or Entity Beans with Option C caching (or both), then you might want to increase your EJB Cache *cleanup interval* to a larger number. The cleanup interval can be set as described in "EJB cache settings" on page 180. Stateless Session Beans are **NOT** in the EJB Cache, and since Entity Beans using Option C caching are never evicted by the caching (LRU) strategy, there is really no need to sweep very often. When using only Stateless Session Beans or Option C caching, you should only see ″Evicted = 0″ in the trace example shown above.

b. Analyze your trace log. Look for the trace string *Cache limit exceeded*.
   - You might find more than one instance of this string. Examine them all to find the highest capacity value of beans in the EJB Cache. Re-set your EJB Cache size to about 110% of this number. Setting the EJB Cache size is explained in a later step.
   - You might find no instances of this string. This means that you have not exceeded the capacity of the EJB Cache (which is your end goal), but not seeing it during your initial analysis could also mean that your cache is too large and using unnecessary memory. In this case, you still need to tune your cache by reducing the cache size until your cache limit is exceeded, then increasing it to the optimum value. Setting the EJB Cache size is explained in a later step.

   Your ultimate goal is to set the cache limit to a value that does not waste resources, but also does not get exceeded. So, a good set-up gives you a trace with only the *Cache limit not reached* message, and a ratio where the capacity number can be near, but below, 100% of the EJB Cache setting.

   Note: It is recommended that you do not set your cache size to anything less than the default of 2053.

5. Modify the cache settings based on your analysis. See "EJB cache settings" on page 180 for information on how to do this.
6. Stop your server, delete all logs, and restart your server.
7. Repeat the above steps until you are satisfied with your settings.
8. Disable the EJB Cache trace. With the cache properly tuned, you can remove the trace, remove old logs, and restart your server.

What to do next

From your analysis, it is possible to set the EJB cache optimally from an EJB Container perspective, but perhaps not optimally from a WebSphere Application Server perspective. A larger cache size provides more hits and better EJB cache performance, but uses more memory. Memory used by the cache is not available to other areas of the product, potentially causing the overall performance to suffer. In a system with ample memory, this might not be an issue and properly tuning the EJB cache might increase overall performance. However, you should take into account this system performance versus EJB cache performance when configuring the cache.

Working with trace
Use trace to obtain detailed information about running the WebSphere Application Server components, including application servers, clients, and other processes in the environment.

Related reference

"EJB cache settings"
Use this page to configure and manage the cache for a specific Enterprise JavaBeans (EJB) container. To avoid errors from attempting to overload the cache, determine the cache absolute limit. Multiply the number of enterprise beans active in any given transaction by the total number of concurrent transactions expected. Then, add the number of active session bean instances. This value is the limit that the cache will hold. You can use the Tivoli Performance Viewer to view bean performance information.

EJB cache settings

Use this page to configure and manage the cache for a specific Enterprise JavaBeans (EJB) container. To avoid errors from attempting to overload the cache, determine the cache absolute limit. Multiply the number of enterprise beans active in any given transaction by the total number of concurrent transactions expected. Then, add the number of active session bean instances. This value is the limit that the cache will hold. You can use the Tivoli Performance Viewer to view bean performance information.

To view this administrative console page, click **Servers** → **Server Types** → **WebSphere application servers** → **server** → **EJB Container Settings** → **EJB cache settings**.

Cleanup interval

Specifies the interval at which the container attempts to remove unused items from the cache in order to reduce the total number of items to the value of the cache size. This setting applies to the cache only.

The cache manager tries to maintain some unallocated entries that can be allocated quickly as needed. A background thread attempts to free some entries while maintaining some unallocated entries. If the thread runs while the application server is idle, when the application server needs to allocate new cache entries, it does not pay the performance cost of removing entries from the cache. In general, increase this parameter as the cache size increases.Timeouts are specified according to the transaction type:

- Container-managed transactions: The bean provider configures the timeout attribute in the deployment desecriptor.
- Bean-managed transaction: An application calls the UserTransaction.setTransactionTimeout method in the codes.

Data type	Integer
Units	Milliseconds
Range	0 to 2 147 483 647
Default	3000

Cache size

Specifies the number of buckets in the active instance list within the EJB container.

A bucket can contain more than one active enterprise bean instance, but performance is maximized if each bucket in the table has a minimum number of instances assigned to it. When the number of active instances within the container exceeds the number of buckets, that is, the cache size, the container periodically attempts to reduce the number of active instances in the table by passivating some of the active instances. For the best balance of performance and memory, set this value to the maximum number of active instances expected during a typical workload.

Data type	Integer
Units	Buckets in the hash table
Range	Greater than 0. The container selects the next largest prime number equal to or greater than the specified value.
Default	2053

Container interoperability

Container interoperability describes the ability of the product clients and servers at different versions to successfully negotiate differences in native Enterprise JavaBeans (EJB) finder methods support and Java EE compliance.

Interoperability of the handle formats in WebSphere Application Server, Version 5 and Version 5.0.1

Applications that attempt to persist handles to enterprise beans and **EJBHome** needed to subclass ObjectInputStream in WebSphere Application Server, Version 5. This action was required so that the subclass ObjectInputStream could utilize the context class loader to resolve the classes for enterprise beans and EJBHome stubs.

In addition, handles created and persisted in WebSphere Application Server, Version 5 only work with objects that have an unchanged remote interface. If the remote interface is changed, the handle is no longer valid because the stub is serialized inside the handle and its serial Version UID changes if the remote interface changes.

This release introduces a new handle persistence mechanism that avoids the implementation drawbacks of the previous version. However, if handles are used for this WebSphere Application Server deployment, you should consider the following issues when applying this update, future WebSphere Application Server Fix Packs and EJB Container cumulative fixes for WebSphere Application Server, Version 5.

If a WebSphere Application Server, Version 5 persisted handle or home handle is encountered by a WebSphere Application Server, Version 5.0.1 system, it can be read and utilized. In addition, it will be converted to WebSphere Application Server, Version 5.0.1 format if it is re-persisted. The WebSphere Application Server, Version 5.0.1 format cannot be read by a WebSphere Application Server, Version 5 system unless PQ72184 is applied.

Problems arise when handles are persisted and shared across systems that are not at the WebSphere Application Server, Version 5.0.1 level or later. However, a Version 5 system can receive a handle from Version 5.0.1 remotely through a call to get a handle on an enterprise bean or a getHomeHandle on an **EJBHome**. The remote call will succeed, however, any attempt to persist it on the Version 5 system will have the same limitations regarding the use of ObjectInputStream and changes in remote interface invalidating the persisted handle.

When your application stores handles persistently and shares this persistence with multiple clients or application servers, apply WebSphere Application Server, Version 5.0.1 or PQ72184 to both the client and server systems at the same time. Failure to do so can result in the inability of these systems to read the handle data stored by upgraded systems. Also, handles stored by the WebSphere Application Server, Version 5 can force the applications of the updated system to still subclass `ObjectInputStream`.

Applications using the WebSphere Application Server Enterprise, Version 5 scheduler and process choreographer, are affected by these changes. These users should update their Version 5 systems at the same time with either Version 5.0.1 or PQ72184.

If the applications store handles in the session context, or locally in a file on the same system, that is not shared by other applications, on different systems, they might be able to update their systems individually, rather than all at once. If Client Container and thin client applications do not share persisted handle data, they can be updated as needed as well. However, handles created and persisted in WebSphere Application Server, Version 5, Version 4.0.3 and later (with the property flag set), or Version 3.5.7 and later (with the property flag set) are not usable if either the home or the remote interface changes.

If any WebSphere Application Server, Version 3.5.7 or Version 4.0.3 and later enables the system property com.ibm.websphere.container.portable to **true**, any handles to objects on that server have the same interoperability limitations. In addition, if any WebSphere Application Server, Version 3.5.7 and later or Version 4.0.3 applications store a handle obtained from a WebSphere Application Server, Version 5 or Version 5.0.1, the same restrictions apply, regarding the need to subclass ObjectInputStream and the usability of handles after a change to the remote interface is made.

Replication of the Http Session and Handles

This note applies to you if you place Handles to Homes or Enterprise JavaBeans, or EJB or EJBHome references in the Http Session in your application and you use Http Session Replication. If you intend to replicate a mixed environment of Version 5.0.0 and Version 5.0.1 or 5.0.2 machines you should first apply the latest Version 5.0.0 container cumulative e-fix to the Version 5.0.0 machines before allowing the Version 5.0.1 or 5.0.2 server into the typology. The reason for this is that Version 5.0.0 servers are not able to understand the persisted Handle format used on the Version 5.0.1 and 5.0.2 server. This is similar to the case of Version 5.0.0 and Version 5.0.1 or 5.0.2 systems trying to use a shared database, mentioned above. But in this case, it is the Http Session object and not the database providing the persistence.

Top Down Deployment Mapping

The size of the Handle objects has grown due to the fix put in to allow serialization and deserialization to occur without the previous requirements of subclassing the ObjectInputStream and so on. Top down deployment of an object that contains EJB and EJBHome references create a database table ddl that has a field of 1000 bytes of VARCHAR for BITDATA which will contain the Handle. It might be that your object's Handle does not fit in the 1000 byte default field, and you might need to adjust this to a higher value. You might try increments of 250 bytes, that is, 1250, 1500, and so on.

EJB 2.1 container tuning

If you use applications that affect the size of the Enterprise JavaBeans (EJB) container cache, it is possible that the performance of your applications can be impacted by an incorrect size setting. Container managed persistence (CMP) is discussed in this topic, although it is important to know that entity beans are not supported in an EJB 3.0 module.

EJB cache size

Monitoring Tivoli Performance Viewer (TPV) is a great way to diagnose if the EJB container cache size setting is tuned correctly for your application.

If the application has filled the cache causing evictions to occur, TPV will show a very high rate of the ejbStores method being called and probably a lower than expected CPU utilization on the application server machine.

All applications using enterprise beans should have this setting adjusted from the default if the following formula works out to more than 2000.

```
EJB_Cache_Size = (Largest number of Option B or C Entity Beans enlisted in a
transaction * maximum number of concurrent transactions) +
(Largest number of unique Option A Entity Beans expected to be accessed during
typical application workload) +
(Number of stateful Session Beans active during typical workload) +
(Number of stateless SessionBean types used during typical workload)

Where:
Option B and C Entity Beans are only held in the EJB cache during the lifetime
of the transaction they are enlisted in. Therefore, the first term in the formula
computes the average EJB cache requirements for these types of beans.

Option A Entity Beans are held in the EJB cache indefinitely, and are only removed
 from the cache if there starts to become more beans in the cache than the cache
size has been set to. If your application uses Read Only Beans, consider them to be Option A beans for the purpose of this tuning calculation.

Stateful Session Beans are held in the EJB cache until they are removed by the
application, or their session timeout value is reached.

Only a single stateless Session Bean instance for each EJB type is held in the
cache during the time any methods are being executed on that stateless Session
Bean. If two or more methods are being executed simultaneously on the same
stateless Session Bean type, each method executes on its own bean instance, but
only one cache location is used for all of these instances.
```

This calculates the upper bound on the maximum possible number of enterprise beans active at one time inside the application server. Because the EJB container's cache is built to contain all these beans for performance optimizations, best performance can be achieved by setting this cache size to be larger than the number resulting from the calculation above.

```
<tuning parameter>
This setting can be found under Servers > Application Servers > serverName >
         EJB Container > EJB Cache Settings
```

Also while adjusting the EJB cache size, the EJB container management thread parameter can be tuned to meet the needs of the application. The management thread is controlled through the Clean Up Interval setting. This setting controls how frequently a daemon thread inside of the product attempts to remove bean instances from the cache that have not been used recently, attempting to keep the number of bean instances at or below the cache size. This ensures that the EJB container places and looks up items in the cache as quickly. It is typically best to leave this interval set to the default, however, in some cases, it might be worthwhile to see if there is a benefit to reducing this interval.

For information about tuning the EJB cache to an even finer degree using the EJB cache trace service, see "Tuning the EJB cache using the trace service" on page 178.

EJB stateful session bean tuning

Stateful session bean timeout values can be configured using an assembly tool. For WebSphere Application Server Version 5.1 and later, the default value is 600 seconds. If this default value is not acceptable, you can change it in the tooling's EJB deployment descriptor editor. Stateless session beans **do not** have a timeout value because they have no conversational state and are not dedicated to any specific client.

You **cannot** set the timeout value globally, or on the server, so that the value applies to all stateful session beans. You can only set the timeout on a bean-by-bean basis.

Dcom.ibm.websphere.ejbcontainer.poolSize

If the application is using the majority of the instances in the pool, the TPV indicates this. When this occurs, then the size of those bean pools that are being exhausted should be increased. This can be done by adding this parameter in the JVM's custom properties tag .

```
-Dcom.ibm.websphere.ejbcontainer.poolSize=<application_name>#<module_name>#
<enterprisebean_name>=<minSize>,<maxSize>

where:
 <application_name> is the J2EE application name as defined in the application
archive (.ear) file deployment descriptor, for the bean whose pool size is being
set
```

```
<module_name> is the .jar file name of the EJB module, for the bean whose pool size
 is being set,

<bean_name> is the J2EE Enterprise Bean name as defined in the EJB module
deployment descriptor, for the bean whose pool size is being set

<minSize> is the number of bean instances the container maintains in the pool,
 irrespective of how long the beans have been in the pool (beans greater than this
 number are cleared from the pool over time to optimize memory usage)

<maxSize> is the number of bean instances in the pool where no more bean instances
 are placed in the pool after they are used (that is, once the pool is at this
 size, any additional beans are discarded rather than added into the pool --
this ensures the number of beans in the pool has an upper limit so memory usage
does not grow in an unbounded fashion).

To keep the number of instances in the pool at a fixed size, minSize and maxSize
can be set to the same number. Note that there is a separate instance pool for
every EJB type running in the application server, and that every pool starts out
with no instances in it - that is, the number of instances grows as beans are
used and then placed in the pool. When a bean instance is needed by the container
and no beans are available in the pool, the container creates a new bean
instance, uses it, then places that instance in the pool (unless there are
already maxSize instances in the pool).

For example, the statement
-Dcom.ibm.websphere.ejbcontainer.poolSize=ivtApp#ivtEJB.jar#ivtEJBObject=125,1327

would set a minSize of 125 and a maxSize of 1327 on the bean named "ivtEJBObject"
within the ivtEJB.jar file, in the application "ivtApp".
```

Where ivtApp is replaced by the actual application name, ivtEJB.jar file is replaced by the JAR that contains the bean that needs to have its pool size increased, and ivtEJBObject is the bean name of the enterprise bean whose pool size should be increased. The minimum number of beans that are held in the pool is 125. The maximum number of beans that are held in the pool is 1327. These should be set so no more evictions occur from the pool and in most cases should be set equal if memory is plentiful because no growth and shrinkage of the pool occurs.

Dcom.ibm.websphere.ejbcontainer.noPrimaryKeyMutation

You should have a good idea of how your application handles the creation of primary key objects for use by CMP beans and bean-managed persistence (BMP) beans inside of the product. The IBM EJB container uses the primary key of an entity bean as an identifier inside of many internal data structures to optimize performance. However, the EJB container must copy these primary key objects upon the first access to the bean to ensure that the objects stored in the internal caches are separate from the ones used in an application, in case the application changes or mutates the primary key, to keep the internal structures consistent. If the application does not mutate any of the primary keys used to create and access entity beans after they are created, a special flag can be used that ensures the EJB container skips the copy of the primary key object, saving CPU cycles and increasing performance. This mechanism can be enabled at your own risk by adding the **–D** property to the JVM custom property field.

```
<tuning parameter>
-Dcom.ibm.websphere.ejbcontainer.noPrimaryKeyMutation=true
```

The performance benefit of this optimization depends on the application. If the application uses primitive types for enterprise beans' primary keys there is no gain because these objects are already immutable and the copy mechanism takes this into account. If, however, the application uses many complex primary keys, that is, an object for a primary key or multiple fields, this parameter can yield significant improvements.

Dcom.ibm.ws.pm.deferredcreate

The persistence manager is used by the EJB container to persist data to the database from CMP entity beans. When creating entity beans by calling the ejbCreate method, by default the persistence manager

immediately inserts the empty row with only the primary key in the database. In most cases, after creating the bean you should modify fields in the bean created or in other beans inside of the same transaction. If you want to postpone the insert into the database until the end of the transaction to eliminate one trip to the database, set the **–D** flag inside of the JVM custom properties field. The data is inserted into the database and consistency is maintained.

```
<tuning parameter>
-Dcom.ibm.ws.pm.deferredcreate=true
```

The performance benefit of this optimization depends on the application. If the EJB applications transactions are insert intensive the application can benefit from this optimization. If the application performs few inserts, the benefit of this optimization is less.

Dcom.ibm.ws.pm.batch

When an EJB application accesses multiple CMP beans inside of a single transaction, depending on the operations performed on the beans, such as updates, inserts, reads, the number of operations issued to the database corresponds directly to the operations performed on the CMP beans. If the database system you are using supports batching of update statements, you can enable this flag and increase performance on all interactions with the database that involve more than two updates in a single transaction.

This flag lets the persistence manager add all the update statements into one single batch statement that is issued to the database. This saves round trips to the database, increasing performance. If the you know that your application exhibits the behavior of updating multiple CMP beans in a single transaction, and the database supports batch updates, you can set the **–D** flag inside of the JVM custom properties field.

```
<tuning parameter>
-Dcom.ibm.ws.pm.batch=true
```

The performance benefit of this optimization depends on the application. If the application never or infrequently updates CMP beans or only updates a single bean per transaction there is no performance gain. If the application updates multiple beans per transaction, this parameter benefits the applications performance.

The following table lists the backend databases that support batch update.

Table 1.

Database	Supports batch update	Supports batch update with Optimistic Concurrency Control
DB2	yes	no
Oracle	yes	no
DB2 Universal Driver	yes	yes
Informix	yes	yes
SQLServer	yes	yes
Apache Derby	yes	yes

Note: Batch update with OCC cannot be performed for databases that do not support it, even if specified by the access intent.

com.ibm.ws.pm.useLegacyCache

Specifies the name of the Java class that the product uses to implement the javax.rmi.CORBA.UtilDelegate interface.

Persistence manager has two types of caching mechanisms, *legacy cache* and *two-level cache*. Typically, two-level cache performs better than legacy cache because of optimizations in this mode. The default is legacy cache, although two-level cache is recommended. Set this configuration through the system property

`com.ibm.ws.pm.useLegacyCache=false`

com.ibm.ws.pm.grouppartialupdate and com.ibm.ws.pm.batch

The partial updates feature enhances the performance of applications with enterprise beans in certain scenarios. Persistence manager has two caching mechanisms available, legacy cache and two-level cache. Typically, two-level cache performs better than legacy cache because of the optimizations in this mode.

In certain applications where you need to perform both batch updates and partial updates, you must configure the following system properties to gain the benefits of both:

`'com.ibm.ws.pm.grouppartialupdate=true' and 'com.ibm.ws.pm.batch=true'`

Deploying EJB modules

When you deploy an Enterprise JavaBeans (EJB) module, you install that module on a server that has been configured to support deployed modules.

Before you begin

Assemble one or more EJB modules, assemble one or more Web modules, and assemble them into a J2EE application.

Assemble one or more EJB 3.0 modules, assemble one or more Web modules, and assemble them into a J2EE application.

For an overview about the changes to the EJB deployment model for EJB 3.0, see the topic ″EJB 3.0 deployment overview.″

1. Prepare the deployment environment.
2. Update the configuration for each EJB module as needed for the deployment environment.
3. Deploy the application.

What to do next

If you specify that the EJBDeploy tool be run during application installation and the installation fails with a NameNotFoundException message, ensure that the input Java archive (JAR) or enterprise archive (EAR) file does not contain source files. Either remove the source files or include all dependent classes and resource files on the class path. If there are source files in the input JAR or EAR file, the EJB deployment tools runs a rebuild before generating the deployment code.

If the module deploys successfully, test and debug the module.

EJB 3.0 deployment overview

Learn about the Enterprise JavaBeans (EJB) 3.0 deployment model, including to *Just-In-Time* (JIT) deployment.

All Java Platform, Enterprise Edition (Java EE) application server products have some form of EJB deployment phase where your application is customized to run in that particular application server implementation. Typically, this is accomplished by an application server-specific deployment tool, which generates code to bridge your EJB interface and implementation code to the application server's EJB

container implementation. Some application server products' deploy tools alter the bytecodes of your application classes rather than using code generation, but the end result is similar.

In WebSphere Application Server, the bridging is accomplished by generating code that *wraps* your EJB implementation classes, connecting them to the product EJB container, which in turn allows the EJB container to host your enterprise beans and provide services to them. If one or more of your enterprise beans has defined remote interfaces, additional code is generated to provide the remote function.

Historically, EJB deployment in the WebSphere product has been performed by the *EJBDeploy* tool that is included with product and packaged with WebSphere product-oriented development tools.

The EJBDeploy tool introspects your EJB external interfaces, generates the wrapper code as .java files, then compiles it using the javac compiler to produce .class files, which are then packaged in your EJB module with your application code. The EJBDeploy tool also runs the rmic tool against the remote EJB interfaces in the application, producing additional *stub* and *tie* class files that interact with the Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) Object Request Broker (ORB), providing remote object support. Typically, you run the EJBDeploy tool either when you install the application on the product or sometime before you install the application from the command-line tool or within a development tool.

Just-In-Time deployment

The EJB 3.0 support in WebSphere Application Server adds a new feature called Just-In-Time Deployment. With Just-In-Time Deployment, the EJB container dynamically generates the wrapper, stub, and tie classes in-memory as needed when the application is running. Additionally, the Web container and application client containers dynamically generate the stub class required for remote EJB invocations. Effectively, this means that you do not need to process EJB 3.0 modules, Web modules that invoke EJB 3.0 beans, or client modules that invoke EJB 3.0 beans, through the EJBDeploy tool prior to running them in WebSphere.

createEJBStubs tool

Even though the Just-In-Time Deployment feature, in many cases, dynamically generates the RMI-IIOP stub classes that are required for invocation of remote EJB interfaces, there remain some cases where these stub classes are not dynamically generated. For EJB 3.0 clients not running inside a Web container, EJB container, or client container, that is upgraded to EJB 3.0 level, you must generate the stub classes with the createEJBStubs tool, then make the generated stubs available in the client environment's classpath. Typically you would accomplish this by copying the generated stubs to the location where the client's business interface class resides.

To summarize, the createEJBStubs tool must be used to generate client-side stubs for the following environments:

- ″Bare″ Java Standard Edition (SE) clients, where a Java SE Java Virtual Machine (JVM) is the client environment.
- WebSphere Application Server container environments prior to Version 7 that do not have the Feature Pack for EJB 3.0 applied.
- Non-WebSphere Application Server environments.

For more information about packaging your EJB module, see the topic, ″EJB 3.0 module packaging overview.″

EJBDEPLOY relationships – troubleshooting tips

Use this information to troubleshoot information for EJBDEPLOY problems.

The converter that is defined for the primary key is not invoked on its foreign key value

The mapping for primary key fields to database columns may use a converter to transform the key values. If a container-managed persistence (CMP) bean uses a converter to map its primary key, and that bean has a relationship where the bean at the other end holds a foreign key, the mapping for the foreign key will not use the converter.

The following errors might occur, indicating that the converter defined for the primary key is not invoked on its foreign key value. During the run of the ejbDeploy command , you receive the following message:

```
No type mapping defined for Java datatype1 to Database datatype2
```

During run time, the application does not find the CMP bean at the other end of the relationship.

To work around this limitation, define your own foreign key in the database table, and create a mapping that uses the same converter as defined for the primary key on the enterprise beans at the other end of its relationship.

EJB module settings

Use this page to configure and manage a specific deployed EJB module.

Note: You cannot start or stop an individual EJB module for modification. You must start or stop the appropriate application entirely.

To view this administrative console page, click **Applications** → **Application Types** → **WebSphere enterprise applications** → **application_name** → **Manage Modules** → **module_name**.

Note: If an application is running, changing an application setting causes the application to restart. On stand-alone servers, the application restarts after you save the change. On multiple-server products, the application restarts after you save the change and files synchronize on the node where the application is installed. To control when synchronization occurs on multiple-server products, deselect **Synchronize changes with nodes** on the Console preferences page.

URI

Specifies location of the module relative to the root of the application EAR file. The URI must match the URI of a ModuleRef URI in the deployment descriptor of the deployed application (EAR).

Alternate deployment descriptor

Specifies an alternate deployment descriptor for the module as defined in the application deployment descriptor according to the J2EE specification.

Starting weight

Specifies the order in which modules are started when the server starts. The module with the lowest starting weight is started first.

Data type	Integer
Default	5000
Range	Greater than 0

Chapter 4. Client applications

Using application clients

An application client module is a Java Archive (JAR) file that contains a client for accessing a Java application.

About this task

Complete the following steps for developing different types of application clients.

1. Decide on a type of application client.
2. Develop the application client code.
   a. Develop ActiveX application client code.
   b. Develop J2EE application client code.
   c. Develop pluggable application client code.
   d. Develop thin application client code.
3. Assemble the application client using the Application Server Toolkit.
4. Deploy the application client.
   Deploy the application client on Windows systems.
5. Run the application client.

Example

The IBM Application Client for WebSphere Application Server Samples gallery is not available on WebSphere Application Server for i5/OS. To access these samples, install WebSphere Application Server Clients on the Windows platform, and retrieve the samples from your local file system as the following command indicates:

`<app_server_root>/samples/index.html`

Application Client for WebSphere Application Server

In a traditional client-server environment, the client requests a service and the server fulfills the request. Multiple clients use a single server. Clients can also access several different servers. This model persists for Java clients except that now these requests use a client runtime environment.

In this model, the client application requires a servlet to communicate with the enterprise bean, and the servlet must reside on the same machine as the WebSphere Application Server.

The Application Client for WebSphere Application Server Version 7.0 (Application Client) consists of the following client applications:

- Java Platform, Enterprise Edition (Java EE) application client application (Uses services provided by the Java EE Client Container)
- Thin application client application (Does not use services provided by the Java EE Client Container)

The Application Client is packaged with the following components:

- The application client on WebSphere Application Server for i5/OS provides the necessary Java extensions to work with the iSeries server Java (TM) Development Kit. The i5/OS product does not include a standalone JRE.
- WebSphere Application Server run time for Java EE application client applications or Thin application client applications

The *Java EE application client* is a Java application program that accesses enterprise beans, Java DataBase Connectivity (JDBC) APIs, and Java Message Service message queues. The Java EE application client program runs on client machines. This program follows the same Java programming model as other Java programs; however, the Java EE application client depends on the Application Client run time to configure its execution environment, and uses the Java Naming and Directory Interface (JNDI) name space to access resources.

The Thin application client provides a lightweight Java client programming model. This client is useful in situations where the client application requires a thinner, more lightweight environment than the one offered by the Java EE application client.

The Java EE application client programming model provides the benefits of the Java EE platform for the Java client application. Use the Java EE application client to develop, assemble, deploy and launch a client application. The tooling provided with the WebSphere Application Server platform supports the seamless integration of these stages to help the developer create a client application from start to finish.

When you develop a client application using and adhering to the Java EE platform, you can put the client application code from one Java EE platform implementation to another. The client application package can require redeployment using each Java EE platform deployment tool, but the code that comprises the client application remains the same.

The Application Client run time supplies a container that provides access to system services for the client application code. The client application code must contain a main method. The Application Client run time invokes this main method after the environment initializes and runs until the Java virtual machine code terminates.

The Java EE platform supports the Application Client use of *nicknames* or *short names*, defined within the client application deployment descriptor. These deployment descriptors identify enterprise beans or local resources (JDBC, Java Message Service (JMS), JavaMail and URL APIs) for simplified resolution through JNDI. This simplified resolution to the enterprise bean reference and local resource reference also eliminates changes to the client application code, when the underlying object or resource either changes or moves to a different server. When these changes occur, the Application Client can require redeployment.

The Application Client also provides initialization of the run-time environment for the client application. The deployment descriptor defines this unique initialization for each client application. The Application Client run time also provides support for security authentication to enterprise beans and local resources.

The Application Client uses the Java Remote Method Invocation-Internet InterORB Protocol (RMI-IIOP). Using this protocol enables the client application to access enterprise bean references and to use Common Object Request Broker Architecture (CORBA) services provided by the Java EE platform implementation. Use of the RMI-IIOP protocol and the accessibility of CORBA services assist users in developing a client application that requires access to both enterprise bean references and CORBA object references.

When you combine the Java EE and CORBA environments or programming models in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

Application client functions

This topic provides information about available functions in the different types of clients.

Use the following table to identify the available functions in the different types of clients.

Available functions	ActiveX client	Applet client	J2EE client	Pluggable client	Thin client

Provides all the benefits of a J2EE platform	Yes	No	Yes	No	No
Portable across all J2EE platforms	No	No	Yes	No	No
Provides the necessary run-time support for communication between a client and a server	Yes	Yes	Yes	Yes	Yes
Supports the use of nicknames in the deployment descriptor files. **Note:** Although you can edit deployment descriptor files, do not use the administrative console to modify them.	Yes	No	Yes	No	No
Supports use of the RMI-IIOP protocol	Yes	Yes	Yes	Yes	Yes
Browser-based application	No	Yes	No	No	No
Enables development of client applications that can access enterprise bean references and CORBA object references	Yes	Yes	Yes	Yes	Yes
Enables the initialization of the client application run-time environment	Yes	No	Yes	No	No
Supports security authentication to enterprise beans	Yes	Limited	Yes	Yes	Yes
Supports security authentication to local resources	Yes	No	Yes	No	No
Requires distribution of application to client machines	Yes	No	Yes	Yes	Yes
Enables access to enterprise beans and other Java classes through Visual Basic, VBScript, and Active Server Pages (ASP) code	Yes	No	No	No	No
Provides a lightweight client suitable for download	No	Yes	No	Yes	Yes
Enables access JNDI APIs for enterprise bean resolution	Yes	Yes	Yes	Yes	Yes
Runs on client machines that use the Sun Java Runtime Environment	No	No	No	Yes	No
Supports CORBA services (using CORBA services can render the application client code nonportable)	No	No	Yes	No	No
Supports JMS connections to the default messaging provider	No	No	Yes	No	Yes
Supports JMS connections to the default messaging provider	No	No	Yes	Yes	Yes

ActiveX application clients

WebSphere Application Server provides an ActiveX to EJB bridge that enables ActiveX programs to access enterprise beans through a set of ActiveX automation objects.

The bridge accomplishes this access by loading the Java virtual machine (JVM) into any ActiveX automation container such as Visual Basic, VBScript, and Active Server Pages (ASP).

There are two main environments in which the ActiveX to EJB bridge runs:

- **Client applications**, such as Visual Basic and VBScript, are programs that a user starts from the command line, desktop icon, or Start menu shortcut.
- **Client services**, such as Active Server Pages, are programs started by some automated means like the Services control panel applet.

The ActiveX to EJB bridge uses the Java Native Interface (JNI) architecture to programmatically access the JVM code. Therefore the JVM code exists in the same process space as the ActiveX application (Visual Basic, VBScript, or ASP) and remains attached to the process until that process terminates. To create JVM code, an ActiveX client program calls the XJBInit() method of the XJB.JClassFactory object. For more information about creating JVM code for an ActiveX program, see ActiveX to EJB bridge, initializing JVM code.

After an ActiveX client program has initialized the JVM code, the program calls several methods to create a proxy object for the Java class. When accessing a Java class or object, the real Java object exists in the JVM code; the automation container contains the proxy for that Java object. The ActiveX program can use the proxy object to access the Java class, object fields, and methods. For more information about using Java proxy objects, see ActiveX to EJB bridge, using Java proxy objects. For more information about calling methods and access fields, see ActiveX to EJB bridge, calling Java methods and ActiveX to EJB bridge, accessing Java fields.

The client program performs primitive data type conversion through the COM IDispatch interface (use of the IUnknown interface is not directly supported). Primitive data types are automatically converted between native automation types and Java types. All other types are handled automatically by the proxy objects For more information about data type conversion, see ActiveX to EJB bridge, converting data types.

Any exceptions thrown in Java code are encapsulated and thrown again as a COM error, from which the ActiveX program can determine the actual Java exceptions. For more information about handling exceptions, see ActiveX to EJB bridge, handling errors.

The ActiveX to EJB bridge supports both free-threaded and apartment-threaded access and implements the free threaded marshaler (FTM) to work in a hybrid environment such as Active Server Pages. For more information about the support for threading, see ActiveX to EJB bridge, using threading.

Applet clients

The applet client provides a browser-based Java run time capable of interacting with enterprise beans directly, instead of indirectly through a servlet.

This client is designed to support users who want a browser-based Java client application programming environment that provides a richer and more robust environment than the one offered by the **Applet > Servlet > enterprise bean** model.

The programming model for this client is a hybrid of the Java application thin client and a servlet client. When accessing enterprise beans from this client, the applet can consider the enterprise bean object references as CORBA object references.

No tooling support exists for this client to develop, assemble or deploy the applet. You are responsible for developing the applet, generating the necessary client bindings for the enterprise beans and CORBA objects, and bundling these pieces together to install or download to the client machine. The Java applet

client provides the necessary run time to support communication between the client and the server. The applet client run time is provided through the Java applet browser plug-in that you install on the client machine.

Generate client-side bindings using an assembly tool. An applet can utilize these bindings, or you can generate client-side bindings using the **rmic** command. This command is part of the IBM Developer Kit, Java edition that is installed with the WebSphere Application Server.

The applet client uses the RMI-IIOP protocol. Using this protocol enables the applet to access enterprise bean references and CORBA object references, but the applet is restricted in using some supported CORBA services.

If you combine the enterprise bean and CORBA environments in one applet, you must understand the differences between the two programming models, and you must use and manage each model appropriately.

The applet environment restricts access to external resources from the browser run-time environment. You can make some of these resources available to the applet by setting the correct security policy settings in the WebSphere Application Server `client.policy` file. If given the correct set of permissions, the applet client must explicitly create the connection to the resource using the appropriate API. This client does not perform initialization of any service that the client applet can need. For example, the client application is responsible for the initialization of the naming service, either through the CosNaming, or the Java Naming and Directory Interface (JNDI) APIs.

Java EE application clients

The Java Platform, Enterprise Edition (Java EE) application client programming model provides the benefits of the Java EE Platform for WebSphere Application Server Enterprise product.

The Java EE platform offers the ability to seamlessly develop, assemble, deploy and launch a client application. The tooling provided with the WebSphere platform supports the seamless integration of these stages to help the developer create a client application from start to finish.

When you develop a client application using and adhering to the Java EE platform, you can put the client application code from one Java EE platform implementation to another. The client application package can require redeployment using each Java EE platform deployment tool, but the code that comprises the client application does not change.

The Java EE application client run time supplies a container that provides access to system services for the application client code. The Java EE application client code must contain a main method. The Java EE application client run time invokes this main method after the environment initializes and runs until the Java virtual machine application terminates.

Application clients can use *nicknames* or *short names*, defined within the client application deployment descriptor with the Java EE platform. These deployment descriptors identify enterprise beans or local resources (Java Database Connectivity (JDBC) data sources, J2C connection factories, Java Message Service (JMS), JavaMail and URL APIs) for simplified resolution through JNDI use. This simplified resolution to the enterprise bean reference and local resource reference also eliminates changes to the application client code, when the underlying object or resource either changes or moves to a different server. When these changes occur, the application client can require redeployment. Although you can edit deployment descriptor files, do not use the administrative console to modify them.

Note: Connection pool is not supported in application client. The application client calls the database directly, without a datasource. If you want to use the getConnection() request from the application client, configure the JDBC provider in the application client deployment descriptors, using Rational® Application Developer (RAD) or assembly tool. The connection is established between application

client and the database. Application client does not have connection pool, but JDBC provider configuration is available in the client deployment descriptors.

The Java EE application client also provides initialization of the run-time environment for the client application. The deployment descriptor defines this unique initialization for each client application. The Java EE application client run time also provides support for security authentication to the enterprise beans and local resources.

The Java EE application client uses the Java Remote Method Invocation technology run over Internet Inter-Orb Protocol (RMI-IIOP). Using this protocol enables the client application to access enterprise bean references and to use Common Object Request Broker Architecture (CORBA) services provided by the Java EE platform implementation. Use of the RMI-IIOP protocol and the accessibility of CORBA services assist users in developing a client application that requires access to both enterprise bean references and CORBA object references.

When you combine the Java EE and the CORBA WebSphere Application Server Enterprise environments or programming models in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

Pluggable application clients

The Pluggable application client provides a lightweight, downloadable Java application run time capable of interacting with enterprise beans.

Note: The Pluggable application client is available only on the Windows platform.

The Pluggable application client requires that you have previously installed the Sun Java Runtime Environment (JRE) files. In all other aspects, the Pluggable application client, and the Thin application client are similar.

This client is designed to support those users who want a lightweight Java client application programming environment, without the overhead of the Java Platform, Enterprise Edition (Java EE) platform on the client machine. The programming model for this client is heavily influenced by the CORBA programming model, but supports access to enterprise beans.

When accessing enterprise beans from this client, the client application can consider the enterprise beans object references as CORBA object references.

Tooling does not exist on the client; however, tooling does exists on the server. You are responsible for developing the client application, generating the necessary client bindings for the enterprise bean and CORBA objects, and after bundling these pieces together, installing them on the client machine.

The Pluggable application client provides the necessary run time to support the communication needs between the client and the server.

The Pluggable application client uses the RMI-IIOP protocol. Using this protocol enables the client application to access enterprise bean references and CORBA object references and use any supported CORBA services. Using the RMI-IIOP protocol along with the accessibility of CORBA services can assist a user in developing a client application that needs to access both enterprise bean references and CORBA object references.

When you combine the Java EE and CORBA environments in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

The Pluggable application client run time provides the necessary support for the client application for object resolution, security, Reliability Availability and Serviceability (RAS), and other services. However, this client does not support a container that provides easy access to these services. For example, no

support exists for using *nicknames* for enterprise beans or local resource resolution. When resolving to an enterprise bean (using either the Java Naming and Directory Interface (JNDI) API or CosNaming) sources, the client application must know the location of the name server and the fully qualified name used when the reference was bound into the name space.

When resolving to a local resource, the client application cannot resolve to the resource through a JNDI lookup. Instead the client application must explicitly create the connection to the resource using the appropriate API (JDBC, Java Message Service (JMS), and so on). This client does not perform initialization of any of the services that the client application might require. For example, the client application is responsible for the initialization of the naming service, either through CosNaming or JNDI APIs.

The Pluggable application client offers access to most of the available client services in the Java EE application client. However, you cannot access the services in the Pluggable application client as easily as you can in the Java EE application client. The Java EE client has the advantage of performing a simple JNDI name space lookup to access the desired service or resource. The Pluggable application client must code explicitly for each resource in the client application. For example, looking up an enterprise bean Home object requires the following code in a Java EE application client:

```
java.lang.Object ejbHome =
 initialContext.lookup("java:/comp/env/ejb/MyEJBHome");
MyEJBHome =
 (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome, MyEJBHome.class);
```

However, you need more explicit code in a Pluggable application client for Java:

```
java.lang.Object ejbHome =
 initialContext.lookup("the/fully/qualified/path/to/actual/home/in/namespace/MyEJBHome");
MyEJBHome =
 (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome, MyEJBHome.class);
```

In this example, the Java EE application client accesses a logical name from the `java:/comp` name space. The Java EE client run time resolves that name to the physical location and returns the reference to the client application. The pluggable client must know the fully qualified physical location of the enterprise bean Home object in the name space. If this location changes, the pluggable client application must also change the value placed on the lookup() statement.

In the Java EE client, the client application is protected from these changes because it uses the logical name. A change can require a redeployment of the EAR file, but the actual client application code remains the same.

The Pluggable application client is a traditional Java application that contains a *main* function. The WebSphere Pluggable application client provides run-time support for accessing remote enterprise beans, and provides the implementation for various services. This client can also access CORBA objects and CORBA-based services. When using both environments in one client application, you need to understand the differences between the enterprise bean and the CORBA programming models to manage both environments.

For instance, the CORBA programming model requires the CORBA CosNaming name service for object resolution in a name space. The enterprise beans programming model requires the JNDI name service. The client application must initialize and properly manage these two naming services.

Another difference applies to the enterprise bean model. Use the JNDI implementation in the enterprise bean model to initialize the Object Request Broker (ORB). The client application is unaware that an ORB is present. The CORBA model, however, requires the client application to explicitly initialize the ORB through the `ORB.init()` static method.

The Pluggable application client provides a batch command that you can use to set the CLASSPATH and JAVA_HOME environment variables to enable the Pluggable application client run time.

Thin application clients

The Thin application client provides a lightweight, downloadable Java application run time capable of interacting with enterprise beans.

WebSphere Application Server supports the pluggable client.

The Thin application client is designed to support those users who want a lightweight Java client application programming environment, without the overhead of the Java Platform, Enterprise Edition (Java EE) platform on the client machine. The programming model for this client is heavily influenced by the CORBA programming model, but supports access to enterprise beans.

When accessing enterprise beans from this client, the client application can consider the enterprise beans object references as CORBA object references.

Tooling does not exist on the client, it exists on the server. You are responsible for developing the client application, generating the necessary client bindings for the enterprise bean and CORBA objects, and bundling these pieces together to install on the client machine.

The Thin application client provides the necessary runtime to support the communication needs between the client and the server.

The Thin application client uses the RMI-IIOP protocol. Using this protocol enables the client application to access not only enterprise bean references and CORBA object references, but also allows the client application to use any supported CORBA services. Using the RMI-IIOP protocol along with the accessibility of CORBA services can assist a user in developing a client application that needs to access both enterprise bean references and CORBA object references.

When you combine the Java EE and CORBA environments in one client application, you must understand the differences between the two programming models, to use and manage each appropriately.

The Thin application client run time provides the necessary support for the client application for object resolution, security, Reliability Availability and Servicability (RAS), and other services. However, this client does not support a container that provides easy access to these services. For example, no support exists for using *nicknames* for enterprise beans or local resource resolution. When resolving to an enterprise bean (using either Java Naming and Directory Interface (JNDI) or CosNaming) sources, the client application must know the location of the name server and the fully qualified name used when the reference was bound into the name space. When resolving to a local resource, the client application cannot resolve to the resource through a JNDI lookup. Instead the client application must explicitly create the connection to the resource using the appropriate API (JDBC, Java Message Service (JMS), and so on). This client does not perform initialization of any of the services that the client application might require. For example, the client application is responsible for the initialization of the naming service, either through CosNaming or JNDI APIs.

The Thin application client offers access to most of the available client services in the Java EE application client. However, you cannot access the services in the thin client as easily as you can in the Java EE application client. The Java EE client has the advantage of performing a simple Java Naming and Directory Interface (JNDI) name space lookup to access the desired service or resource. The thin client must code explicitly for each resource in the client application. For example, looking up an enterprise bean Home requires the following code in a Java EE application client:

```
java.lang.Object ejbHome =  initialContext.lookup("java:comp/env/ejb/MyEJBHome");
MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,  MyEJBHome.class);
```

However, you need more explicit code in a Thin application client:

```
java.lang.Object ejbHome =
  initialContext.lookup("the/fully/qualified/path/to/actual/home/in/namespace/MyEJBHome");
MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,  MyEJBHome.class);
```

In this example, the Java EE application client accesses a logical name from the `java:comp` name space. The Java EE client run time resolves that name to the physical location and returns the reference to the client application. The Thin application client must know the fully qualified physical location of the enterprise bean Home in the name space. If this location changes, the thin client application must also change the value placed on the lookup() statement.

In the Java EE client, the client application is protected from these changes because it uses the logical name. A change might require a redeployment of the EAR file, but the actual client application code remains the same.

The Thin application client is a traditional Java application that contains a *main* function. The WebSphere Thin application client provides run-time support for accessing remote enterprise beans, and provides the implementation for various services. This client can also access CORBA objects and CORBA based services. When using both environments in one client application, you need to understand the differences between the enterprise bean and CORBA programming models to manage both environments.

For instance, the CORBA programming model requires the CORBA CosNaming name service for object resolution in a name space. The enterprise beans programming model requires the JNDI name service. The client application must initialize and properly manage these two naming services.

Another difference applies to the enterprise bean model. Use the Java Naming and Directory Interface (JNDI) implementation in the enterprise bean model to initialize the Object Request Broker (ORB). The client application is unaware that an ORB is present. The CORBA model, however, requires the client application to explicitly initialize the ORB through the `ORB.init()` static method.

The Thin application client provides a batch command that you can use to set the CLASSPATH and JAVA_HOME environment variables to enable the Thin application client run time.

WebSphere Application Server Version 6.1 and the Application client for WebSphere Application Server Version 6.1 also provides specialized types of Thin application client. The Web Services Thin Client is an unmanaged, stand-alone Java client environment that allows you to run JAX-RPC Web services client applications to invoke Web services that are hosted by the application server. The Administration Thin Client enables client applications to perform administration tasks outside of the application server environment.

Application client troubleshooting tips

This topic provides debugging tips for resolving common Java 2 Platform Enterprise Edition (J2EE) application client problems. To use this troubleshooting guide, review the trace entries for one of the J2EE application client exceptions, and then locate the exception in the guide.

Some of the errors in the guide are samples, and the actual error you receive can be different than what is shown here. You might find it useful to rerun the `launchClient` command specifying the `-CCverbose=true` option. This option provides additional information when the J2EE application client run time is initializing.

Error: java.lang.NoClassDefFoundError

Explanation This exception is thrown when Java code cannot load the specified class.

Possible causes
- Invalid or non-existent class
- Class path problem
- Manifest problem

Recommended response

Check to determine if the specified class exists in a Java Archive (JAR) file within your Enterprise Archive (EAR) file. If it does, make sure the path for the class is correct. For example, if you get the exception:

```
java.lang.NoClassDefFoundError:
WebSphereSamples.HelloEJB.HelloHome
```

verify that the HelloHome class exists in one of the JAR files in your EAR file. If it exists, verify that the path for the class is WebSphereSamples.HelloEJB.

If both the class and path are correct, then it is a class path issue. Most likely, you do not have the failing class JAR file specified in the client JAR file manifest. To verify this situation, perform the following steps:

1. Open your EAR file with an assembly tool, and select the Application Client.
2. Add the names of the other JAR files in the EAR file to the Classpath field.

This exception is generally caused by a missing Enterprise Java Beans (EJB) module name from the Classpath field.

If you have multiple JAR files to enter in the Classpath field, be sure to separate the JAR names with spaces.

If you still have the problem, you have a situation where a class is loaded from the file system instead of the EAR file. This error is difficult to debug because the offending class is not the one specified in the exception. Instead, another class is loaded from the file system before the one specified in the exception. To correct this error, review the class paths specified with the -CCclasspath option and the class paths configured with the Application Client Resource Configuration Tool.

Look for classes that also exist in the EAR file. You must resolve the situation where one of the classes is found on the file system instead of in the `.ear` file. Remove entries from the classpaths, or include the `.jar` files and classes in the `.ear` file instead of referencing them from the file system.

If you use the -CCclasspath parameter or resource classpaths in the tool, and you have configured multiple JAR files or classes, verify they are separated with the correct character for your operating system. Unlike the Classpath field, these class path fields use platform-specific separator characters.
Note: The system class path is not used by the Application Client run time if you use the launchClient batch or shell files. In this case, the system class path would not cause this problem. However, if you load the launchClient class directly, you do have to search through the system class path as well.

Error: com.ibm.websphere.naming.CannotInstantiateObjectException: Exception occurred while attempting to get an instance of the object for the specified reference object. [Root exception is javax.naming.NameNotFoundException: xxxxxxxxxx]

Explanation

This exception occurs when you perform a lookup on an object that is not installed on the host server. Your program can look up the name in the local client Java Naming and Directory Interface (JNDI) name space, but received a NameNotFoundException exception because it is not located on the host server. One typical example is looking up an EJB component that is not installed on the host server that you access. This exception might also occur if the JNDI name you configured in your Application Client module does not match the actual JNDI name of the resource on the host server.

Possible causes

- Incorrect host server invoked
- Resource is not defined
- Resource is not installed
- Application server is not started
- Invalid JNDI configuration

Recommended response

If you are accessing the wrong host server, run the `launchClient` command again with the -CCBootstrapHost parameter specifying the correct host server name. If you are accessing the correct host server, use the product `dumpnamespace` command line tool to see a listing of the host server JNDI name space. If you do not see the failing object name, the resource is either not installed on the host server or the appropriate application server is not started. If you determine the resource is already installed and started, your JNDI name in your client application does not match the global JNDI name on the host server. Use the Application Server Toolkit to compare the JNDI bindings value of the failing object name in the client application to the JNDI bindings value of the object in the host server application. The values must match.

Error: javax.naming.ServiceUnavailableException: A communication failure occurred while attempting to obtain an initial context using the provider url: ″iiop://[invalidhostname]″. Make sure that the host and port information is correct and that the server identified by the provider URL is a running name server. If no port number is specified, the default port number 2809 is used. Other possible causes include the network environment or workstation network configuration. Root exception is org.omg.CORBA.INTERNAL: JORB0050E: In Profile.getIPAddress(), InetAddress.getByName[invalidhostname] threw an UnknownHostException. minor code: 4942F5B6 completed: Maybe

Explanation

This exception occurs when you specify an invalid host server name.

Possible causes

- Incorrect host server invoked
- Invalid host server name

Recommended response

Run the `launchClient` command again and specify the correct name of your host server with the -CCBootstrapHost parameter.

Error: javax.naming.CommunicationException: Could not obtain an initial context due to a communication failure. Since no provider URL was specified, either the bootrap host and port of an existing ORB was used, or a new ORB instance was created and initialized with the default bootstrap host of ″localhost″ and the default bootstrap port of 2809. Make sure the ORB bootstrap host and port resolve to a running name server. Root exception is org.omg.CORBA.COMM_FAILURE: WRITE_ERROR_SEND_1 minor code: 49421050 completed: No

Explanation

This exception occurs when you run the `launchClient` command to a host server that does not have the Application Server started. You also receive this exception when you specify an invalid host server name. This situation might occur if you do not specify a host server name when you run the launchClient tool. The default behavior is for the launchClient tool to run to the local host, because WebSphere Application Server does not know the name of your host server. This default behavior only works when you are running the client on the same machine with WebSphere Application Server is installed.

Possible causes

- Incorrect host server invoked
- Invalid host server name
- Invalid reference to `localhost`
- Application server is not started
- Invalid bootstrap port

Recommended response

If you are not running to the correct host server, run the `launchClient` command again and specify the name of your host server with the `-CCBootstrapHost` parameter. Otherwise, start the Application Server on the host server and run the `launchClient` command again.

Error: javax.naming.NameNotFoundException: Name comp/env/ejb not found in context ″java:″

Explanation

This exception is thrown when the Java code cannot locate the specified name in the local JNDI name space.

Possible causes

- No binding information for the specified name
- Binding information for the specified name is incorrect
- Wrong class loader was used to load one of the program classes
- A resource reference does not include any client configuration information

Recommended response

Open the EAR file with the Application Server Toolkit, and check the bindings for the failing name. Ensure this information is correct. If you are using Resource References, open the EAR file with the Application Client Resource Configuration Tool, and verify that the Resource Reference has client configuration information and the name of the Resource Reference exactly matches the JNDI name of the client configuration. If the values are correct, you might have a class loader error. For detailed information about the configuration tool and opening EAR files, read the Starting the Application Client Resource Configuration Tool in the *Developing and deploying applications* PDF book.

Error: java.lang.ClassCastException: Unable to load class: org.omg.stub.WebSphereSamples.HelloEJB._HelloHome_Stub at com.ibm.rmi.javax.rmi.PortableRemoteObject.narrow(portableRemoteObject.java:269)

Explanation

This exception occurs when the application program attempts to narrow to the EJB home class and the class loaders cannot find the EJB client side bindings.

Possible causes

- The files, *_Stub.class and _Tie.class, are not in the EJB `.jar` file
- Class loader could not find the classes

Recommended response

Look at the EJB `.jar` file located in the `.ear` file and verify the class contains the Enterprise Java Beans (EJB) client side bindings. These are class files with file names that end in `_Stub` and `_Tie`. If the binding classes are in the EJB `.jar` file, then you might have a class loader error.

Error: WSCL0210E: The Enterprise archive file [EAR file name] could not be found. com.ibm.websphere.client.applicationclient.ClientContainerException: com.ibm.etools.archive.exception.OpenFailureException

Explanation

This error occurs when the application client run time cannot read the Enterprise Archive (EAR) file.

Possible causes

The most likely cause of this error is that the system cannot find the EAR file in the path specified on the `launchClient` command.

Recommended response

Verify that the path and file name specified on the `launchclient` command are correct.

The launchClient command appears to hang and does not return to the command line when the client application has finished.

Explanation

When running your application client using the `launchClient` command the WebSphere Application Server run time might need to display the security login dialog. To display this dialog, WebSphere Application Server run time creates an Abstract Window Toolkit (AWT) thread. When your application returns from its main method to the application client run time, the application client run time attempts to return to the operating system and end the Java virtual machine (JVM) code. However, since there is an AWT thread, the JVM code will not end until `System.exit` is called.

Possible causes

The JVM code does not end because there is an AWT thread. Java code requires that `System.exit()` be called to end AWT threads.

Recommended response

- Modify your application to call `System.exit(0)` as the last statement.
- Use the `-CCexitVM=true` parameter when you call the `launchClient` command.

IBM Support has documents and tools that can save you time gathering information needed to resolve problems as described in Troubleshooting help from IBM. Before opening a problem report, see the Support page:

- http://www.ibm.com/servers/eserver/support/iseries/allproducts/index.html

clientUpgrade script

The clientUpgrade script migrates application client modules and their resources in an enterprise archive (EAR) file so that these application clients can run in WebSphere Application Server Version 7. The script converts an EAR file that you want to migrate and then overwrites the original EAR file with the converted EAR file.

The following title provides information about the clientUpgrade script.

Note: This command was deprecated in Version 6.1.

Type	Description
Product	The clientUpgrade script is available in the WebSphere Application Server (Express and Base) product only.
Authority	To run this script, your user profile must have *ALLOBJ authority.

Syntax	The syntax of the clientUpgrade script is:
	`clientUpgrade` *`EAR_file`* `[ -clientJAR` *`client_JAR_file`* `]`
	`[ -logFileLocation` *`logFileLocation`* `]`
	`[ -traceString` *`trace_spec`* `[ -traceFile` *`file_name`* `] ]`

Parameters	The parameters of the clientUpgrade script are: • *EAR_file* -- This is a required parameter. The value EAR_file specifies the fully-qualified path of the EAR file that contains the application client modules that you want to migrate. • -clientJAR -- This is an optional parameter. The value client_JAR_file specifies a JAR file that you want to migrate. The script overwrites the original EAR file with a new EAR file that contains only the specified JAR files. If you do not specify this parameter, the clientUpgrade script migrates all client JAR files in the EAR file. • -logFileLocation -- Use this optional parameter to specify an alternate location to store the log output. • -traceString -- This is an optional parameter. The value trace_spec specifies the trace information that you want to collect. To gather all trace information, specify ″*=all=enabled″ (including the double quotation marks (″)). By default, the script does not gather trace information. If you specify this parameter, you must also specify the -traceFile parameter. • -traceFile -- This is an optional parameter. The value file_name The value file_name specifies the name of the output file for trace information. If you specify the -traceString parameter but do not specify the -traceFile parameter, the script does not generate a trace file.
Logging	The clientUpgrade script displays status while it runs. It also saves more extensive logging information to the clientupgrade.log file. This file is located in the /QIBM/UserData/WebSphere/AppServer/V7/edition/profiles/default/logs directory (for a default installation using the default profile) or in the location specified by the -logFileLocation parameter.

These examples demonstrate correct syntax. In this example, the My51Application.ear file is migrated from WebSphere Application Server Version 5.1, The script overwrites the original EAR file with a new file that you can deploy in your WebSphere Application Server Version 7 profile.

```
clientUpgrade /My51Application/My51Application.ear
```

In this example, only the `myJarFile.jar` client JAR file is migrated. The script overwrites `My51Application.ear` with an EAR file that contains `myJarFile.jar`. You can deploy the new EAR file in your WebSphere Application Server profile.

```
clientUpgrade /My51Application/My51Application.ear -clientJAR myJarFile.jar
```

Running application clients

The Java Platform, Enterprise Edition (Java EE) specification requires support for a client container that runs stand-alone Java applications (known as Java EE application clients) and provides Java EE services to the applications. Java EE services include naming, security, and resource connections.

About this task

You are ready to run your application client using this tool after you:
1. Write the application client program.
2. Assemble and install an application module (`.ear` file) in the application server run time.
3. Deploy the application using the Application Client Resource Configuration Tool (ACRCT) on Windows.

This task only applies to Java EE application clients. To launch Java EE application clients using the launchClient script, perform the following steps:

1. Start the Qshell environment.

   On the CL command line, enter the command:

   ```
   STRQSH
   ```

2. Enter the following command to launch Java EE application clients:

   app_server_root`/bin/launchClient`

   where *app_server_root* is /QIBM/ProdData/WebSphere/AppServer/V7/Base or /QIBM/ProdData/WebSphere/AppServer/V7/ND

3. Pass parameters to the `launchClient` command or to your application client program as well. The `launchClient` command allows you to do both. The `launchClient` command requires that the first parameter is either:
   - An EAR file specifying the application client to launch.
   - A request for `launchClient` usage information.

   The following example illustrates the command line invocation syntax for the launchClient tool:

   ```
   launchClient [-profileName pName | -JVMOptions options | -help | -?] <userapp> [-CC<name>=<value>] [app args]
   ```

   where

   - *userapp* is the path and the name of the EAR file that contains the application client.
   - *-CC<name>=<value>* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.
   - *app args* are arguments that pass to the application client.
   - *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation.
   - *-JVMOptions* is a valid Java standard or non-standard option string. Insert quotation marks around the string.
   - *-help, -?* prints the usage information.

   All other parameters intended for the `launchClient` command must begin with the -CC prefix.

   Parameters that are not EAR files, or usage requests, or that do not begin with the -CC prefix, are ignored by the application client run time, and are passed directly to the application client program.

   The `launchClient` command retrieves parameters from three places:
   - The command line
   - A properties file
   - System properties

   The parameters are resolved in the order listed above, with command line values having the highest priority and system properties the lowest. Using this prioritization you can set and override default values.

4. Specify the server name.

   By default, the **launchClient** command uses *your_server_name* for the `BootstrapHost` property value.

   This setting is effective for testing your application client when it is installed on the same computer as the server. However, in other cases override this value with the name of your server. You can override the `BootstrapHost` value by invoking `launchClient` command with the following parameters:

   ```
   launchClient myapp.ear -CCBootstrapHost=abc.midwest.mycompany.com
   ```

   You can also override the default by specifying the value in a properties file and passing the file name to the launchClient shell.

   Security is controlled by the server. You do not need to configure security on the client because the client assumes that security is enabled. If server security is not enabled, then the server ignores the security request, and the application client functions as expected.

Example

You can store launchClient values in a properties file, which is a good method for distributing default values. You can then override one or more values on the command line. The format of the file is one `launchClient -CC` parameter per line without the `-CC` prefix. For example:

```
 verbose=true classpath=/usr/lpp/mydir/util.jar;/usr/lpp/mydir/harness.jar;/usr/lpp
/production/G19/global.jar BootstrapHost=abc.westcoast.mycompany.com tracefile=/usr
/lpp/WebSphere/mylog.txt
```

launchClient tool

This topic describes the Java Platform, Enterprise Edition (Java EE) command line syntax for the launchClient tool for WebSphere Application Server.

Note: All users who run commands from a specific profile must have authority to modify files that are created by other users that use the same profile. Otherwise, you might see a permission denied error in the log files. To avoid this issue, consider one of the following policies:

- Use specific profiles for distinct user authorities
- Always use the same user for all of the commands that are run in a given profile
- Ensure that all users of a specific profile belong to the same group. In addition, ensure that each user of a group has the read and write authority to the files that are created by other members in the same profile.

The following example illustrates the command line invocation syntax for the launchClient tool:

```
launchClient [-profileName pName | -JVMOptions options | -help | -?] <userapp> [-CC<name>=<value>] [app args]
```

where

- *userapp* is the path and the name of the EAR file that contains the application client.
- *-CC<name>=<value>* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.
- *app args* are arguments that pass to the application client.
- *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation.
- *-JVMOptions* is a valid Java standard or nonstandard option string, except `-cp` or `-classpath`. Insert quotation marks around the string.
- *-help, -?* prints the usage information.

The first parameter must be `-help`, `-?` or contain no parameter at all. The `-profileName pName` and `-JVMOptions` options are optional parameters. If used, they must appear before the *<userapp>* parameter.

All other parameters are optional and can appear in any order after the *<userapp>* parameter. The Java EE Application client run time ignores any optional parameters that do not begin with a `-CC` prefix and passes those parameters to the application client.

Client container parameters

Supported arguments include:

-CCadminConnectorHost
Specifies the host name of the server from which configuration information is retrieved.

The default is the value of the `-CCBootstrapHost` parameter or the value, `your.server.name`, if the `-CCBootstrapHost` parameter is not specified.

-CCadminConnectorPort
Indicates the port number for the administrative client function to use. The default value is `8880` for SOAP connections and `2809` for Remote Method Invocation (RMI) connections.

-CCadminConnectorType
Specifies how the administrative client connects to the server. Specify `RMI` to use the RMI connection type, or specify `SOAP` to use the SOAP connection type. The default value is `SOAP`.

-CCadminConnectorUser
Administrative clients use this user name when a server requires authentication. If the connection type is SOAP, and security is enabled on the server, this parameter is required.

-CCadminConnectorPassword
The password for the user name that the `-CCadminConnectorUser` parameter specifies.

-CCaltDD
The name of an alternate deployment descriptor file. This parameter is used with the `-CCjar` parameter to specify the deployment descriptor to use. Use this argument when a client JAR file is configured with more than one deployment descriptor. Set the value to `null` to use the client JAR file standard deployment descriptor.

-CCBootstrapHost
The name of the host server you want to connect to initially. The format is:
your_server_of_choice.com

-CCBootstrapPort
The server port number. If you do not specify this argument, the WebSphere Application Server default value is `used`.

-CCclassLoaderMode
Specifies the class loader mode. If PARENT_LAST is specified, the class loader loads classes from the local class path before delegating the class loading to its parent. The classes loaded for the following are affected:

- Classes defined for the Java EE application client
- Resources defined in the Java EE application
- Classes specified on the manifest of the Java EE client JAR file
- Classes specified using the -CCclasspath option

If PARENT_LAST is not specified, then the default mode, PARENT_FIRST, causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path.

-CCclasspath
A class path value. When you launch an application, the system class path is used. If you want to access classes that are not in the EAR file or part of the system class paths, specify the appropriate class path here. Multiple paths can be concatenated.

-CCD
Use this option to have the WebSphere Application Server set the specified system property during initialization. Do not use the equals (=) character after the `-CCD`. For example: `-CCDcom.ibm.test.property=testvalue`. You can specify multiple `-CCD` parameters. The general format of this parameter is `-CCD<property key>=<property value>`. For example, `-CCDI18NService.enable=true`.

-CCdumpJavaNameSpace
Controls generation of a dump of the java: name space for the application that is launched, which can be used for debugging purposes. A value of **true** generates a dump in short format, and includes the name and object type for each binding. A value of **long** generates a dump in long format, and includes additional information for each binding over short format, such as the local object type and string representation of the local object. The default value is **false**, and does not generate a dump.

-CCexitVM
Use this option to have the WebSphere Application Server call the `System.exit()` method after the client application completes. The default is `false`.

-CCinitonly
Use this option to initialize application client run time for ActiveX application clients without launching the client application. The default is `false`.

-CCjar
The name of the client Java Archive (JAR) file that resides within the EAR file for the application you wish to launch. Use this argument when you have multiple client JAR files in the EAR file.

-CCpropfile
Indicates the name of a properties file that contains launchClient properties. Specify the properties without the `-CC` prefix in the file, with the exception of the securityManager, securityMgrClass and securityMgrPolicy properties. See the following example: `verbose=true`.

-CCproviderURL
Provides bootstrap server information that the initial context factory can use to obtain an initial context. WebSphere Application Server initial context factory can use either a Common Object Request Broker Architecture (CORBA) object URL or an Internet Inter-ORB Protocol (IIOP) URL. CORBA object URLs are more flexible than IIOP URLs and are the recommended URL format to use. This value can contain more than one bootstrap server address. This feature can be used when attempting to obtain an initial context from a server cluster. You can specify bootstrap server addresses, for all servers in the cluster, in the URL. The operation will succeed if at least one of the servers is running, eliminating a single point of failure. The address list does not process in a particular order. For naming operations, this value overrides the `-CCBootstrapHost` and `-CCBootstrapPort` parameters. A CORBA object URL specifying multiple systems is illustrated in the following example:

```
-CCproviderURL=corbaloc:iiop:myserver.mycompany.com:9810,:mybackupserver.mycompany.com:2809
```

This value is mapped to the `java.naming.provider.url` system property.

-CCsecurityManager
Enables and runs the WebSphere Application Server with a security manager. The default is `disable`.

-CCsecurityMgrClass
Indicates the fully qualified name of a class that implements a security manager. Only use this argument if the `-CCsecurityManager` parameter is set to `enable`. The default is `java.lang.SecurityManager`.

-CCsecurityMgrPolicy
Indicates the name of a security manager policy file. Only use this argument if the `-CCsecurityManager` parameter is set to enable. When you enable this parameter, the `java.security.policy` system property is set. The default is *<app_server_root>*/ `properties/client.policy`.

-CCsoapConnectorPort
The Simple Object Access Protocol (SOAP) connector port. If you do not specify this argument, the WebSphere Application Server default value is used.

-CCtrace
Use this option to obtain debug trace information. You might need this information when reporting a problem to IBM customer support. The default is `false`. For more information, read the topic ″Enabling trace.″

-CCtracefile
Indicates the name of the file to which trace information is written. The default is to write output to the console.

-CCtraceMode
Specifies the trace format to use for tracing. If the valid value, `basic`, is not specified the default is advanced. Basic tracing format is a more compact form of tracing.

For more information on basic and advanced trace formatting, see Interpreting trace output.

-CCverbose
This option displays additional information messages. The default is `false`.

If you are using an EJB client application with security enabled, edit the `sas.client.props` file, which is located in the *profile_root*`/properties` directory. Within the file, change the `com.ibm.CORBA.loginSource` value to *none*.

For more information on the `sas.client.props` utility, see Manually encoding passwords in properties files and the PropFilePasswordEncoder command reference.

RMI connection with security. Used with the EJB and administrative client application.

Using Jacl:

```
wsadmin -conntype RMI -port  rmiportnumber -user userid
-password password
```

Using Jython:

```
wsadmin -lang jython -conntype RMI -port  rmiportnumber -user userid
-password password
```

rmiportnumber for your connection displays in the administrative console as BOOTSTRAP_ADDRESS.

Note: On the AIX®, HP-UX, Linux®, i5/OS, Solaris, and z/OS operating systems, the use of -password option may result in security exposure as the password information becomes visible to the system status program, such as ps command, which can be invoked by other users to display all of the running processes. Do not use this option if security exposure is a concern. Instead, specify user and password information in the `soap.client.props` file for SOAP connector or `sas.client.props` file for RMI connector. The `soap.client.props` and `sas.client.props` files are located in the properties directory of your WebSphere Application Server profile.

If Kerberos (KRB5) is enabled for administrative authentication, the authentication target supports BasicAuth and KRB5. To use KRB5, update the `sas.client.props`, `soap.client.props`, and `ipc.client.props` files, according to the connector type.

Note: When using Kerberos authentication, the user password does not flow across the wire. A one-way hash of password is used to identify the client.

The following examples demonstrate correct syntax.

/QIBM/ProdData/WebSphere/AppServer/V61/Base/bin/launchClient /home/earfiles/myapp.ear -profileName myprofile -CCBootstrapHost=myWASServer -CCverbose=true app_parm1 app_parm2

Specifying the directory for an expanded EAR file

You can archive the `Manifest.mf` client Java Archive (JAR) files instead of automatically cleaning them up after the application exits.

Before you begin

Each time the launchClient tool is called, it extracts the Enterprise Archive (EAR) file to a random directory name in the temporary directory on your hard drive. Then the tool sets up the thread ClassLoader to use the extracted EAR file directory and JAR files included in the `Manifest.mf` client Java Archive (JAR) file. In a normal J2EE Java client, these files are automatically cleaned up after the application exits. This cleanup occurs when the client container shutdown hook is called. To avoid extracting the EAR file (and removing the temporary directory) each time the launchClient tool is called, complete the following steps:

1. Specify a directory to extract the EAR file by setting the `com.ibm.websphere.client.applicationclient.archivedir` Java system property. If the directory does not exist or is empty, the EAR file is extracted normally. If the EAR file was previously extracted, the launchClient tool reuses the directory.
2. Delete the directory before running the launchClient tool again, if you need to update your EAR file. When you call the `launchClient` command, it extracts the new EAR file to the directory. If you do not delete the directory or change the system property value to point to a different directory, the launchClient tool reuses the currently extracted EAR file and does not use your changed EAR file. When specifying the `com.ibm.websphere.client.applicationclient.archivedir` property, make sure that the directory you specify is unique for each EAR file you use. For example, do not point the `MyEar1.ear` and the `MyEar2.ear` files to the same directory.

Using Java Web Start

Learn about the Java Web Start technology that is provided by the Java Standard Edition runtime environment to deploy Java Enterprise Edition application clients, including Thin application clients, on the remote client machine with a single click from Web browser on the client machine.

Before you begin

The supported client platforms for deploying application clients using the Java Web Start are the same as the IBM Application Client for WebSphere Application Server supported platforms, except Linux on Power and OS/400 operating systems.

Before you begin this task, see the following topics to understand Java Web Start technology and its components:

- “Java Web Start architecture for deploying application clients” on page 210
- “Client application Java Network Launcher Protocol deployment descriptor file” on page 211
- “ClientLauncher class” on page 215

You can use the following resources:

- The IBM implementation of Java Web Start on Java Platform Standard Edition 6 (Java SE 6) that is packaged in the Application Client for WebSphere Application Server.

Note: When using the Sun JRE with the Application Client runtime, application resources cannot be downloaded using the https protocol. This is a Sun Microsystems limitation. Install the IBM JRE on the client machine and use IBM Java Web Start to run the WebSphere Application Client application. Sun Java Web Start is supported, but with a limitation that only the http protocol can be used to download the application resource, including the application jnlp description file.

About this task

To deploy application clients using Java Web Start, the client machine must have at least a Java SE runtime environment installed. The Java SE runtime environment includes the Java Web Start, which implements the JSR 56: Java Network Launching Protocol and API. The application clients Enterprise Archive (EAR) file is a Java archive (JAR) resource in a JNLP descriptor file that resides on a central server. The JNLP descriptor file also specifies the runtime environment requirement for running the application.

WebSphere Application Server provides a launcher class to launch the Java EE application client in the application client container inside of Java Web Start. The client machine might not have the IBM Application Client for WebSphere Application Server installed. If this is the case, create and install an application client container and runtime package as a runtime environment through Java Web Start. The JNLP descriptor file specifies this runtime environment as the required runtime environment for running the Java EE application client.

WebSphere Application Server also provides command-line utility programs to create this application client container and runtime package from an existing IBM Application Client for WebSphere Application Server installation, as well as an installer class to install this package as a runtime environment for the application client container and also the Java Runtime Environment (JRE) in the IBM Application Client for WebSphere Application Server installation. To run the Java EE application client, the EAR file is deployed as a JAR resource that is described in the JNLP descriptor file.

1. Identify the client machine operating system, and install the corresponding IBM Application Client for WebSphere Application Server on a development machine. For example, if the Java EE application clients are targeted to run on Windows operating systems, install the IBM Application Client for WebSphere Application Server for Windows. Follow the instructions for “Installing Application Client for WebSphere Application Server” on page 242.
2. Run the utility programs to create the application client container and runtime package.
   a. Use the “buildClientRuntime tool” on page 218 utility to create the package.
   b. Use the “buildClientLibJars tool” on page 211 utility to create the JAR files containing the launcher and the installer class. This utility also zips up the properties files in the <app_client_root>/ properties directory.
3. Create the runtime installer JNLP descriptor file. The JNLP response must be included in the JNLP version ID to indicate the current runtime version in the response header, for example, `x-java-jnlp-version-id=1.6.0`. Using a servlet of a Java Server Pages (JSP) file to provide a dynamic JNLP response.
4. Create the Java EE application client launch JNLP descriptor file.
5. Package the application client container runtime environments and the Java EE application in an Enterprise Archive (EAR) file. Depending on your preferred deployment strategy, the files can be in two separate Web modules, or combined into one.
6. All JAR resources must be Java signed, including the Java EE application client EAR file.
7. Deploy the Enterprise Archive file on an application server, and start the application. The Java EE application client is ready to be deployed.

Example

A Java Web Start deployment Sample is included in the client samples. This Sample demonstrates the steps to deploy a Java EE application client with an automated ANT script. The Sample has a servlet to generate the runtime installer JNLP response with JNLP version ID, for example, `x-java-jnlp-version-id`.

Note: When the application client initially launches using Java Web Start from Sun Microsystems Java SE Runtime Environment 6.0, it installs the Application Client runtime, which includes the IBM JRE. An null pointer exception (NPE) is thrown from the `com.sun.deploy.services.WPlatformService.getSecureRandom()` method. This is a known bug in

Sun Java SE 6 (http://bugs.sun.com/bugdatabase/view_bug.do?bug_id=6505528). If you experience this exception, relaunch the application. The NPE only occurs on the first launch of the application client.

Java Web Start architecture for deploying application clients

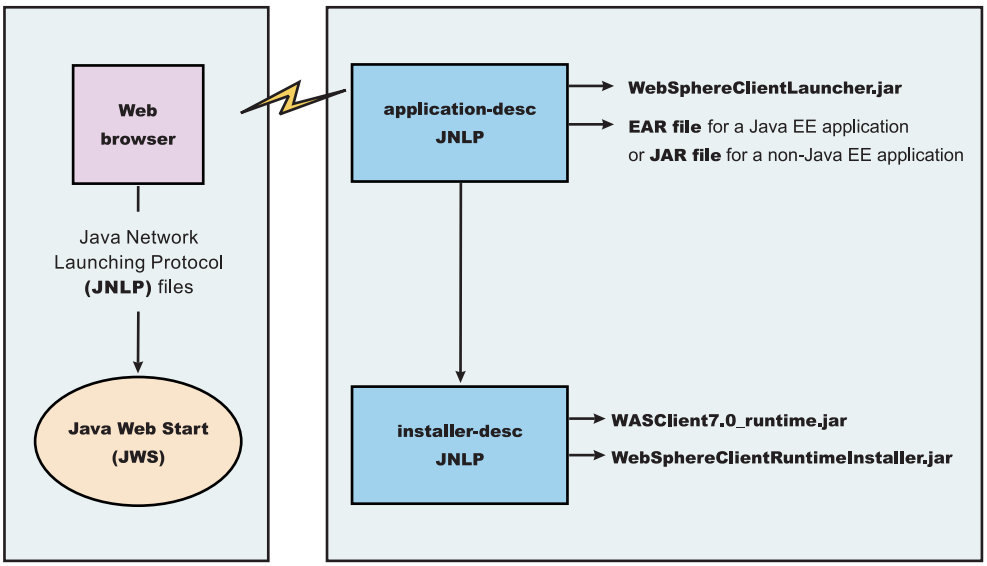
Java Web Start is an application-deployment technology that includes the portability of applets, the maintainability of servlets and JavaServer Pages (JSP) file technology, and the simplicity of mark-up languages such as XML and HTML. It is a Java application that allows full-featured Java EE client applications to be launched, deployed and updated from a standard Web server. The Java Web Start client is used with platforms that support a Web browser.

Java Web Start is not supported.

Upon launching Java Web Start for the first time, you might download new client applications from the Web. Each time you launch JWS thereafter, you can initiate applications either through a link on a Web page or (in Windows) from desktop icons or the Start menu. You can deploy applications quickly using Java Web Start, cache applications on the client machine, and launch applications remotely offline. Additionally, because Java Web Start is built from the Java Platform, Enterprise Edition (Java EE) infrastructure, the technology inherits the complete security architecture of the Java EE platform.

The technology underlying Java Web Start is the Java Network Launching Protocol & API (JNLP). Java Web Start is a JNLP client and it reads and parses a JNLP descriptor file (JNLP file). Based on the JNLP descriptor, it downloads appropriate pieces of a client application and any of its dependencies. If any of the pieces of the application are already cached on the client machine, then those components are not downloaded again, unless they have been updated on the server machine. After you download and cache the client application, JWS launches it natively on the client machine.

The following diagram shows an overview of launching a client application, include the Application Client for WebSphere Application Server as a dependent resource, using Java Web Start.



The Web browser running on a client machine connects to a Web application located on a server machine. The client application JNLP descriptor file is downloaded and processed by Java Web Start on the client machine.

In this diagram, there are two JNLP descriptor files:

- Client application JNLP descriptor (application-desc in the diagram)
- Application Clients run-time installer JNLP descriptor (installer-desc in the diagram)

Each of these JNLP descriptor files, the client application (JAR or EAR) and the dependent resource JAR files are packaged as Web applications in an EAR file. This EAR file is deployed to an Application server. The client machine with JWS installed uses a Web browser to connect to the url of the client application JNLP descriptor file to download and run the client application.

Using Java Web Start from Java SE Runtime Environment 6.0 or later is highly recommended. All the platforms supported by the application client for WebSphere Application Server are supported with the exception Linux on Power and OS/400 platforms.

You can use the following:

- Java Web Start on the Java Standard Edition Developer Kits that IBM provides, packaged in Application Client for WebSphere Application Server
- Java Web Start on Sun Microsystems Java SE 6 Development Kit or Java SE Runtime Environment 6.0, which you can download from the Sun Microsystems Web site for Windows, Linux and Solaris operating systems
- Java Web Start on HP-UX JDK or JRE for Java Platform, Standard Edition, version 6, which you can download from the HP Web site

buildClientLibJars tool:

For a Java Platform, Enterprise Edition (Java EE) application client application and or Thin application client application to be launched using Java Web Start (JWS), the properties files bundled in Application Client for WebSphere Application Server must be installed in the Java Web Start. Use this tool to create those property JAR files. The Java Web Start client is used with platforms that support a Web browser.

Java Web Start is not supported on WebSphere Application Server for i5/OS.

The buildClientLibJars tool copies the JAR files from the Application Client for WebSphere Application Server installation and creates a `properties.jar` file, which contains the properties files from the Application Clients installation properties directory to a specified location. When this property is created, the tool uses the value of `keystore`, `storepass`, `alias` and `storetype` to sign all of the JAR files in the specified location.

```
Windows usage: buildClientLibJars.bat  [-help] [-verbose] destdir keystore storepass alias storetype

Unix usage:    buildClientLibJars.sh  [-help] [-verbose] destdir keystore storepass alias storetype
```

where:

- `-help` will display the message
- `-verbose` will turn on verbose message
- `destdir` will output the destination directory name
- `keystore` is the key store file
- `storepass` is the key store password
- `alias` key is the alias name
- `storetype` is the key store type

Client application Java Network Launcher Protocol deployment descriptor file

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application.

Location

The client application has an Application Clients run-time dependency that provides the following:

- Java SE Runtime Environment from IBM

- Application Clients run-time properties
- SSL KeyStore and TrustStore file
- Application Clients run-time library JAR files (optional for Thin Application client applications)

If the Application Clients run-time dependency is not met, it is downloaded and installed in Java Web Start (JWS), as described by the Application Clients run-time installer JNLP descriptor file. For example:

```
<j2se version="1.6" href="http://your_server.com/jws/wasappclient/download.jnlp"/>
```

Usage notes

The client application must also include the `WebSphereClientLauncher.jar` file, which contains the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, that completes one of the following actions:

- If it is a Java Platform, Enterprise Edition (Java EE) Application client application (that is the resources for the application contain an EAR file with a client application), the EAR file must be specified as a JAR resource so that it can be downloaded to JWS and specified in the system property, `com.ibm.websphere.client.launcher.ear`. See “JNLP descriptor file for a Java EE Application client application” on page 213 for an example.
- If it is a Thin Application client application, the Thin Application client application JAR file must be specified as a JAR resource so that it can be downloaded to JWS and the name of the class containing main method entry point is specified in the system property, `com.ibm.websphere.launcher.main`. See “JNLP descriptor file for a Thin Application client application” on page 213 for an example.

The JNLP specification requires all the resource (JAR or EAR) files used in a JNLP file to be signed.

You can specify the –CC arguments defined in the launchClient tool for a J2EE Application client application in application arguments section of the JNLP descriptor files. However, only –CCD is supported for a Thin Application client application to define system properties and the JNLP <property> tag can also be used to define system properties. See the following example for details:

```
<property name="java.naming.provider.url" value="corbaloc:iiop:myserver.com:9089"/>
```

For a J2EE Application client application, specify the following application arguments as defined in the JNLP.

1. Specify your target server provider URL, as shown in the following example:

   ```
   <argument> >-CCDjava.naming.provider.url =corbaloc:iiop:myserver.mydomain.com:9080 </argument>
   ```

2. Specify the SSL Key File and SSL Trust File location. These files are expected to be available in the client machine. To use the ones in the Application Clients run-time dependency installed in JWS cache, specify these application arguments:

   ```
   <argument> -CCDcom.ibm.ssl.keyStore=${WAS_ROOT}/etc/key.p12 </argument>
   <argument>-CCDcom.ibm.ssl.trustStore=${WAS_ROOT}/etc/trust.p12 </argument>
   ```

3. Specify the initial naming context factor, as shown in the following example:

   ```
   <argument>-CCDjava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory </argument>
   ```

   For a Thin Application client application, you also need to specify the actual location of the `sas.client.props` and `ssl.client.props` files located in the Application Clients run-time dependency that is installed in the JWS cache.

   ```
   <argument>-CCDcom.ibm.CORBA.ConfigURL=file:${WAS_ROOT}/properties/sas.client.props </argument>
   <argument>-CCDcom.ibm.SSL.ConfigURL=file:${WAS_ROOT}/properties/ssl.client.props </argument>
   ```

   If any of the default settings in the `sas.client.props` and `ssl.client.props` file need modifying, use the –CCD to change the settings through the system properties, as shown in the following example:

   ```
   <argument>-CCDjavacom.ibm.CORBA.securityEnabled=false </argument>
   ```

   Note: The ${WAS_ROOT} token used in the JNLP file is replaced by the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, to the actual location of the Application Clients run-time dependency installation in the JWS cache. If you are using JSP to dynamically

create this JNLP description file, you must escape this token because it has a different meaning in JSP 2.0. See the following example for details:

```
<argument>-CCDcom.ibm.ssl.keyStore=\${WAS_ROOT}/etc/key.p12 </argument>
<argument>-CCDcom.ibm.ssl.trustStore=\${WAS_ROOT}/etc/trust.p12 </argument>
```

JNLP descriptor file for a Java EE Application client application:

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application.

Here is an example of the client application JNLP descriptor file for a Java EE Application client application:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
This sample program is provided AS IS and may be used, executed, copied and modified

JNLP descriptor file for a Thin Application client application:

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application. If it is a Thin Application client application, then the launcher class uses the current JVM from the Application Clients run-time dependency and invokes the Thin Application client application main method.

Here is an example of the JNLP descriptor file for a Thin Application client application.

```

ClientLauncher class:

The class, com.ibm.websphere.client.installer.ClientLauncher, contains a main() method that is called by Java Web Start (JWS) to launch the client application. The Java Web Start client is used with platforms that support a Web browser.

Java Web Start is not supported.

This client is packaged in the `WebSphereClientLauncher.jar` file that is located in the Application Client for WebSphere Application Server installation under the <*app_client_root*>/ lib/webstart directory.

The launcher class requires that the following properties are defined. These properties are not defined in a separate properties file. Instead, the properties are defined as part of the Java Network Launching Protocol (JNLP) files.

com.ibm.websphere.client.launcher.main
If the client application is a Thin Application client, then this property should be specified. It specifies the class where the main entry point of the client application resides.

com.ibm.websphere.client.launcher.ear
If the client application is a Java Platform, Enterprise Edition (Java EE) Application client, then this property should be specified. It specifies the name of the EAR file to be executed. This property takes precedence over com.ibm.websphere.client.launcher.main. However, only one of the two properties should be specified.

Application client launcher for Java Web Start:

The application client launcher for Java Web Start is a Java class, com.ibm.websphere.client.installer.ClientLauncher, which has a main() method that Java Web Start calls to start the application client container and to invoke the application client's main() method. It provides similar functions as the **lauchClient** command line tool to start application clients from the command line.

The com.ibm.websphere.client.launcher.ClientLauncher class is packaged in the WebSphereClientLauncher.jar file under the <app_client_root>/lib/webstart directory.

The launcher tool requires that the following properties are defined.

com.ibm.websphere.client.launcher.main
If the client that is to be run is a thin client, then this property should be specified. It specifies the class where the main entry point of the application resides. It is the main class name for a Thin application client. If it is set, the launcher will not start the client container, it will rather invoke the main method for the application directly. However, if `com.ibm.websphere.client.launcher.ear` is also set, it will be ignored.

com.ibm.websphere.client.launcher.ear
If the client that is to run is the Java Platform, Enterprise Edition (Java EE) client, then this property should be specified. It specifies the name of the ear file to be executed. This property takes precedence over `com.ibm.websphere.client.launcher.main` although only one of the two properties should be specified.

These properties are not defined in a separate properties file. Instead, they are defined as part of the Java Network Launching Protocol files.

When `com.ibm.websphere.client.launcher.ear` is set, the application client launcher for JWS supports almost all of the –CC arguments as the **lauchClient** command line tool supports. However, if only `com.ibm.websphere.client.launcher.main` is set, the launcher will only support the –CCD argument. The following table shows the comparison of the supported –CC arguments for the **launchClient** command line tool and the application client launcher for JWS:

-CC argument	launchClient	Application client launcher for JWS
-CCverbose	Yes	Yes
-CCjar	Yes	Yes
-CCclasspath	Yes	N/A
-CCadminConnectorHost	Yes	Yes
-CCadminConnectorPort	Yes	Yes
-CCadminConnectorType	Yes	Yes
-CCadminConnectorUser	Yes	Yes
-CCaltDD	Yes	Yes
-CCBootstrapHost	Yes	Yes
-CCBootstrapPort	Yes	Yes
-CCproviderURL	Yes	Yes
-CCinitonly	Yes	N/A
-CCtrace	Yes	Yes
-CCtracefile	Yes	Yes
-CCsecurityManager	Yes	N/A
-CCsecurityMgrClass	Yes	N/A
-CCsecurityMgrPolicy	Yes	N/A
-CCD	Yes	Yes
-CCexitVM	Yes	Yes
-CCdumpJavaNameSpace	Yes	Yes
-CCsoapConnectorPort	Yes	Yes
-CCtraceMode	Yes	Yes
-CCclassLoaderMode	Yes	Yes

Macro expansion is supported for the –CCD argument by the application client launcher for JWS. The launcher will automatically substitute certain macro keys (enclosed with ${...}) with the calculated value at runtime. For example, if a macro key is used in the –CCD argument in the application client JNLP manifest file,

```
<argument>-CCDcom.ibm.ssl.keyStore= ${WAS_ROOT}/etc/key.p12</argument>
```

it will be expanded to the JWS cache installation root location and the argument will become:

```
-CCDcom.ibm.ssl.keyStore=/home/tiu/.java/deployment/cache/javaws/ext/E1134532441112/etc/key12.p12
```

The following table shows the 3 macro keys that are currently supported and will be substituted by the launcher:

Table 2.

Macro key	Value
${WAS_ROOT}	Installation root location within the JWS cache that is used by the application client container and runtime installer for JWS.
${JAVA_HOME}	Location of Java home. The return value of System.getProperty("java.home").
${USER_HOME}	Location of user home. The return value of System.getProperty("user.home").

Preparing the application client run time dependency component for Java Web Start

To launch a Java Platform, Enterprise Edition (Java EE) application client application, a Thin application client application, or both using Java Web Start (JWS), a Java Runtime Environment implementation Java archive (JAR) that IBM provides, the library JAR files and properties files bundled in Application Client for WebSphere Application Server must be installed in the JWS. Learn the steps to build the application client run time dependency component from an application client installation. It is packaged as a Web Archive Resource (WAR) file that can be installed in an Application Server.

Before you begin

Install the Application Client for WebSphere Application Server for the operating system to which the client application deploys. If there is a requirement to deploy the client application to multiple operating systems, the application client run time dependency component must be built separately for each operating system that client application supports.

1. Install the Application Client for WebSphere Application Server for the client application supported operating systems.
2. Change the directory to the installation bin directory.
3. Run the "buildClientRuntime tool" on page 218 to generate the application client run time JAR file, which contains the Java Standard Edition Runtime Environment, the run time library JAR files, properties files, and the SSL KeyStore and TrustStore files from the application client installation.
4. Run the buildClientLibJars tools to package up the properties files in the properties directory of the application client installation into a properties.jar file in the specified location. The buildClientLibJars tools will also copy the `WebSphereClientLauncher.jar` file and `WebSphereClientRuntimeInstaller.jar` file from the application client installation to the specified location. All jar files in the specified location will be signed by the provided certificate.

   For example, if you are using Version 7.0 and using the test certificate that is included in the application client installation:

   ```
   buildClientLibJars C:\Temp\webstart ..\etc\DummyClientKeyFilejar WebAS "websphere dummy client" JKS
   ```
5. Create a JavaServer Pages (JSP) file or use a servlet to generate the application client run time installer Java Network Launching Protocol (JNLP) descriptor to respond to Java Web Start request. See the Java Web Start Deployment sample in the application client installation.
6. Package the two signed JAR files, `WASClient7.0_windows.jar` and `WebSphereClientRuntimeInstaller.jar`, and the JSP file or servlet for generating the Application Client run time installer JNLP descriptor into a Web archive (WAR) file. This WAR file is packaged into an EAR file that can be deployed to an application server. See the Java Web Start Deployment sample in the application client installation.

Results

Your Web application is ready to serve the application client run time and the JRE environment.

buildClientRuntime tool:

For a Java Platform, Enterprise Edition (Java EE) application client application and or Thin application client application to be launched using Java Web Start (JWS), the library JAR files bundled in Application Client for WebSphere Application Server must be installed in the Java Web Start. Use this tool to build those JAR files. The Java Web Start client is used with platforms that support a Web browser.

The Java Web Start client is not supported on WebSphere Application Server for OS/400.

The buildClientRuntime tool builds the required components from the WebSphere Application Server clients installation into the JAR file specified on the command. This JAR file contains:

- License files
- Java SE Runtime Environment 6 (JRE 6) that IBM provides
- Application Clients runtime properties and configuration
- SSL KeyStore and TrustStore files
- Runtime library JAR files

In the case of building an Application Clients runtime JAR file only for serving Thin Application client applications and not for Java EE Application client applications, the runtime library JAR files and the Application Clients runtime properties files are not included, except the configuration files, `sas.client.props`, `ssl.client.props` and `soap.client.props`, located in the `WAS_ROOT/properties` directory. The Java Web Start client is used with platforms that support a Web browser.

The command-line invocation syntax for the buildClientRuntime tool is shown in the following example:

```
Windows Usage:    buildClientRuntime.bat  [-help] [-verbose] outfile keystore storepass alias storetype

Unix Usage:         buildClientRuntime.sh    [-help] [-verbose] outfile keystore storepass alias storetype
```

where:

- -help will display the message
- -verbose will turn on verbose message
- outfile is the output file name
- keystore is the key store file
- storepass is the key store password
- alias is the key alias name
- storetype is the key store type

ClientRuntimeInstaller class:

This section provides information on the ClientRuntimeInstaller class.

This class, com.ibm.websphere.client.installer.ClientRuntimeInstaller, contains a main() method that Java Web Start (JWS) calls to install the Application Client for WebSphere Application Server run-time dependency component in JWS cache. It is packaged in `WebSphereClientRuntimeInstaller.jar` file located in the Application Client for WebSphere Application Server installation in the *<app_server_root>*/`JWS` directory.

Specify the WebSphereClientRuntimeInstaller.jar file and the Application Client run-time dependency component JAR file as JAR resources in the Application Client run-time installer Java Network Launcher Protocol (JNLP) descriptor file. See the following example for details:

```
<jar href="Launcher/WebSphereClientRuntimeInstall.jar" main="true"/>
<jar href="Launcher/WASClient6.1_windows.jarRuntimeInstall.jar" main="true"/>
```

The ClientRuntimeInstaller class main method requires the following properties to be set in the JNLP file:

com.ibm.websphere.client.jre.version
Specifies a Java Runtime Environment (JRE) version name that is to be used when referring to the Application Client run-time dependency component.

com.ibm.websphere.client.jre.launch.java
Specifies the relative location of the javaw.exe program in the Application Client run-time dependency component JAR file.

The previously mentioned properties, JRE version name and the location of the javaw.exe program are registered to the Java Web Start Application Manager, as shown in the following example:

```
<property name="com.ibm.websphere.client.jre.version" value="WASclient6.1"/>
<property name="com.ibm.websphere.client.jre.launch.java" value="java\jre\bin\javaw.exe"/>
```

Using the Java Web Start sample

The EAR file, WebSphereClientRuntime.ear, is provided in the JWS directory of the Client Application for WebSphere Application Server installation. This EAR file provides a sample Application Clients run-time installer JNLP descriptor file and a sample Application Clients run-time library component JNLP descriptor file. Follow the steps in this task to build the Application Clients run-time dependency component and the Application Clients run-time library component. Add these components to the WebSphereClientRuntime.ear file, and then install the EAR file in an Application Server to be used by the client application.

About this task

There is a new Java Web Start sample available in the client sample gallery for WebSphere Application Server V7.0. Refer to the client sample gallery in the Application Client for WebSphere Application Server product. The name of the new sample is ″Java Web Start Deployment Sample″.

Installing Java Web Start

Learn about the steps that are necessary to install Java Web Start (JWS) on the AIX platform. Java Web Start technology is provided by the Java SE runtime environment to deploy Java EE application clients (including Thin application clients) on the remote client machine with a single click from Web browser on the client machine.

Before you begin

Note: This topic applies only to the AIX operating system.

Before you begin this task, see the “Preparing the application client run time dependency component for Java Web Start” on page 217 topic to understand Java Web Start (JWS) technology and components.

Note:

You can use the following resources:

- The IBM implementation of Java Web Start on Java Platform Standard Edition 6 (Java SE 6) that is packaged in the Application Client for WebSphere Application Server

Note: You can use Java Web Start on Java Platform, Standard Edition Developer Kit 6 that IBM provides, packaged in the Application Client for WebSphere Application Server, Version 7.0; Java Web Start on Sun Microsystems Java Standard Edition Software Development Kit 6 or Java SE Runtime

Environment 6.0, which you can download from the Sun Microsystems Web site for Windows, Linux and Solaris operating systems, or the Java Web Start on HP Software Development Kit (SDK) or RTE for Java 2 version 5.0, which you can download from the HP Web site.

About this task

Use the following steps to install JWS on the AIX platform.

1. Install IBM Application Client for WebSphere Application Server.
2. Change your directory to the client_install_root/java/jre/lib/javaws path.
3. Run the updateSetting.sh script from the path mentioned in the previous step.
4. Change your path to the JWS installed path. For example, enter: `client_install_root/java/jre/javaws`.
5. Run `./javaws` from the path mentioned in the previous step.

Using a static JNLP file with Java Web Start for Application clients

Do not use JSP to dynamically generate a JNLP file, otherwise the JNLP jsp page cannot be opened in some IE browsers.

About this task

To use a static JNLP file, you will need to add the following mime type mapping in the web.xml file:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_ID" version="2.4" xmlns="http://java.sun.com/xml/ns/j2ee"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee
http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd">
       <display-name>
       WAS Client runtime for Java Web Start</display-name>
       <welcome-file-list>
              <welcome-file>index.html</welcome-file>
              <welcome-file>index.htm</welcome-file>
              <welcome-file>index.jsp</welcome-file>
              <welcome-file>default.html</welcome-file>
              <welcome-file>default.htm</welcome-file>
              <welcome-file>default.jsp</welcome-file>
       </welcome-file-list>
       <mime-mapping>
       <extension>jnlp</extension>
       <mime-type>application/x-java-jnlp-file</mime-type>
       </mime-mapping>
</web-app>
```

Running the IBM Thin Client for Enterprise JavaBeans (EJB)

An EJB Client is a Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) Java Platform, Standard Edition (Java SE) application that accesses remote Enterprise Java Beans from a server through Java Naming and Directory Interface (JNDI) look up. IBM Thin Client for EJB offers a smaller footprint and is easy to deploy to a Java SE environment and an Eclipse Rich Client Platform (RCP) environment. You can bundle the IBM Thin Client for EJB library using the WebSphere Application Server installation or the Application Client for WebSphere Application Server installation with your application. The IBM Thin Client for EJB also extends the choice of Java SE runtime. It can be run in the Java Runtime Environment (JRE) that is packaged with the WebSphere Application Server product, the Sun Microsystems JRE that is downloaded from the Sun Microsystems Web site, or the JRE that is downloaded from the HP Web site.

Before you begin

The IBM ORB implementation library is required if the IBM Thin Client for EJB is running with a non-IBM product JRE on a non-IBM product platform. For example, running the IBM Thin Client for EJB with Sun

Microsystems JRE on Windows, Linux, or Solaris, and with the HP JRE on HPUX. The IBM-provided Solaris hybrid and HP hybrid JRE are not considered non-IBM product JRE environments. The IBM Thin Client for EJB can access version 2.x and version 3.0 EJB on the WebSphere Application Server using the JNDI lookup, but it cannot access version 3.0 EJB through resource injection. Resource injection is supported if the client application is a Java Platform, Enterprise Edition (Java EE) Application Client running within the Java Platform, Enterprise Edition (Java EE) Application Client Container.

Before you set up an EJB Thin Client environment, obtain the Java archive (JAR) file for the EJB Thin Client for WebSphere Application Server. To obtain the EJB Thin Client for WebSphere Application Server, install WebSphere Application Server or Application Client. The EJB Thin Client for WebSphere Application Server file, `com.ibm.ws.ejb.thinclient_7.0.0.jar`, is located in the *app_server_root*`\runtimes` directory.

Copy the Java archive (JAR) file for the IBM Thin Client for EJB with WebSphere Application Server product, `com.ibm.ws.ejb.thinclient_7.0.0.jar` , to other machines to create a lightweight client environment that enables communications with the products. Copies of the IBM Thin Client for EJB are subject to the same terms and conditions of the license agreement for Version 7.0 WebSphere Application Server where you obtained the Thin Client for EJB. Refer to the license agreements for correct usage and other limitations.

The IBM Thin Client for EJB with WebSphere Application Server runs on distributed operating systems with JDK support, including both Version 5 and Version 6. When using the IBM Thin Client for EJB as a standalone Java SE application with a non-IBM product JRE, you must override the default ORB implementation for the JRE through one of following methods:

- Include the com.ibm.ws.orb_7.0.0.jar file in the Java system classpath.
- Override the default ORB implementation in the JRE, using Java Endorsed Standards Override Mechanism.
- Set the java.endorsed.dirs path to a directory that contains the com.ibm.ws.orb_7.0.0.jar file.

When running the IBM Thin Client for EJB as an Eclipse RCP application, it is recommended to use method two, to override the default JRE ORB implementation.

Note: The Pluggable Application Client feature in the application client installer is deprecated. It is replaced by the IBM Thin Client for EJB.

About this task

Run the IBM Thin Client for EJB, by completing the following steps.

1. Invoke the client application. Run the following Java command:

   Add the following system properties to the Java command if you want authentication and SSL enabled:
2. Provide IIOP authentication configuration and Client SSL Configuration. Add the following system properties to the Java command:

   ```
   -Dcom.ibm.SSL.ConfigURL=file:///home/user1/ssl.client.props
   -Dcom.ibm.CORBA.ConfigURL=file:///home/user1/sas.client.props
   ```

   You can obtain the `ssl.client.props` file and `sas.client.props` file from the WebSphere Application Server installation and modify the file to suit your environment. You must, at a minimum, update the location of the key files in the `ssl.client.props` file to the match location of your target environment. For example,

   ```
   -Dcom.ibm.ssl.keyStore=/home/user1/etc/key.p12
   -Dcom.ibm.ssl.trustStore=/home/user1/etc/trust.p12
   ```

   Recommended SSL configuration settings when running the application with a non-IBM product JRE:

   ```
   com.ibm.ssl.protocol=SSL
   com.ibm.ssl.trustManager=SunX509
   com.ibm.ssl.keyManager=SunX509
   com.ibm.ssl.contextProvider=SunJSSE
   ```

```
com.ibm.ssl.keyStoreType=JKS
com.ibm.ssl.keyStoreProvider=SUN
com.ibm.ssl.keyStore=/home/user1/etc/key.jks

com.ibm.ssl.trustStoreType=JKS
com.ibm.ssl.trustStoreProvider=SUN
com.ibm.ssl.trustStore=/home/user1/etc/trust.jks
```

The key store file and trust store file must be created using the Java keytool utility before the application runs. The automatic key file generation is not supported with a non-IBM product JRE.

You must override the default ORB implementation of the non-IBM product JRE with the `com.ibm.ws.orb_7.0.0.jar` file, or add it to the classpath.

What to do next

Enable trace for the IBM Thin Client for EJB by adding the following to the Java command.

```
-Dcom.ibm.ejs.ras.lite.traceSpecification=*=all
```

Related tasks

Example 1: Configuring basic authentication and identity assertion
This example presents a pure Java client, C, that accesses a secure enterprise bean on server, S1, through user bob. The following steps take you through the configuration of C, S1, and S2.

Using JMS to connect to a WebSphere Application Server default messaging provider messaging engine

Related reference

ssl.client.props client configuration file
Use the `ssl.client.props` file to configure Secure Sockets Layer (SSL) for clients. In previous releases of WebSphere Application Server, SSL properties were specified in the `sas.client.props` or `soap.client.props` files or as system properties. By consolidating the configurations, WebSphere Application Server enables you to manage security in a manner that is comparable to server-side configuration management. You can configure the `ssl.client.props` file with multiple SSL configurations.

Running application clients

The Java Platform, Enterprise Edition (Java EE) specification requires support for a client container that runs stand-alone Java applications (known as Java EE application clients) and provides Java EE services to the applications. Java EE services include naming, security, and resource connections.

About this task

You are ready to run your application client using this tool after you:
1. Write the application client program.
2. Assemble and install an application module (`.ear` file) in the application server run time.
3. Deploy the application using the Application Client Resource Configuration Tool (ACRCT) on Windows.

This task only applies to Java EE application clients. To launch Java EE application clients using the launchClient script, perform the following steps:

1. Start the Qshell environment.

   On the CL command line, enter the command:

   ```
   STRQSH
   ```

2. Enter the following command to launch Java EE application clients:

   app_server_root`/bin/launchClient`

   where *app_server_root* is /QIBM/ProdData/WebSphere/AppServer/V7/Base or /QIBM/ProdData/WebSphere/AppServer/V7/ND

3. Pass parameters to the `launchClient` command or to your application client program as well. The `launchClient` command allows you to do both. The `launchClient` command requires that the first parameter is either:
   - An EAR file specifying the application client to launch.
   - A request for `launchClient` usage information.

   The following example illustrates the command line invocation syntax for the launchClient tool:

   ```
   launchClient [-profileName pName | -JVMOptions options | -help | -?] <userapp> [-CC<name>=<value>] [app args]
   ```

   where
   - *userapp* is the path and the name of the EAR file that contains the application client.
   - *-CC<name>=<value>* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.
   - *app args* are arguments that pass to the application client.
   - *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation.
   - *-JVMOptions* is a valid Java standard or non-standard option string. Insert quotation marks around the string.
   - *-help, -?* prints the usage information.

   All other parameters intended for the `launchClient` command must begin with the -CC prefix.

   Parameters that are not EAR files, or usage requests, or that do not begin with the -CC prefix, are ignored by the application client run time, and are passed directly to the application client program.

   The `launchClient` command retrieves parameters from three places:
   - The command line
   - A properties file
   - System properties

   The parameters are resolved in the order listed above, with command line values having the highest priority and system properties the lowest. Using this prioritization you can set and override default values.
4. Specify the server name.

   By default, the **launchClient** command uses *your_server_name* for the `BootstrapHost` property value.

   This setting is effective for testing your application client when it is installed on the same computer as the server. However, in other cases override this value with the name of your server. You can override the `BootstrapHost` value by invoking `launchClient` command with the following parameters:

   ```
   launchClient myapp.ear -CCBootstrapHost=abc.midwest.mycompany.com
   ```

   You can also override the default by specifying the value in a properties file and passing the file name to the launchClient shell.

   Security is controlled by the server. You do not need to configure security on the client because the client assumes that security is enabled. If server security is not enabled, then the server ignores the security request, and the application client functions as expected.

Example

You can store launchClient values in a properties file, which is a good method for distributing default values. You can then override one or more values on the command line. The format of the file is one `launchClient -CC` parameter per line without the `-CC` prefix. For example:

```
 verbose=true classpath=/usr/lpp/mydir/util.jar;/usr/lpp/mydir/harness.jar;/usr/lpp
/production/G19/global.jar BootstrapHost=abc.westcoast.mycompany.com tracefile=/usr
/lpp/WebSphere/mylog.txt
```

launchClient tool

This topic describes the Java Platform, Enterprise Edition (Java EE) command line syntax for the launchClient tool for WebSphere Application Server.

Note: All users who run commands from a specific profile must have authority to modify files that are created by other users that use the same profile. Otherwise, you might see a permission denied error in the log files. To avoid this issue, consider one of the following policies:

- Use specific profiles for distinct user authorities
- Always use the same user for all of the commands that are run in a given profile
- Ensure that all users of a specific profile belong to the same group. In addition, ensure that each user of a group has the read and write authority to the files that are created by other members in the same profile.

The following example illustrates the command line invocation syntax for the launchClient tool:

```
launchClient [-profileName pName | -JVMOptions options | -help | -?] <userapp> [-CC<name>=<value>] [app args]
```

where

- *userapp* is the path and the name of the EAR file that contains the application client.
- *-CC<name>=<value>* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.
- *app args* are arguments that pass to the application client.
- *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation.
- *-JVMOptions* is a valid Java standard or nonstandard option string, except `-cp` or `-classpath`. Insert quotation marks around the string.
- *-help, -?* prints the usage information.

The first parameter must be `-help`, `-?` or contain no parameter at all. The `-profileName pName` and `-JVMOptions` options are optional parameters. If used, they must appear before the *<userapp>* parameter. All other parameters are optional and can appear in any order after the *<userapp>* parameter. The Java EE Application client run time ignores any optional parameters that do not begin with a `-CC` prefix and passes those parameters to the application client.

Client container parameters

Supported arguments include:

-CCadminConnectorHost
Specifies the host name of the server from which configuration information is retrieved.

The default is the value of the `-CCBootstrapHost` parameter or the value, `your.server.name`, if the `-CCBootstrapHost` parameter is not specified.

-CCadminConnectorPort
Indicates the port number for the administrative client function to use. The default value is `8880` for SOAP connections and `2809` for Remote Method Invocation (RMI) connections.

-CCadminConnectorType
Specifies how the administrative client connects to the server. Specify `RMI` to use the RMI connection type, or specify `SOAP` to use the SOAP connection type. The default value is `SOAP`.

-CCadminConnectorUser
Administrative clients use this user name when a server requires authentication. If the connection type is SOAP, and security is enabled on the server, this parameter is required.

-CCadminConnectorPassword
The password for the user name that the `-CCadminConnectorUser` parameter specifies.

-CCaltDD
The name of an alternate deployment descriptor file. This parameter is used with the `-CCjar` parameter to specify the deployment descriptor to use. Use this argument when a client JAR file is configured with more than one deployment descriptor. Set the value to `null` to use the client JAR file standard deployment descriptor.

-CCBootstrapHost
The name of the host server you want to connect to initially. The format is: *your_server_of_choice.com*

-CCBootstrapPort
The server port number. If you do not specify this argument, the WebSphere Application Server default value is `used`.

-CCclassLoaderMode
Specifies the class loader mode. If PARENT_LAST is specified, the class loader loads classes from the local class path before delegating the class loading to its parent. The classes loaded for the following are affected:

- Classes defined for the Java EE application client
- Resources defined in the Java EE application
- Classes specified on the manifest of the Java EE client JAR file
- Classes specified using the -CCclasspath option

If PARENT_LAST is not specified, then the default mode, PARENT_FIRST, causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path.

-CCclasspath
A class path value. When you launch an application, the system class path is used. If you want to access classes that are not in the EAR file or part of the system class paths, specify the appropriate class path here. Multiple paths can be concatenated.

-CCD
Use this option to have the WebSphere Application Server set the specified system property during initialization. Do not use the equals (=) character after the `-CCD`. For example: `-CCDcom.ibm.test.property=testvalue`. You can specify multiple `-CCD` parameters. The general format of this parameter is `-CCD<property key>=<property value>`. For example, `-CCDI18NService.enable=true`.

-CCdumpJavaNameSpace
Controls generation of a dump of the java: name space for the application that is launched, which can be used for debugging purposes. A value of **true** generates a dump in short format, and includes the name and object type for each binding. A value of **long** generates a dump in long format, and includes additional information for each binding over short format, such as the local object type and string representation of the local object. The default value is **false**, and does not generate a dump.

-CCexitVM
Use this option to have the WebSphere Application Server call the `System.exit()` method after the client application completes. The default is `false`.

-CCinitonly
Use this option to initialize application client run time for ActiveX application clients without launching the client application. The default is `false`.

-CCjar
The name of the client Java Archive (JAR) file that resides within the EAR file for the application you wish to launch. Use this argument when you have multiple client JAR files in the EAR file.

-CCpropfile
Indicates the name of a properties file that contains launchClient properties. Specify the properties without the `-CC` prefix in the file, with the exception of the securityManager, securityMgrClass and securityMgrPolicy properties. See the following example: `verbose=true`.

-CCproviderURL
Provides bootstrap server information that the initial context factory can use to obtain an initial context. WebSphere Application Server initial context factory can use either a Common Object Request Broker Architecture (CORBA) object URL or an Internet Inter-ORB Protocol (IIOP) URL. CORBA object URLs are more flexible than IIOP URLs and are the recommended URL format to use. This value can contain more than one bootstrap server address. This feature can be used when attempting to obtain an initial context from a server cluster. You can specify bootstrap server addresses, for all servers in the cluster, in the URL. The operation will succeed if at least one of the servers is running, eliminating a single point of failure. The address list does not process in a particular order. For naming operations, this value overrides the `-CCBootstrapHost` and `-CCBootstrapPort` parameters. A CORBA object URL specifying multiple systems is illustrated in the following example:

```
-CCproviderURL=corbaloc:iiop:myserver.mycompany.com:9810,:mybackupserver.mycompany.com:2809
```

This value is mapped to the `java.naming.provider.url` system property.

-CCsecurityManager
Enables and runs the WebSphere Application Server with a security manager. The default is `disable`.

-CCsecurityMgrClass
Indicates the fully qualified name of a class that implements a security manager. Only use this argument if the `-CCsecurityManager` parameter is set to `enable`. The default is `java.lang.SecurityManager`.

-CCsecurityMgrPolicy
Indicates the name of a security manager policy file. Only use this argument if the `-CCsecurityManager` parameter is set to enable. When you enable this parameter, the `java.security.policy` system property is set. The default is *<app_server_root>*/ `properties/client.policy`.

-CCsoapConnectorPort
The Simple Object Access Protocol (SOAP) connector port. If you do not specify this argument, the WebSphere Application Server default value is used.

-CCtrace
Use this option to obtain debug trace information. You might need this information when reporting a problem to IBM customer support. The default is `false`. For more information, read the topic ″Enabling trace.″

-CCtracefile
Indicates the name of the file to which trace information is written. The default is to write output to the console.

-CCtraceMode
Specifies the trace format to use for tracing. If the valid value, `basic`, is not specified the default is advanced. Basic tracing format is a more compact form of tracing.

For more information on basic and advanced trace formatting, see Interpreting trace output.

-CCverbose
This option displays additional information messages. The default is `false`.

If you are using an EJB client application with security enabled, edit the `sas.client.props` file, which is located in the *profile_root*`/properties` directory. Within the file, change the `com.ibm.CORBA.loginSource` value to *none*.

For more information on the `sas.client.props` utility, see Manually encoding passwords in properties files and the PropFilePasswordEncoder command reference.

RMI connection with security. Used with the EJB and administrative client application.

Using Jacl:

```
wsadmin -conntype RMI -port  rmiportnumber -user userid
-password password
```

Using Jython:

```
wsadmin -lang jython -conntype RMI -port  rmiportnumber -user userid
-password password
```

rmiportnumber for your connection displays in the administrative console as BOOTSTRAP_ADDRESS.

Note: On the AIX, HP-UX, Linux, i5/OS, Solaris, and z/OS operating systems, the use of -password option may result in security exposure as the password information becomes visible to the system status program, such as ps command, which can be invoked by other users to display all of the running processes. Do not use this option if security exposure is a concern. Instead, specify user and password information in the `soap.client.props` file for SOAP connector or `sas.client.props` file for RMI connector. The `soap.client.props` and `sas.client.props` files are located in the properties directory of your WebSphere Application Server profile.

If Kerberos (KRB5) is enabled for administrative authentication, the authentication target supports BasicAuth and KRB5. To use KRB5, update the `sas.client.props`, `soap.client.props`, and `ipc.client.props` files, according to the connector type.

Note: When using Kerberos authentication, the user password does not flow across the wire. A one-way hash of password is used to identify the client.

The following examples demonstrate correct syntax.

/QIBM/ProdData/WebSphere/AppServer/V61/Base/bin/launchClient /home/earfiles/myapp.ear -profileName myprofile -CCBootstrapHost=myWASServer -CCverbose=true app_parm1 app_parm2

Specifying the directory for an expanded EAR file

You can archive the `Manifest.mf` client Java Archive (JAR) files instead of automatically cleaning them up after the application exits.

Before you begin

Each time the launchClient tool is called, it extracts the Enterprise Archive (EAR) file to a random directory name in the temporary directory on your hard drive. Then the tool sets up the thread ClassLoader to use the extracted EAR file directory and JAR files included in the `Manifest.mf` client Java Archive (JAR) file. In a normal J2EE Java client, these files are automatically cleaned up after the application exits. This cleanup occurs when the client container shutdown hook is called. To avoid extracting the EAR file (and removing the temporary directory) each time the launchClient tool is called, complete the following steps:

1. Specify a directory to extract the EAR file by setting the `com.ibm.websphere.client.applicationclient.archivedir` Java system property. If the directory does not exist or is empty, the EAR file is extracted normally. If the EAR file was previously extracted, the launchClient tool reuses the directory.
2. Delete the directory before running the launchClient tool again, if you need to update your EAR file. When you call the `launchClient` command, it extracts the new EAR file to the directory. If you do not delete the directory or change the system property value to point to a different directory, the launchClient tool reuses the currently extracted EAR file and does not use your changed EAR file. When specifying the `com.ibm.websphere.client.applicationclient.archivedir` property, make sure that the directory you specify is unique for each EAR file you use. For example, do not point the `MyEar1.ear` and the `MyEar2.ear` files to the same directory.

Using Java Web Start

Learn about the Java Web Start technology that is provided by the Java Standard Edition runtime environment to deploy Java Enterprise Edition application clients, including Thin application clients, on the remote client machine with a single click from Web browser on the client machine.

Before you begin

The supported client platforms for deploying application clients using the Java Web Start are the same as the IBM Application Client for WebSphere Application Server supported platforms, except Linux on Power and OS/400 operating systems.

Before you begin this task, see the following topics to understand Java Web Start technology and its components:

- "Java Web Start architecture for deploying application clients" on page 210
- "Client application Java Network Launcher Protocol deployment descriptor file" on page 211
- "ClientLauncher class" on page 215

You can use the following resources:

- The IBM implementation of Java Web Start on Java Platform Standard Edition 6 (Java SE 6) that is packaged in the Application Client for WebSphere Application Server.

Note: When using the Sun JRE with the Application Client runtime, application resources cannot be downloaded using the https protocol. This is a Sun Microsystems limitation. Install the IBM JRE on the client machine and use IBM Java Web Start to run the WebSphere Application Client application. Sun Java Web Start is supported, but with a limitation that only the http protocol can be used to download the application resource, including the application jnlp description file.

About this task

To deploy application clients using Java Web Start, the client machine must have at least a Java SE runtime environment installed. The Java SE runtime environment includes the Java Web Start, which implements the JSR 56: Java Network Launching Protocol and API. The application clients Enterprise Archive (EAR) file is a Java archive (JAR) resource in a JNLP descriptor file that resides on a central server. The JNLP descriptor file also specifies the runtime environment requirement for running the application.

WebSphere Application Server provides a launcher class to launch the Java EE application client in the application client container inside of Java Web Start. The client machine might not have the IBM Application Client for WebSphere Application Server installed. If this is the case, create and install an application client container and runtime package as a runtime environment through Java Web Start. The JNLP descriptor file specifies this runtime environment as the required runtime environment for running the Java EE application client.

WebSphere Application Server also provides command-line utility programs to create this application client container and runtime package from an existing IBM Application Client for WebSphere Application Server installation, as well as an installer class to install this package as a runtime environment for the application client container and also the Java Runtime Environment (JRE) in the IBM Application Client for WebSphere Application Server installation. To run the Java EE application client, the EAR file is deployed as a JAR resource that is described in the JNLP descriptor file.

1. Identify the client machine operating system, and install the corresponding IBM Application Client for WebSphere Application Server on a development machine. For example, if the Java EE application clients are targeted to run on Windows operating systems, install the IBM Application Client for WebSphere Application Server for Windows. Follow the instructions for "Installing Application Client for WebSphere Application Server" on page 242.

2. Run the utility programs to create the application client container and runtime package.
   a. Use the "buildClientRuntime tool" on page 218 utility to create the package.
   b. Use the "buildClientLibJars tool" on page 211 utility to create the JAR files containing the launcher and the installer class. This utility also zips up the properties files in the <app_client_root>/ properties directory.
3. Create the runtime installer JNLP descriptor file. The JNLP response must be included in the JNLP version ID to indicate the current runtime version in the response header, for example, `x-java-jnlp-version-id=1.6.0`. Using a servlet of a Java Server Pages (JSP) file to provide a dynamic JNLP response.
4. Create the Java EE application client launch JNLP descriptor file.
5. Package the application client container runtime environments and the Java EE application in an Enterprise Archive (EAR) file. Depending on your preferred deployment strategy, the files can be in two separate Web modules, or combined into one.
6. All JAR resources must be Java signed, including the Java EE application client EAR file.
7. Deploy the Enterprise Archive file on an application server, and start the application. The Java EE application client is ready to be deployed.

Example

A Java Web Start deployment Sample is included in the client samples. This Sample demonstrates the steps to deploy a Java EE application client with an automated ANT script. The Sample has a servlet to generate the runtime installer JNLP response with JNLP version ID, for example, `x-java-jnlp-version-id`.

Note: When the application client initially launches using Java Web Start from Sun Microsystems Java SE Runtime Environment 6.0, it installs the Application Client runtime, which includes the IBM JRE. An null pointer exception (NPE) is thrown from the `com.sun.deploy.services.WPlatformService.getSecureRandom()` method. This is a known bug in Sun Java SE 6 (http://bugs.sun.com/bugdatabase/view_bug.do?bug_id=6505528). If you experience this exception, relaunch the application. The NPE only occurs on the first launch of the application client.

Java Web Start architecture for deploying application clients

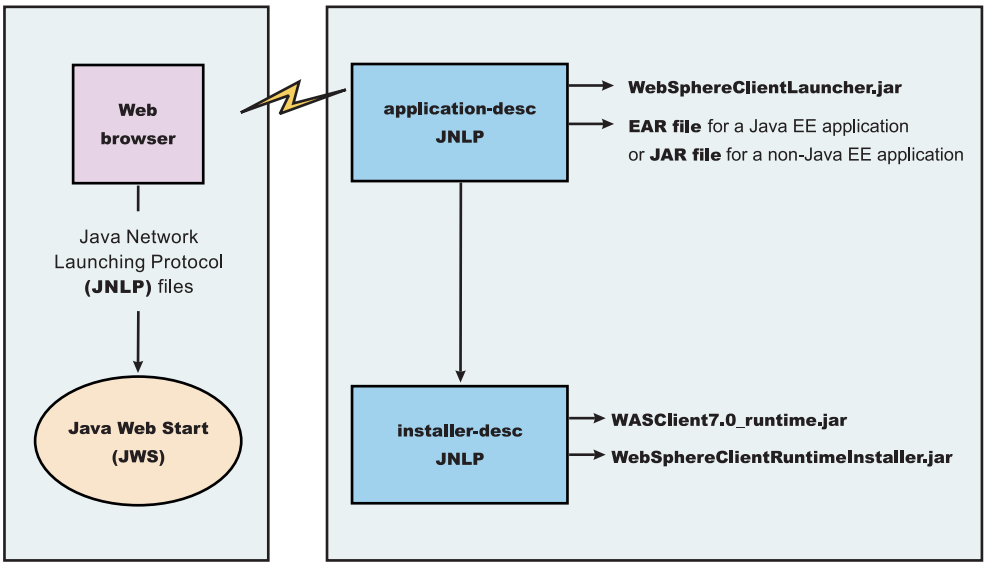
Java Web Start is an application-deployment technology that includes the portability of applets, the maintainability of servlets and JavaServer Pages (JSP) file technology, and the simplicity of mark-up languages such as XML and HTML. It is a Java application that allows full-featured Java EE client applications to be launched, deployed and updated from a standard Web server. The Java Web Start client is used with platforms that support a Web browser.

Java Web Start is not supported.

Upon launching Java Web Start for the first time, you might download new client applications from the Web. Each time you launch JWS thereafter, you can initiate applications either through a link on a Web page or (in Windows) from desktop icons or the Start menu. You can deploy applications quickly using Java Web Start, cache applications on the client machine, and launch applications remotely offline. Additionally, because Java Web Start is built from the Java Platform, Enterprise Edition (Java EE) infrastructure, the technology inherits the complete security architecture of the Java EE platform.

The technology underlying Java Web Start is the Java Network Launching Protocol & API (JNLP). Java Web Start is a JNLP client and it reads and parses a JNLP descriptor file (JNLP file). Based on the JNLP descriptor, it downloads appropriate pieces of a client application and any of its dependencies. If any of the pieces of the application are already cached on the client machine, then those components are not downloaded again, unless they have been updated on the server machine. After you download and cache the client application, JWS launches it natively on the client machine.

The following diagram shows an overview of launching a client application, include the Application Client for WebSphere Application Server as a dependent resource, using Java Web Start.



The Web browser running on a client machine connects to a Web application located on a server machine. The client application JNLP descriptor file is downloaded and processed by Java Web Start on the client machine.

In this diagram, there are two JNLP descriptor files:

- Client application JNLP descriptor (application-desc in the diagram)
- Application Clients run-time installer JNLP descriptor (installer-desc in the diagram)

Each of these JNLP descriptor files, the client application (JAR or EAR) and the dependent resource JAR files are packaged as Web applications in an EAR file. This EAR file is deployed to an Application server. The client machine with JWS installed uses a Web browser to connect to the url of the client application JNLP descriptor file to download and run the client application.

Using Java Web Start from Java SE Runtime Environment 6.0 or later is highly recommended. All the platforms supported by the application client for WebSphere Application Server are supported with the exception Linux on Power and OS/400 platforms.

You can use the following:

- Java Web Start on the Java Standard Edition Developer Kits that IBM provides, packaged in Application Client for WebSphere Application Server
- Java Web Start on Sun Microsystems Java SE 6 Development Kit or Java SE Runtime Environment 6.0, which you can download from the Sun Microsystems Web site for Windows, Linux and Solaris operating systems
- Java Web Start on HP-UX JDK or JRE for Java Platform, Standard Edition, version 6, which you can download from the HP Web site

buildClientLibJars tool:

For a Java Platform, Enterprise Edition (Java EE) application client application and or Thin application client application to be launched using Java Web Start (JWS), the properties files bundled in Application Client for WebSphere Application Server must be installed in the Java Web Start. Use this tool to create those property JAR files. The Java Web Start client is used with platforms that support a Web browser.

Java Web Start is not supported on WebSphere Application Server for i5/OS.

The buildClientLibJars tool copies the JAR files from the Application Client for WebSphere Application Server installation and creates a `properties.jar` file, which contains the properties files from the Application Clients installation properties directory to a specified location. When this property is created, the tool uses the value of `keystore`, `storepass`, `alias` and `storetype` to sign all of the JAR files in the specified location.

```
Windows usage: buildClientLibJars.bat  [-help] [-verbose] destdir keystore storepass alias storetype

Unix usage:    buildClientLibJars.sh  [-help] [-verbose] destdir keystore storepass alias storetype
```

where:

- `-help` will display the message
- `-verbose` will turn on verbose message
- `destdir` will output the destination directory name
- `keystore` is the key store file
- `storepass` is the key store password
- `alias` key is the alias name
- `storetype` is the key store type

Client application Java Network Launcher Protocol deployment descriptor file

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application.

Location

The client application has an Application Clients run-time dependency that provides the following:

- Java SE Runtime Environment from IBM
- Application Clients run-time properties
- SSL KeyStore and TrustStore file
- Application Clients run-time library JAR files (optional for Thin Application client applications)

If the Application Clients run-time dependency is not met, it is downloaded and installed in Java Web Start (JWS), as described by the Application Clients run-time installer JNLP descriptor file. For example:

```
<j2se version="1.6" href="http://your_server.com/jws/wasappclient/download.jnlp"/>
```

Usage notes

The client application must also include the `WebSphereClientLauncher.jar` file, which contains the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, that completes one of the following actions:

- If it is a Java Platform, Enterprise Edition (Java EE) Application client application (that is the resources for the application contain an EAR file with a client application), the EAR file must be specified as a JAR resource so that it can be downloaded to JWS and specified in the system property, `com.ibm.websphere.client.launcher.ear`. See “JNLP descriptor file for a Java EE Application client application” on page 213 for an example.
- If it is a Thin Application client application, the Thin Application client application JAR file must be specified as a JAR resource so that it can be downloaded to JWS and the name of the class containing main method entry point is specified in the system property, `com.ibm.websphere.launcher.main`. See “JNLP descriptor file for a Thin Application client application” on page 213 for an example.

The JNLP specification requires all the resource (JAR or EAR) files used in a JNLP file to be signed.

You can specify the –CC arguments defined in the launchClient tool for a J2EE Application client application in application arguments section of the JNLP descriptor files. However, only –CCD is supported for a Thin Application client application to define system properties and the JNLP <property> tag can also be used to define system properties. See the following example for details:

```
<property name="java.naming.provider.url" value="corbaloc:iiop:myserver.com:9089"/>
```

For a J2EE Application client application, specify the following application arguments as defined in the JNLP.

1. Specify your target server provider URL, as shown in the following example:

   ```
   <argument> >-CCDjava.naming.provider.url =corbaloc:iiop:myserver.mydomain.com:9080 </argument>
   ```

2. Specify the SSL Key File and SSL Trust File location. These files are expected to be available in the client machine. To use the ones in the Application Clients run-time dependency installed in JWS cache, specify these application arguments:

   ```
   <argument> -CCDcom.ibm.ssl.keyStore=${WAS_ROOT}/etc/key.p12 </argument>
   <argument>-CCDcom.ibm.ssl.trustStore=${WAS_ROOT}/etc/trust.p12 </argument>
   ```

3. Specify the initial naming context factor, as shown in the following example:

   ```
   <argument>-CCDjava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory </argument>
   ```

   For a Thin Application client application, you also need to specify the actual location of the `sas.client.props` and `ssl.client.props` files located in the Application Clients run-time dependency that is installed in the JWS cache.

   ```
   <argument>-CCDcom.ibm.CORBA.ConfigURL=file:${WAS_ROOT}/properties/sas.client.props </argument>
   <argument>-CCDcom.ibm.SSL.ConfigURL=file:${WAS_ROOT}/properties/ssl.client.props </argument>
   ```

   If any of the default settings in the `sas.client.props` and `ssl.client.props` file need modifying, use the –CCD to change the settings through the system properties, as shown in the following example:

   ```
   <argument>-CCDjavacom.ibm.CORBA.securityEnabled=false </argument>
   ```

   Note: The ${WAS_ROOT} token used in the JNLP file is replaced by the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, to the actual location of the Application Clients run-time dependency installation in the JWS cache. If you are using JSP to dynamically create this JNLP description file, you must escape this token because it has a different meaning in JSP 2.0. See the following example for details:

   ```
   <argument>-CCDcom.ibm.ssl.keyStore=\${WAS_ROOT}/etc/key.p12 </argument>
   <argument>-CCDcom.ibm.ssl.trustStore=\${WAS_ROOT}/etc/trust.p12 </argument>
   ```

JNLP descriptor file for a Java EE Application client application:

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application.

Here is an example of the client application JNLP descriptor file for a Java EE Application client application:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
This sample program is provided AS IS and may be used, executed, copied and modified
without royalty payment by customer (a) for its own instruction and study, (b) in order
to develop applications designed to run with an IBM WebSphere product, either for customer's
own internal use or for redistribution by customer, as part of such an application, in
customer's own products.

JNLP descriptor file for a Thin Application client application:

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application. If it is a Thin Application client application, then the launcher class uses the current JVM from the Application Clients run-time dependency and invokes the Thin Application client application main method.

Here is an example of the JNLP descriptor file for a Thin Application client application.

```

ClientLauncher class:

The class, com.ibm.websphere.client.installer.ClientLauncher, contains a main() method that is called by Java Web Start (JWS) to launch the client application. The Java Web Start client is used with platforms that support a Web browser.

Java Web Start is not supported.

This client is packaged in the `WebSphereClientLauncher.jar` file that is located in the Application Client for WebSphere Application Server installation under the *<app_client_root>*/ lib/webstart directory.

The launcher class requires that the following properties are defined. These properties are not defined in a separate properties file. Instead, the properties are defined as part of the Java Network Launching Protocol (JNLP) files.

com.ibm.websphere.client.launcher.main
: If the client application is a Thin Application client, then this property should be specified. It specifies the class where the main entry point of the client application resides.

com.ibm.websphere.client.launcher.ear
If the client application is a Java Platform, Enterprise Edition (Java EE) Application client, then this property should be specified. It specifies the name of the EAR file to be executed. This property takes precedence over com.ibm.websphere.client.launcher.main. However, only one of the two properties should be specified.

Application client launcher for Java Web Start:

The application client launcher for Java Web Start is a Java class, com.ibm.websphere.client.installer.ClientLauncher, which has a main() method that Java Web Start calls to start the application client container and to invoke the application client's main() method. It provides similar functions as the **lauchClient** command line tool to start application clients from the command line.

The com.ibm.websphere.client.launcher.ClientLauncher class is packaged in the WebSphereClientLauncher.jar file under the <app_client_root>/lib/webstart directory.

The launcher tool requires that the following properties are defined.

com.ibm.websphere.client.launcher.main
If the client that is to be run is a thin client, then this property should be specified. It specifies the class where the main entry point of the application resides. It is the main class name for a Thin application client. If it is set, the launcher will not start the client container, it will rather invoke the main method for the application directly. However, if `com.ibm.websphere.client.launcher.ear` is also set, it will be ignored.

com.ibm.websphere.client.launcher.ear
If the client that is to run is the Java Platform, Enterprise Edition (Java EE) client, then this property should be specified. It specifies the name of the ear file to be executed. This property takes precedence over `com.ibm.websphere.client.launcher.main` although only one of the two properties should be specified.

These properties are not defined in a separate properties file. Instead, they are defined as part of the Java Network Launching Protocol files.

When `com.ibm.websphere.client.launcher.ear` is set, the application client launcher for JWS supports almost all of the –CC arguments as the **lauchClient** command line tool supports. However, if only `com.ibm.websphere.client.launcher.main` is set, the launcher will only support the –CCD argument. The following table shows the comparison of the supported –CC arguments for the **launchClient** command line tool and the application client launcher for JWS:

-CC argument	launchClient	Application client launcher for JWS
-CCverbose	Yes	Yes
-CCjar	Yes	Yes
-CCclasspath	Yes	N/A
-CCadminConnectorHost	Yes	Yes
-CCadminConnectorPort	Yes	Yes
-CCadminConnectorType	Yes	Yes
-CCadminConnectorUser	Yes	Yes
-CCaltDD	Yes	Yes
-CCBootstrapHost	Yes	Yes
-CCBootstrapPort	Yes	Yes
-CCproviderURL	Yes	Yes
-CCinitonly	Yes	N/A

-CC argument	launchClient	Application client launcher for JWS
-CCtrace	Yes	Yes
-CCtracefile	Yes	Yes
-CCsecurityManager	Yes	N/A
-CCsecurityMgrClass	Yes	N/A
-CCsecurityMgrPolicy	Yes	N/A
-CCD	Yes	Yes
-CCexitVM	Yes	Yes
-CCdumpJavaNameSpace	Yes	Yes
-CCsoapConnectorPort	Yes	Yes
-CCtraceMode	Yes	Yes
-CCclassLoaderMode	Yes	Yes

Macro expansion is supported for the –CCD argument by the application client launcher for JWS. The launcher will automatically substitute certain macro keys (enclosed with ${...}) with the calculated value at runtime. For example, if a macro key is used in the –CCD argument in the application client JNLP manifest file,

```
<argument>-CCDcom.ibm.ssl.keyStore= ${WAS_ROOT}/etc/key.p12</argument>
```

it will be expanded to the JWS cache installation root location and the argument will become:

```
-CCDcom.ibm.ssl.keyStore=/home/tiu/.java/deployment/cache/javaws/ext/E1134532441112/etc/key12.p12
```

The following table shows the 3 macro keys that are currently supported and will be substituted by the launcher:

Table 3.

Macro key	Value
${WAS_ROOT}	Installation root location within the JWS cache that is used by the application client container and runtime installer for JWS.
${JAVA_HOME}	Location of Java home. The return value of System.getProperty(“java.home”).
${USER_HOME}	Location of user home. The return value of System.getProperty(“user.home”).

Preparing the application client run time dependency component for Java Web Start

To launch a Java Platform, Enterprise Edition (Java EE) application client application, a Thin application client application, or both using Java Web Start (JWS), a Java Runtime Environment implementation Java archive (JAR) that IBM provides, the library JAR files and properties files bundled in Application Client for WebSphere Application Server must be installed in the JWS. Learn the steps to build the application client run time dependency component from an application client installation. It is packaged as a Web Archive Resource (WAR) file that can be installed in an Application Server.

Before you begin

Install the Application Client for WebSphere Application Server for the operating system to which the client application deploys. If there is a requirement to deploy the client application to multiple operating systems,

the application client run time dependency component must be built separately for each operating system that client application supports.

1. Install the Application Client for WebSphere Application Server for the client application supported operating systems.
2. Change the directory to the installation bin directory.
3. Run the “buildClientRuntime tool” on page 218 to generate the application client run time JAR file, which contains the Java Standard Edition Runtime Environment, the run time library JAR files, properties files, and the SSL KeyStore and TrustStore files from the application client installation.
4. Run the buildClientLibJars tools to package up the properties files in the properties directory of the application client installation into a properties.jar file in the specified location. The buildClientLibJars tools will also copy the `WebSphereClientLauncher.jar` file and `WebSphereClientRuntimeInstaller.jar` file from the application client installation to the specified location. All jar files in the specified location will be signed by the provided certificate.

   For example, if you are using Version 7.0 and using the test certificate that is included in the application client installation:

   ```
   buildClientLibJars C:\Temp\webstart ..\etc\DummyClientKeyFilejar WebAS "websphere dummy client" JKS
   ```
5. Create a JavaServer Pages (JSP) file or use a servlet to generate the application client run time installer Java Network Launching Protocol (JNLP) descriptor to respond to Java Web Start request. See the Java Web Start Deployment sample in the application client installation.
6. Package the two signed JAR files, `WASClient7.0_windows.jar` and `WebSphereClientRuntimeInstaller.jar`, and the JSP file or servlet for generating the Application Client run time installer JNLP descriptor into a Web archive (WAR) file. This WAR file is packaged into an EAR file that can be deployed to an application server. See the Java Web Start Deployment sample in the application client installation.

Results

Your Web application is ready to serve the application client run time and the JRE environment.

buildClientRuntime tool:

For a Java Platform, Enterprise Edition (Java EE) application client application and or Thin application client application to be launched using Java Web Start (JWS), the library JAR files bundled in Application Client for WebSphere Application Server must be installed in the Java Web Start. Use this tool to build those JAR files. The Java Web Start client is used with platforms that support a Web browser.

The Java Web Start client is not supported on WebSphere Application Server for OS/400.

The buildClientRuntime tool builds the required components from the WebSphere Application Server clients installation into the JAR file specified on the command. This JAR file contains:

- License files
- Java SE Runtime Environment 6 (JRE 6) that IBM provides
- Application Clients runtime properties and configuration
- SSL KeyStore and TrustStore files
- Runtime library JAR files

In the case of building an Application Clients runtime JAR file only for serving Thin Application client applications and not for Java EE Application client applications, the runtime library JAR files and the Application Clients runtime properties files are not included, except the configuration files, `sas.client.props`, `ssl.client.props` and `soap.client.props`, located in the `WAS_ROOT/properties` directory. The Java Web Start client is used with platforms that support a Web browser.

The command-line invocation syntax for the buildClientRuntime tool is shown in the following example:

```
Windows Usage:    buildClientRuntime.bat  [-help] [-verbose] outfile keystore storepass alias storetype

Unix Usage:         buildClientRuntime.sh    [-help] [-verbose] outfile keystore storepass alias storetype
```

where:

- -help will display the message
- -verbose will turn on verbose message
- outfile is the output file name
- keystore is the key store file
- storepass is the key store password
- alias is the key alias name
- storetype is the key store type

ClientRuntimeInstaller class:

This section provides information on the ClientRuntimeInstaller class.

This class, com.ibm.websphere.client.installer.ClientRuntimeInstaller, contains a main() method that Java Web Start (JWS) calls to install the Application Client for WebSphere Application Server run-time dependency component in JWS cache. It is packaged in `WebSphereClientRuntimeInstaller.jar` file located in the Application Client for WebSphere Application Server installation in the *<app_server_root>*/`JWS` directory.

Specify the `WebSphereClientRuntimeInstaller.jar` file and the Application Client run-time dependency component JAR file as JAR resources in the Application Client run-time installer Java Network Launcher Protocol (JNLP) descriptor file. See the following example for details:

```
<jar href="Launcher/WebSphereClientRuntimeInstall.jar" main="true"/>
<jar href="Launcher/WASClient6.1_windows.jarRuntimeInstall.jar" main="true"/>
```

The ClientRuntimeInstaller class main method requires the following properties to be set in the JNLP file:

com.ibm.websphere.client.jre.version
: Specifies a Java Runtime Environment (JRE) version name that is to be used when referring to the Application Client run-time dependency component.

com.ibm.websphere.client.jre.launch.java
: Specifies the relative location of the javaw.exe program in the Application Client run-time dependency component JAR file.

The previously mentioned properties, JRE version name and the location of the javaw.exe program are registered to the Java Web Start Application Manager, as shown in the following example:

```
<property name="com.ibm.websphere.client.jre.version" value="WASclient6.1"/>
<property name="com.ibm.websphere.client.jre.launch.java" value="java\jre\bin\javaw.exe"/>
```

Using the Java Web Start sample

The EAR file, `WebSphereClientRuntime.ear`, is provided in the JWS directory of the Client Application for WebSphere Application Server installation. This EAR file provides a sample Application Clients run-time installer JNLP descriptor file and a sample Application Clients run-time library component JNLP descriptor file. Follow the steps in this task to build the Application Clients run-time dependency component and the Application Clients run-time library component. Add these components to the `WebSphereClientRuntime.ear` file, and then install the EAR file in an Application Server to be used by the client application.

About this task

There is a new Java Web Start sample available in the client sample gallery for WebSphere Application Server V7.0. Refer to the client sample gallery in the Application Client for WebSphere Application Server

product. The name of the new sample is ″Java Web Start Deployment Sample″.

Installing Java Web Start

Learn about the steps that are necessary to install Java Web Start (JWS) on the AIX platform. Java Web Start technology is provided by the Java SE runtime environment to deploy Java EE application clients (including Thin application clients) on the remote client machine with a single click from Web browser on the client machine.

Before you begin

Note: This topic applies only to the AIX operating system.

Before you begin this task, see the “Preparing the application client run time dependency component for Java Web Start” on page 217 topic to understand Java Web Start (JWS) technology and components.

Note:

You can use the following resources:

- The IBM implementation of Java Web Start on Java Platform Standard Edition 6 (Java SE 6) that is packaged in the Application Client for WebSphere Application Server

Note: You can use Java Web Start on Java Platform, Standard Edition Developer Kit 6 that IBM provides, packaged in the Application Client for WebSphere Application Server, Version 7.0; Java Web Start on Sun Microsystems Java Standard Edition Software Development Kit 6 or Java SE Runtime Environment 6.0, which you can download from the Sun Microsystems Web site for Windows, Linux and Solaris operating systems, or the Java Web Start on HP Software Development Kit (SDK) or RTE for Java 2 version 5.0, which you can download from the HP Web site.

About this task

Use the following steps to install JWS on the AIX platform.

1. Install IBM Application Client for WebSphere Application Server.
2. Change your directory to the client_install_root/java/jre/lib/javaws path.
3. Run the updateSetting.sh script from the path mentioned in the previous step.
4. Change your path to the JWS installed path. For example, enter: `client_install_root/java/jre/javaws`.
5. Run `./javaws` from the path mentioned in the previous step.

Using a static JNLP file with Java Web Start for Application clients

Do not use JSP to dynamically generate a JNLP file, otherwise the JNLP jsp page cannot be opened in some IE browsers.

About this task

To use a static JNLP file, you will need to add the following mime type mapping in the web.xml file:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_ID" version="2.4" xmlns="http://java.sun.com/xml/ns/j2ee"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee
http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd">
       <display-name>
       WAS Client runtime for Java Web Start</display-name>
       <welcome-file-list>
              <welcome-file>index.html</welcome-file>
              <welcome-file>index.htm</welcome-file>
              <welcome-file>index.jsp</welcome-file>
```

```
            <welcome-file>default.html</welcome-file>
            <welcome-file>default.htm</welcome-file>
            <welcome-file>default.jsp</welcome-file>
        </welcome-file-list>
        <mime-mapping>
        <extension>jnlp</extension>
        <mime-type>application/x-java-jnlp-file</mime-type>
        </mime-mapping>
</web-app>
```

Running the IBM Thin Client for Enterprise JavaBeans (EJB)

An EJB Client is a Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) Java Platform, Standard Edition (Java SE) application that accesses remote Enterprise Java Beans from a server through Java Naming and Directory Interface (JNDI) look up. IBM Thin Client for EJB offers a smaller footprint and is easy to deploy to a Java SE environment and an Eclipse Rich Client Platform (RCP) environment. You can bundle the IBM Thin Client for EJB library using the WebSphere Application Server installation or the Application Client for WebSphere Application Server installation with your application. The IBM Thin Client for EJB also extends the choice of Java SE runtime. It can be run in the Java Runtime Environment (JRE) that is packaged with the WebSphere Application Server product, the Sun Microsystems JRE that is downloaded from the Sun Microsystems Web site, or the JRE that is downloaded from the HP Web site.

Before you begin

The IBM ORB implementation library is required if the IBM Thin Client for EJB is running with a non-IBM product JRE on a non-IBM product platform. For example, running the IBM Thin Client for EJB with Sun Microsystems JRE on Windows, Linux, or Solaris, and with the HP JRE on HPUX. The IBM-provided Solaris hybrid and HP hybrid JRE are not considered non-IBM product JRE environments. The IBM Thin Client for EJB can access version 2.x and version 3.0 EJB on the WebSphere Application Server using the JNDI lookup, but it cannot access version 3.0 EJB through resource injection. Resource injection is supported if the client application is a Java Platform, Enterprise Edition (Java EE) Application Client running within the Java Platform, Enterprise Edition (Java EE) Application Client Container.

Before you set up an EJB Thin Client environment, obtain the Java archive (JAR) file for the EJB Thin Client for WebSphere Application Server. To obtain the EJB Thin Client for WebSphere Application Server, install WebSphere Application Server or Application Client. The EJB Thin Client for WebSphere Application Server file, `com.ibm.ws.ejb.thinclient_7.0.0.jar`, is located in the *app_server_root*`\runtimes` directory.

Copy the Java archive (JAR) file for the IBM Thin Client for EJB with WebSphere Application Server product, `com.ibm.ws.ejb.thinclient_7.0.0.jar` , to other machines to create a lightweight client environment that enables communications with the products. Copies of the IBM Thin Client for EJB are subject to the same terms and conditions of the license agreement for Version 7.0 WebSphere Application Server where you obtained the Thin Client for EJB. Refer to the license agreements for correct usage and other limitations.

The IBM Thin Client for EJB with WebSphere Application Server runs on distributed operating systems with JDK support, including both Version 5 and Version 6. When using the IBM Thin Client for EJB as a standalone Java SE application with a non-IBM product JRE, you must override the default ORB implementation for the JRE through one of following methods:

- Include the com.ibm.ws.orb_7.0.0.jar file in the Java system classpath.
- Override the default ORB implementation in the JRE, using Java Endorsed Standards Override Mechanism.
- Set the java.endorsed.dirs path to a directory that contains the com.ibm.ws.orb_7.0.0.jar file.

When running the IBM Thin Client for EJB as an Eclipse RCP application, it is recommended to use method two, to override the default JRE ORB implementation.

Note: The Pluggable Application Client feature in the application client installer is deprecated. It is replaced by the IBM Thin Client for EJB.

About this task

Run the IBM Thin Client for EJB, by completing the following steps.

1. Invoke the client application. Run the following Java command:

   Add the following system properties to the Java command if you want authentication and SSL enabled:

2. Provide IIOP authentication configuration and Client SSL Configuration. Add the following system properties to the Java command:

   ```
   -Dcom.ibm.SSL.ConfigURL=file:///home/user1/ssl.client.props
   -Dcom.ibm.CORBA.ConfigURL=file:///home/user1/sas.client.props
   ```

   You can obtain the `ssl.client.props` file and `sas.client.props` file from the WebSphere Application Server installation and modify the file to suit your environment. You must, at a minimum, update the location of the key files in the `ssl.client.props` file to the match location of your target environment. For example,

   ```
   -Dcom.ibm.ssl.keyStore=/home/user1/etc/key.p12
   -Dcom.ibm.ssl.trustStore=/home/user1/etc/trust.p12
   ```

   Recommended SSL configuration settings when running the application with a non-IBM product JRE:

   ```
   com.ibm.ssl.protocol=SSL
   com.ibm.ssl.trustManager=SunX509
   com.ibm.ssl.keyManager=SunX509
   com.ibm.ssl.contextProvider=SunJSSE

   com.ibm.ssl.keyStoreType=JKS
   com.ibm.ssl.keyStoreProvider=SUN
   com.ibm.ssl.keyStore=/home/user1/etc/key.jks

   com.ibm.ssl.trustStoreType=JKS
   com.ibm.ssl.trustStoreProvider=SUN
   com.ibm.ssl.trustStore=/home/user1/etc/trust.jks
   ```

   The key store file and trust store file must be created using the Java keytool utility before the application runs. The automatic key file generation is not supported with a non-IBM product JRE.

   You must override the default ORB implementation of the non-IBM product JRE with the `com.ibm.ws.orb_7.0.0.jar` file, or add it to the classpath.

What to do next

Enable trace for the IBM Thin Client for EJB by adding the following to the Java command.

```
-Dcom.ibm.ejs.ras.lite.traceSpecification=*=all
```

Related tasks

Example 1: Configuring basic authentication and identity assertion
This example presents a pure Java client, C, that accesses a secure enterprise bean on server, S1, through user bob. The following steps take you through the configuration of C, S1, and S2.

Using JMS to connect to a WebSphere Application Server default messaging provider messaging engine

Related reference

ssl.client.props client configuration file
Use the `ssl.client.props` file to configure Secure Sockets Layer (SSL) for clients. In previous releases of WebSphere Application Server, SSL properties were specified in the `sas.client.props` or `soap.client.props` files or as system properties. By consolidating the configurations, WebSphere Application Server enables you to manage security in a manner that is comparable to server-side configuration management. You can configure the `ssl.client.props` file with multiple SSL configurations.

Installing Application Client for WebSphere Application Server

This topic describes how to install the Application Client for WebSphere Application Server using the installation image on the product CD-ROM.

Before you begin

Running client applications that communicate with a WebSphere Application Server requires that elements of the Application Server are installed on the system on which the client applications run. However, if the system does not have the Application Server installed, you can install Application Client, which provides a stand-alone client run-time environment for your client applications.

The i5/OS Application Client supports the following types of client:

- Java thin client
- Java Platform, Enterprise Edition (Java EE) application client
- Web services thin client

The steps that follow provide enough detail to guide you through preparing for, choosing, and installing the variety of options and features provided. To prepare for installation and to make yourself familiar with installation options, complete the steps in this topic and read the related topics, before you start to use the installation tools. Specifically, read these topics before installing the product:

- Installing WebSphere Application Client from a Windows workstation
- Installing WebSphere Application Client from an i5/OS Qshell command line
- Best practices for installing

It is recommended that you have 350 MB of temporary disk space available before beginning the installation.

1. Install WebSphere Application Client from your iSeries server. Installing the product from the CD-ROM drive of your iSeries server requires direct physical access to the server. The local installation requires less time to complete than a remote installation. The local installation reads installation options from a response file.

   See Installing WebSphere Application Client from your iSeries server.
2. Run the GUI installation tool from a Windows workstation

   The interactive GUI uses an InstallShield interface to prompt you for installation options. Installing the product from a Windows workstation does not require direct physical access to the iSeries server.

   See “Installing Application Client for WebSphere Application Server from a Windows workstation” on page 245.

Results

You successfully installed the Application Client for WebSphere Application Server and the features you selected.

What to do next

Use the installation verification utility to verify a successful installation. If the installation is not successful, fix the error as indicated in the installation error message. For example, if you do not have enough disk space, add more space, and reinstall the Application Client.

Best practices for installing Application Client for WebSphere Application Server

This topic provides tips for installing Application Client on multiple platforms.

All platforms

The following tips pertain to installing Application Client on all platforms:

- Reserve at least 4 to 5MB free space in the target platform temporary directory.
- When specifying a different temporary directory while installing Application Client, the following message is displayed if the target platform default temporary directory does not have enough free space to install Application Client:

  ```
  Error writing file =  There may not be enough
  temporary disk space.
  Try using -is:tempdir to use a temporary
  directory on a partition with more disk
  space.
  ```

  Use the `-is:tempdir` installation option to specify a different temporary directory. For example, the following command uses `/swap` as a temporary directory during installation:

  ```
  ./install -is:tempdir /swap
  ```

- After the installation, when changing the installation settings for the WebSphere Application Server host name and the port number, edit the setupClient file.

  Change the `DEFAULTSERVERNAME` and `SERVERPORTNUMBER` to the new WebSphere Application Server host name and port number, respectively. If the `SERVERPORTNUMBER` is not set, then the default is 2809. Review the following example:

  ```
  set DEFAULTSERVERNAME=NDServerName
  set SERVERPORTNUMBER=9810
  ```

  The setupClient file is located in the `bin` subdirectory under the Application Client installation destination.

Specific platforms

The following tips pertain to installing Application Client on the designated platforms:

Installing Application Client for WebSphere Application Server silently

This topic provides the steps necessary to use the installation wizard and perform a silent installation.

About this task

Use these steps to perform a silent installation, which uses the installation wizard to install the product. Instead of displaying a user interface, the silent installation provides interaction between you and the wizard by reading all of your responses from a file that you must customize.

1. Verify that the host server jobs are started on your iSeries server. The host server jobs allow the installation code to run on iSeries. Enter this command on a CL command line: `STRHOSTSVR SERVER(*ALL)`
2. Verify that your user profile has the *ALLOBJ and *SECADM special authorities.
3. Place the WebSphere Application Server **Supplements** disc in the disc drive of your iSeries server.
4. Customize the options response file.
   a. Locate the sample options response file. The file name is setup.response in the operating system platform directory on the product CD-ROM.
   b. Use the Copy (CPY) command to create a copy of the setup.response file from the disk. For example:

      ```
      CPY OBJ('/QOPT/WEBSPHERE/AppClient/setup.response') TODIR('/MYDIR')
      ```

      Where:

      QOPT is the disk mount point.

      WEBSPHERE is the disk volume label.

      /AppClient is the product directory on the disk. This will be referred to in later steps.

      Note: For DVD media, an additional directory prefix is required before the product directory that reflects the operating system and architecture of the installation. Using the previous example, the following installation path applies when you use CD-ROM media:

      ```
      CPY OBJ('/QOPT/WEBSPHERE/AppClient/setup.response') TODIR('/MYDIR')
      ```

      However, the following installation path applies when you use DVD media:

      ```
      CPY OBJ('/QOPT/WEBSPHERE/os400_ppc64/AppClient/setup.response') TODIR('/MYDIR')
      ```

   c. Edit the copy of the file using EDTF from the i5/OS command line or using Wordpad from a mapped drive. Accept the license agreement by making the following change in the response file: `-OPT silentInstallLicenseAcceptance="true'` This is the only required change in the response file. Read the information in the response file to determine if you want to change any other options.
   d. Save the file.
5. Invoke the installation program for WebSphere Application Client for i5/OS. To do this, run the INSTALL command from Qshell :
   a. From the i5/OS command line, start a Qshell session: STRQSH
   b. Change directory to the AppClient subdirectory of CD-ROM or DVD-ROM drive: cd /QOPT/WEBSPHERE/AppClient **OR** cd /QOPT/WebSphere/os400_ppc64/AppClient
   c. Issue the INSTALL command to start the installation program: `install –options /MYDIR/setup.response`

      Important: Do not exit the Qshell session (PF3) until the installation has completed. Doing so might cause the installation to stop prematurely.

      A JDK is automatically selected for invoking the installer and configuring the product based on what JDKs are installed on the machine. The priority for selection is done in the following order:

      - IBM Technology for JDK 6 - 32 bit (5722-JV1 or 5761JV1 option 11)
      - IBM Technology for JDK 6 - 64 bit (5722-JV1 or 5761JV1 option 12)
      - IBM Developer Kit for Java 1.6 (5722-JV1 or 5761JV1 option 10)

      To force IBM Technology for JDK 6 - 64 bit add the parameter: `-devkit16_64`.

      To force IBM Developer Kit for Java 1.6 add the parameter: `-devkit16_CLASSIC`.

      Consider the following example to force the use of IBM Technology for JDK 6 - 64 bit:

      ```
      install –options /MYDIR/setup.response -devkit16_64
      ```

Results

You installed application clients silently by using the response file.

What to do next

Use the installation verification utility to verify a successful installation. If the installation is not successful, fix the error as indicated in the installation error message. For example, if you do not have enough disk space, add more space, and reinstall the Application Client.

Installing Application Client for WebSphere Application Server from a Windows workstation

This topic describes how to install the Application Client for WebSphere Application Server on your i5/OS system from a Windows workstation.

About this task

The steps that follow guide you through installing the WebSphere Application Client from a Windows workstation using the graphical installation wizard.

1. If TCP/IP is not started or if you don't know if TCP/IP is started, enter the Start TCP/IP (STRTCP) command on the Control Language (CL) command line.
2. Verify that the host server jobs are started on your iSeries server. The host server jobs allow the installation code to run on iSeries. Enter this command on a CL command line: STRHOSTSVR SERVER(*ALL)
3. Verify that your user profile has the *ALLOBJ and *SECADM special authorities.
4. Place the WebSphere Application Server **Supplements** disc in the disc drive of your workstation.
5. Install Application Client for WebSphere Application Server using the launchpad. Read the Using the launchpad to start the installation topic for more information.
6. Enter your user profile, password and the host name or IP address for the system you wish to install when prompted. Click **OK** to continue.
7. Click Next to continue when the Welcome panel is displayed. Click the radio button beside the ″I accept the terms in the license agreement″ message if you agree to the license agreement, and click **Next** to continue.
8. The installation wizard checks the system for prerequisites. Click **Next** if you see a success message on the wizard panel. If a warning message is displayed on the panel, click **Cancel** to exit the installation wizard and install the proper prerequisites to the system.

   If more than one Java SE Development Kit 6 (JDK 6) option is installed on the machine, then select one of the following:

   - IBM Technology for JDK 6 - 32 bit (5722-JV1 or 5761JV1 option 11)
   - IBM Technology for JDK 6 - 64 bit (5722-JV1 or 5761JV1 option 12)
   - IBM Development Kit for Java 1.6 (5722-JV1 or 5761JV1 option 10)

   Note: Application Client may be fully functional even if some prerequisites are not installed on the system, however it is recommended you update your system to the required level.
9. Specify the installation directory and the default profile directory. Click **Next** to continue.
   a. Specify the target directories for the Application Client product and default profile if you do not want to use the default directories.
   b. Deleting the default target location and leaving an installation directory field empty prevents you from continuing the installation process.

10. Choose a type of installation, and click **Next**. If you use the GUI you can choose a Typical installation type, which installs J2EE and Thin application client, or you can choose the custom installation type. For i5/OS, the custom installation type allows you to include the Web Services thin client and Administration thin client features.
    a. Install the Administration Thin Client, if you need a runtime jar that is customized to enable client applications to perform WebSphere administration tasks. The Administration Thin Client is installed into *app_server_root*/`runtimes`.
    b. Install the Web Services Thin Client, if you need a JAX-RPC Web services runtime JAR that is customized to enable client applications to communicate with the Application Server through Web Services. The Web Services Thin Client is installed into *app_server_root*/`runtimes`.
11. Enter the host name of the WebSphere Application Server machine. Click **Next** to continue. The default port number is 2809. If you do not know the host name of the system on which the application server will run, enter any string to proceed with the install.
12. Review the summary information, and click **Next** to install the product code or you might also click **Back** to change your specifications.
13. Click **Finish** to exit the wizard, after the Application Client installs.
14. Verify the success of the installer program by examining the Completion panel and the `app_client_root/logs/install/log.txt` file for installation status. The installer program records the following indicators of success in the logs:

    `INSTCONFSUCCESS` indicates that the installation is successful and that no further log analysis is required.

    `INSTCONFFAILED` indicates an installation failure that you cannot retry or recover from without reinstalling.

Results

You successfully installed the Application Client for WebSphere Application Server and the features you selected.

What to do next

Use the installation verification utility to verify a successful installation. If the installation is not successful, fix the error as indicated in the installation error message. For example, if you do not have enough disk space, add more space, and reinstall the Application Client.

Uninstalling Application Client for WebSphere Application Server

This task describes using the uninstall program to uninstall the Application Client for WebSphere Application Server.

Before you begin

If you want to uninstall IBM Application Client for WebSphere Application Server manually, read the Uninstalling the product on i5/OS topic.

Note: If you have a feature pack installed, uninstalling the Application Client for WebSphere Application Server using the Version 6.1.0 uninstaller program causes the feature pack to stop working because the uninstallation removes the server. However, you can uninstall the feature pack after uninstalling the WebSphere Application Server product.

Note: If you are logged in as a root user and attempt to uninstall an instance of Application Client for WebSphere Application Server that a non-root user installed, the Windows registry will also be

wiped clean for the application client instance that the root user installed. If you need to uninstall an instance of application client that a non-root user has installed, be sure that you are logged in as the non-root user.

1. Stop any browsers and any Java processes related to Application Client products.

   Read the Uninstalling the product on i5/OS topic for more information.
2. Change directories to the `uninstall` directory before issuing the command to uninstall the application client. The command file is located in the `uninstall` directory.
3. Issue the command to uninstall the product.

   Use the **uninstall all** command.

   The Uninstall wizard begins and displays the Welcome panel.
4. Click **Next** to begin uninstalling the product. The Uninstall wizard displays a Confirmation panel that lists the product and features that you are uninstalling.
5. Click **Next** to continue uninstalling the product. The Uninstall wizard deletes existing profiles first.

   After deleting profiles, the Uninstall wizard deletes core product files by component.
6. Click **Finish** to close the wizard after the wizard removes the product.

Results

Application Client for WebSphere Application Server is uninstalled.

What to do next

Verify the uninstall procedure by viewing the *app_server_root*`/logs/uninstall/log.txt` file for errors. Look for the `INSTCONFSUCCESS`, indicating a successful uninstall in the log file:

```
Uninstall, com.ibm.ws.install.ni.ismp.actions.ISMPLogSuccessMessageAction, msg1,
   INSTCONFSUCCESS
```

The uninstallation wizard records uninstallation events in the uninstallation log files. Examine messages that the uninstallation program displays. If the Application Client for WebSphere Application Server does not uninstall successfully, read the messages to identify why the uninstallation failed. Correct the problems identified and try uninstalling the product again.

Note: If you are logged in as non-root or non-admin user, the uninstall may not be successful. When the uninstaller program runs, a log file is created in your home directory. If the uninstaller program fails, an attempt is made to move the log to the *app_server_root* directory; however, without the necessary permission to move the file to the *app_server_root* directory, the attempt to move fails and the log remains in your home directory. Look for the following log files in the *user_home*`/waslogs` directory:

- `log.txt`
- `trace.txt.gz`
- `trace.xml.gz`

Uninstalling IBM Application Client for WebSphere Application server on i5/OS

You can uninstall IBM Application Client for WebSphere Application Server for i5/OS product by running commands from your iSeries server.

About this task

Uninstall IBM Application Client for WebSphere Application Server for i5/OS from your iSeries server. To uninstall the product, run the following command from the Qshell command line:

app_client_root`/bin/uninstall`

Uninstalling IBM Application Client for WebSphere Application Server from the iSeries server removes all the product libraries and directories. If you later decide that you do not need the user-defined data, you can manually remove it.

Results

After completing the procedure, the IBM Application Client for WebSphere Application Server product is uninstalled.

installRegistryUtils command

The installRegistryUtils command-line tool runs on any supported operating system. The installRegistryUtils tool lists installed products and packages and assists in cleaning a particular registered product (including the associated packages), package, or all registered products (including all associated packages) which are visible to the current user.

Location of the command file: The command file is located on both the product disc and the installed product.

Note: When using the product disc, the command must be invoked on the machine targeted by the command. The tool does not work remotely.

To invoke the command file from the product disc, run the following command file from the root of the product CD:

- `installRegistryUtils/bin/installRegistryUtils`

To invoke the command file from the installed product, use the following command:

- *app_server_root*`/bin/installRegistryUtils`

The common location for the command file is /QIBM/WAS/bin/installRegistryUtils.

Syntax for the installRegistryUtils command: Clean up all accessible products and packages.

```
./installRegistryUtils -cleanAll
 [-userHome user_home]
```

Clean up the specified product and all associated packages.

```
./installRegistryUtils -cleanProduct
  -offering offering_ID
  -installLocation installation_location
 [-userHome user_home]
```

Clean up the specified package.

```
./installRegistryUtils -cleanPackage
  -pakName package_name
  -installLocation installation_location
 [-userHome user_home]
```

List all visible products.

```
./installRegistryUtils -listProducts
 [-userHome user_home]
```

List all visible packages.

```
./installRegistryUtils -listPackages
 [-userHome user_home]
```

Parameters: Supported arguments include:

-installLocation *installation_location*
Specifies the full path to the product installation.

-offering *offering_ID*
Identifies the offering ID, also known as the product ID, of the specified product.

-pakName *package_name*
Identifies a package name of the specified product.

-userHome *user_home*
Specifies the full path to a user home directory. This parameter is not required for a root user unless you want to invoke the installRegistryUtils command on the home directory of a non-root user.

Deploying J2EE application clients on workstation platforms

You can deploy the J2EE application clients on workstation platforms using the methods described in this topic.

Before you begin

After developing an application client, deploy this application on client machines. *Deployment* consists of pulling together the various artifacts that the application client requires.

The *Application Client Resource Configuration Tool* (ACRCT) defines resources for the application client. These configurations are stored in the client `.jar` file within the application `.ear` file. The application client run time uses these configurations for resolving and creating an instance of the resources for the application client.

Note: This task only applies to J2EE application clients. Only perform this task if you configured your J2EE application client to use resource references.

About this task

1. Start the ACRCT and open an EAR file.
2. Configure new data source providers.
3. Configure mail providers and sessions.
4. Configure URL providers and sessions.
5. Configure Java messaging resources.
6. Configure new environment entries.
7. (Optional) Remove application client resources.
8. Save the EAR file.

Resource Adapters for the client

A resource adapter is a system-level software driver that a Java application uses to connect to an enterprise information system (EIS). A resource adapter plugs into an application client and provides connectivity between the EIS and the enterprise application.

The resource adapter support for the J2EE client applications is a subset of the support for the server. For any resource adapter installed using the clientRAR tool, the client resource adapter is used in a non-managed environment and must conform to the J2EE Connector Architecture Specification Version 1.5 or higher. Only outbound connections to the EIS are supported through the ManagedConnectionFactory interfaces. The inbound messaging support (from the EIS), life cycle management, and work management aspects of the specification are not supported on the client.

For a client application to use a resource adapter, it must be installed in the directory specified by the environment variable, CLIENT_CONNECTOR_INSTALL_ROOT, defined when the setupCmdLine script

runs. The launchClient tool, Application Client Resource Configuration Tool (ACRCT) and clientRAR tool all use this variable to find the default location of all installed resource adapters. To install a resource adapter in the client, use the clientRAR tool. Once the resource adapter is installed, it must be configured using the ACRCT. The client configuration tool adds the resource adapter configuration to the EAR file. Then, connection factories and administered objects are defined.

When running J2EE application clients, the `launchClient` script specifies a system property called `com.ibm.ws.client.installedConnector`, which is set to the same value as the `CLIENT_CONNECTOR_INSTALL_ROOT` variable. This is the default location for installed resource adapters and can be overridden for each `launchClient` call by specifying the `-CCD` parameter. When the client container is activated, all resource adapter subdirectories under the specified default location for the resource adapters directory are added to the classpath. This action allows the client application to use the resource adapters without using the ACRCT to specify any of the client resources.

Using resource adapters is a new mechanism for easily extending client applications.

Configuring resource adapters

Use the Application Client Resource Configuration Tool (ACRCT) to configure resource adapters.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new resource adapters. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new resource adapters from the tree.
4. Expand the JAR file to view its contents.
5. Right-click the **Resource Adapters** folder, and click **New**.
6. Configure the resource adapter settings in the resulting property dialog.
7. Click **OK**.
8. Click **File** > **Save** on the menu bar to save your changes.

clientRAR tool

This topic describes the command line syntax for the client resource adapter installation tool.

If this tool is used to add or delete resource adapters on the server, then only the client can use the resource adapter. If the resource adapter is installed on the server using the wsadmin tool or the administrative console, then do not use the clientRAR tool remove it. Only resource adapters that are installed using the clientRAR tool should be removed using the clientRAR tool.

The command line invocation syntax for the `clientRAR` tool follows:

```
clientRAR [-help | -?] [-CRDcom.ibm.ws.client.installedConnectors=<dir>] <task> <archive>

where
-help, -?
Print the usage information.
-CRDcom.ibm.ws.client.installedConnectors
The directory where resource adapters are installed.
This will override the system property of the same name
(com.ibm.ws.client.installedConnectors).

<task>
The task to perform: add - install, delete - uninstall.

<archive>
if task=add then this is the fully qualified name of the resource adapter archive file.
If task=delete then this is the filename of the resource adapter archive to be uninstalled.
```

The following examples demonstrate correct syntax.

Configuring new connection factories for resource adapters

Use the Application Client Resource Configuration Tool (ACRCT) to configure new connection factories for resource adapters.

About this task

Complete this task to configure new connection factories for resource adapters.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new connection factories. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new connection factories from the tree.
4. Expand the JAR file to view its contents.
5. Click the **Resource Adapters** folder.
6. Expand the resource adapter for which you want to create connection factories.
7. Right-click the **Connection Factories** folder and click **New**.
8. Configure the connection factory properties in the resulting property dialog.
9. Click **OK**.
10. Click **File** > **Save** on the menu bar to save your changes.

Resource adapter connection factory settings:

Use this panel to view or change the configuration properties of the selected resource adapter connection factory.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapters**. Right-click the **Connection Factories** folder, and click **New**. The following fields appear on the **General** tab.

Name:

The name by which this connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the resource adapter connection factories across the product administrative domain.

Data type String

Description:

An optional description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name that is used to match this resource adapter connection factory definition to the deployment descriptor. This entry should be a `resource-ref` name.

Data type String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly when getting a connection. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly when getting a connection.

Data type String

Password:

Specifies an encrypted password. If you complete this field, then the **Password** field in the Properties box is ignored.

If you specify a value for the **UserName** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Type:

A drop-down list of all the `connectionFactoryInterfaces` as defined for the factories in the Resource Adapter Archive.

For each **Type**, there is a set of properties specified in the Properties box. This set of properties is constructed by retrieving the properties from each connection definition object. For any existing connection factories that are displayed for updating, this list of properties is overlaid with the properties specified for the objects. When the **Type** field is changed, the properties also change to reflect the correct properties for that type.

Data type String

Configuring administered objects

This section helps you configure new administered objects.

Before you begin

Before you configure new administered objects, you must complete the following prerequisites:

1. Install the Resource Adapter Archive file (RAR) using the clientRAR tool.
2. Configure the resource adapter for the `.ear` file, using the Application Client Resource Configuration Tool (ACRCT) tool.

About this task

Complete this task to configure new administered objects for installed resource adapters.

1. Start the Application Client Resource Configuration Tool (ACRCT).

2. Open the EAR file for which you want to configure new administered objects. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new administered objects from the tree.
4. Expand the JAR file to view its contents.
5. Click the **Resource Adapters** folder.
6. Expand the resource adapter for which you want to create administered objects.
7. Right-click the **Administered Objects** folder and click **New**.
8. Configure the administered object properties in the resulting property dialog.
9. Click **OK**.
10. Click **File** > **Save** on the menu bar to save your changes.

Administered objects settings:

Use this panel to view or change the configuration properties of the selected administered objects.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapters** > *resource_adapter_instance*. Right-click **Administered Objects** and click **New**. The following fields appear on the **General** tab.

The settings for administered objects are handled similarly to connection factories. When updating administered objects, use the same panels that you used to create administered objects.

Name:

The name by which this administered object is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the resource adapter administered objects across the product administrative domain.

Data type String

Description:

An optional description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

This entry is a `resource-env-ref` name, a `message-destination-ref` name (if the `message-destination-ref` has no link), or a `message-destination` link.

Data type String

Type:

A drop-down list of all the administered object class-interface pairs as defined for the admin objects in the Resource Adapter Archive (RAR) file.

For each **Type**, there is a set of properties specified in the Properties box. This set of properties is constructed by retrieving the properties from each administered object definition. For any existing administered objects that are displayed for updating, this list of properties is overlaid with the properties

specified for the objects. When the **Type** field is changed, the properties also change to reflect the correct properties for that type.

Data type String

Resource adapter settings

Use this panel to view or change the configuration properties of the resource adapter. These configuration properties control how resource adapters are created.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapter**. Right-click **Resource Adapter** and click **New**. The following fields appear on the **General** tab.

Name

The name by which this Resource Adapter is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the Resource Adapters across the product administrative domain.

Data type String

Description

A description of this resource adapter for administrative purposes within IBM WebSphere Application Server.

Data type String

Class Path

Any additional class path. The path to the resource adapter directory is automatically added.

Data type String
Default The path to your Resource Adapter directory.

Native Path

The native path where the Resource Adapter is located. Enter any additional native class path here.

Data type String

Resource Adapter Name

A mandatory field that points to an installed resource adapter subdirectory. The entry does not represent the full directory name for the resource adapter. The full directory name is the installed resource adapter path, plus the resource adapter name.

Data type String

Installed Resource Adapter Path

The directory where resource adapters are installed. If you do not complete this field, then the default takes effect.

If you specify the value, `${CONNECTOR_INSTALL_ROOT}`, then this value replaces the value of the `CLIENT_CONNECTOR_INSTALL_ROOT` variable on the machine on which the client application runs. This action allows the application to run easily on different machines, where the client installation might be in different locations.

Data type String
Default ${CONNECTOR_INSTALL_ROOT}

Starting the Application Client Resource Configuration Tool and opening an EAR file

You can perform many tasks by starting the Application Client Resource Configuration Tool (ACRCT). Many of these tasks also involve then opening an EAR file.

Before you begin

Note: This task only applies to J2EE application clients.

About this task

Use these steps to start the Application Client Resource Configuration Tool. When you start the tool, one of the most common tasks that you perform is opening and modifying the components of EAR files.

1. Open a command prompt and change to the *app_server_root*\bin directory.
2. Run the clientConfig.bat file.
3. Open an EAR file within the Application Client Resource Configuration Tool (ACRCT):
   a. Click **File** > **Open**.
   b. Select the file and click **Open**.
   •
4. Save your changes to the file and close the tool:
   a. Click **File** > **Save**.
   b. Click **File** > **Exit**.
   •

Data sources for the Application Client

WebSphere Application Server and the Application Client for WebSphere Application Server do not provide client database drivers to be used directly from a J2EE application client. If your application client accesses a database directly, you must provide the database drivers on the client machine.

You can contact your database vendor to acquire client database driver code and licenses. In addition, data sources configured on the server and looked up on the client do not participate in global transactions. Instead of accessing the database directly, it is recommended that your client application use an enterprise bean. Accessing a database through an enterprise bean eliminates the need to have database drivers on the client machine because the database access is handled by the enterprise bean running on WebSphere Application Server. For a current list of providers that are supported on WebSphere Application Server visit the WebSphere Application Server prerequisite Web site. (See the following link.)

Data source properties for application clients

Use this page to create or modify the data sources.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Data Source Providers** > *Data source provider instance*. Right-click **Data Sources** and click **New**. The following fields are displayed on the **General** tab:

Name

Specifies the display name of this data source.

Data type String

Description
Specifies a text description of the data source.

Data type String

JNDI Name
The application client run time uses this field to retrieve configuration information.

Database Name
The name of the database to which you want to connect.

User
Use the user ID with the Password property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the User ID property, then you must also specify a value for the Password property. The connection factory User ID and Password properties are used if the calling application does not provide a user ID and password explicitly.

Password
Use the password with the User ID property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the Password property, then you must also specify a value for the User ID property.

Re-Enter Password
Confirms the password.

Custom Properties
Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new data source providers (JDBC providers) for application clients
You can create new data source providers, also known as JDBC providers, for your application client using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create new data source providers, also known as JDBC providers, for your application client. In a separate administrative task, install the Java code for the required data source provider on the client machine on which the application client resides.

About this task

Use this task to connect application clients to relational databases.

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the EAR file for which you want to configure the new data source provider. The EAR file contents display in a tree view.
2. Select the JAR file in which you want to configure the new data source provider from the tree.

3. Expand the JAR file to view its contents.
4. Click the **Data Source Providers** folder. Do one of the following:
   - Right-click the folder and click **New Provider**.
   - Click **Edit > New** on the menu bar.
5. Configure the data source provider properties in the resulting property dialog.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Example: Configuring data source provider and data source settings

You can configure data source provider and data source settings.

The purpose of this article is to help you to configure data source provider and data source settings.

- Required fields:
  - Data Source Provider Properties page: name
  - Data Source Properties page: name, jndiName
- Special cases:
  - The user name and password fields have no equivalent XMI tags. You must specify these fields in the custom properties.
  - The password is encrypted when you use the Application Client Resource Configuration Tool (ACRCT). If you do not use the ACRCT the field cannot be encrypted.
- Example:

```
<resources.jdbc:JDBCProvider xmi:id="JDBCProvider_1" name="jdbcProvider:name"
description="jdbcProvider:description" implementationClassName="jdbcProvider:
ImplementationClass">
<classpath>jdbcProvider:classPath</classpath>
<factories xmi:type="resources.jdbc:WAS40DataSource" xmi:id="WAS40DataSource_1"
name="jdbcFactory:name" jndiName="jdbcFactory:jndiName"
description="jdbcFactory:description" databaseName="jdbcFactory:databasename">
<propertySet xmi:id="J2EEResourcePropertySet_13">
<resourceProperties xmi:id="J2EEResourceProperty_13" name="jdbcFactory:customName"
value="jdbcFactory:customValue"/>
<resourceProperties xmi:id="J2EEResourceProperty_14" name="user"
value="jdbcFactory:user"/>
<resourceProperties xmi:id="J2EEResourceProperty_15" name="password"
value="{xor}NTs9PBk+PCswLSZlMT4yOg==/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_14">
<resourceProperties xmi:id="J2EEResourceProperty_16" name="jdbcProvider:customName"
value="jdbcProvider:customeValue"/>
</propertySet>
</resources.jdbc:JDBCProvider>
```

Data source provider settings for application clients

Use this page to create a data source under a JDBC provider which provides the specific JDBC driver implementation class.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Data Source Providers** > and click **New**. The following fields appear on the **General** tab:

Name:

Specifies the display name for the data source.

For example you can set this field to *Test Data Source*.

Data type String

Description:

Specifies a text description for the resource.

Data type	String

Class Path:

A list of paths or `.jar` file names which together form the location for the resource provider classes.

Implementation class:

Use this setting to perform database specific functions.

Data type	String
Default	Dependent on JDBC driver implementation class

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new data sources for application clients

About this task

During this task, you create new data sources for your application client.

1. Click the data source provider for which you want to create a data source in the tree. Take one of the following actions as needed:
   - Configure a new data source provider.
   - Click an existing data source provider.
2. Expand the data source provider to view its **Data Sources** folder.
3. Click the data source folder. Take one of the following actions as needed:
   - Right click the data source folder and click **New Factory**.
   - Click **Edit > New** on the menu bar.
4. Configure the data source properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring mail providers and sessions for application clients

You can edit the configurations of mail sessions and providers for your application clients using the Application Client Resource Configuration Tool (ACRCT).

About this task

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of mail sessions and providers for your application clients to use.

1. Start the ACRCT.
2. Open an EAR file.

3. Locate the mail objects in the tree that is displayed for the EAR file. For example, if your file contains mail sessions, expand **Resources** → ***application*.jar** → **Mail Providers** → ***java_mail_provider_instance*** → **Mail Sessions**.

   In this example, ***java_mail_provider_instance*** is a particular mail provider.

Results

The mail session instances are located in the **JavaMail Sessions** folder.

Mail provider settings for application clients

Use this page to implement the JavaMail API and create mail sessions.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Mail Providers** > and click **New**. The following fields appear on the **General** tab:

Name:

The name of the JavaMail resource provider.

Description:

An optional description for the resource provider.

Class Path:

Specifies a list of paths or JAR file names which together form the location for the resource provider classes.

Protocol:

Specifies the name of the protocol.

Classname:

Specifies the name of the class implementing the protocol. Leave this field blank if you want to use the default implementation.

Type:

This menu contains the following two values: `TRANSPORT` or `STORE`.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Mail session settings for application clients

Use this page to configure mail session properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Mail Providers** > *mail provider instance*. Right-click **Mail Sessions** and click **New**. The following fields appear on the **General** tab:

Name:

Represents the administrative name of the JavaMail session object.

Description:

Provides an optional description for your administrative records.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Mail Transport Host:

Specifies the server to connect to when sending mail.

Mail Transport Protocol:

Specifies the transport protocol to use when sending mail.

Mail Transport User:

Specifies the user ID to use when the mail transport host requires authentication.

Mail Transport Password:

Specifies the password to use when the mail transport host requires authentication.

Enable strict Internet address parsing:

Specifies whether the recipient addresses must be parsed strictly in compliance with RFC 822, which is a specifications document issued by the Internet Architecture Board.

This setting is not generally used for most mail applications. RFC 822 syntax for parsing addresses effectively enforces a strict definition of a valid e-mail address. If you select this setting, JavaMail will adhere to RFC 822 syntax and reject recipient addresses that do not parse into valid e-mail addresses (as defined by the specification). If you do not select this setting, JavaMail will not adhere to RFC 822 syntax and will accept recipient addresses that do not comply with the specification. By default, this setting is deselected. You can view the RFC 822 specification at the following URL for the World Wide Web Consortium (W3C): http://www.w3.org/Protocols/rfc822/.

Re-Enter Password:

Confirms the password.

Mail From:

Specifies the mail originator.

Mail Store Host:

Specifies the mail account host (or ″domain″) name.

Mail Store User:

Specifies the user ID of the mail account.

Mail Store Password:

Specifies the password of the mail account.

Re-Enter Password:

Confirms the password.

Mail Store Protocol:

Specifies the protocol to be used when receiving mail.

Mail Debug:

When `true`, JavaMail interaction with mail servers, along with these mail session properties are printed to the `stdout` file.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring mail provider and mail session settings for application clients

You can configure mail provider and mail session settings. This topic provides the required fields, special cases, and an example.

The purpose of this topic is to help you configure mail provider and mail session settings.

- Required fields:
  - Mail Provider Properties page: name, and at least one protocol provider
  - Mail Session Properties page: name, jndiName, outgoing server and protocol, and/or incoming server and protocol
- Special cases:
  - If you use the ACRCT tool, the password field will be encrypted. You cannot encrypt the password field if you do not use the ACRCT tool.
- Example:

```
<resources.mail:MailProvider xmi:id="builtin_mailprovider" name="Built-in Mail Provider" description="The built-in mail provider">
  <factories xmi:type="resources.mail:MailSession"
             xmi:id="MailSession_1207766754834" name="MailSession"
             jndiName="mail/session" description="Sample mail session" category="Sample"
             mailTransportHost="smtp.coldmail.com" mailTransportUser="transportUser"
             mailTransportPassword="{xor}Lz4sLChvLTs="
             mailFrom="smith@coldmail.com" mailStoreHost="imap.coldmail.com" mailStoreUser="storeUser"
             mailStorePassword="{xor}Lz4sLChvLTs="
             debug="true" strict="true"
             mailTransportProtocol="builtin_smtp" mailStoreProtocol="builtin_imap">
    <propertySet xmi:id="J2EEResourcePropertySet_1207766778585">
      <resourceProperties xmi:id="J2EEResourceProperty_1207766778585" name="key" type="java.lang.String" value="value" required="false"/>
    </propertySet>
  </factories>
  <protocolProviders xmi:id="builtin_smtp" protocol="smtp" classname="com.sun.mail.smtp.SMTPTransport" type="TRANSPORT"/>
  <protocolProviders xmi:id="builtin_pop3" protocol="pop3" classname="com.sun.mail.pop3.POP3Store" type="STORE"/>
  <protocolProviders xmi:id="builtin_imap" protocol="imap" classname="com.sun.mail.imap.IMAPStore" type="STORE"/>
```

```
  <protocolProviders xmi:id="builtin_smtps" protocol="smtps" classname="com.sun.mail.smtp.SMTPSSLTransport" type="TRANSPORT"/>
  <protocolProviders xmi:id="builtin_pop3s" protocol="pop3s" classname="com.sun.mail.pop3.POP3SSLStore" type="STORE"/>
  <protocolProviders xmi:id="builtin_imaps" protocol="imaps" classname="com.sun.mail.imap.IMAPSSLStore" type="STORE"/>
</resources.mail:MailProvider>
```

Configuring new mail sessions for application clients

You can use the Application Client Resource Configuration Tool (ACRCT) to configure new mail sessions for your application client.

Before you begin

During this task, you configure new mail sessions for your application client. The mail sessions are associated with the pre-configured default mail provider supplied by the product.

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the EAR file. The EAR file contents are displayed in a tree view.
2. Select the JAR file in which you want to configure the new JavaMail session.
3. Expand the JAR file to view its contents.
4. Click **Mail Providers** > **Mail Provider** > **Mail Sessions**. Complete one of the following actions:
   - Right click the **Mail Sessions** folder and select **New Factory**.
   - Click **Edit** > **New** on the menu bar.
5. Configure the Mail Session properties in the displayed fields.
6. Click **OK**.
7. Click **File** > **Save** on the menu bar to save your changes.

URLs for application clients

A *Uniform Resource Locator* (URL) is an identifier that points to an electronically accessible resource, such as a directory file on a machine in a network, or a document stored in a database.

URLs appear in the format *scheme*:*scheme_information*.

You can represent a *scheme* as `http`, `ftp`, `file`, or another term that identifies the type of resource and the mechanism by which you can access the resource.

In a World Wide Web browser location or address box, a URL for a file available using HyperText Transfer Protocol (HTTP) starts with `http:`. An example is `http://www.ibm.com`. Files available using File Transfer Protocol (FTP) start with `ftp:`. Files available locally start with `file:`.

The *scheme_information* commonly identifies the Internet machine making a resource available, the path to that resource, and the resource name. The scheme_information for HTTP, FTP and File generally starts with two slashes (//), then provides the Internet address separated from the resource path name with one slash (/). For example,

```
http://www.ibm.com/software/webservers/appserv/library.html.
```

For HTTP and FTP, the path name ends in a slash when the URL points to a directory. In such cases, the server generally returns the default index for the directory.

URL providers for the Application Client Resource Configuration Tool

A URL provider implements the function for a particular URL protocol, such as HyperText Transfer Protocol (HTTP). This provider, comprised of a pair of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Configuring new URL providers for application clients

You can create URL providers and URLs for your client application using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create URL providers and URLs for your client application. In a separate administrative task, you must install the Java code for the required URL provider on the client machine on which the client application resides.

About this task

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new URL provider. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new URL provider from the tree.
4. Expand the JAR file to view the contents.
5. Click the folder called **URL Providers**. Complete one of the following actions:
   - Right click the folder and select **New**.
   - Click **Edit** > **New** on the menu bar.
6. Configure the URL provider properties in the resulting property dialog.
7. Click **OK**.
8. Click **File** > **Save** on the menu bar to save your changes.

Configuring URL providers and sessions using the Application Client Resource Configuration Tool

You can edit the configurations of URL providers and URLs to be used by your application clients using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of URL providers and URLs to be used by your application clients.

About this task

1. Start the ACRCT.
2. Open an EAR file.
3. Locate the URL objects in the tree that displays. For example, if your file contains URL providers and URLs, expand **Resources** -> ***application*.jar** -> **URL Providers** -> ***url_provider_instance***

   where ***url_provider_instance*** is a particular URL provider.
4. If you expand the tree further, you will also see the **URLs** folders containing the URL instances for each URL provider instance.

URL settings for application clients:

Use this page to implement the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP).

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **URL Providers** > *URL provider instance*. Right-click **URLs** and click **New**. The following fields appear on the **General** tab.

This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Name:

The administrative name for the URL.

Description:

This is an optional description of the URL for your administrative records.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

URL:

A Uniform Resource Locator (URL) name that points to an Internet or intranet resource. For example: `http://www.ibm.com`.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

URL provider settings for application clients:

Use this page create new URL providers.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **URL Providers**, and click **New**. The following fields appear on the **General** tab.

A URL provider implements the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP). This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Name:

Administrative name for the URL.

Description:

Optional description of the URL, for your administrative records.

Class Path:

A list of paths or JAR file names which together form the location for the resource provider classes.

Protocol:

Protocol supported by this stream handler. For example, `nntp`, `smtp`, `ftp`, and so on.

To use the default protocol, leave this field blank.

Stream handler class:

Fully qualified name of a User-defined Java class that extends the `java.net.URLStreamHandler` for a particular URL protocol, such as FTP.

To use the default stream handler, leave this field blank.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring URL and URL provider settings for application clients

You can configure URL and URL provider settings. This topic provides the required fields and an example.

The purpose of this article is to help you to configure URL and URL provider settings.

- Required fields:
  - URL Properties page: name, jndiName, url
  - URL Provider Properties page: name
- Example:

```
<resources.url:URLProvider xmi:id="URLProvider_1" name="urlProvider:name"
description="urlProvider:description"
streamHandlerClassName="urlProvider:streamHandlerClass"
protocol="urlProvider:protocol">
<classpath>urlProvider:classpath</classpath>
<factories xmi:type="resources.url:URL" xmi:id="URL_1" name="urlFactory:name"
jndiName="urlFactory:jndiName" description="urlFactory:description"
spec="urlFactory:url">
<propertySet xmi:id="J2EEResourcePropertySet_18">
<resourceProperties xmi:id="J2EEResourceProperty_20" name="urlFactory:customName"
value="urlFactory:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_19">
<resourceProperties xmi:id="J2EEResourceProperty_21" name="urlProvider:customName"
value="urlProvider:customValue"/>
</propertySet>
</resources.url:URLProvider>
```

Configuring new URLs with the Application Client Resource Configuration Tool

You can use URLs for your client application using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create URLs for your client application.

About this task

1. Click the URL provider for which you want to create a URL in the tree. Complete one of the following:
   - Configure a new URL provider.
   - Click an existing URL provider.

2. Expand the URL provider to view the **URLs** folder.
3. Click the URL folder. Complete one of the following actions:
   - Right click the folder and click **New**.
   - Click **Edit -> New** on the menu bar.
4. Configure the URL properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File** > **Save** in the menu bar to save your changes.

Asynchronous messaging in WebSphere Application Server using JMS

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface. The JMS interface provides a common way for Java programs (clients and Java Platform, Enterprise Edition (Java EE) applications) to create, send, receive, and read asynchronous requests as JMS messages.

This topic provides a generic overview of asynchronous messaging using the JMS support provided by WebSphere Application Server.

The base support for asynchronous messaging using the JMS API provides the common set of JMS interfaces and associated semantics that define how a JMS client can access the facilities of a JMS provider. This support enables WebSphere product Java EE applications, as JMS clients, to exchange messages asynchronously with other JMS clients, by using JMS destinations (queues or topics). A Java EE application can use JMS queue destinations for point-to-point messaging and JMS topic destinations for publish and subscribe messaging. A Java EE application can explicitly poll for messages on a destination, and then retrieve messages for processing by business logic beans (enterprise beans).

With the base JMS and XA support, the Java EE application uses standard JMS calls to process messages, including any responses or outbound messaging. An enterprise bean can handle responses acting as a sender bean, or within the enterprise bean that receives the incoming messages. Optionally, this process can use two-phase commit within the scope of a transaction. This level of function for asynchronous messaging is called *bean-managed messaging*, and gives an enterprise bean complete control over the messaging infrastructure, for example, connection and session pool management. The common container has no role in bean-managed messaging.

WebSphere Application Server also supports automatic asynchronous messaging using message-driven beans (a type of enterprise bean defined in the Enterprise JavaBeans (EJB) 2.0 specification) and JMS listeners (part of the JMS application server facilities). Messages are automatically retrieved from JMS destinations, optionally within a transaction, then sent to the message-driven bean in a Java EE application, without the application having to explicitly poll JMS destinations.

Java Message Service providers for clients

This topic describes the different ways client applications can use Java Message Service (JMS) providers with WebSphere Application Server.

IBM WebSphere Application Server supports asynchronous messaging through the use of a JMS provider and its related messaging system. JMS providers must conform to the JMS specification version 1.1. To use message-driven beans the JMS provider must support the optional Application Server Facility (ASF) function defined within that specification, or support an inbound resource adapter as defined in the JCA specification version 1.5.

The service integration technologies of IBM WebSphere Application Server can act as a messaging system when you have configured a service integration bus that is accessed through the default messaging provider. This support is installed as part of WebSphere Application Server, administered through the administrative console, and is fully integrated with the WebSphere Application Server runtime.

WebSphere Application Server also includes support for the following JMS providers:

WebSphere MQ
Provided for use with supported versions of WebSphere MQ.

Generic
Provided for use with any 3rd party messaging system which supports ASF.

For backwards compatibility with earlier releases, WebSphere Application Server also includes support for the V5 default messaging provider which enables you to configure resources for use with the WebSphere Application Server version 5 Embedded Messaging system. The V5 default messaging provider can also be used with a service integration bus.

WebSphere applications can use messaging resources provided by any of these JMS providers. However the choice of provider is most often dictated by requirements to use or integrate with an existing messaging system. For example, you may already have a messaging infrastructure based on WebSphere MQ. In this case you may either connect directly using the included support for WebSphere MQ as a JMS provider, or configure a service integration bus with links to a WebSphere MQ network and then access the bus through the default messaging provider.

The service integration bus also provides access to a default messaging provider. This is a J2EE 1.4 compliant JMS messaging provider which is fully integrated with WebSphere Application Server. You can use it in multiple server configurations for messaging interactions with a WebSphere MQ network.

Configuring Java messaging client resources

To configure Java messaging client resources, you create new JMS provider configurations for your application client. The application client can use a messaging service through the Java Message Service APIs. A JMS provider provides two kinds of J2EE factories. One is a *JMS connection factory*, and the other is a *JMS destination factory*.

Before you begin

In a separate administrative task, install the Java Message Service (JMS) client on the client machine where the application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

Note: When completing this task, you can either create a new messaging provider, or you can use an existing one.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new JMS provider. The EAR file contents are in the displayed tree view.
3. Select the JAR file in which you want to configure the new JMS provider from the tree.
4. Expand the JAR file to view its contents.
5. Optionally right-click **Messaging Providers** and select **New**, if you want to create and use a new messaging provider.
6. Configure the JMS provider properties in the resulting property dialog.
7. Click **OK**.
8. Click **File** > **Save**.

Configuring new JMS providers with the Application Client Resource Configuration Tool

You can create new Java Message Service (JMS) provider configurations for the Application Client. The Application Client makes use of a messaging service through the JMS interfaces.

Before you begin

During this task, you create new Java Message Service (JMS) provider configurations for the Application Client. The Application Client makes use of a messaging service through the JMS interfaces. A JMS provider provides two kinds of J2EE resources. One is a JMS connection factory, and the other is a JMS destination.

In a separate administrative task, you must install the JMS client on the client machine where your particular application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

About this task

1. Start the Application Client Resource Configuration Tool and open the EAR file for which you want to configure the new JMS provider. The EAR file contents are displayed in a tree view.
2. From the tree, select the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Right-click **Messaging Providers**. Complete one of the following actions:
   - Right click the folder and select **New**.
   - On the menu bar, click **Edit > New**.
5. In the resulting property dialog, configure the JMS provider properties.
6. Click **OK** when finished.
7. Click **File -> Save** on the menu bar to save your changes.

JMS provider settings for application clients

Use this page to configure properties of the Java Message Service (JMS) provider, if you want to use a JMS provider other than the default messaging provider or the WebSphere MQ as a JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **Messaging Providers**, and click **New**. The following fields appear on the **General** tab.

Name:

The name by which the JMS provider is known for administrative purposes.

Data type String

Description:

A description of the JMS provider, for administrative purposes.

Data type String

Class Path:

A list of paths or `.jar` file names which together form the location for the resource provider classes.

Context factory class:

The Java class name of the initial context factory for the JMS provider.

For example, for an LDAP service provider the value has the form: `com.sun.jndi.ldap.LdapCtxFactory`.

Data type String

Provider URL:

The JMS provider URL for external JNDI lookups.

For example, an LDAP URL for a JMS provider has the form: `ldap://hostname.company.com/contextName`.

Data type String

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Default Provider connection factory settings

Use this panel to view or change the configuration properties of the selected JMS connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display the appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the connection factory.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name that is used to match this Resource Adapter connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Data type String

User Name:

The **User Name** used with the **Password** property for connecting to an application.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Data type String

Password:

The password used to authenticate connection to an application.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the connection factory connects.

Data type String

Client Identifier:

The name of the client. Required for durable topic subscriptions.

Data type String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Durable Subscription Home:

The name of the durable subscription home.

Data type String

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Normally, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Data type Selection list
Default In cluster
Range

In cluster
Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared
Durable subscriptions can be shared across connections.

Never shared
Durable subscriptions are never shared across connections.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Default Default
Range Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Data type String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Default BusMember
Range BusMember, Custom, ME

Target Significance:

The priority of significance for the target specified.

Default Preferred
Range Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Data type String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Example `merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging`

where

`BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).

Default

- If the host name is not specified, then the default `localhost` is used as a default value.
- If the port number is not specified, then `7276` is used as a default value.
- If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Default	Bus
Range	Bus, Host, Cluster, Server

Temporary Queue Name Prefix:

The prefix to apply to the names of temporary queues. This name is a maximum of 12 characters.

Data type	String

Temporary Topic Name Prefix:

The prefix to apply to the names of temporary topics. This name is a maximum of 12 characters.

Data type	String

Default Provider queue connection factory settings

Use this panel to view or change the configuration properties of the selected JMS queue connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Queue Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display the appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the queue connection factory.

Data type	String

Description:

A description of this queue connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String

JNDI Name:

The JNDI name that is used to match this queue connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Data type	String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Data type String

Password:

The password used to create an encrypted. If you complete this field, then the Password field in the Properties box is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the queue connection factory connects.

Data type String

Client Identifier:

The client identifier. Required for durable topic subscriptions.

Data type String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Default Default
Range Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Data type String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Default BusMember
Range BusMember, Custom, Destination, ME

Target Significance:

The priority of significance for the target specified.

Default Preferred
Range Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Data type String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Example `localhost:7777:BootstrapBasicMessaging`

where

`BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).

Default

- If the host name is not specified, then the default `localhost` is used as a default value.
- If the port number is not specified, then `7276` is used as a default value.
- If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Default Bus, Cluster, Server
Range Bus, Host

Temporary Queue Name Prefix:

The prefix to apply to the names of temporary queues. This name is a maximum of 12 characters.

Data type String

Default Provider topic connection factory settings

Use this panel to view or change the configuration properties of the selected JMS topic connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Topic Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display that appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the topic connection factory.

Data type String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name that is used to match this topic connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Data type String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Data type String

Password:

The password used to create an encrypted. If you complete this field, then the Password field in the Properties box is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the topic connection factory connects.

Data type String

Client Identifier:

The name of the client. This field is required for durable topic subscriptions.

Data type String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Durable Subscription Home:

The name of the durable subscription home.

Data type String

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Normally, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Data type Selection list
Default In cluster
Range

In cluster
Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared
Durable subscriptions can be shared across connections.

Never shared
Durable subscriptions are never shared across connections.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Default	Default
Range	Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Data type	String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Default	BusMember
Range	BusMember, Custom, ME

Target Significance:

The priority of significance for the target specified.

Default	Preferred
Range	Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Data type	String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Example	`localhost:7777:BootstrapBasicMessaging` where `BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).
Default	• If the host name is not specified, then the default `localhost` is used as a default value. • If the port number is not specified, then `7276` is used as a default value. • If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Default	Bus
Range	Bus, Host, Cluster, Server

Temporary Topic Name Prefix:

The prefix to apply to the names of temporary topics. This name is a maximum of 12 characters.

Data type	String

Default Provider queue destination settings

Use this panel to view or change the configuration properties of the selected JMS queue destination for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Queue Destinations**. Click **New**. The following fields appear on the **General** tab.

Name:

The name of the queue destination factory. You must complete this field.

Data type	String

Description:

A description of this queue destination for administrative purposes within WebSphere Application Server.

Data type	String

JNDI Name:

The JNDI name used to match this definition to a deployment descriptor `resource-env-ref` name.

Data type	String

Queue Name:

The name of the queue.

Data type	String

Delivery Mode:

The delivery mode for messages sent to this destination.

Data type	String
Range	Application, Persistent or NonPersistent
Default	Application

Time to Live:

The default length of time from its dispatch time that a message sent to this destination should be retained by the system, where **0** indicates that time to live value does not expire. Value from the producer is used if the Time to Live field is not completed.

Data type	Integer
Units	Milliseconds

Priority:

The priority for messages sent to this destination. The value from the producer is used if not completed.

Data type	Integer
Range	0 to 9 with **0** as the lowest priority and **9** as the highest priority

Read Ahead:

Used to control read-ahead optimization during message delivery.

Data type	String
Range	AsConnection, AlwaysOn and AlwaysOff
Default	AsConnection

Default Provider topic destination settings

Use this panel to view or change the configuration properties of the selected JMS topic destination for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Topic Destinations**, and click **New**. The following fields appear on the **General** tab.

Name:

The name of the topic destination entry.

Data type	String

Description:

A description of the entry.

Data type	String

JNDI Name:

The JNDI name used to match this definition to a deployment descriptor `resource-env-ref` name.

Data type	String

Topic Space:

The name of the topic space. This field is required.

Data type	String
Default	DEFAULT_TOPIC_SPACE

Topic Name:

The name of the topic. This field is required.

Data type	String

Delivery Mode:

The default mode for messages sent to this destination.

Data type	String
Range	Application, Persistent or NonPersistent
Default	Application

Time to Live:

The default length of time from its dispatch time that a message sent to this destination should be retained by the system, where **0** indicates that time to live value does not expire. Value from the producer is used if not completed.

Data type	Long
Units	Milliseconds

Priority:

The priority for messages sent to this destination. Value from producer is used if not completed.

Data type	Integer
Range	0 to 9 with **0** as the lowest priority and **9** as the highest priority

Read Ahead:

Used to control read-ahead optimization during message delivery.

Data type	String
Range	AsConnection, AlwaysOn and AlwaysOff
Default	AsConnection

Version 5 Default Provider queue connection factory settings for application clients

Use this panel to browse or change the configuration properties of the selected JMS queue connection factory for point-to-point messaging for use by WebSphere Application Server version 5 applications. These configuration properties control how connections are created between the JMS provider and the default messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Provider** > **Version 5 Default Provider**. Right-click **Queue Connection Factories** and click **New**. The following fields appear on the **General** tab.

A queue connection factory is used to create JMS connections to queue destinations. The queue connection factory is created by the internal WebSphere Application Server product JMS provider. A Version 5 Default Provider queue connection factory has the following properties:

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The User ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a User ID and password explicitly, for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Re-Enter Password:

Confirms the password.

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type String

Application Server:

Enter the name of the application server. This name is not the host name of the machine, but the name of the configured application server.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider topic connection factory settings for application clients

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the internal product Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and the messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Topic Connection Factories** and click **New**. The following fields appear on the **General** tab.

A Version 5 Default Provider topic connection factory has the following properties.

Name:

The name by which this queue connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere Application Server administrative domain.

Data type String

Description:

A description of this topic connection factory for administrative purposes within WebSphere Application Server.

Data type String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly, for example, if the calling application uses the method createTopicConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Node:

The WebSphere Application Server node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type Enum
Range Pull-down list of nodes in the WebSphere Application Server administrative domain.

Application Server:

Enter the name of the application server. This name is not the host name of the machine, but the name of the configured application server.

Port:

Which of the two ports that connections use to connect to the JMS Server. The QUEUED port is for full-function JMS publish/subscribe support, the DIRECT port is for nonpersistent, nontransactional, nondurable subscriptions only.

Note: Message-driven beans cannot use the direct listener port for publish or subscribe support. Therefore, any topic connection factory configured with the Port set to `Direct` cannot be used with message-driven beans.

Data type Enum
Default QUEUED

Range

QUEUED
The listener port used for full-function JMS compliant, publish or subscribe support.

DIRECT
The listener port used for direct TCP/IP connection (nontransactional, nonpersistent, and nondurable subscriptions only) for publish or subscribe support.

The TCP/IP port numbers for these ports are defined on the product internal JMS server.

Client ID:

The JMS client identifier used for connections to the MQSeries® queue manager.

Data type String

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider queue destination settings for application clients

Use this panel to view or change the configuration properties of the selected queue destination for use with product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Queue Destinations** and click **New**. The following fields are displayed on the **General** tab.

A queue destination is used to configure the properties of a JMS queue. A Version 5 Default Provider queue destination has the following properties.

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type String

Description:

A description of the queue, for administrative purposes.

Data type String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
Messages on the destination have their persistence defined by the application that put them onto the queue.
Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
Persistent
Messages on the destination are persistent.
Nonpersistent
Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
The priority of messages on this destination is defined by the application that put them onto the destination.
Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
Specified
The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type Integer
Units Message priority level
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or whether messages on the queue expire (have an unlimited expiry timeout).

Data type Enum

Default APPLICATION_DEFINED

Range

Application defined
The expiry timeout for messages in this queue is defined by the application that put them onto the queue.

Specified
The expiry timeout for messages in this queue is defined by the **Specified expiry** property.If you select this option, you must define a time out on the **Specified expiry** property.

Unlimited
Messages in this queue have no expiry timeout, and those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, specify the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type Integer

Units Milliseconds

Range Greater than or equal to 0

- 0 indicates that messages never timeout.
- Other values are an integer number of milliseconds.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider topic destination settings for application clients

Use this panel to view or change the configuration properties of the selected topic destination for use with the internal product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Topic Destinations** and click **New**. The following fields appear on the **General** tab.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. A Version 5 Default Provider topic has the following properties.

Name:

The name by which the topic is known for administrative purposes.

Data type String

Description:

A description of the topic, for administrative purposes within WebSphere Application Server.

Data type String

JNDI Name:

The application client run-time environment uses this field to retrieve configuration information.

Topic Name: The name of the topic as defined to the JMS provider.

Data type String

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type Enum
Default APPLICATION_DEFINED
Range

Application defined
Messages on the destination have their persistence defined by the application that put them onto the queue.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Persistent
Messages on the destination are persistent.

Nonpersistent
Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type Enum
Default APPLICATION_DEFINED
Range

Application defined
The priority of messages on this destination is defined by the application that put them onto the destination.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Specified
The priority of messages on this destination is defined by the **Specified priority** property.*If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type	Integer
Units	Message priority level
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout).

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined** The expiry timeout for messages on this queue is defined by the application that put them onto the queue. **Specified** The expiry timeout for messages on this queue is defined by the **Specified expiry** property. *If you select this option, you must define a timeout on the **Specified expiry** property.* **Unlimited** Messages on this queue have no expiry timeout, so those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type	Integer
Units	Milliseconds
Range	Greater than or equal to 0 • 0 indicates that messages never time out. • Other values are an integer number of milliseconds.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

WebSphere MQ Provider queue connection factory settings for application clients

Use this panel to view or change the configuration properties of the selected queue connection factory for use with the MQSeries product Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and WebSphere MQ.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right click **Queue Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see WebSphere MQ *Using Java*, available from the WebSphere MQ library.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

A queue connection factory for the JMS provider has the following properties.

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a userid and password explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly; for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type String

Default Null

Re-Enter Password:

Confirms the password.

Queue Manager:

The name of the MQSeries queue manager for this connection factory.

Connections created by this factory connect to that queue manager.

Data type String

Host:

The name of the host on which the WebSphere MQ queue manager runs for client connection only.

Data type String
Default Null
Range A valid TCP/IP host name

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type Integer
Default Null
Range A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Channel:

The name of the channel used for connection to the WebSphere MQ queue manager, for client connection only.

Data type String
Default Null
Range 1 through 20 ASCII characters

Transport type:

Specifies whether the WebSphere MQ client connection or JNDI bindings are used for connection to the WebSphere MQ queue manager. The external JMS provider controls the communication protocols between JMS clients and JMS servers. Tune the transport type when you are using non-ASF nonpersistent, nondurable, nontransactional messaging or when you want to satisfy security issues and the client is local to the queue manager node.

Data type Enum
Units Not applicable

Default BINDINGS

Range

BINDINGS
JNDI bindings are used to connect to the queue manager. BINDINGS is a shared memory protocol and can only be used when the queue manager is on the same node as the JMS client and poses security risks that should be addressed through the use of EJB roles.

CLIENT
WebSphere MQ client connection is used to connect to the queue manager. CLIENT is a typical TCP-based protocol.

DIRECT
For WebSphere MQ Event Broker using DIRECT mode. DIRECT is a lightweight sockets protocol used in nontransactional, nondurable and nonpersistent Publish/Subscribe messaging. DIRECT only works for clients and message-driven beans using the non-ASF protocol.

QUEUED
QUEUED is a standard TCP protocol.

Recommended

Queue connection factory transport type
BINDINGS is faster by 30% or more, but it lacks security. When you have security concerns, BINDINGS is more desirable than CLIENT.

Topic connection factory transport type
DIRECT is the fastest type and should be used where possible. Use BINDINGS when you want to satisfy additional security tasks and the queue manager is local to the JMS client. QUEUED is the fallback for all other cases. WebSphere MQ 5.3 before CSD2 with the DIRECT setting can lose messages when used with message-driven beans and under load. This loss also happens with client-side applications unless the broker maxClientQueueSize is set to 0. You can set this to 0 with the command:

```
#wempschangeproperties WAS_nodeName_server1
 -e default -o DynamicSubscriptionEngine -n
 maxClientQueueSize -v 0 -x executionGroupUUID
```

where executionGroupUUID can be found by starting the broker and looking in the Event Log/Applications for event 2201. This value is usually ffffffff-0000-0000-000000000000.

Note: The WebSphere MQ 5.3 JMS cannot be used within WAS 6.1 because WAS 6.1 has a Java 5 runtime. Therefore, cross-memory connections cannot be established with WebSphere MQ 5.3 queue managers. This can result in a performance degradation if you were previously using WebSphere MQ 5.3 and BINDINGS for your connections and move to CLIENT network connections in migrating to WAS 6.1.

Client ID:

The JMS client identifier used for connections to the MQSeries queue manager.

Data type String

CCSID:

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type String

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ*

Application Programming Reference books. These references are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at http://www.ibm.com/software/integration/wmq/library/, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Message Retention:

Select this check box to specify that unwanted messages are to be left on the queue. Otherwise, unwanted messages are handled according to their disposition options.

Data type Enum
Units Not applicable
Default Cleared
Range **Selected**
Unwanted messages are left on the queue.
Cleared
Unwanted messages are handled according to their disposition options.

Temporary model:

The name of the model definition used to create temporary connection factories if a connection factory does not already exist.

Data type String
Range 1 through 48 ASCII characters

Temporary queue prefix:

The prefix used for dynamic queue naming.

Data type String

Fail if quiesce:

Specifies whether applications return from a method call if the queue manager has entered a controlled failure.

Data type Check box
Default Selected

Local Server Address:

Specifies the local server address.

Data type String

Polling Interval:

Specifies the interval, in milliseconds, between scans of all receivers during asynchronous message delivery

Data type Integer
Units Milliseconds

Default	5000

Rescan interval:

Specifies the interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

This interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

Data type	Integer
Units	Milliseconds
Default	5000

SSL cipher suite:

Specifies the cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider. The value must match the CipherSpec specified on the SVRCONN channel as the **Channel** property.

You must set this property, if you set the **SSL Peer Name** property.

SSL certificate store:

Specifies a list of zero or more Certificate Revocation List (CRL) servers used to check for SSL certificate revocation. If you specify a value for this property, you must use WebSphere MQ JVM at Java 2 version 1.4.

The value is a space-delimited list of entries of the form:
`ldap://`*`hostname`*`:[`*`port`*`]`

A single slash (/) follows this value. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the section “Working with Certificate Revocation Lists” in the *WebSphere MQ Security book*; for example at: http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas012w.htm#IDX2254.

SSL peer name:

For SSL, a *distinguished name* skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connection time.

If this property is not set, such certificate checking is performed.

The SSL peer name property is ignored if **SSL Cipher Suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:
`CN=QMGR.*, OU=IBM, OU=WEBSPHERE`

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the section "Distinguished Names" in the WebSphere MQ Security book.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Data type	Check box
Default	Selected

WebSphere MQ Provider topic connection factory settings for application clients

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the WebSphere MQ product Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and WebSphere MQ.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right-click **Topic Connection Factories** and click **New**.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ product JMS resources. For more information about configuring WebSphere MQ product JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

MA0C broker: When creating a WebSphere Application Server v6 topic connection factory for the MA0C broker, you should consider the following attribute values:

BrokerControlQueue
: This value is fixed at SYSTEM.BROKER.CONTROL.QUEUE for the MA0C broker and is the queue the broker reads from.

BrokerVersion
: Set this value to BASIC for the MA0C broker.

ClientID
: Set this value to whatever you like for the MA0C broker (the value is string and is merely an identifier for your client application).

XA Enabled
Set this value to TRUE or FALSE for the MA0C broker (the setting you use is a performance enhancement flag - you will probably want to set this to 'true' most of the time).

BrokerMessage Selection
This value is fixed at CLIENT for the MA0C broker because the broker relies on client side message selection.

Direct Broker Authorization Type
This value is not required by the MA0C broker.

A topic connection factory for the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which this topic connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS provider.

Data type	String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String

JNDI Name:

The Java Naming and Directory Interface (JNDI) name that is used to bind the topic connection factory into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String
Units	En_US ASCII characters
Range	1 through 45 ASCII characters

User ID:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User** property, you must also specify a value for the **Password** property.

The connection factory **User** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly, for example, if the calling application uses the method createTopicConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Queue Manager:

The name of the WebSphere MQ queue manager for this connection factory. Connections created by this factory connect to that queue manager.

Data type String

Host:

The name of the host on which the WebSphere MQ queue manager runs for client connections only.

Data type String
Range A valid TCP/IP host name

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type Integer
Range A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Channel:

The name of the channel used for client connections to the WebSphere MQ queue manager for client connection only.

Data type String
Range 1 through 20 ASCII characters

Transport Type:

Whether WebSphere MQ client connection or JNDI bindings are used for connection to the WebSphere MQ queue manager.

Data type Enum
Default BINDINGS
Range
CLIENT
WebSphere MQ client connection is used to connect to the WebSphere MQ queue manager.
BINDINGS
JNDI bindings are used to connect to the WebSphere MQ queue manager.

Client ID:

The JMS client identifier used for connections to the WebSphere MQ queue manager.

Data type String

CCSID:

The coded character set identifier to be used with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type String

Broker Control Queue:

The name of the broker control queue to which all command messages (except publications and requests to delete publications) are sent.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

Broker Queue Manager:

The name of the WebSphere MQ queue manager that provides the Publisher and Subscriber message broker.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

Broker Publish Queue:

The name of the broker input queue that receives all publication messages for the default stream.

The name of the broker's input queue (stream queue) that receives all publication messages for the default stream. Applications can also send requests to delete publications on the default stream to this queue.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

Broker Subscribe Queue:

The name of the broker queue from which nondurable subscription messages are retrieved.

The name of the broker queue from which nondurable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a subscription.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

Broker CCSubQ:

The name of the broker queue from which nondurable subscription messages are retrieved for a ConnectionConsumer request. This property applies only for use of the Web container.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

Broker Version:

Specifies whether the message broker is provided by the WebSphere MQ MA0C SupportPac™ or newer versions of WebSphere family message broker products.

Data type Enum
Default Advanced
Range
Advanced The message broker is provided by newer versions of WebSphere family message broker products (MQ Integrator and MQ Publish and Subscribe).
Basic The message broker is provided by the WebSphere MQ MA0C SupportPac (WebSphere MQ - Publish and Subscribe).

Cleanup level:

Specifies the level of clean up provided by the publish or subscribe cleanup utility.

Data type Enum
Default SAFE
Range
ASPROP
NONE
STRONG

Cleanup interval:

Specifies the interval, in milliseconds, between background executions of the publish/subscribe cleanup utility.

Data type Integer

Units Milliseconds
Default 6000

Message selection:

Specifies where broker message selection is performed.

Data type Enum
Default BROKER
Range

BROKER
Message selection is done at the broker location.

Message CLIENT
Message selection is done at the client location.

Publish acknowledge interval:

The interval, in number of messages, between publish requests that require acknowledgement from the broker.

Data type Integer
Default 25

Sparse subscriptions:

Enables sparse subscriptions.

Data type Check box
Default Cleared

Status refresh interval:

The interval, in milliseconds, between transactions to refresh publish or subscribe status.

Data type Integer
Default 6000

Subscription store:

Specifies where WebSphere MQ stores data relating to active JMS subscriptions.

Data type Enum
Default MIGRATE
Range

MIGRATE

QUEUE

BROKER

Multicast:

Specifies whether this connection factory uses multicast transport.

Data type Enum
Default NOT USED
Range

NOT USED
This connection factory does not use multicast transport.

ENABLED
This connection factory always uses multicast transport.

ENABLED_IF_AVAILABLE
This connection factory uses multicast transport.

ENABLED_RELIABLE
This connection factory uses reliable multicast transport.

ENABLED_RELIABLE_IF_AVAILABLE
This connection factory uses reliable multicast transport if available.

Direct authentication:

Specifies whether to use direct broker authorization.

Data type Enum
Default NONE
Range

NONE Direct broker authorization is not used.

PASSWORD
Direct broker authorization is authenticated with a password.

CERTIFICATE
Direct broker authorization is authenticated with a certificates.

Proxy Host Name:

Specifies the host name of a proxy to be used for communication with WebSphere MQ.

Data type String

Proxy Port:

Specifies the port number of a proxy to be used for communication with WebSphere MQ.

Data type Integer
Default 0

Fail if quiesce:

Specifies whether applications return from a method call if the queue manager has entered a controlled failure.

Data type Check box
Default Selected

Local Server Address:

Specifies the local server address.

Data type	String

Polling Interval:

Specifies the interval, in milliseconds, between scans of all receivers during asynchronous message delivery.

Data type	Integer
Units	Milliseconds
Default	5000

Rescan interval:

Specifies the interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

This interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

Data type	Integer
Units	Milliseconds
Default	5000

SSL cipher suite:

Specifies the cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider. The value must match the CipherSpec specified on the SVRCONN channel as the **Channel** property.

You must set this property, if you set the **SSL Peer Name** property.

SSL certificate store:

Specifies a list of zero or more Certificate Revocation List (CRL) servers used to check for SSL certificate revocation. If you specify a value for this property, you must use WebSphere MQ JVM at Java 2 version 1.4.

The value is a space-delimited list of entries of the form:

`ldap://`*`hostname`*`:[`*`port`*`]`

A single slash (/) follows this value. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the section “Working with Certificate Revocation Lists” in the *WebSphere MQ Security book*; for example at: http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas012w.htm#IDX2254.

SSL peer name:

For SSL, a *distinguished name* skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connection time.

If this property is not set, such certificate checking is performed.

The SSL peer name property is ignored if **SSL Cipher Suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:

```
CN=QMGR.*, OU=IBM, OU=WEBSPHERE
```

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the section "Distinguished Names" in the WebSphere MQ Security book.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Data type	Check box
Default	Selected

WebSphere MQ Provider queue destination settings for application clients

Use this panel to view or change the configuration properties of the selected queue destination for use with the WebSphere MQ product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right-click **Queue Destinations** and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ product for JMS resources. For more information about configuring WebSphere MQ product for JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters.

A queue for use with the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

Data type String

Description:

A description of the queue, for administrative purposes.

Data type String

JNDI Name:

The application client run-time environment uses this field to retrieve configuration information.

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent or have their persistence defined by the application.

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
Messages on the destination have their persistence defined by the application that put them onto the queue.
Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
Persistent
Messages on the destination are persistent.
Nonpersistent
Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type Enum
Units Not applicable
Default APPLICATION_DEFINED
Range
Application defined
The priority of messages on this destination is defined by the application that put them onto the destination.
Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
Specified
The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

Data type Integer
Units Message priority level
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout value for this queue is defined by the application or the by **Specified expiry** property or whether messages on the queue never expire (have an unlimited expiry time out).

Data type Enum
Units Not applicable
Default APPLICATION_DEFINED
Range

Application defined
The expiry timeout for messages on this queue is defined by the application that put them onto the queue.

Specified
The expiry timeout for messages on this queue is defined by the **Specified expiry** property. If you select this option, you must define a timeout on the **Specified expiry** property.

Unlimited
Messages on this queue have no expiry timeout and those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type Integer
Units Milliseconds
Range Greater than or equal to 0
- 0 indicates that messages never time out
- Other values are an integer number of milliseconds

Base Queue Name:

The name of the queue to which messages are sent, on the queue manager specified by the **Base queue manager name** property.

Data type String

Base Queue Manager Name:

The name of the WebSphere MQ queue manager to which messages are sent.

This queue manager provides the queue specified by the **Base queue name** property.

Data type String

Units En_US ASCII characters
Range A valid WebSphere MQ Queue Manager name, as 1 through 48 ASCII characters

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSID identifier supported by WebSphere MQ queue manager.

Data type String

Integer encoding:

If native encoding is not enabled, select whether integer encoding is normal or reversed.

Data type Enum
Default NORMAL
Range
NORMAL
Normal integer encoding is used.
REVERSED
Reversed integer encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Decimal encoding:

Indicates that if native encoding is not enabled to select whether decimal encoding is normal or reversed.

Data type Enum
Default NORMAL
Range
NORMAL
Normal decimal encoding is used.
REVERSED
Reversed decimal encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Floating point encoding:

Indicates that if native encoding is not enabled to select the type of floating point encoding.

Data type Enum
Default IEEENORMAL
Range
IEEENORMAL
IEEE normal floating point encoding is used.
IEEEREVERSED
IEEE reversed floating point encoding is used.
S390 S390 floating point encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Native encoding:

Indicates that the queue destination use native encoding (appropriate encoding values for the Java platform) when you select this check box.

Data type Enum
Default Cleared
Range
Cleared
Native encoding is not used, so specify the following properties for integer, decimal and floating point encoding.
Selected
Native encoding is used (to provide appropriate encoding values for the Java platform).

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Target client:

Whether the receiving application is JMS-compliant or is a traditional WebSphere MQ application.

Data type Enum
Default WebSphere MQ
Range
WebSphere MQ
The target is a traditional WebSphere MQ application that does not support JMS.
JMS The target application supports JMS.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

WebSphere MQ Provider topic destination settings for application clients

Use this panel to view or change the configuration properties of the selected topic destination for use with the WebSphere MQ product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right click **Topic Destinations**, and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ product JMS resources. For more information about configuring WebSphere MQ product JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. A topic for use with the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which the topic is known for administrative purposes.

Data type String

Description:

A description of the topic for administrative purposes within IBM WebSphere Application Server.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Persistence:

Specifies whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
Messages on the destination have their persistence defined by the application that put them in the queue.
Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
Persistent
Messages on the destination are persistent.
Nonpersistent
Messages on the destination are not persistent.

Priority:

Specifies whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
The priority of messages on this destination is defined by the application that put them in the destination.
Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
Specified
The priority of messages on this destination is defined by the **Specified priority** property. If you select this option, you must define a priority for the **Specified priority** property.

Specified Priority:

If the **Priority** property is set to `Specified`, type the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type Integer
Units Message priority level
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or by the **Specified expiry** property or by messages on the queue never expire (have an unlimited expiry timeout).

Data type Enum
Default APPLICATION_DEFINED
Range

Application defined
The expiry timeout for messages on this queue is defined by the application that put them in the queue.

Specified
The expiry timeout for messages in this queue is defined by the **Specified expiry** property. If you select this option, you must define a timeout value for the **Specified expiry** property.

Unlimited
Messages on this queue have no expiry timeout, and these messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type Integer
Units Milliseconds
Range Greater than or equal to 0

- 0 indicates that messages never time out.
- Other values are an integer number of milliseconds.

Base Topic Name:

The name of the topic to which messages are sent.

Data type String

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSID identifiers that WebSphere MQ supports.

Data type String

Units Integer
Range 1 through 65535

Integer encoding:

Indicates whether integer encoding is normal or reversed when native encoding is not enabled.

Data type Enum
Default NORMAL
Range
NORMAL
Normal integer encoding is used.
REVERSED
Reversed integer encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Decimal encoding:

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

Data type Enum
Default NORMAL
Range
NORMAL
Normal decimal encoding is used.
REVERSED
Reversed decimal encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Floating point encoding:

Indicates the type of floating point encoding when native encoding is not enabled.

Data type Enum
Default IEEENORMAL
Range
IEEENORMAL
IEEE normal floating point encoding is used.
IEEEREVERSED
IEEE reversed floating point encoding is used.
S390 S/390® floating point encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Native encoding:

Indicates that the queue destination uses native encoding (appropriate encoding values for the Java platform) when you select this check box.

Data type Enum
Default Cleared

Range

Cleared
Native encoding is not used, so specify the previous properties for integer, decimal and floating point encoding.

Selected
Native encoding is used (to provide appropriate encoding values for the Java platform).

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

BrokerDurSubQueue:

The name of the broker queue from which durable subscription messages are retrieved.

The subscriber specifies the name of the queue when it registers a subscription.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

BrokerCCDurSubQueue:

The name of the broker queue from which durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the Web container.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

Target Client:

Specifies whether the receiving application is JMS compliant or is a traditional WebSphere MQ application.

Data type Enum
Default WebSphere MQ
Range

WebSphere MQ
The target is a traditional WebSphere MQ application that does not support JMS.

JMS The target is a JMS compliant application.

Multicast:

Specifies whether this connection factory uses multicast transport.

Data type Enum
Default AS_CF

Range

AS_CF This connection factory uses multicast transport.

DISABLED
This connection factory does not use multicast transport.

NOT_RELIABLE
This connection factory always uses multicast transport.

RELIABLE
This connection factory uses multicast transport when the topic destination is not reliable.

ENABLED
This connection factory uses reliable multicast transport.

Generic JMS connection factory settings for application clients

Use this panel to view or change the configuration properties of the selected Java Message Service (JMS) connection factory for use with the associated JMS provider. These configuration properties control how connections are created between the JMS provider and the messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > *new_JMS_Provider_instance*. Right-click **Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

A Java Message Service (JMS) connection factory creates connections to JMS destinations. The JMS connection factory is created by the associated JMS provider. A JMS connection factory for a generic JMS provider (other than the internal default messaging provider or WebSphere MQ as a JMS provider) has the following properties:

Name:

The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the associated JMS provider.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

Indicates the user ID used with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a userid and password explicitly; for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type String

Password:

The password used with the **User ID** property for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type String
Default Null

Re-Enter Password:

Confirms the password entered in the **Password** field.

External JNDI Name:

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name, for example, `jms/`*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI API by the platform.

Data type String

Connection Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publication or subscription).

Select one of the following options:
Queue
A JMS queue destination for point-to-point messaging.
Topic A JMS topic destination for publish subscribe messaging.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Generic JMS destination settings for application clients

Use this panel to view or change the configuration properties of the selected JMS destination for use with the associated JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > *new JMS Provider instance*. Right-click **Destinations**, and click **New**. The following fields are displayed on the **General** tab.

A JMS destination is used to configure the properties of a JMS destination for the associated generic JMS provider. Connections to the JMS destination are created by the associated JMS connection factory. A JMS destination for use with a generic JMS provider (not the default messaging provider or WebSphere MQ as a JMS provider) has the following properties.

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type String

Description:

A description of the queue, for administrative purposes.

JNDI Name:

The JNDI name of the actual (physical) name of the JMS destination bound into JNDI.

External JNDI Name:

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Destination Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publishing or subscribing).

Select one of the following options:

Queue
A JMS queue destination for point-to-point messaging.

Topic A JMS topic destination for pub/sub messaging.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring JMS provider, JMS connection factory and JMS destination settings for application clients

You can configure JMS Provider, JMS Connection Factory and JMS Destination settings. This topic provides the required fields, special cases, and an example.

The purpose of this article is to help you to configure JMS Provider, JMS Connection Factory and JMS Destination settings.

- Required fields include:
  - JMS Provider Properties page: name, and at least one protocol provider
  - JMS Connection Factory Properties page: name, jndiName, destination type
  - JMS Destination Properties page: name, jndiName, destination type
- Special cases:
  - The destination type must be `QUEUE`, or `TOPIC`.
- Example:

```
<resources.jms:JMSProvider xmi:id="JMSProvider_3" name="genericJMSProvider:name"
description="genericJMSProvider:description"
externalInitialContextFactory="genericJMSProvider:contextFactoryClass"
externalProviderURL="genericJMSProvider:providerUrl">
<classpath>genericJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms:GenericJMSDestination"
xmi:id="GenericJMSDestination_1" name="jmsDestination:name"
jndiName="jmsDestination:jndiName" description="jmsDestination:description"
externalJNDIName="jmsDestination:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_15">
<resourceProperties xmi:id="J2EEResourceProperty_17" name="jmsDestination:customName"
value="jmsDestination:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms:GenericJMSConnectionFactory"
xmi:id="GenericJMSConnectionFactory_1" name="jmsCF:name" jndiName="jmsCF:jndiName"
description="jmsCF:description" userID="jmsCF:user" password="{xor}NTIsHBllMT4yOg=="
externalJNDIName="jmsCF:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_16">
<resourceProperties xmi:id="J2EEResourceProperty_18" name="jmsCF:customName"
value="jmsCF:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_17">
<resourceProperties xmi:id="J2EEResourceProperty_19"
name="genericJMSProvider:customName" value="genericJMSProvider:customValue"/>
</propertySet>
</resources.jms:JMSProvider>
```

Configuring new JMS connection factories for application clients

Use this task to create a new Java Message Service (JMS) connection factory configuration for your application client.

1. Click the JMS provider for which you want to create a connection factory in the tree. Complete one of the following actions:
   - Configure a new JMS provider.
   - Click an existing JMS provider.
2. Expand the JMS provider to view its **Connection Factories** folder.
3. Click the connection factory folder, and complete one of the following actions:
   - Right-click the folder and select**New**.
   - Click **Edit > New** on the menu bar.
4. Configure the JMS connection factory properties in the displayed fields.

5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring new JMS destinations for application clients

Use this task to create a new Java Message Service (JMS) destination configuration for your application client.

1. Click the JMS provider in the tree for which you want to create a destination. Complete one of the following actions:
   - Configure a new JMS provider.
   - Click an existing JMS provider.
2. Expand the JMS provider to view its **Destinations** folder.
3. Click the provider folder, and complete one of the following actions:
   - Right-click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
4. Configure the JMS destination properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring new resource environment providers for application clients

You can create new resource environment provider configurations for your application client using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create new resource environment provider configurations for your application client.

About this task

To configure a new resource environment provider, perform the following steps:

1. Start the Application Configuration Resource Tool and open the EAR file for which you want to configure the new Java Message Service (JMS) provider. The EAR file contents display in a tree view.
2. Select from the tree the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Click the **Resource Environment Providers** folder. Take one of the following actions:
   - Right-click the provider folder, and click **New**.
   - Click **Edit > New** on the menu bar.
5. Configure the JMS provider properties in the displayed fields.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Resource environment provider settings for application clients

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected Java Archive (JAR) file. Right-click **Resource Environment Providers**, and click **New**. The following fields are displayed on the **General** tab:

Name:

Specifies the administrative name for the resource environment provider.

Description:

Specifies a description of the resource environment provider for your administrative records.

Class Path:

Specifies the path to the JAR file that contains the implementation classes for the resource environment provider.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new resource environment entries for application clients

You can create new resource environment entries for your client application using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create new resource environment entries for your client application.

About this task

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new resource environment entry. The EAR file contents are in the displayed tree view.
3. Click the desired resource environment provider, and complete the following action to configure new providers:
   - Configure a new resource environment provider.
4. Expand the resource environment provider to view the **Resource Environment Entries** folder.
5. Click the resource environment entries folder, and complete one of the following actions:
   - Right-click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
6. Configure the resource environment entry properties in the displayed fields.
7. Click **OK**.
8. Click **File > Save** on the menu bar to save your changes.

Resource environment entry settings for application clients

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Environment Providers** > *resource environment instance*. Right-click **Resource Environment Entries**, and click **New**. The following fields appear on the **General** tab:

Name:

Specifies the administrative name for the resource environment entry.

Description:

Specifies a description of the URL for your administrative records.

JNDI Name:

Specifies the Java Naming and Directory Interface (JNDI) name for the resource, including any naming subcontexts.

Use this name to link to the binding information of the platform. The binding associates the resources defined in the deployment descriptor of the module to the actual (or physical) resources bound into JNDI by the platform.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Managing application clients

You can manage Java Platform, Enterprise Edition (Java EE) application clients using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

Perform the following tasks after deploying application clients. This task only applies to Java EE application clients.

1. Update data source and data source provider configurations.
2. Update URLs and URL provider configurations.
3. Update mail session configurations.
4. Update JMS provider, connection factories, and destination configurations.
5. Update MQ JMS provider, MQ connection factories and MQ destination configurations.
6. Update Resource Environment Entry and Resource Environment Provider configurations.
7. (Optional) Remove application client resources.

Updating data source and data source provider configurations with the Application Client Resource Configuration Tool

You can update the configuration of an existing data source or data source provider using the Application Client Resource Configuration Tool (ACRCT).

About this task

During this task, you update the configuration of an existing data source or data source provider. Perform this task when your database configuration changes.

1. Start the Application Client Resource Configuration Tool (ACRCT), and open the Enterprise Archive (EAR) file containing the data source or data source provider. The EAR file contents display in a tree view.
2. Select Java Archive (JAR) file from the navigation tree containing the data source or data source provider to update.
3. Expand the JAR file to view its contents until you locate the particular data source or data source provider to update. Take one of the following actions:
   - Right-click the data source object and click **Properties**.

- Click **Edit > Properties** on the menu bar.

4. Update the properties in the displayed fields. For detailed field help, see:
   - Data source provider properties
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Updating URLs and URL provider configurations for application clients

You can update URLs and URL provider configurations for application clients using the Application Client Resource Configuration Tool (ACRCT).

1. Start the tool and open the Enterprise Archive (EAR) file containing the URL or URL provider. The EAR file contents are displayed in a tree view.
2. Select from the tree the Java Archive (JAR) file containing the URL or URL provider to update.
3. Expand the JAR file to view its contents.
4. Keep expanding the JAR file contents until you locate the particular URL or URL provider to update. Take one of the following actions:
   a. Right-click the URL object and click **Properties**.
   b. Click **Edit** > **Properties** on the menu bar.
5. Update the properties in the displayed fields.
6. Click **OK** when you finish.
7. Click **File** > **Save** on the menu bar to save your changes.

Updating mail session configurations for application clients

You can update the configuration of an existing JavaMail session using the Application Client Resource Configuration Tool (ACRCT).

About this task

During this task, you update the configuration of an existing JavaMail session. You cannot update the name of the default JavaMail provider, and you cannot delete the default JavaMail provider from the navigation tree.

1. Start the tool and open the Enterprise Archive (EAR) file containing the JavaMail session. The EAR file contents are displayed in the navigation tree view.
2. Select the Java Archive (JAR) file containing the JavaMail session to update from the navigation tree.
3. Expand the JAR file to view its contents.
4. Keep expanding the JAR file contents until you locate the particular JavaMail session to update. Take one of the following actions:
   a. Right-click the object and click **Properties**
   b. Click **Edit** > **Properties** from the menu bar.
5. Update the properties in the displayed fields.
6. Click **OK** when you finish.
7. Select **File** > **Save** from the menu bar to save your changes.

Updating Java Message Service provider, connection factories, and destination configurations for application clients

You can update the configuration of an existing Java Message Service (JMS) provider, connection factory or destination using the Application Client Resource Configuration Tool (ACRCT).

About this task

During this task, you update the configuration of an existing Java Message Service (JMS) provider, connection factory or destination.

1. Start the tool and open the Enterprise Archive (EAR) file containing the Java Message Service (JMS) provider, connection factory, or destination. The EAR file contents display in a tree view.
2. Select the Java Archive (JAR) file containing the JMS provider, connection factory, or destination to update from the navigation tree.
3. Expand the JAR file to view its contents until you locate the particular JMS provider, connection factory, or destination to update. When you find it, do one of the following actions:
   - Right-click the provider, and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, see:
   - JMS provider properties
   - WebSphere Application Server Queue connection factory properties
   - WebSphere Application Server Topic connection factory properties
   - WebSphere Application Server Queue destination properties
   - WebSphere Application Server Topic destination properties
5. Click **OK**.
6. Click **File > Save** to save your changes.

Updating WebSphere MQ as a Java Message Service provider, and its JMS resource configurations, for application clients

You can update an existing configuration of WebSphere MQ as a Java Message Service (JMS) provider, and update the configuration of WebSphere MQ connection factories or WebSphere MQ destinations.

About this task

Use this task to update an existing configuration of WebSphere MQ as a Java Message Service (JMS) provider, and to update the configuration of WebSphere MQ connection factories or WebSphere MQ destinations.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the Enterprise Archive (EAR) file containing the WebSphere MQ JMS provider, WebSphere MQ connection factory, or WebSphere MQ destination. The EAR file contents are displayed in the navigation tree view.
3. Select the Java Archive (JAR) file containing the JMS provider, connection factory, or destination to update.
4. Expand the JAR file to view its contents until you locate the particular JMS provider, connection factory, or destination that you want to update. Complete one of the following actions:
   - Right-click the appropriate object and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
5. Update the properties in the displayed fields. For detailed field help, see:
   - JMS provider properties
   - MQ Queue connection factory properties
   - MQ Topic connection factory properties
   - MQ Queue destination properties
   - MQ Topic destination properties
6. Click **OK**.
7. Click **File > Save** to save your changes.

Updating resource environment entry and resource environment provider configurations for application clients

You can update the configuration of an existing resource environment entry or resource environment provider using the Application Client Resource Configuration Tool (ACRCT).

About this task

During this task, you update the configuration of an existing resource environment entry or resource environment provider.

1. Start the tool and open the Enterprise Archive (EAR) file containing the resource environment entry or resource environment provider. The EAR file contents display in a navigation tree view.
2. Select from the tree the Java Archive (JAR) file containing the resource environment entry or resource environment provider to update.
3. Expand the JAR file to view its contents until you locate the resource environment entry or resource environment provider to update. Take one of the following actions:
   - Right-click the resource environment object, and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, see:
   - Resource environment provider properties
   - Resource environment entry properties
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Example: Configuring Resource Environment settings:

You can configure Resource Environment settings. This topic provides the required fields and an example.

The purpose of this topic is to help you configure Resource Environment settings.

- Required fields:
  - Resource Environment Provider page: **Name**
  - Resource Environment Entry page: **Name, JNDI Name**
- Example:

```
<resources.env:ResourceEnvironmentProvider xmi:id="ResourceEnvironmentProvider_1"
name="resourceEnvProvider:name" description="resourceEnvProvider:description">
<classpath>resourceEnvProvider:classpath</classpath>
<factories xmi:type="resources.env:ResourceEnvEntry" xmi:id="ResourceEnvEntry_1"
name="resourceEnvEntry:name" jndiName="resourceEnvEntry:jndiName"
description="resourceEnvEntry:description">
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_21">
<resourceProperties xmi:id="J2EEResourceProperty_23"
name="resourceEnvProvider:customName" value="resourceEnvProvider:customValue"/>
</propertySet>
</resources.env:ResourceEnvironmentProvider>
```

Example: Configuring resource environment custom settings for application clients:

You can configure resource environment custom settings.

The purpose of this topic is to help you configure resource environment custom settings.

- The custom page applies to every resource type. You can specify as many custom names and values as you need.
- Example:

```
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
```

Removing application client resources

You can remove Java Platform, Enterprise Edition (Java EE) application client resources using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

The option to delete an item does not offer a confirmation dialog. As a safeguard, consider saving your work right before you begin this task. If you change your mind after removing an item, you can close the EAR file without saving your changes, canceling your deletion. Remember to close the EAR file immediately after the deletion, or you also lose any unsaved work that you performed since the deletion.

This task only applies to Java EE application clients.

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the Enterprise Archive (EAR) file from which you want to remove an object. The EAR file contents display in the navigation tree view. If you already have an EAR file open and have made some changes, click **File** > **Save** to save your work before preceding to delete an object.
2. Locate the object that you want to remove in the tree.
3. Right-click the object, and click **Delete**.
4. Click **File** > **Save**.

Chapter 5. Web services

Task overview: Implementing Web services applications

Use this topic as an introduction to using Web services. WebSphere Application Server supports Web services that are developed and implemented based on a variety of Java programming models. Use Web services when operating across a variety of platforms, including Java Platform, Enterprise Edition (Java EE) and non-Java EE platforms.

Before you begin

Decide if a Web services implementation benefits your business process.

About this task

Note: IBM WebSphere Application Server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation Web services programming model extending the foundation provided by the JAX-RPC programming model. Using the strategic JAX-WS programming model, development of Web services and clients is simplified through support of a standards-based annotations model. Although the JAX-RPC programming model and applications are still supported, take advantage of the easy-to-implement JAX-WS programming model to develop new Web services applications and clients.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

Implementing Web services applications is an easy way to integrate application systems together within or outside your business infrastructure that function as stand-alone systems. For example, your customer information database is a stand-alone application, but you want your accounting application to access the customer data. You can create a Web service for the customer database and then enable the accounting application as a Web service client. The accounting application can now access the customer information. By implementing a Web service, these two applications can share information in an efficient way.

Because Web services are easily applied to existing applications and information technology assets, you can develop, deploy and recompose new solutions quickly to address new opportunities. As Web services become more popular, the pool of services grows, promoting development of more robust models of just-in-time application and business integration over the Internet.

You can use Web services applications with the application server by following the steps provided:

1. Plan to use Web services. Review all of the components of Web services to learn how you can make your Web services plan more robust.
2. (Optional) Migrate existing Web services.

   Because Java EE environments emphasize compatibility, most application servers that offer support for the newer JAX-WS and JAXB specifications continue to support the older JAX-RPC specification. A consequence of this is that, existing Web services are likely to remain JAX-RPC based while new ones are developed using JAX-WS and JAXB.

   However, as time passes and applications are revised and rewritten, there might be times when the best strategy is to migrate a JAX-RPC based Web service to one based on JAX-WS and JAXB. This might result from a vendor choosing to provide enhancements to qualities of service that are only available in the new programming models. For example, SOAP 1.2 and SOAP Message Transmission Optimization Mechanism (MTOM) support are only available within the JAX-WS 2.x and JAXB 2.x

programming models and not JAX-RPC. Read about Web services migration best practices to learn more about best practices and examples when migrating JAX-RPC Web services to JAX-WS and JAXB Web services.

Note: Existing JAX-RPC applications wanting to use JAX-WS features must be rewritten using the JAX-WS programming model.

If you have used Web services based on Apache SOAP and now want to develop and implement Web Services for Java EE specification, you need to migrate client applications developed with all versions of 4.0, and versions of 5.0 prior to 5.0.2. See the topic, Migrating Apache SOAP Web services to JAX-RPC Web Services based on Java EE standards.

3. Develop Web services applications. You can develop Web services in one of the following ways:
   a. Develop Web services from existing WSDL files using JAX-WS.

      You can create a JAX-WS Web service by starting with an existing Web Services Description Language (WSDL) file describing the service interface for a JavaBeans or enterprise beans application. Typically, the WSDL file is defined as part of the application modeling process. Using an existing service definition or WSDL file to generate a new application is called a top-down approach to developing Web services.

   b. Develop Web services applications using JAX-WS.

      You can use the Java API for XML-Based Web Services (JAX-WS) programming model to develop Web services. JAX-WS simplifies application development through a standard, annotation-based model to develop Web services applications and clients. A common set of binding rules for XML and Java objects make it easy to incorporate XML data and process functions in Java applications. A further set of enhancements help you optimally send binary attachments, such as images or files, with the Web services requests.

      When developing a JAX-WS Web service starting from existing JavaBeans or stateless session enterprise beans, you can expose the bean as a JAX-WS Web service by using annotations. Adding the @WebService or @WebServiceProvider annotation to the bean defines the bean as a JAX-WS Web service. Enterprise beans that are exposed as JAX-WS Web services must be packaged in EJB 3.0 or higher modules.

      Transforming an existing application into Web services is called a bottoms-up approach to developing Web services. This process is called bottoms-up because you are starting with the implementation rather than starting with an existing service or Web Services Description Language (WSDL) file.

   c. Develop and deploy JAX-WS Web services clients Web services clients that can both access and invoke JAX-WS Web services are developed based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. The application server supports Enterprise JavaBeans™ (EJB) clients, Java EE application clients, JavaServer Pages (JSP) files and servlets that are based on the JAX-WS programming model.

   d. Develop Web services applications from existing WSDL files with JAX-RPC.

      You can create a JAX-RPC Web service by starting with an existing WSDL file describing the service interface of an enterprise bean implementation using a top-down approach to developing Web services.

   e. Develop Web services applications with JAX-RPC.

      You can use the Java API for XML-based RPC (JAX-RPC) programming model to develop Web services. When developing a JAX-RPC Web service starting from existing JavaBeans or enterprise beans, you need develop a WSDL file. You can use existing JavaBeans or enterprise beans and then enable the implementation for Web services.

   f. Develop and deploy JAX-RPC Web services clients You can develop Web services clients based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification and the Java API for XML-based remote procedure call (JAX-RPC) specification. The application server supports Enterprise JavaBeans™ (EJB) clients, Java EE application clients, JavaServer Pages (JSP) files and servlets that are based on the JAX-RPC programming model.

g. Enable Web services through service integration technologies

   You can use the Web services enablement of the service integration bus (SIBus) to achieve the following goals:

   - Make an internally hosted service that is available at a bus destination available as a Web service.
   - Make an external Web service available internally at a bus destination.
   - Use the Web services gateway to map an existing service, either an internally-hosted service or an external Web service, to a new Web service that is provided by the gateway.

You can develop Web services to take advantage of Web Services Addressing (WS-Addressing), Web Services Resource Framework (WSRF), and Web Services Transaction (WS-Transaction) support.

- Use the WS-Addressing SPI: Performing more advanced Web Service Addressing tasks.

  You can develop Web services to take advantage of Web Services Addressing (WS-Addressing), which aids interoperability between Web services using a standard way to address Web services and providing addressing information in messages.
- Create stateful Web services using the Web Services Resource Framework.

  With the Web Services Resource Framework (WSRF) support in the application server, you can implement a stateful Web service as a WS-Resource, and reference that service it using a WS-Addressing endpoint reference.
- Use WS-Transaction policy to coordinate transactions or business activities for Web services.

  WS-Transaction is an interoperability standard that includes the WS-AtomicTransaction, WS-BusinessActivity, and WS-Coordination specifications. The Web Services Atomic Transaction (WS-AT) support in the application server provides transactional quality of service to the Web services environment. Distributed Web services applications, and the resources they use, can take part in distributed global transactions. With Web Services Business Activity (WS-BA) support in the application server, Web services on different systems can coordinate activities that are more loosely coupled than atomic transactions. Such activities can be difficult or impossible to roll back atomically, and therefore require a compensation process if an error occurs.
- Use WS-Policy to exchange policies in a standard format.

  WS-Policy is an interoperability standard that is used to describe and communicate the policies of a Web service so that service providers can export policy requirements in a standard format. Clients can combine the service provider requirements with their own capabilities to establish the policies required for a specific interaction.

4. Assemble Web services.

   Read about what you need to assemble a Web service and the order in which to assemble the parts, for example an enterprise archive (EAR) file.
5. Deploy Web services.

   Read about the steps necessary to deploy the EAR file that has been configured and enabled for Web services.
6. Administer deployed Web services.

   Once your Web services application is deployed, you can configure security settings, view deployment descriptors and WSDL documents, set the scope of a Web service port, and manage policy sets and service providers. These tasks can be done using the administrative console or with command-line tools.
7. Secure Web services.

   - Manage policy sets using the administrative console.

     Read about creating policy sets that you can use to simplify the security configuration of your Web services applications. Policy sets are only supported by JAX-WS applications.
   - Secure Web services applications using message level security.

Consider a broad set of security requirements, including authentication, authorization, privacy, trust, integrity, confidentiality, secure communications channels, delegation, and auditing across a spectrum of application and business topologies.

8. Publish the WSDL file.

   After installing a Web services application, and optionally modifying the endpoint information, you might need Web Services Description Language (WSDL) files containing the updated endpoint information. Read about the steps necessary to publish the WSDL files so that this information is available.

9. Monitor the performance of Web services applications.

   Read about using the Performance Monitoring Infrastructure (PMI) to measure the time required to process Web services requests.

10. Troubleshoot Web services.

    Read about troubleshooting different processes used to develop, implement and use Web services, including command-line tools, Java compiling errors, client runtime errors and exceptions, serialization and deserialization errors, and authentication challenges and authorization failures with Web services security.

Example

The following example illustrates how a business might use Web services.

The owner of a flower shop wants to start receiving orders from customers through the Web. This owner starts the process by finding wholesale flower suppliers, pricing the product, and completing contracts for future flower orders.

Using Web services, the flower shop owner can find wholesale flower suppliers. One way to find new suppliers is to use a Universal Description, Discovery and Integration (UDDI) registry to search for potential suppliers. When the suppliers are chosen, the registry sends back information on how to contact the flower distributors that meet the criteria of the flower shop owner.

The flower shop owner can request price lists from each of the suppliers by obtaining a WSDL file for each potential supplier. The WSDL can be downloaded from the Web page of the supplier, received through e-mail, or retrieved from the UDDI registry entry of the supplier.

The WSDL describes the procedure call. When using the application server, the procedure call is a JAX-RPC or a JAX-WS procedure call. Either of these procedure call types retrieves the price list. The WSDL file also specifies the Universal Resource Locator (URL), where the request is sent.

The flower shop owner now has to compare the prices received from each supplier, decide which suppliers to do business with, and make arrangements for future orders to fill. The flower shop can now sell merchandise through the Web by using Web services to communicate with suppliers for the best prices and complete the ordering processes. The merchandise price lists need publishing to the Web site and a mechanism is needed for customers to order flowers.

The Web services clients of the flower supplier are deployed on the flower shop server. When a customer makes a transaction to purchase flowers through the Web, the order is sent to the supplier through the procedure call. The supplier responds by sending a confirmation with the order number and shipping date. The suppliers maintain the inventory and the flower shop owner handles billing and customer order management.

Similarly, the flower shop catalog can be composed automatically from the catalogs of each supplier. If the supplier delivers directly to the customer, then the order tracking inquiries can pass directly to the order tracking system of the supplier. The supplier can also use Web services to send invoices for orders by the

flower shop. Processes that previously required forms to fill manually, and fax or mail, can now be done automatically, saving labor costs for both the flower shop and the supplier.

Using Web services is beneficial because a much larger inventory is made available to the flower shop. No merchandise maintenance overhead exists, and the flower shop can offer their customers products that they otherwise might not have. Selling flowers through the Web increases capital for the flower shop without overhead of another store or resources invested into additional products.

For a more detailed scenario, see Web services scenario: Overview which tells the story of a fictional online garden supply retailer, Plants by WebSphere, and how they incorporated the Web services concept.

Refer to the Samples Gallery for additional Samples that demonstrate JAX-WS and JAX-RPC Web services.

Service-oriented architecture

A *service-oriented architecture* (SOA) is a collection of services that communicate with each other, for example, passing data from one service to another or coordinating an activity between one or more services.

Companies want to integrate existing systems to implement Information Technology (IT) support for business processes that cover the entire business value chain. A variety of designs are used, ranging from rigid point-to-point electronic data interchange (EDI) to Web auctions. By using the Internet, companies can make their IT systems available to internal departments or external customers, but the interactions are not flexible and are without standardized architecture.

Because of this increasing demand for technologies that support connecting and sharing resources and data, a need exists for a flexible, standardized architecture. SOA is a flexible architecture that unifies business processes by structuring large applications into building blocks, or small modular functional units or services, for different groups of people to use inside and outside the company. The building blocks can be one of three roles: service provider, service broker, or service requestor. See Web services approach to a service-oriented architecture to learn more about these roles.

Requirements for an SOA

To efficiently use an SOA, follow these requirements:

- **Interoperability between different systems and programming languages**.

  The most important basis for a simple integration between applications on different platforms is to provide a communication protocol. This protocol is available for most systems and programming languages.
- **Clear and unambiguous description language**.

  To use a service offered by a provider, it is not only necessary to be able to access the provider system, but the syntax of the service interface must also be clearly defined in a platform-independent fashion.
- **Retrieval of the service**.

  To support a convenient integration at design time or even system run time, a search mechanism is required to retrieve suitable services. Classify these services as *computer-accessible*, *hierarchical* or *taxonomies* based on what the services in each category do and how they can be invoked.

Web services approach to a service-oriented architecture

You can use Web services in a service-oriented architecture (SOA) environment.

You can use Web services to implement a SOA. A major focus of Web services is to make functional building blocks accessible over standard Internet protocols that are independent from platforms and programming languages. These services can be new applications or just wrapped around existing legacy systems to make them network-enabled. A service can rely on another service to achieve its goals.

Each SOA building block can assume one or more of three roles:

- **Service provider**

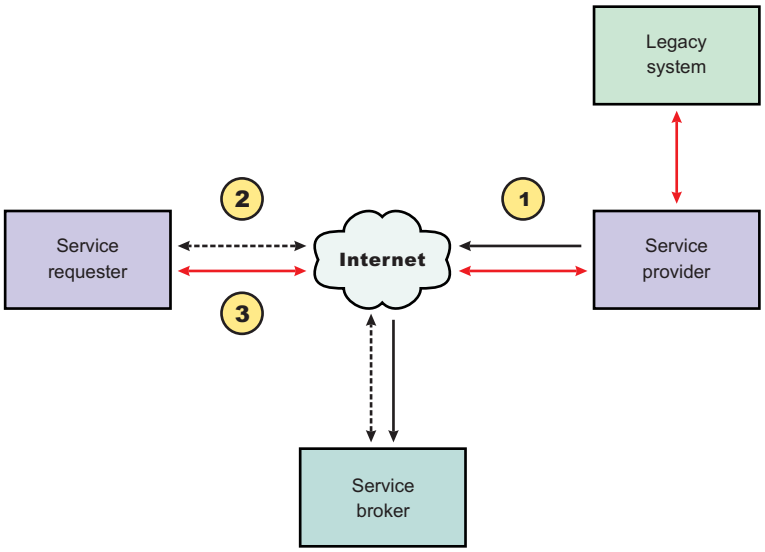
  The service provider creates a Web service and possibly publishes its interface and access information to the service registry. Each provider must decide which services to expose, how to make trade-offs between security and easy availability, how to price the services, or how to exploit free services for other value. The provider also has to decide which category to list the service in for a given broker service and what sort of trading partner agreements are required to use the service.

- **Service broker**

  The service broker, also known as *service registry*, is responsible for making the Web service interface and implementation access information available to any potential service requestor. The implementer of the broker decides the scope of the broker. Public brokers are available through the Internet, while private brokers are only accessible to a limited audience, for example, users of a company intranet. Furthermore, some decisions need to be made about the amount of the offered information. Some brokers specialize in many listings. Others offer high levels of trust in the listed services. Some cover a broad landscape of services and others focus within an industry. Some brokers catalog other brokers. Depending on the business model, brokers can attempt to maximize look-up requests, the number of listings or the accuracy of the listings. The Universal Description, Discovery and Integration (UDDI) specification defines a way to publish and discover information about Web services.

- **Service requester**

  The service requestor or Web service client locates entries in the broker registry using various find operations and then binds to the service provider to invoke one of its Web services.



Characteristics of the SOA

The presented SOA illustrates a loose coupling between the participants, which provides greater flexibility in the following ways:

- A client is coupled to a service. Therefore, the integration of the server takes place outside the scope of the client application programs.
- Old and new functional blocks or applications and systems, are encapsulated into components that work as services.
- Functional components and their interfaces are separate so that new interfaces can be plugged in more easily.
- Within complex applications, the control of business processes can be isolated. A business rule engine can be incorporated to control the workflow of a defined business process. Depending on the state of the workflow, the engine calls the respective services.

- Services can be incorporated dynamically during run time.
- Bindings are specified using configuration files and can be easily adapted to new needs.

Properties of a service-oriented architecture

The service-oriented architecture offers the following properties:

- **Web services are self-contained**

  On the client side, no additional software is required. A programming language with Extensible Markup Language (XML) and HTTP client support is enough to get you started. On the server side, a Web server and a SOAP server are required. It is possible to enable an existing application for Web services without writing a single line of code.
- **Web services are self-describing**

  Neither the client nor the server knows or cares about anything besides the format and content of the request and response messages (loosely coupled application integration). The definition of the message format travels with the message; no external metadata repositories or code generation tool are required.
- **Web services can be published, located, and invoked across the Internet**

  This technology uses established lightweight Internet standards such as HTTP and it leverages the existing infrastructure. Some other standards that are required include, SOAP, Web Services Description Language (WSDL), and UDDI.
- **Web services are language-independent and interoperable**

  The client and server can be implemented in different environments. Existing code does not have to change in order to be Web services-enabled.
- **Web services are inherently open and standard-based**

  XML and HTTP are the major technical foundation for Web services. A large part of the Web service technology has been built using open-source projects.
- **Web services are dynamic**

  Dynamic e-business can become reality using Web services because with UDDI and WSDL you can automate the Web service description and discovery.
- **Web services are composable**

  Simple Web services can be aggregated to more complex ones, either using workflow techniques or by calling lower-layer Web services from a Web service implementation. Web services can be chained together to perform higher-level business functions. This chaining shortens development time and enables best-of-breed implementations.
- **Web services are loosely coupled**

  Traditionally, application design has depended on tight interconnections at both ends. Web services require a simpler level of coordination that supports a more flexible reconfiguration for an integration of the services.
- **Web services provide programmatic access**

  The approach provides no graphical user interface; it operates at the code level. Service consumers need to know the interfaces to Web services, but do not need to know the implementation details of services.
- **Web services provide the ability to wrap existing applications**

  Already existing stand-alone applications can easily integrate into the SOA by implementing a Web service as an interface.

Web services business models supported

This article explains the concept and business models that can be implemented by using Web services in a service-oriented architecture (SOA).

The properties and benefits of using a SOA such as Web services is well suited for binding small modules that perform independent tasks within a highly heterogeneous e-business model. Web services can be easily wrapped around existing applications in your business model and plugged into different business processes.

For connecting to a large monolithic system that does not support the implementation of different flexible business processes, other approaches might be better suited, for example, to satisfy specialized features, such as performance or security.

The following business models are easily implemented by using an architecture including Web services:

- **Business information**

  Sharing of information with consumers or other businesses. Web services can be used to expand the reach through such services as news streams, local weather reports, integrated travel planning, and intelligent agents.
- **Business integration**

  Providing transactional, fee-based services for customers. A global network of suppliers can be easily created. Web services can be implemented in auctions, e-marketplaces, and reservation systems.
- **Business process externalization**

  Web services can be used to model value chains by dynamically integrating processes to a new solution within an organizational unit or even with those of other e-businesses. This modeling can be achieved by dynamically linking internal applications to new partners and suppliers, to offer their services to complement internal services.

To see how these models are implemented using all aspects of Web services, see Web services scenario: Overview which tells the story of a fictional online garden supply retailer named Plants by WebSphere and how this retailer incorporates the Web services concept.

Web services

Web services are self-contained, modular applications that you can describe, publish, locate, and invoke over a network.

The application server supports Web services that are developed and implemented based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. The application server supports the Java API for XML Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. The JAX-WS is a strategic programming model that simplifies application development through support of a standard, annotation-based model to develop Web services applications and clients.

A typical Web services scenario is a business application requesting a service from another existing application. The request is processed through a given Web address using SOAP messages over a HTTP, Java Message Service (JMS) transport or invoked directly as Enterprise JavaBeans (EJB). The service receives the request, processes it, and returns a response. Examples of a simple Web service include weather reports or getting stock quotes. The method call is synchronous, that is, the method waits until the result is available. Transaction Web services, supporting quotes, business-to-business (B2B) or business-to-client (B2C) operations include airline reservations and purchase orders.

Web services can include the actual service or the client that accesses the service.

Web services are Web applications that help improve the flexibility of your business processes by integrating with applications that otherwise do not communicate. The inner-library loan program at your local library is a good example of the Web services concept and its evolution. The Web service concept existed even before the term; the concept became widely accepted with the creation of the Internet. Before the Internet was created, you visited your library, searched the collections and checked out your books. If you did not find the book that you wanted, the librarian ran a search for you by computer or phone and

located the book at a nearby library. The librarian ordered the book for you and you picked it up after it was delivered to your local library. By incorporating Web services applications, you can streamline your library visit.

Now, you can search the local library collection and other local libraries at the same time. When other libraries provide your library with a Web service to search their collection (the service might have been provided through Universal Description Discovery and Integration (UDDI), your results yield their resources. You might use another Web service application to check out and send the book to your home. Using Web services applications saves time and provides a convenience for you, as well as freeing the librarian to do other business tasks.

Web services reflect the service-oriented architecture (SOA) approach to programming. This approach is based on the idea of building applications by discovering and implementing network-available services, or by invoking the available applications to accomplish a task. Web services deliver interoperability, for example, Web services applications provide components created in different programming languages to work together as if they were created using the same language. Web services rely on existing transport technologies, such as HTTP, and standard data encoding techniques, such as Extensible Markup Language (XML), for invoking the implementation.

The key components of Web services include:

- Web Services Description Language (WSDL)

  WSDL is the XML-based file that describes the Web service. The Web service request uses this file to bind to the service.
- SOAP

  SOAP is the XML-based protocol that the Web service request uses to invoke the service.

For a more detailed scenario, see Web services scenario: Overview, which tells the story of a fictional online garden supply retailer named Plants by WebSphere, and how this retailer incorporated the Web services concept.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

Web Services for Java EE specification

The *Web Services for Java Platform, Enterprise Edition (Java EE)* specification defines the programming model and runtime architecture for implementing Web services based on the Java language. Another name for the Web Services for Java EE specification is the Java Specification Requirements (JSR) 109. The specification includes open standards for developing and implementing Web services.

The Web Services for Java EE specification is based on the Java EE technology and supports the Java API for XML Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) programming model for Web services and clients in a manner that is interoperable and portable across application servers within environments that are scalable and secure. This specification is based on industry standards for Web services, including Web Services Description Language (WSDL) and SOAP, and it describes the development and deployment of Web services.

The application server supports the Web Services for Java EE specification, Version 1.2. This specification supports WSDL Version 1.1, SOAP Version 1.1 and SOAP Version 1.2. Prior to Web Services for Java EE Version 1.2, the JSR 109 specification name was Web Services for Java 2 Platform, Enterprise Edition (J2EE).

You can integrate the Java EE technology with Web services in a variety of ways. You can expose Java EE components as Web services, for example, JavaBeans and enterprise beans. When you expose Java EE components as Web services, clients that are written in Java code or existing Web service clients that are not written in Java code can access these services. Java EE components can also act as Web service clients.

The Web Services for Java EE specification is the preferred platform for Web-based programming because it provides open standards permitting different types of languages, operating systems and software to communicate seamlessly through the Internet.

For a Java application to act as Web service client, a mapping between the WSDL file and the Java application must exist. For JAX-WS applications, the mapping is defined using annotations. You can optionally use the webservices.xml deployment descriptor to specify the location of the WSDL file and override the value defined in the @WebServices annotation. For JAX-RPC applications, you must define the JAX-RPC mapping file. To learn more about the mapping that is defined between the WSDL file and your Web service application, see the JAX-WS specification or the JAX-RPC specification in the Web services specifications and API documentation depending on the programming model used.

You can use a Java component to implement a Web service by specifying the component interface and binding information in the WSDL file and designing the application server infrastructure to accept the service request.

This entire process encompassed is based on the Web Services for Java EE specification.

The specification defines the webservices.xml deployment descriptor specifically for Web services. The webservices.xml deployment descriptor file defines the set of Web services that you can deploy in a Web Services for Java EE enabled container.

For JAX-WS Web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

For example, if your service implementation class for your JAX-WS Web service includes the @WebService annotation as follows:

```
@WebService(wsdlLocation="http://myhost.com/location/of/the/wsdl/ExampleService.wsdl")
```

and the webservices.xml specifies a different filename for the WSDL document as follows:

```
<webservices>
<webservice-description>
<webservice-description-name>ExampleService</webservice-description-name>
<wsdl-file>META-INF/wsdl/ExampleService.wsdl</wsdl-file>
...
</webservice-description>
</webservices>
```

then the value that is specified in the deployment descriptor, META-INF/wsdl/ExampleService.wsdl overrides the annotation value.

See section 5 of the Web Services for Java EE specification for details regarding the correlation between values specified in the Web services deployment descriptor file and the attributes of the @WebService and the @WebServiceProvider annotations.

For JAX-RPC Web services, you must define the deployment characteristics in the webservices.xml deployment descriptor file.

You are responsible for providing various elements to the deployment descriptor, including:

- Port name
- Port service implementation
- Port service endpoint interface
- Port WSDL definition

- Port QName
- MTOM/XOP support for JAX-WS Web services
- Protocol binding for JAX-WS Web services
- JAX-RPC mapping
- Handlers (optional)
- Servlet mapping (optional)

The Enterprise JavaBeans (EJB) 2.1 specification also states that for a Web service developed from a session bean, the EJB deployment descriptor, `ejb-jar.xml`, must contain the service-endpoint element. The service-endpoint value must be the same as that stated in the webservices.xml deployment descriptor.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

Artifacts used to develop Web services

With *development artifacts* you can develop an enterprise bean or a JavaBeans module into a Web service. This topic describes artifacts used to develop Web services that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification.

To create a Web service from an enterprise bean or from a JavaBeans module, the following files are added to the respective Java archive (JAR) file or Web archive (WAR) modules at assembly time:

- **Web Services Description Language (WSDL) Extensible Markup Language (XML) file**

  The WSDL XML file describes the Web service that is implemented.
- **Service Endpoint Interface**

  A Service Endpoint Interface is the Java interface corresponding to the Web service port type implemented. The Service Endpoint Interface is defined by the Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) Web services run time that you are using.
- **webservices.xml**

  The webservices.xml file contains the Java EE deployment descriptor of the Web service specifying how the Web service is implemented. The webservices.xml file is defined in the Web Services for Java EE specification.

  For JAX-WS Web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

  For JAX-RPC applications, deployment descriptors are required to specify how the Web service is implemented.
- **ibm-webservices-bnd.xmi (JAX-RPC applications only)**

  This file contains WebSphere product-specific deployment information and is defined in ibm-webservices-bnd.xmi assembly properties.
- **Java API for XML-based remote procedure call (JAX-RPC) mapping file**

  The JAX-RPC mapping deployment descriptor specifies how Java elements are mapped to and from WSDL file elements.

The following files are added to an application client, enterprise beans or Web module to permit a Web Services for Java Platform, Enterprise Edition (Java EE) client access to Web services:

- **WSDL file**

  The WSDL file is provided by the Web service implementer.
- **Java interfaces for the Web service**

  The Java interfaces are generated from the WSDL file as specified by the JAX-WS or JAX-RPC specification. These bindings are the Service Endpoint Interface based on the WSDL port type, or the service interface, which is based on the WSDL service.

- **ibm-webservicesclient-bnd.xmi (JAX-RPC applications only)**

  This file contains WebSphere product-specific deployment information, such as security information for JAX-RPC applications. For JAX-WS applications, deployment descriptors are not supported and have been replaced by the use of annotations.
- **Other JAX-RPC binding files**

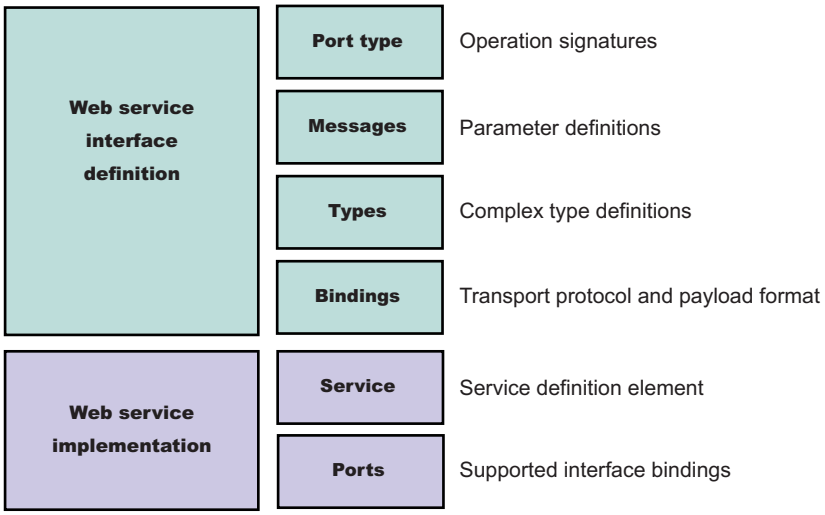
  Additional JAX-RPC binding files that support the client application in mapping SOAP to the Java language are generated from WSDL by the WSDL2Java command tool.

WSDL

Web Services Description Language (WSDL) is an Extensible Markup Language (XML)-based description language. This language was submitted to the World-Wide Web Consortium (W3C) as the industry standard for describing Web services. The power of WSDL is derived from two main architectural principles: the ability to describe a set of business operations and the ability to separate the description into two basic units. These units are a description of the operations and the details of how the operation and the information associated with it are packaged.

A WSDL document defines services as collections of network endpoints, or ports. In WSDL, the abstract definitions of endpoints and messages are separated from their concrete network deployment or data format bindings. This separation supports the reuse of abstract definitions: messages, which are abstract descriptions of exchanged data, and port types, which are abstract collections of operations. The concrete protocol and data format specifications for a particular port type constitutes a reusable binding. A port is defined by associating a network address with a reusable binding, and a collection of ports defines a service. Therefore, a WSDL document is composed of several elements.

The following is the structure of the information in a WSDL file:



A WSDL file contains the following parts:

- **Web service interface definition**

  This part contains the elements and the namespaces.
- **Web service implementation**

  This part contains the definition of the service and ports.

A WSDL file describes a Web service with the following elements:

portType

The description of the operations and associated messages. The portType element defines abstract operations.

```
<portType name="EightBall">
 <operation name="getAnswer">
  <input message="ebs:IngetAnswerRequest"/>
  <output message="ebs:OutgetAnswerResponse"/>
 </operation>
</portType>
```

message

The description of input and output parameters and return values.

```
<message name="IngetAnswerRequest">
 <part name="meth1_inType" type="ebs:questionType"/>
</message>
<message name="OutgetAnswerResponse">
 <part name="meth1_outType" type="ebs:answerType"/>
</message>
```

types

The schema for describing XML types used in the messages.

```
<types>
 <xsd:schema targetNamespace="...">
  <xsd:complexType name="questionType">
   <xsd:element name="question" type="string"/>
  </xsd:complexType>
  <xsd:complexType name="answerType">
  ...
</types>
```

binding

The bindings describe the protocol that is used to access a portType, as well as the data formats for the messages that are defined by a particular portType element.

```
<binding name="EightBallBinding" type="ebs:EightBall">
 <soap:binding style="rpc" transport="schemas.xmlsoap.org/soap/http">
 <operation name="ebs:getAnswer">
 <soap:operation soapAction="urn:EightBall"/>
  <input>
   <soap:body namespace="urn:EightBall" ... />
  ...
```

Service

The services and ports define the location of the Web service.

The service contains the Web service name and a list of ports.

Ports

The ports contain the location of the Web service and the binding used for service access.

```
<service name="EightBall">
 <port binding="ebs:EightBallBinding" name="EightBallPort">
  <soap:address location="localhost:8080/axis/EightBall"/>
 </port>
</service>
```

When creating Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) Web services, you can use a bottom-up development approach when you start from JavaBeans or an enterprise bean, or you can use a top-down development approach when you start with an existing Web Services Description Language (WSDL) file.

When creating JAX-WS Web services for this product, you can start with either a WSDL or an implementation bean class. If you start with an implementation bean class, then use the wsgen command line tool to generate all the Web services server artifacts, including a WSDL if requested. If you start with a WSDL, then use the wsimport command line tool to generate all the Web services artifacts for either the server or client side.

When creating JAX-RPC Web services for this product, you must first have an implementation bean that includes a service endpoint interface. Then, you use the Java2WSDL command-line tool to create a WSDL file that defines the Web services. If you are starting with the WSDL to generate the implementation bean class, run the WSDL2Java command line tool against the WSDL file to create Java APIs and deployment descriptor templates.

Multipart WSDL and WSDL publication

The product supports deployment of Web services using a multipart Web Services Description Language (WSDL) file. In multipart WSDL files, an implementation WSDL file contains the wsdl:service. This implementation WSDL file imports an interface WSDL file, which contains the other WSDL constructs. This supports multiple Web services using the same WSDL interface definition.

The <wsdl:import> element indicates a reference to another WSDL file. If the <wsdl:import> element location attribute does not contain a URL, that is, it contains only a file name, and does not begin with http://, https:// or file://, the imported file must be located in the same directory and must not contain a relative path component. For example, if META-INF/wsdl/A_Impl.wsdl is in your module and contains the <wsdl:import=″A.wsdl″ namespace=″...″/> import statement, the A.wsdl file must also be located in the module META-INF/wsdl directory.

It is recommended that you place all WSDL files in either the META-INF/wsdl directory, if you are using Enterprise JavaBeans (EJB), or the WEB-INF/wsdl directory, if you are using JavaBeans components, even if relative imports are located within the WSDL files. Otherwise, implications exist with the WSDL publication when you use a path like <location=″../interfaces/A_Interface.wsdl″namespace=″...″/>. Using a path like this example fails because the presence of the relative path, regardless of whether the file is located at that path or not. If the location is a Web address, it must be readable at both deployment and server startup.

You can publish the files located in the META-INF/wsdl or the WEB-INF/wsdl directory through either a URL address or file, including WSDL or XML Schema Definition (XSD) files. For example, if the file referenced in the <wsdl-file> element of the webservices.xml deployment descriptor is located in the META-INF/wsdl or the WEB-INF/wsdl directory, it is publishable. If the files imported by the <wsdl-file> are located in the wsdl/ directory or its subdirectory, they are publishable.

If the WSDL file referenced by the <wsdl-file> element is located in a directory other than wsdl, or its subdirectories, the file and its imported files, either WSDL or XSD files, which are in the same directory, are copied to the wsdl directory without modification when the application is installed. These types of files can also be published.

If the <wsdl-file> imports a file located in a different directory (a directory that is not -INF/wsdl or a subdirectory), the file is not copied to the wsdl directory and not available for publishing.

For JAX-WS Web services, you can use an annotation to specify the location of the WSDL. Use the @WebService annotation with the WSDLLocation attribute. The WSDLLocation attribute is optional. If this attribute is not specified, then WSDL is generated and published from the information that is found in the

Web service classes. You can optionally specify the location of the WSDL file in the webservices.xml deployment descriptor. However, any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

SOAP

SOAP is a specification for the exchange of structured information in a decentralized, distributed environment. As such, it represents the main way of communication between the three key actors in a service oriented architecture (SOA): service provider, service requestor and service broker. The main goal of its design is to be simple and extensible. A SOAP message is used to request a Web service.

SOAP 1.1

WebSphere Application Server follows the standards outlined in SOAP 1.1.

SOAP was submitted to the World Wide Web Consortium (W3C) as the basis of the Extensible Markup Language (XML) Protocol Working Group by several companies, including IBM and Lotus. This protocol consists of three parts:

- An *envelope* that defines a framework for describing message content and processing instructions.
- A set of *encoding rules* for expressing instances of application-defined data types.
- A *convention* for representing remote procedure calls and responses.

SOAP 1.1 is a protocol-independent transport and can be used in combination with a variety of protocols. In Web services that are developed and implemented with WebSphere Application Server, SOAP is used in combination with HTTP, HTTP extension framework, and Java Message Service (JMS). SOAP is also operating-system independent and not tied to any programming language or component technology.

As long as the client can issue XML messages, it does not matter what technology is used to implement the client. Similarly, the service can be implemented in any language, as long as the service can process SOAP messages. Also, both server and client sides can reside on any suitable platform.

SOAP 1.2

The SOAP 1.2 specification is also a W3C recommendation, and WebSphere Application Server follows the standards that are outlined in SOAP 1.2. The SOAP 1.2 specification comes in three parts plus some assertions and a test collection:

- Part 0: Primer
- Part 1: Messaging Framework
- Part 2: Adjuncts
- Specification Assertions and Test Collection

SOAP 1.2 provides a more specific definition of the SOAP processing model, which removes many of the ambiguities that sometimes led to interoperability problems in the absence of the Web Services-Interoperability (WS-I) profiles. SOAP 1.2 should reduce the chances of interoperability issues with SOAP 1.2 implementations between different vendors.

Some of the more significant changes in the SOAP 1.2 specification include:

- The ability to now officially define other transport protocols other than the HTTP protocol as long as vendors conform to the binding framework that is defined in SOAP 1.2. While HTTP is ubiquitous, it is not as reliable of a transport as other things such as TCP/IP, MQ, and so forth.
- The fact that SOAP 1.2 is based on the XML Information Set (XML Infoset). The information set provides a way to describe the XML document using the XSD schema but does not necessarily serialize the document by using XML 1.0 serialization. SOAP 1.1 is based upon XML 1.0 serialization. The information set will make it easier to use other serialization formats such as a binary protocol format.

You can use a binary protocol format shrink the message into a much more compact format where some of the verbose tagging information might not be required.

The Java API for XML Web Services (JAX-WS) standard introduces the ability to support both SOAP 1.1 as well as SOAP 1.2.

See “Differences in SOAP versions” on page 352 for additional differences between SOAP 1.1 and SOAP 1.2.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

SOAP with Attachments API for Java interface:

The *SOAP with Attachments API for Java* (SAAJ) interface is used for SOAP messaging that provides a standard way to send XML documents over the Internet from a Java programming model. SAAJ is used to manipulate the SOAP message to the appropriate context as it traverses through the runtime environment.

Note: IBM WebSphere Application Server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation Web services programming model extending the foundation provided by the JAX-RPC programming model. Using the strategic JAX-WS programming model, development of Web services and clients is simplified through support of a standards-based annotations model. Although the JAX-RPC programming model and applications are still supported, take advantage of the easy-to-implement JAX-WS programming model to develop new Web services applications and clients.

The Java API for XML-Based RPC (JAX-RPC) programming model supports SAAJ 1.2 to manipulate the XML.

The JAX-WS programming model supports SAAJ 1.2 and 1.3. SAAJ 1.3 includes support for SOAP 1.2 messages.

The differences in the SAAJ 1.2 and SAAJ 1.3 specification can be reviewed in the topic ″Differences in SAAJ versions.″

How are messages used in Web services?

Web services use XML technology to exchange messages. These messages conform to XML schema. When developing Web services applications, there are limited XML APIs to work with, for example, Document Object Model (DOM). It is more efficient to manipulate the Java objects and have the serialization and deserialization completed during run time.

Web services uses SOAP messages to represent remote procedure calls between the client and the server. Typically, the SOAP message is deserialized into a series of Java value-type business objects that represent the parameters and return values. In addition, the Java programming model provides APIs that support applications and handlers to manipulate the SOAP message directly. Because there are a limited number of XML schema types that are supported by the programming models, the specification provides the SAAJ data model as an extension to manipulate the message.

To manipulate the XML schema types, you need to map the XML schema types to Java types with a *custom data binder*.

The SAAJ interface

The SAAJ-related classes are located in the javax.xml.soap package. SAAJ builds on the interfaces and abstract classes and many of the classes begin by invoking factory methods to create a factory such as SOAPConnectionFactory and SOAPFactory.

The most commonly used classes are:

- SOAPMessage: Contains the message, both the XML and non-XML parts
- SOAPHeader: Represents the SOAP header XML element
- SOAPBody: Represents the SOAP body XML element
- SOAPElement: Represents the other elements in the SOAP message

Other parts of the SAAJ interface include:

- MessageContext: Contains a SOAP message and related properties
- AttachmentPart: Represents a binary attachment
- SOAPPart: Represents the XML part of the message
- SOAPEnvelope: Represents the SOAP envelope XML element
- SOAPFault: Represents the SOAP fault XML element

The primary interface in the SAAJ model is javax.xml.soap.SOAPElement, also referred to as SOAPElement. Using this model, applications can process an SAAJ model that uses pre-existing DOM code. It is also easier to convert pre-existing DOM objects to SAAJ objects.

Messages created using the SAAJ interface follow SOAP standards. A SOAP message is represented in the SAAJ model as a javax.xml.soap.SOAPMessage object. The XML content of the message is represented by a javax.xml.soap.SOAPPart object. Each SOAP part has a SOAP envelope. This envelope is represented by the SAAJ javax.xml.SOAPEnvelope object. The SOAP specification defines various elements that reside in the SOAP envelope; SAAJ defines objects for the various elements in the SOAP envelope.

The SOAP message can also contain non-XML data that is called attachments. These attachments are represented by SAAJ AttachmentPart objects that are accessible from the SOAPMessage object.

A number of reasons exist as to why handlers and applications use the generic SOAPElement API instead of a tightly bound mapping:

- The Web service might be a conduit to another Web service. In this case, the SOAP message is only forwarded.
- The Web service might manipulate the message using a different data model, for example a Service Data Object (SDO). It is easier to convert the message from a SAAJ DOM to a different data model.
- A handler, for example, a digital signature validation handler, might want to manipulate the message generically.

You might need to go a step further to map your XML schema types, because the SOAPElement interface is not always the best alternative for legacy systems. In this case you might want to use a generic programming model, such as SDO, which is more appropriate for data-centric applications.

The XML schema can be configured to include a custom data binding that pairs the SDO or data object with the Java object. For example, the run time renders an incoming SOAP message into a SOAPElement interface and passes it to the customer data binder for more processing. If the incoming message contains an SDO, the run time recognizes the data object code, queries its type mapping to locate a custom binder, and builds the SOAPElement interface that represents the SDO code. The SOAPElement is passed to the SDOCustomBinder.

See Custom data binders for more information about the process of developing applications with SOAPElement, SDO and custom binders.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

Related concepts

“SOAP” on page 341
SOAP is a specification for the exchange of structured information in a decentralized, distributed environment. As such, it represents the main way of communication between the three key actors in a service oriented architecture (SOA): service provider, service requestor and service broker. The main goal of its design is to be simple and extensible. A SOAP message is used to request a Web service.

“Differences in SOAP versions” on page 352
Both SOAP Version 1.1 and SOAP Version 1.2 are World Wide Web Consortium (W3C) standards. Web services can be deployed that support not only SOAP 1.1 but also support SOAP 1.2. Some changes from SOAP 1.1 that were made to the SOAP 1.2 specification are significant, while other changes are minor.

“Differences in SAAJ versions”
The SOAP with Attachments API for Java (SAAJ) interface Version 1.3 expands the support of SOAP 1.2 messages in a Web services environment. There are several differences between SAAJ 1.2 and SAAJ 1.3 that are presented in this topic.

Related reference

Web services specifications and APIs

Differences in SAAJ versions:

The SOAP with Attachments API for Java (SAAJ) interface Version 1.3 expands the support of SOAP 1.2 messages in a Web services environment. There are several differences between SAAJ 1.2 and SAAJ 1.3 that are presented in this topic.

In a typical Web services environment, you rely on the underlying code that is based on Java standards to translate a set of Java objects. The SAAJ interface provides APIs to read, write, send and receive SOAP messages, and advocates binary content sent as an attachment to a SOAP message.

SAAJ 1.3 aligns with SOAP 1.1 and SOAP 1.2 messages and is supported by the Java API for XML Web Services (JAX-WS) programming model and the Java API for XML-Based RPC (JAX-RPC) programming model. SAAJ 1.2 works with SOAP 1.1 messages only.

If you migrate your code from SOAP 1.1 to SOAP 1.2, you can continue to use your existing SOAP 1.1 code, if the message is a SOAP 1.2 message. If you upgrade your base code to use SAAJ 1.3, then you can continue to use the existing code that operates on a SOAP 1.1 message. An example of these differences is in SOAP 1.1, where the human readable text of a fault is stored in the faultString element. In SOAP 1.2, the human readable text is stored in the Reason element. Your code might look like the following example:

```
String text = soapFault.getFaultString();
```

The getFaultString () returns the faultString value if the message is based on SOAP 1.1. If you are using SOAP 1.2, the getFaultString () returns the Reason value. In addition, the SAAJ 1.3 interface provides a new method, getReasonText (Locale), that gets a specific Reason value. The getReasonText (Locale) method returns a documented exception if the message is based on SOAP 1.1. The SAAJ 1.3 interface supports existing code to process both SOAP 1.1 and SOAP 1.2 messages.

Other differences between SAAJ 1.2 and SAAJ 1.3 are in the following list:

- SAAJMetaFactory interface

  The SAAJMetaFactory SPI is introduced to support creating SOAP factory classes in a single place.
- SAAJResult class

The SAAJResult object acts as a holder for the results of a Java API for XML Processing (JAX-P) transformation or a Java Architecture for XML Binding (JAXB) marshalling, in the SAAJ tree. The SAAJResult class is introduced for improved usability when transformation results are expected to be a valid SAAJ tree.

- Overloaded methods that accept a QName instead of a Name

  It is preferred that a QName represents an XML-qualified name. Therefore, overloaded methods are introduced in all of the SAAJ APIs, where a corresponding method accepts a javax.xml.soap.Name name as an argument.
- New methods in AttachmentPart, SOAPBody and SOAPElement interfaces and classes

  Use these new methods to assist you when you are working with the new SOAP features.
- SOAPPart is now a javax.xml.soap.Node method.

  The SOAPPart object is now also considered to be a SOAP node method.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

Message Transmission Optimization Mechanism:

SOAP Message Transmission Optimization Mechanism (MTOM) is a standard that is developed by the World Wide Web Consortium (W3C). MTOM describes a mechanism for optimizing the transmission or wire format of a SOAP message by selectively re-encoding portions of the message while still presenting an XML Information Set (Infoset) to the SOAP application.

There are many reasons why you might want to send binary attachments, such as images or files, along with a Web services request. There are ways to accomplish this, such as:

- Encoding with base64 inline in the SOAP payload. However, encoding inline tends to enlarge the size of the SOAP message. Note that base64 encoding might double the size of the binary data.
- Encoding the messages by using SOAP with Attachments (SwA) and to follow the Web Services Interoperability Organization (WS-I) Attachments Profile. WebSphere Application Server currently supports this method.
- Providing optimization of binary message transportation by using XML-binary Optimized Packaging (XOP). Optimization is available only for binary data or content. MTOM uses XOP in the context of SOAP and MIME over HTTP.

XOP defines a serialization mechanism for the XML Infoset with binary content that is not only applicable to SOAP and MIME packaging, but to any XML Infoset and any packaging mechanism. It is an alternate serialization of XML that just happens to look like a MIME multipart/related package, with an XML documents as the root part. That root part is very similar to the XML serialization of the document, except that base64-encoded data is replaced by a reference to one of the MIME parts, which is not base64 encoded. This reference enables you to avoid the bulk and overhead in processing that is associated with encoding. Encoding is the only way a binary data can fit directly into an XML world.

If MTOM mapping generation is disabled, then XOP is disabled. If XOP is disabled, the binary data are not sent by using MIME attachments. Instead, the binary data is base64 encoded as usual.

The MTOM specification is defined in three different parts:

- An abstract feature for optimized transmission or wire format for SOAP messages. This feature is abstract in the sense that the description of the optimization technique as well as the behavior of the SOAP processors at sender, receiver and intermediaries is generic and does not include any references to technologies such as MIME, HTTP, and so forth. The optimization technique centers around ensuring a SOAP envelope Infoset view for the SOAP processors while encoding selectively certain contents of the SOAP Envelope Infoset that are accessible as canonical lexical representation of the xs:base64Binary data type.

Implementing these abstract features requires concrete specification of two aspects: the optimized wire format and how the optimized wire format flows on a particular transport

- The second part of the MTOM specification addresses the serialization aspect and depends normatively upon MIME Multipart/Related XOP packaging. The serialization aspect is where MTOM relates to XOP.
- As a concrete SOAP HTTP binding level feature, MTOM expands upon the serialization. This part describes how HTTP binding can be used to transport the XOP packages that are holding the SOAP MTOM messages. This part also puts some restrictions on the possible serializations of the SOAP MTOM messages as XOP packages, such as use of XML 1.0 only.

The Java API for XML Web Services (JAX-WS) adds support for sending binary data attachments using MTOM. JAX-WS is the centerpiece of a newly re-architected API stack for Web service that includes JAX-WS 2.0, JAXB 2.0, and SAAJ 1.3. The API stack is sometimes referred to as the integrated stack. JAX-WS is designed to take the place of JAX-RPC in Web services and Web applications.

Attachment approach

Attachment by value or by reference has been the widely accepted technique for handling opaque data in XML-formatted messages.

- **By value** is when the opaque data content is embedded as an element or as an attribute by using either base64 or hexadecimal text encoding approach, which is codified in the XML schema as data types xs:base64Binary and xs:hexBinary, respectively.
- **By reference** is when the opaque data content is referenced externally as element or as attribute by using a URI, which is codified in the XML schema as data type xs:anyURI.

The use of either of these two techniques has its advantages and disadvantages. MTOM is the specification that is focused on resolving these inherent attachments problems.

A different standard is defined by World Wide Web Consortium (W3C) and is called SOAP with Attachments (SwA). SwA was developed as a way to package SOAP messages with attachments. Because some vendors do not support SwA, SwA can be replaced by the more powerful MTOM and XOP mechanisms. SwA and MTOM are conceptually similar, and both encode binary data as a MIME attachment in a MIME document. Using MIME attachments improves the performance of large binary payloads transport.

Additional differences between SwA and MTOM include:

- MTOM uses a standard called XOP, which defines a XOP reference that exists within the SOAP payload. This reference points to the MIME attachment that contains the binary data.
- With MTOM, the XOP reference logically includes the binary data into the XML Information Set (Infoset). With SwA, the href points to data that is not only physically outside the XML document but is not logically included within its Infoset.
- With MTOM, binary attachments can be logically signed as if they were part of the SOAP XML document.
- In additional to IBM, Microsoft® .NET supports MTOM, which eliminates some of the interoperability problems found with SwA. Interoperability was treated as the main goal when the co-submitters discussed the suggested modifications.

The MTOM attachment approach takes advantage of the SOAP infrastructure while also gaining transport efficiencies that are provided by SOAP with Attachment (SwA) solution.

SOAP 1.2 and SOAP 1.1

SOAP 1.1 is based on the XML specification. Likely, the SOAP 1.1 implementation will continue to exist for a few years. For those who are still running SOAP 1.1, there is now an interoperable way to use MTOM for attachments support. SAP, Oracle, Microsoft, and IBM have submitted a SOAP 1.1 Binding for MTOM 1.0 specification to W3C, which defines how MTOM can be used with SOAP 1.1 payloads. The

specification details the necessary modifications to the SOAP MTOM and XOP specifications that are necessary to successfully use these technologies with SOAP 1.1. See the information at this Web site:http://schemas.xmlsoap.org/soap/mtom/SOAP11MTOM10.pdf

MTOM is a SOAP Version 1.2 feature, which is based on the Infoset. For more information, see “XML information set” on page 350.

Without MTOM, the data is encoded in whatever format is described in the schema (base64 or hex) and then is contained in the XML document. The following example shows a SOAP message with an <xsd:base64Binary> element:

```
... other transport headers ...
Content-Type: text/xml; charset=UTF-8

<?xml version="1.0" encoding="UTF-8"?>
   <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
      <soapenv:Header/>
      <soapenv:Body>
         <sendImage xmlns="http://org/apache/axis2/jaxws/sample/mtom">
            <input>
               <imageData>R0lGODl  ... more base64 encoded data ...  KTJk8giAAA7</imageData>
            </input>
         </sendImage>
      </soapenv:Body>
   </soapenv:Envelope>
```

When MTOM is enabled, the binary data that represents the attachment is included as a MIME attachment to the SOAP message. The following example shows an MTOM-enabled SOAP message with attachment data:

```
... other transport headers ...
Content-Type: multipart/related; boundary=MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812;
type="application/xop+xml"; start="<0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>";
start-info="text/xml"; charset=UTF-8

--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: application/xop+xml; charset=UTF-8; type="text/xml";
content-transfer-encoding: binary
content-id:
   <0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>

<?xml version="1.0" encoding="UTF-8"?>
         <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
            <soapenv:Header/>
            <soapenv:Body>
               <sendImage xmlns="http://org/apache/axis2/jaxws/sample/mtom">
                  <input>
                     <imageData>
                        <xop:Include xmlns:xop="http://www.w3.org/2004/08/xop/include"
                             href="cid:1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org"/>
                     </imageData>
                  </input>
               </sendImage>
            </soapenv:Body>
         </soapenv:Envelope>
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: text/plain
content-transfer-encoding: binary
content-id:
         <1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org>

... binary data goes here ...
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812--
```

XML-binary Optimized Packaging:

XML-binary Optimized Packaging (XOP) specification was standardized by the World Wide Web (W3C) on January 25, 2005. SOAP Message Transmission Optimization Mechanism (MTOM) uses XOP in the context of SOAP and MIME over HTTP.

XML is widely used for data transfer. XML is a popular format for exchanging well-formed documents because it is plain text, human-readable, and structured. For example, SOAP messaging in Web services is based on XML (or is based on XML Infoset with SOAP 1.2). People want to leverage legacy formats like PDF, GIF, JPEG and similar things, while still using an XML model. The desire to integrate XML with pre-existing data formats has been a long-standing and persistent issue for the XML community. Users often want to leverage the structured, extensible markup conventions of XML without abandoning existing data formats that do not readily adhere to XML 1.0 syntax.

As SOAP messaging in Web services becomes more widespread, the next step is how to send non-text based data, such as images and workflow data, along with your message. For example, you might want to send a scanned document in .jpeg format between two applications. The question becomes whether this data can be understood between the various applications.

Much of the value of XML and Web services resides in the ability to use generic XML tools to work with content. Many XML tools and standards for describing and manipulating XML (such as parsers, XPath, XQuery, XSLT, XML encryption and digital signature and XML schema) are not designed to work with non-text data, such as images. These XML tools do not work with non-XML content; these tools require text. The challenge is how non-text data (also called *binary data*) can be embedded or attached with XML. In other words, a way to attach a binary file to a SOAP message is needed.

Encoding is the only way binary data can fit directly into an XML world. Normally, you can embed binary data in an XML document by encoding it as text using Base 64. Base 64 is a serialization that has existed for some time, can be easily implemented out of the box, and has interoperability across platforms. The xsi:base64binary datatype supports this serialization in the XML Schema. Base 64 encodes your binary data into a textual representation that can squeeze into an XML document. Base 64 takes your binary data and translates it into a series of ASCII characters by encoding three octets at a time. Because each octet consists of eight bits, representing them as four printable characters in the ASCII standard, it uses 64 ASCII characters to represent the binary. All platforms can decode and encode using this convention. 6-bit ASCII is widely supported, and no special characters need to be dealt with. However, there is a performance impact for larger messages.

For applications that require speedy operation, Base 64 might not be the solution. If you want to index into such content, query it, transform it, encrypt it, sign it, or describe it, you need to use a different mechanism.

The first attachment specification known as SOAP with Attachments (SwA) was developed. The basic idea of SwA is that the binary message part (the attachment) is thought of as a Multipurpose Internet Mail Extensions (MIME) attachment. MIME is a widely implemented specification for formatting non-ASCII mail message attachments. SwA specifies that the SOAP body can contain a reference to the MIME message part (the attachment) simply by using a URI. The binary part is attached by a reference.

A few disadvantages of SwA include:

- SwA fails in its usability or interoperability. The SOAP infrastructure was created around the SOAP envelope, which didn't work well for attachments. An attachment using SwA means that two data models are used in one message. These two data models do not operate with existing XML technology.
- SwA does not work with the composable character of SOAP. Basically standards, such as WS-Security, were not written to work with attachments. WS-Security needs to work on all the data that needs to be digitally signed or encrypted, and that means all the data in the attachment also. But if it cannot access it, then it will not work and the signature is effectively invalid.

Often, users want to leave their existing non-XML formats as is, to be treated as opaque sequences of octets by XML tools and infrastructure. Such an approach permits widely used formats such as .jpeg and .wav to peacefully coexist with XML. XOP makes it a bit more realistic to use base64-encoded data. At the current time, XOP only permits base64-encoded data to be optimized.

Using XOP means that instances of XML-type base64Binary, if enabled, are transported by using MIME attachments. If XOP is in use, the implementation can automatically encode it. XOP maintains the data model of the XML message because the attachment is treated as base64-encoded data. If an XML stack understands XOP encoding, your application does not need to be changed at all. For example, when it wants to access a .jpeg picture, it can get the character value of the content as a base64-encoded string.

XOP gives people a way to think about MIME messages in a data exchange that they are comfortable with and already use for a lot of other data. The XOP format uses multipart MIME to enable raw binary data to be included into an XML 1.0 document without resorting to base64 encoding.

A companion specification, SOAP Message Transmission Optimization Method (MTOM) then specifies how to bind this format to SOAP. The XOP and MTOM standards should enhance SOAP 1.2 performance. XOP and MTOM together provide the preferred approach for mixing binary data with text-based XML. Coupled together, MTOM and XOP enables us to select what parts of the message need to be sent over the wire as binary while still maintaining the Infoset. These standards enable the attachment of binary data outside of the SOAP envelope as a message part. However, unlike SwA, the binary data is treated very much as it was within the SOAP envelope, meaning one Infoset.

XOP defines a serialization mechanism for XML Infoset with binary content that is not only applicable to SOAP and MIME packaging, but applicable to any XML Infoset and any packaging mechanism. On the other hand, XML is not a good general-purpose packaging mechanism.

An XOP package is created by placing a serialization of the XML Infoset inside of an extensible packaging format (such a MIME). Note that XOP does reuse MIME for the actual packaging on the wire. Then, selected portions of its content that are base64-encoded binary data are extracted and re-encoded, meaning the data is decoded from base64 and placed into the package. The locations of those selected portions are marked in the XML with a special element that links to the packaged data by using URIs.

The SOAP processing engines performs a temporary Base 64 encoding of the binary data just before the message hits the wire. This temporary encoding enables the SOAP processor to work on the Base 64 data; for example, enabling a WS-Signature of the data to be taken and placed into the header. There is no need for expensive decoding at the other end, and the process works in reverse.

Implementations of MTOM and XOP are available in Java (JAX-WS).

This example shows an XML Infoset prior to XOP processing (SOAP):

```
<soap:Envelope
    xmlns:soap='http://www.w3.org/2003/05/soap-envelope'
    xmlns:xmlmime='http://www.w3.org/2004/11/xmlmime'>
  <soap:Body>
    <m:data xmlns:m='http://example.org/stuff'>
      <m:photo
  xmlmime:contentType='image/png'>/aWKKapGGyQ=</m:photo>
      <m:sig
  xmlmime:contentType='application/pkcs7-signature'>Faa7vROi2VQ=</m:sig>
    </m:data>
  </soap:Body>
</soap:Envelope>
```

This example shows an XML Infoset that is serialized as a XOP package (SOAP)

```
MIME-Version: 1.0
Content-Type: Multipart/Related;boundary=MIME_boundary;
    type="application/xop+xml";
```

```
    start="<mymessage.xml@example.org>";
    startinfo="application/soap+xml; action=\"ProcessData\""
Content-Description: A SOAP message with my pic and sig in it

--MIME_boundary
Content-Type: application/xop+xml;
    charset=UTF-8;
    type="application/soap+xml; action=\"ProcessData\""
Content-Transfer-Encoding: 8bit
Content-ID: <mymessage.xml@example.org>

<soap:Envelope
    xmlns:soap='http://www.w3.org/2003/05/soap-envelope'
    xmlns:xmlmime='http://www.w3.org/2004/11/xmlmime'>
  <soap:Body>
    <m:data xmlns:m='http://example.org/stuff'>
      <m:photo
  xmlmime:contentType='image/png'><xop:Include
    xmlns:xop='http://www.w3.org/2004/08/xop/include'
    href='cid:http://example.org/me.png'/></m:photo>
      <m:sig
  xmlmime:contentType='application/pkcs7-signature'><xop:Include
    xmlns:xop='http://www.w3.org/2004/08/xop/include'
    href='cid:http://example.org/my.hsh'/></m:sig>
    </m:data>
  </soap:Body>
</soap:Envelope>

--MIME_boundary
Content-Type: image/png
Content-Transfer-Encoding: binary
Content-ID: <http://example.org/me.png>

// binary octets for png

--MIME_boundary
Content-Type: application/pkcs7-signature
Content-Transfer-Encoding: binary
Content-ID: <http://example.org/my.hsh>

// binary octets for signature

--MIME_boundary--
```

XML information set:

XML Information Set (Infoset) is a World Wide Web Consortium (W3C) specification, dated February 4, 2004. An XML information set is an abstract model of the information that is stored in an XML document. The information set establishes a separation between data and information in a way that suits most common uses of XML. Several of the concrete XML data models are defined by referring to XML information set items and their properties.

Whereas an *XML information set* is an abstract model of the information that is stored in an XML document, an *information item* is an abstract representation of some component of an XML document. SOAP Version 1.2 makes use of this abstraction to define the information in a SOAP message without ever referring to XML Version 1.*x*. The SOAP HTTP binding specifically permits alternative media types that provide for, as a minimum, the transfer of the SOAP XML Infoset.

SOAP Message Transmission Optimization Mechanism (MTOM) describes SOAP 1.2 constructs in terms of information items whereas SOAP 1.1 is defined in terms of XML elements. MTOM enables SOAP bindings to optimize the transmission or wire format (or both) of a SOAP message by selectively encoding portions of the message while still presenting an XML information set to the SOAP application. The SOAP 1.2 attribute is now in the SOAP namespace. The XML information sets require the support of XML

namespaces. The core XML recommendation does not require the support of XML namespaces; however namespaces are required to support the XML schema.

The XML information set does not require or favor a specific interface or class of interfaces. The XML information set specification presents the information set as a tree for the sake of clarity and simplicity, but there is no requirement that the XML information set be made available through a tree structure. Other types of interfaces, including but not limited to event-based and query-based interfaces, are also capable of providing information conforming to the information set. As long as the information in the information set is made available to XML applications in one way or another, the requirements of the XML information set are satisfied.

The XML information set provides a set of definitions to be used in other specifications that refer to the information in a well-formed XML document. For any given XML document, there are a number of corresponding information sets.

- A unique minimal information set consisting of the core properties of the core items and nothing else.
- A unique maximal information set consisting of all the core and all the peripheral items with all the peripheral properties, and one for every combination of present and absent peripheral items and properties in between. The in-between information sets must be fully consistent with the maximal information set.

Information set items

The XML information set is a description of the information that is available in a well-formed XML document, and it describes an abstract data model of an XML document in terms of a set of information set items. An information item is an abstract description of some part of an XML document, and each information item has a set of associated named properties. All other information items are accessible from the properties of the document information item, either directly or indirectly through the properties of other information items.

Guidelines for using information set items include:

- There is no requirement for an XML document to be valid in order to have an information set.
- An XML document has an information set if it satisfies the namespace constraints.
- An XML document has an information set if it is well-formed
- Only one document information item is permited in the information set.
- An information set for an XML document consists of two or more information items.
- The information set for any well-formed XML document will contain at least the minimum information items: one document information item and one element information item.
- Each information item has a set of associated properties, some of which are core and some of which are peripheral.

An information set can contain up to eleven different types of information items:

- Document information item
- Element information items
- Attribute information items
- Processing instruction information items
- Unexpanded entity reference information items
- Character information items
- Comment information items
- The Document Type Declaration (DTD) information item
- Unparsed entity information items
- Notation information items
- Namespace information items

Note that the information set of the XML document might not be a complete list of all information items.

Certain kinds of invalidity affect the values assigned to some properties. Entities, notations, elements and attributes can be undeclared. You can have multiple declarations for notations and elements. Multiple declarations are valid for entities and attributes. An ID can be undefined or multiply defined. Such cases are noted where relevant in the information item definitions in the XML Information Set specification.

Syntax

The XML information set uses a square-bracket syntax, meaning the property names are shown in square brackets. For example, the document information item has the following properties:

Table 4.

Property	Description
[children]	An ordered list of child information items, in document order.
[document element]	The element information item corresponding to the document element.
[notations]	An unordered set of notation information items, one for each notation declared in the DTD. If any notation is multiply declared, this property has no value.
[unparsed entities]	An unordered set of unparsed entity information items, one for each unparsed entity declared in the DTD.
[base URI]	The base URI of the document entity.
[character encoding scheme]	The name of the character encoding scheme in which the document entity is expressed.
[standalone]	An indication of the standalone status of the document, either yes or no. This property is derived from the optional standalone document declaration in the XML declaration at the beginning of the document entity, and has no value if there is no standalone document declaration.
[version]	A string representing the XML version of the document. This property is derived from the XML declaration optionally present at the beginning of the document entity, and has no value if there is no XML declaration.
[all declarations processed]	This property is not strictly speaking part of the information set of the document. Rather it is an indication of whether the processor has read the complete DTD. Its value is a boolean. If it is false, then certain properties (indicated in their descriptions below) might be unknown. If it is true, those properties are never unknown.

All information sets are understood to describe the XML document with all entity references already expanded; that is, represented by the information items corresponding to their replacement text. In the case that an entity reference cannot be expanded, because an XML processor has not read its declaration or its value, explicit provision is made for representing such a reference in the information set.

Differences in SOAP versions:

Both SOAP Version 1.1 and SOAP Version 1.2 are World Wide Web Consortium (W3C) standards. Web services can be deployed that support not only SOAP 1.1 but also support SOAP 1.2. Some changes from SOAP 1.1 that were made to the SOAP 1.2 specification are significant, while other changes are minor.

The SOAP 1.2 specification introduces several changes to SOAP 1.1. This information is not intended to be an in-depth description of all the new or changed features for SOAP 1.1 and SOAP 1.2. Instead, this information highlights some of the more important differences between the current versions of SOAP.

The changes to the SOAP 1.2 specification that are significant include the following updates:

- SOAP 1.1 is based on XML 1.0. SOAP 1.2 is based on XML Information Set (XML Infoset).

  The XML information set (infoset) provides a way to describe the XML document with XSD schema. However, the infoset does not necessarily serialize the document with XML 1.0 serialization on which SOAP 1.1 is based.. This new way to describe the XML document helps reveal other serialization

formats, such as a binary protocol format. You can use the binary protocol format to compact the message into a compact format, where some of the verbose tagging information might not be required.

In SOAP 1.2 , you can use the specification of a binding to an underlying protocol to determine which XML serialization is used in the underlying protocol data units. The HTTP binding that is specified in SOAP 1.2 - Part 2 uses XML 1.0 as the serialization of the SOAP message infoset.

- SOAP 1.2 provides the ability to officially define transport protocols, other than using HTTP, as long as the vendor conforms to the binding framework that is defined in SOAP 1.2. While HTTP is ubiquitous, it is not as reliable as other transports including TCP/IP and MQ.
- SOAP 1.2 provides a more specific definition of the SOAP processing model that removes many of the ambiguities that might lead to interoperability errors in the absence of the Web Services-Interoperability (WS-I) profiles. The goal is to significantly reduce the chances of interoperability issues between different vendors that use SOAP 1.2 implementations.
- SOAP with Attachments API for Java (SAAJ) can also stand alone as a simple mechanism to issue SOAP requests. A major change to the SAAJ specification is the ability to represent SOAP 1.1 messages and the additional SOAP 1.2 formatted messages. For example, SAAJ Version 1.3 introduces a new set of constants and methods that are more conducive to SOAP 1.2 (such as getRole(), getRelay()) on SOAP header elements. There are also additional methods on the factories for SAAJ to create appropriate SOAP 1.1 or SOAP 1.2 messages.
- The XML namespaces for the envelope and encoding schemas have changed for SOAP 1.2. These changes distinguish SOAP processors from SOAP 1.1 and SOAP 1.2 messages and supports changes in the SOAP schema, without affecting existing implementations.
- Java Architecture for XML Web Services (JAX-WS) introduces the ability to support both SOAP 1.1 and SOAP 1.2. Because JAX-RPC introduced a requirement to manipulate a SOAP message as it traversed through the run time, there became a need to represent this message in its appropriate SOAP context. In JAX-WS, a number of additional enhancements result from the support for SAAJ 1.3.
- The Web Services Description Language (WSDL) Version 1.1 specification does not discuss SOAP 1.2. SOAP 1.2 is discussed in the draft versions of WSDL 2.0. WSDL Version 1.1 only defines how to render a SOAP 1.1 payload in a WSDL 1.1 document. To resolve how to represent SOAP 1.2-based services, there is another W3C document that defines how to define a SOAP 1.2 payload within a WSDL 1.1 document. Read about WSDL 1.1 binding extensions for SOAP 1.2.
- SOAP 1.1 is a single document. The SOAP 1.2 specification is organized in the following parts:
  - Part 0 is a non-normative introduction to SOAP.
  - Part 1 describes the structure of SOAP messages, the SOAP processing model and a framework for binding SOAP to underlying protocols. Conformant SOAP implementations must implement everything in Part 1.
  - Part 2 describes optional add-ins to the core of SOAP including a data model and encoding, an RPC convention and a binding to HTTP. Conformant SOAP implementations might implement any of the add-ins in Part 2. However, if add-ins are implemented, they must conform to the relevant parts of the specification.

  A fourth document is the Specification Assertions and Test Collection

SOAP 1.2 has a number of changes in syntax and provides additional, clarified semantics from those that are described in SOAP 1.1. The SOAP 1.2 Primer document lists and describes these syntax changes.

JAX-WS

Java API for XML-Based Web Services (JAX-WS) is the next generation Web services programming model complimenting the foundation provided by the Java API for XML-based RPC (JAX-RPC) programming model. Using JAX-WS, development of Web services and clients is simplified with more platform independence for Java applications by the use of dynamic proxies and Java annotations.

JAX-WS is a programming model that simplifies application development through support of a standard, annotation-based model to develop Web Service applications and clients. The JAX-WS technology strategically aligns itself with the current industry trend towards a more document-centric messaging model

and replaces the remote procedure call programming model as defined by JAX-RPC. While the JAX-RPC programming model and applications are still supported by this product, JAX-RPC has limitations and does not support various complex document-centric services. JAX-WS is the strategic programming model for developing Web services and is a required part of the Java Platform, Enterprise Edition 5 (Java EE 5). JAX-WS is also known as JSR 224.

Note: WebSphere Application Server Version 7.0 supports the JAX-WS 2.1 specification. JAX-WS 2.1 extends the functionality of JAX-WS 2.0 to provide support for the WS-Addressing in a standardized API. Using this function, you can create, transmit and use endpoint references to target a Web service endpoint. You can use this API to specify the action uniform resource identifiers (URIs) that are associated with the Web Services Description Language (WSDL) operations of your Web service. JAX-WS 2.1 introduces the concept of *features* as a way to programmatically control specific functions and behaviors. There are three standard features: the AddressingFeature for WS-Addressing, the MTOMFeature when optimizing the transmission of binary attachments, and the RespectBindingFeature for wsdl:binding extensions. JAX-WS 2.1 requires Java Architecture for XML Binding (JAXB) Version 2.1 for data binding.

The implementation of the JAX-WS programming standard provides the following enhancements for developing Web services and clients:

- **Better platform independence for Java applications.**

  Using JAX-WS APIs, development of Web services and clients is simplified with better platform independence for Java applications. JAX-WS takes advantage of the dynamic proxy mechanism to provide a formal delegation model with a pluggable provider. This is an enhancement over JAX-RPC, which relies on the generation of vendor-specific stubs for invocation.

- **Annotations**

  JAX-WS introduces support for annotating Java classes with metadata to indicate that the Java class is a Web service. JAX-WS supports the use of annotations based on the Metadata Facility for the Java Programming Language (JSR 175) specification, the Web Services Metadata for the Java Platform (JSR 181) specification and annotations defined by the JAX-WS 2.1 specification. Using annotations within the Java source and within the Java class simplifies development of Web services. Use annotations to define information that is typically specified in deployment descriptor files, WSDL files, or mapping metadata from XML and WSDL files into the source artifacts.

  For example, you can embed a simple @WebService tag in the Java source to expose the bean as a Web service.

  ```
  @WebService

  public class QuoteBean implements StockQuote {

         public float getQuote(String sym) { ... }

  }
  ```

  The @WebService annotation tells the server runtime environment to expose all public methods on that bean as a Web service. Additional levels of granularity can be controlled by adding additional annotations on individual methods or parameters. Using annotations makes it much easier to expose Java artifacts as Web services. In addition, as artifacts are created from using some of the top-down mapping tools starting from a WSDL file, annotations are included within the source and Java classes as a way of capturing the metadata along with the source files.

  Using annotations also improves the development of Web services within a team structure because you do not need to define every Web service in a single or common deployment descriptor as required with JAX-RPC Web services. Taking advantage of annotations with JAX-WS Web services enables parallel development of the service and the required metadata.

  For JAX-WS Web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS

annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

For example, if your service implementation class for your JAX-WS Web service includes the following:

– the @WebService annotation:

```
@WebService(wsdlLocation="http://myhost.com/location/of/the/wsdl/ExampleService.wsdl")
```

– the webservices.xml file specifies a different file name for the WSDL document as follows:

```
<webservices>
<webservice-description>
<webservice-description-name>ExampleService</webservice-description-name>
<wsdl-file>META-INF/wsdl/ExampleService.wsdl</wsdl-file>
...
</webservice-description>
</webservices>
```

In this case, the value that is specified in the deployment descriptor, META-INF/wsdl/ExampleService.wsdl overrides the annotation value.

- **Invoking Web services asynchronously**

  With JAX-WS, Web services are called both synchronously and asynchronously. JAX-WS adds support for both a polling and callback mechanism when calling Web services asynchronously. Using a polling model, a client can issue a request, get a response object back, which is polled to determine if the server has responded. When the server responds, the actual response is retrieved. Using the callback model, the client provides a callback handler to accept and process the inbound response object. Both the polling and callback models enable the client to focus on continuing to process work without waiting for a response to return, while providing for a more dynamic and efficient model to invoke Web services.

  For example, a Web service interface might have methods for both synchronous and asynchronous requests. Asynchronous requests are identified in bold in the following example:

```
@WebService
public interface CreditRatingService {
      // sync operation
      Score      getCreditScore(Customer customer);
      // async operation with polling
      Response<Score> getCreditScoreAsync(Customer customer);
      // async operation with callback
      Future<?> getCreditScoreAsync(Customer customer,
         AsyncHandler<Score> handler);
}
```

  The asynchronous invocation that uses the callback mechanism requires an additional input by the client programmer. The callback is an object that contains the application code that is run when an asynchronous response is received. Use the following code example to invoke an asynchronous callback handler:

```
CreditRatingService svc = ...;

Future<?> invocation = svc.getCreditScoreAsync(customerFred,
 new AsyncHandler<Score>() {
    public void handleResponse (
        Response<Score> response)
      {
        Score score = response.get();
        // do work here...
      }
   }
);
```

  Use the following code example to invoke an asynchronous polling client:

```
CreditRatingService svc = ...;
Response<Score> response = svc.getCreditScoreAsync(customerFred);

while (!response.isDone()) {
  // Complete an action while we wait.
```

```
}

// No cast needed, because of generics.
Score score = response.get();
```

- **Using resource injection**

  JAX-WS supports resource injection to further simplify development of Web services. JAX-WS uses this key feature of Java EE 5 to shift the burden of creating and initializing common resources in a Java runtime environment from your Web service application to the application container environment, itself. JAX-WS provides support for a subset of annotations that are defined in JSR-250 for resource injection and application life cycle in its runtime environment.

  The application server also supports the usage of the @Resource or @WebServiceRef annotation to declare JAX-WS managed clients and to request injection of JAX-WS services and ports. When either of these annotations are used on a field or method, they result in injection of a JAX-WS service or port instance. The usage of these annotations also results in the type specified by the annotation being bound into the JNDI namespace.

  The @Resource annotation is defined by the JSR-250, Common Annotations specification that is included in Java Platform, Enterprise Edition 5 (Java EE 5). By placing the @Resource annotation on a variable of type javax.xml.ws.WebServiceContext within a service endpoint implementation class, you can request a resource injection and collect the javax.xml.ws.WebServiceContext interface related to that particular endpoint invocation. From the WebServiceContext interface, you can collect the MessageContext for the request associated with the particular method call using the getMessageContext() method.

  The @WebServiceRef annotation is defined by the JAX-WS specification.

  The following example illustrates using the @Resource and @WebServiceRef annotations for resource injection:

```
@WebService
public class MyService {

    @Resource
    private WebServiceContext ctx;

    @Resource
    private SampleService svc;

    @WebServiceRef
    private SamplePort port;

    public String echo (String input) {
        ...
    }

}
```

  Refer to sections 5.2.1 and 5.3 of the JAX-WS specification for more information on resource injection.

- **Data binding with JAXB 2.1**

  JAX-WS leverages the Java Architecture for XML Binding (JAXB) 2.1 API and tools as the binding technology for mappings between Java objects and XML documents. JAX-WS tooling relies on JAXB tooling for default data binding for two-way mappings between Java objects and XML documents. JAXB data binding replaces the data binding described by the JAX-RPC specification.

  The JAXB 2.1 specification provides enhancements such as improved compilation support and introduces support for the @XMLSeeAlso annotation. With the improved compilation support, you now have the flexibility to control the whether a new schema file is generated when using the schemagen schema generator and you can configure the xjc schema compiler so that it does not automatically generate new classes for a particular schema. You can use the @XMLSeeAlso annotation to ensure that JAXB is aware of all the classes included in an inheritance hierarchy for a service endpoint interface.**Dynamic and static clients**

The dynamic client API for JAX-WS is called the dispatch client (javax.xml.ws.Dispatch). The dispatch client is an XML messaging oriented client. The data is sent in either PAYLOAD or MESSAGE mode. When using the PAYLOAD mode, the dispatch client is only responsible for providing the contents of the <soap:Body> and JAX-WS adds the <soap:Envelope> and <soap:Header> elements. When using the MESSAGE mode, the dispatch client is responsible for providing the entire SOAP envelope including the <soap:Envelope>, <soap:Header>, and <soap:Body> elements. JAX-WS does not add anything additional to the message. The dispatch client supports asynchronous invocations using a callback or polling mechanism.

The static client programming model for JAX-WS is the called the proxy client. The proxy client invokes a Web service based on a Service Endpoint interface (SEI), which must be provided.

- **Support for MTOM**

  Using JAX-WS, you can send binary attachments such as images or files along with Web services requests. JAX-WS adds support for optimized transmission of binary data as specified by Message Transmission Optimization Mechanism (MTOM).

- **Multiple data binding technologies**

  JAX-WS exposes the following binding technologies to the end user: XML Source, SOAP Attachments API for Java (SAAJ) 1.3, and Java Architecture for XML Binding (JAXB) 2.1. XML Source enables a user to pass a javax.xml.transform.Source into the runtime environment which represents the data in a Source object to be processed. SAAJ 1.3 now has the ability to pass an entire SOAP document across the interface rather than just the payload itself. This action is done by the client passing the SAAJ SOAPMessage object across the interface. JAX-WS leverages the JAXB 2.1 support as the data binding technology of choice between Java and XML.

- **Support for SOAP 1.2**

  Support for SOAP 1.2 has been added to JAX-WS 2.0. JAX-WS supports both SOAP 1.1 and SOAP 1.2 so that you can send binary attachments such as images or files along with Web services requests. JAX-WS adds support for optimized transmission of binary data as specified by MTOM.

- **Development tools**

  JAX-WS provides the wsgen and wsimport command-line tools for generating portable artifacts for JAX-WS Web services. When creating JAX-WS Web services, you can start with either a WSDL file or an implementation bean class. If you start with an implementation bean class, use the wsgen command-line tool to generate all the Web services server artifacts, including a WSDL file if requested. If you start with a WSDL file, use the wsimport command-line tool to generate all the Web services artifacts for either the server or the client. The wsimport command-line tool processes the WSDL file with schema definitions to generate the portable artifacts, which include the service class, the service endpoint interface class, and the JAXB 2.1 classes for the corresponding XML schema.

- **Support for WS-Addressing (JAX-WS 2.1)**

  JAX-WS 2.1 integrates support for the WS-Addressing standard in to the API. The new API enables you to create, transmit and use endpoint references to target a specific Web service endpoint. You can also explicitly specify the action URIs associated with the Web Services Description Language (WSDL) operations of your Web service.

- **Support for JAX-WS 2.1 features**

  JAX-WS 2.1 introduces the concept of features as a way to programmatically control certain functions or behaviors. There are three standard features: the AddressingFeature , the MTOMFeature, and the RespectBindingFeature. The AddressingFeature is used to enable or disable support for the WS-Addressing Version 1.0 specification. The MTOMFeature is used to enable or disable support for Message Transmission Optimized Mechanism (MTOM) when sending binary attachments. The RespectBindingFeature is used to enable or disable support for wsdl:binding extensions. The application server supports an additional feature, the SubmissionAddressingFeature, which is used to enable or disable support for WS-Addressing Member Submission specification (prior to the WS-Addressing Version 1.0 level of specification).

JAX-WS client programming model:

The Java API for XML-Based Web Services (JAX-WS) Web service client programming model supports both the Dispatch client API and the Dynamic Proxy client API. The Dispatch client API is a dynamic client programming model, whereas the static client programming model for JAX-WS is the Dynamic Proxy client. The Dispatch and Dynamic Proxy clients enable both synchronous and asynchronous invocation of JAX-WS Web services.

- Dispatch client: Use this client when you want to work at the XML message level or when you want to work without any generated artifacts at the JAX-WS level.
- Dynamic Proxy client: Use this client when you want to invoke a Web service based on a service endpoint interface.

Dispatch client

XML-based Web services use XML messages for communications between Web services and Web services clients. The JAX-WS APIs provide high-level methods to simplify and hide the details of converting between Java method invocations and their associated XML messages. However, in some cases, you might desire to work at the XML message level. Support for invoking services at the XML message level is provided by the Dispatch client API. The Dispatch client API, `javax.xml.ws.Dispatch`, is a dynamic JAX-WS client programming interface. To write a Dispatch client, you must have expertise with the Dispatch client APIs, the supported object types, and knowledge of the message representations for the associated Web Services Description Language (WSDL) file. The Dispatch client can send data in either `MESSAGE` or `PAYLOAD` mode. When using the `javax.xml.ws.Service.Mode.MESSAGE` mode, the Dispatch client is responsible for providing the entire SOAP envelope including the `<soap:Envelope>`, `<soap:Header>`, and `<soap:Body>` elements. When using the `javax.xml.ws.Service.Mode.PAYLOAD` mode, the Dispatch client is only responsible for providing the contents of the `<soap:Body>` and JAX-WS includes the payload in a `<soap:Envelope>` element.

The Dispatch client API requires application clients to construct messages or payloads as XML which requires a detailed knowledge of the message or message payload. The Dispatch client supports the following types of objects:

- `javax.xml.transform.Source`: Use `Source` objects to enable clients to use XML APIs directly. You can use `Source` objects with SOAP or HTTP bindings.
- JAXB objects: Use JAXB objects so that clients can use JAXB objects that are generated from an XML schema to create and manipulate XML with JAX-WS applications. JAXB objects can only be used with SOAP or HTTP bindings.
- `javax.xml.soap.SOAPMessage`: Use `SOAPMessage` objects so that clients can work with SOAP messages. You can only use `SOAPMessage` objects with SOAP bindings.
- `javax.activation.DataSource`: Use `DataSource` objects so that clients can work with Multipurpose Internet Mail Extension (MIME) messages. Use `DataSource` only with HTTP bindings.

For example, if the input parameter type is `javax.xml.transform.Source`, the call to the Dispatch client API is similar to the following code example:

```
Dispatch<Source> dispatch = ... create a Dispatch<Source>
Source request = ... create a Source object
Source response = dispatch.invoke(request);
```

The Dispatch parameter value determines the return type of the `invoke()` method.

The Dispatch client is invoked in one of three ways:

- Synchronous invocation for requests and responses using the `invoke` method
- Asynchronous invocation for requests and responses using the `invokeAsync` method with a callback or polling object
- One-way invocation using the `invokeOneWay` methods

Refer to Chapter 4, section 3 of the JAX-WS specification for more information on using a Dispatch client.

Dynamic Proxy client

The static client programming model for JAX-WS is the called the Dynamic Proxy client. The Dynamic Proxy client invokes a Web service based on a Service Endpoint Interface (SEI) which must be provided. The Dynamic Proxy client is similar to the stub client in the Java API for XML-based RPC (JAX-RPC) programming model. Although the JAX-WS Dynamic Proxy client and the JAX-RPC stub client are both based on the Service Endpoint Interface (SEI) that is generated from a WSDL file , there is a major difference. The Dynamic Proxy client is dynamically generated at run time using the Java 5 Dynamic Proxy functionality, while the JAX-RPC-based stub client is a non-portable Java file that is generated by tooling. Unlike the JAX-RPC stub clients, the Dynamic Proxy client does not require you to regenerate a stub prior to running the client on an application server for a different vendor because the generated interface does not require the specific vendor information.

The Dynamic Proxy instances extend the `java.lang.reflect.Proxy` class and leverage the Dynamic Proxy function in the base Java SE Runtime Environment (JRE) 6. The client application can then provide an interface that is used to create the proxy instance while the runtime is responsible for dynamically creating a Java object that represents the SEI.

The Dynamic Proxy client is invoked in one of three ways:

- Synchronous invocation for requests and responses using the `invoke` method
- Asynchronous invocation for requests and responses using the `invokeAsync` method with a callback or polling object
- One-way invocation using the `invokeOneWay` methods

Refer to Chapter 4 of the JAX-WS specification for more information on using Dynamic Proxy clients.

Related concepts

"JAX-WS" on page 353
Java API for XML-Based Web Services (JAX-WS) is the next generation Web services programming model complimenting the foundation provided by the Java API for XML-based RPC (JAX-RPC) programming model. Using JAX-WS, development of Web services and clients is simplified with more platform independence for Java applications by the use of dynamic proxies and Java annotations.

Related tasks

Developing and deploying JAX-WS Web services clients
You can develop Web services clients based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification and the Java API for XML-Based Web Services (JAX-WS) programming model.

Developing a JAX-WS client from a WSDL file
Java API for XML-Based Web Services (JAX-WS) tooling supports generating Java artifacts you need to develop static JAX-WS Web services clients when starting with a Web Services Description Language (WSDL) file.

Invoking JAX-WS Web services asynchronously
Java API for XML-Based Web Services (JAX-WS) provides support for invoking Web services using an asynchronous client invocation. JAX-WS provides support for both a callback and polling model when calling Web services asynchronously. Both the callback model and the polling model are available on the Dispatch client and the Dynamic Proxy client.

JAX-WS annotations:

Java API for XML-Based Web Services (JAX-WS) relies on the use of annotations to specify metadata associated with Web services implementations and to simplify the development of Web services. Annotations describe how a server-side service implementation is accessed as a Web service or how a client-side Java class accesses Web services.

The JAX-WS programming standard introduces support for annotating Java classes with metadata that is used to define a service endpoint application as a Web service and how a client can access the Web service. JAX-WS supports the use of annotations based on the Metadata Facility for the Java Programming Language (Java Specification Request (JSR) 175) specification, the Web Services Metadata for the Java Platform (JSR 181) specification and annotations defined by the JAX-WS 2.0 and later (JSR 224) specification which includes JAXB annotations. Using annotations from the JSR 181 standard, you can simply annotate the service implementation class or the service interface and now the application is enabled as a Web service. Using annotations within the Java source simplifies development and deployment of Web services by defining some of the additional information that is typically obtained from deployment descriptor files, WSDL files, or mapping metadata from XML and WSDL into the source artifacts.

Use annotations to configure bindings, handler chains, set names of portType, service and other WSDL parameters. Annotations are used in mapping Java to WSDL and schema, and at runtime to control how the JAX-WS runtime processes and responds to Web service invocations.

For JAX-WS Web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

Note: In WebSphere Application Server Version 7.0, the default annotation support behavior has changed. In the Version 6.1 Feature Pack for Web services, the default behavior is to scan pre- Java Platform, Enterprise Edition (Java EE) 5 Web application modules to identify JAX-WS services and to scan pre-Java EE 5 Web application modules and EJB modules for service clients during application installation. For Version 7.0, the default behavior is to not scan pre-Java EE 5 modules for annotations during application installation or server startup. You can preserve backward compatibility with the feature pack in either of two ways:

- You can set the `UseWSFEP61ScanPolicy` property in the META-INF/MANIFEST.MF of a WAR file or EJB module to `true`. For example:

  ```
  Manifest-Version: 1.0
  UseWSFEP61ScanPolicy: true
  ```

  When this property is set to `true` in the module's META-INF/MANIFEST.MF file, the module is scanned for JAX-WS annotations regardless of the Java EE version of the module. The default value is `false` and when the default value is in effect, JAX-WS annotations are only supported in modules whose version is Java EE 5 or later.
- You can set the `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` custom Java virtual machine (JVM) property using the administrative console. See the JVM custom properties documentation for the correct navigation path to use. To request annotation scanning in all modules regardless of their Java EE version, set the custom property `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` to `true`. You must change the setting on each server that requires a change in the default behavior.

If the property is set within a module's META-INF/MANIFEST.MF file, this setting takes precedence over the server's custom JVM property. When using either property, you must establish the desired annotation scanning behavior before the application is installed. You cannot dynamically change the scanning behavior once an application is installed. If changes to the behavior are required after your application is installed, you must first uninstall the application, specify the desired scanning behavior using the appropriate property and then install the application again. When federating

nodes that have the `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` set to `true` in the configuration of the servers contained within the node, this property does not affect the deployment manager. You must set the property to `true` on the deployment manager before the node is federated to preserve the behavior as it was on the node before federation.

Annotations supported by JAX-WS are listed in the table below. The target for annotations is applicable for these Java objects:

- types such as a Java class, enum or interface
- methods
- fields representing local instance variables within a Java class
- parameters within a Java method

Web Services Metadata Annotations (JSR 181)

Annotation class	Annotation	Properties
`javax.jws.WebService`	The **@WebService** annotation marks a Java class as implementing a Web service or marks a service endpoint interface (SEI) as implementing a Web service interface. **Important:** • A Java class that implements a Web service must specify either the @WebService or @WebServiceProvider annotation. Both annotations cannot be present. This annotation is applicable on a client or server SEI or a server endpoint implementation class. • If the annotation references an SEI through the `endpointInterface` attribute, the SEI must also be annotated with the @WebService annotation. • See “Rules for methods on classes annotated with @WebService” on page 379 for additional information.	• Annotation target: Type • Properties: **- name** The name of the `wsdl:portType`. The default value is the unqualified name of the Java class or interface. (String) **- targetNamespace** Specifies the XML namespace of the WSDL and XML elements generated from the Web service. The default value is the namespace mapped from the package name containing the Web service. (String) **- serviceName** Specifies the service name of the Web service: `wsdl:service`. The default value is the simple name of the Java class + *Service*. (String) **- endpointInterface** Specifies the qualified name of the service endpoint interface that defines the services’ abstract Web service contract. If specified, the service endpoint interface is used to determine the abstract WSDL contract. (String) **- portName** The `wsdl:portName`. The default value is WebService.name +*Port* . (String) **- wsdlLocation** Specifies the Web address of the WSDL document defining the Web service. The Web address is either relative or absolute. (String)

Annotation class	Annotation	Properties
`javax.jws.` `WebMethod`	The **@WebMethod** annotation denotes a method that is a Web service operation. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class. **Important:** • The @WebMethod annotation is only supported on classes that are annotated with the @WebService annotation.	• Annotation target: Method • Properties: **- operationName** Specifies the name of the `wsdl:operation` matching this method. The default value is the name of Java method. (String) **- action** Defines the action for this operation. For SOAP bindings, this value determines the value of the SOAPAction header. The default value is the name of Java method. (String) **- exclude** Specifies whether to exclude a method from the Web service. The default value is `false`. (Boolean)
`javax.jws.` `Oneway`	The **@Oneway** annotation denotes a method as a Web service one-way operation that only has an input message and no output message. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Method • There are no properties on the Oneway annotation.

Annotation class	Annotation	Properties
`javax.jws.` `WebParam`	The **@WebParam** annotation customizes the mapping of an individual parameter to a Web service message part and XML element. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Parameter • Properties: **- name** The name of the parameter. If the operation is remote procedure call (RPC) style and the `partName` attribute is not specified, then this is the name of the `wsdl:part` attribute representing the parameter. If the operation is document style or the parameter maps to a header, then `-name` is the local name of the XML element representing the parameter. This attribute is required if the operation is document style, the parameter style is `BARE`, and the mode is `OUT` or `INOUT`. (String) **- partName** Defines the name of `wsdl:part` attribute representing this parameter. This is only used if the operation is RPC style, or the operation is document style and the parameter style is `BARE`. (String) **- targetNamespace** Specifies the XML namespace of the XML element for the parameter. Applies only for document bindings when the attribute maps to an XML element. The default value is the `targetNamespace` for the Web service. (String) **- mode** The value represents the direction the parameter flows for this method. Valid values are `IN`, `INOUT`, and `OUT`. (String) **- header** Specifies whether the parameter is in a message header rather than a message body. The default value is `false`. (Boolean)

Annotation class	Annotation	Properties
`javax.jws.` `WebResult`	The **@WebResult** annotation customizes the mapping of a return value to a WSDL part or XML element. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Method • Properties: **- name** Specifies the name of the return value as it is listed in the WSDL file and found in messages on the wire. For RPC bindings, this is the name of the `wsdl:part` attribute representing the return value. For document bindings, the `-name` parameter is the local name of the XML element representing the return value. The default value is `return` for RPC and DOCUMENT/WRAPPED bindings. The default value is the method name + `Response` for DOCUMENT/BARE bindings. (String) **- targetNamespace** Specifies the XML namespace for the return value. This parameter is only used if the operation is RPC style or if the operation is DOCUMENT style and the parameter style is BARE. (String) **- header** Specifies whether the result is carried in a header. The default value is `false`. (Boolean) **- partName** Specifies the part name for the result with RPC or DOCUMENT/BARE operations. The default value is `@WebResult.name`. (String)

Annotation class	Annotation	Properties
`javax.jws.HandlerChain`	The **@HandlerChain** annotation associates the Web service with an externally defined handler chain. You can only configure the server side handler by using the @HandlerChain annotation on the Service Endpoint Interface (SEI) or the server endpoint implementation class. Use one of several ways to configure a client side handler. You can configure a client side handler by using the @HandlerChain annotation on the generated service class or SEI. Additionally, you can programmatically register your own implementation of the HandlerResolver interface on the Service, or programmatically set the handler chain on the Binding object.	• Annotation target: Type • Properties: **- file** Specifies the location of the handler chain file. The file location is either an absolute java.net.URL in external form or a relative path from the class file. (String) **- name** Specifies the name of the handler chain in the configuration file. (String)
`javax.jws.SOAPBinding`	The **@SOAPBinding** annotation specifies the mapping of the Web service onto the SOAP message protocol. Apply this annotation to a type or methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class. The method level annotation is limited in what it can specify and is only used if the `style` property is `DOCUMENT`. If the method level annotation is not specified, the **@SOAPBinding** behavior from the type is used.	• Annotation target: Type or Method • Properties: **- style** Defines encoding style for messages sent to and from the Web service. The valid values are `DOCUMENT` and `RPC`. The default value is `DOCUMENT`. (String) **- use** Defines the formatting used for messages sent to and from the Web service. The default value is `LITERAL`. `ENCODED` is not supported. (String) **- parameterStyle** Determines whether the method's parameters represent the entire message body or whether parameters are elements wrapped inside a top-level element named after the operation. Valid values are `WRAPPED` or `BARE`. You can only use the `BARE` value with `DOCUMENT` style bindings. The default value is `WRAPPED`. (String)

JAX-WS Annotations (JSR 224)

Annotation class	Annotation	Properties
`javax.xml.ws.Action`	The **@Action** annotation specifies the WS-Addressing action that is associated with a Web service operation. When you use this annotation with a particular method, and generate the corresponding WSDL document, the WS-Addressing Action extension attribute is added to the input and output elements of the WSDL operation that corresponds to that method. To add this attribute to the WSDL operation, you must also specify the @Addressing annotation on the server endpoint implementation class. If you do not want to use the @Addressing annotation you can supply your own WSDL document with the Action attribute already defined.	• Annotation target: Method • Properties: **- fault** Specifies the array of FaultAction for the wsdl:fault of the operation. (String) **- input** Specifies the action for thewsdl:input of the operation. (String) **- output** Specifies the action for thewsdl:output of the operation. (String)
`javax.xml.ws.BindingType`	The **@BindingType** annotation specifies the binding to use when publishing an endpoint of this type. Apply this annotation to a server endpoint implementation class. **Important:** • You can use the @BindingType annotation on the JavaBeans endpoint implementation class to enable MTOM by specifying either `javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_MTOM_BINDING` or `javax.xml.ws.soap.SOAPBinding.SOAP12HTTP_MTOM_BINDING` as the value for the annotation.	• Annotation target: Type • Properties: **- value** Indicates the binding identifier Web address. Valid values are `javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_BINDING`, `javax.xml.ws.soap.SOAPBinding.SOAP12HTTP_BINDING`, and `javax.xml.ws.http.HTTPBinding.HTTP2HTTP_BINDING`. The default value is `javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_BINDING`. (String)

Annotation class	Annotation	Properties
`javax.xml.ws.FaultAction`	The **@FaultAction** annotation specifies the WS-Addressing action that is added to a fault response. This annotation must be contained within an @Action annotation. When you use this annotation with a particular method, the WS-Addressing FaultAction extension attribute is added to the fault element of the WSDL operation that corresponds to that method. To add this attribute to the WSDL operation, you must also specify the @Addressing annotation on the server endpoint implementation class. If you do not want to use the @Addressing annotation you can supply your own WSDL document with the Action attribute already defined.	• Annotation target: Method • Properties: **- value** Specifies the action of the wsdl:fault of the operation. (String) **- output** Specifies the name of the exception class. (String) **- className** Specifies the name of the class representing the request wrapper. (String)
`javax.xml.ws.RequestWrapper`	The **@RequestWrapper** annotation supplies the JAXB generated request wrapper bean, the element name, and the namespace for serialization and deserialization with the request wrapper bean that is used at runtime. When starting with a Java object, this element is used to resolve overloading conflicts in document literal mode. Only the `className` attribute is required in this case. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Method • Properties: **- localName** Specifies the local name of the XML schema element representing the request wrapper. The default value is the `operationName` as defined in javax.jws.WebMethod annotation. (String) **- targetNamespace** Specifies the XML namespace of the request wrapper method. The default value is the target namespace of the SEI. (String) **- className** Specifies the name of the class representing the request wrapper. (String)

Annotation class	Annotation	Properties
`javax.xml.ws.ResponseWrapper`	The **@ResponseWrapper** annotation supplies the JAXB generated response wrapper bean, the element name, and the namespace for serialization and deserialization with the response wrapper bean that is used at runtime. When starting with a Java object, this element is used to resolve overloading conflicts in document literal mode. Only the `className` attribute is required in this case. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Method • Properties: **- localName** Specifies the local name of the XML schema element representing the request wrapper. The default value is the `operationName` + *Response*. `operationName` is defined in javax.jws.WebMethod annotation. (String) **- targetNamespace** Specifies the XML namespace of the request wrapper method. The default value is the target namespace of the SEI. (String) **- className** Specifies the name of the class representing the response wrapper. (String)
`javax.xml.ws.RespectBinding`	The **@RespectBinding** annotation specifies whether the JAX-WS implementation must use the contents of the wsdl:binding for an endpoint. When this annotation is specified, a check is performed to ensure all required WSDL extensibility elements with the enabled attribute set to true are supported. Apply this annotation to methods on a server endpoint implementation class.	• Annotation target: Method • Properties: **- enabled** Specifies whether the wsdl:binding must be used or not. The default value is `true`. (Boolean)
`javax.xml.ws.ServiceMode`	The **@ServiceMode** annotation specifies whether a service provider needs to have access to an entire protocol message or just the message payload. **Important:** • The @ServiceMode annotation is only supported on classes that are annotated with the @WebServiceProvider annotation.	• Annotation target: Type • Properties: **- value** Indicates whether the provider class accepts the payload of the message, `PAYLOAD` or the entire message `MESSAGE`. The default value is `PAYLOAD`. (String)

Annotation class	Annotation	Properties
`javax.xml.ws.soap.Addressing`	The **@Addressing** annotation specifies that this service wants to enable WS-Addressing support. Apply this annotation to methods on a server endpoint implementation class.	• Annotation target: Type • Properties: **- enabled** Specifies if WS-Addressing is enabled or not. The default value is `true`. (Boolean) **- required** Specifies that WS-Addressing headers must be present on incoming messages. The default value is `false`. (Boolean)
`javax.xml.ws.soap.MTOM`	The **@MTOM** annotation specifies whether binary content in the body of a SOAP message is sent using MTOM. Apply this annotation to a service endpoint implementation class.	• Annotation target: Class • Properties: **- enabled** Specifies if MTOM is enabled for the JAX-WS endpoint. The default value is `true`. (Boolean) **- threshold** Specifies the minimum size for messages that are sent using MTOM. When the message size is less than this specified integer, the message is inlined in the XML document as base64 or hexBinary data. (integer)

Annotation class	Annotation	Properties
`javax.xml.ws.WebFault`	The **@WebFault** annotation maps WSDL faults to Java exceptions. It is used to capture the name of the fault during the serialization of the JAXB type that is generated from a global element referenced by a WSDL fault message. It can also be used to customize the mapping of service specific exceptions to WSDL faults. This annotation can only be applied to a fault implementation class on the client or server.	• Annotation target: Type • Properties: **- name** Specifies the local name of the XML element that represents the corresponding fault in the WSDL file. The actual value must be specified. (String) **- targetNamespace** Specifies the namespace of the XML element that represents the corresponding fault in the WSDL file. (String) **- faultBean** Specifies the name of the fault bean class. (String)
`javax.xml.ws.WebServiceProvider`	The **@WebServiceProvider** annotation denotes that a class satisfies requirements for a JAX-WS Provider implementation class. **Important:** • A Java class that implements a Web service must specify either the @WebService or @WebServiceProvider annotation. Both annotations cannot be present. • The @WebServiceProvider annotation is only supported on the service implementation class. Any class with the @WebServiceProvider annotation must implement the javax.xml.ws.Provider interface.	• Annotation target: Type • Properties: **- targetNamespace** Specifies the XML namespace of the WSDL and XML elements generated from the Web service. The default value is the namespace mapped from the package name containing the Web service. (String) **- serviceName** Specifies the service name of the Web service: `wsdl:service`. The default value is the simple name of the Java class + *Service*. (String) **- portName** The `wsdl:portName`. The default value is the name of the class + *Port*. (String) **- wsdlLocation** The Web address of the WSDL document defining the Web service. This attribute is required. (String)

Annotation class	Annotation	Properties
`javax.xml.ws.WebServiceRef`	The **@WebServiceRef** annotation defines a reference to a Web service invoked by the client. **Important:** • The @WebServiceRef annotation can be used to inject instances of JAX-WS services and ports. • The @WebServiceRef annotation is only supported in certain class types. Examples are JAX-WS endpoint implementation classes, JAX-WS handler classes, Enterprise JavaBeans classes, and servlet classes. This annotation is supported in the same class types as the @Resource annotation. See the Java Platform, Enterprise Edition (Java EE) 5 specification for a complete list of supported class types.	• Annotation target: Type, Field or Method • Properties: **- name** Specifies the JNDI name of the resource. The field name is the default for field annotations. The JavaBeans property name that corresponds to the method is the default for method annotations. You must specify a value for class annotations as there is no default. (String) **- type** Indicates the Java type of the resource. The field type is the default for field annotations. The type of the JavaBeans property is the default for method annotations. You must specify a value for class annotations as there is no default. (Class) **- mappedName** Specified the name to map this resource to. (String) **- value** Indicates the value of the service class and it is a type that extends `javax.xml.ws.Service`. This attribute is required when the type of the reference is a service endpoint interface. (Class) **- wsdlLocation** The Web address of the WSDL document defining the Web service. This attribute is required. (String)
`javax.xml.ws.WebServiceRefs`	The **@WebServiceRefs** annotation associates multiple @WebServiceRef annotations with a specific class. **Important:** • The @WebServiceRef annotation is only supported in certain class types. Examples are JAX-WS endpoint implementation classes, JAX-WS handler classes, Enterprise JavaBeans classes, and servlet classes. This annotation is supported in the same class types as the @Resource annotation. See the Java Platform, Enterprise Edition (Java EE) 5 specification for a complete list of supported class types.	• Annotation target: Type • Properties: **- value** Specifies an array for multiple Web service reference declarations. This attribute is required.

JAX-WS Common Annotations (JSR 250)

Annotation class	Annotation	Properties
`javax.annotation.Resource`	The **@Resource** annotation marks a WebServiceContext resource needed by the application. **Important:** Applying this annotation to a WebServiceContext type field on the server endpoint implementation class for a JavaBeans endpoint or a Provider endpoint results in the container injecting an instance of the WebServiceContext into the specified field. When this annotation is used in place of the @WebServiceRef annotation, the rules described for the @WebServiceRef annotation apply.	• Annotation target: Field or Method • Properties: **- type** Indicates the Java type of the resource. You are required to use the default, `java.lang.Object` or `javax.xml.ws.Web ServiceContext` value. If the type is the default, the resource must be injected into a field or a method. In this case, the type of the field or the type of the JavaBeans property defined by the method must be `javax.xml.ws.WebServiceContext`. (Class) If you are using this annotation to inject a Web service, see the description of the @WebServiceRef type attribute.
`javax.annotation.Resources`	The **@Resources** annotation associates multiple @Resource annotations with a specific class and serves as a container for multiple resource declarations.	• Annotation target: Field or Method • Properties: **- value** Specifies an array for multiple @Resource annotations. This attribute is required.
`javax.annotation.PostConstruct`	The **@PostConstruct** annotation marks a method that needs to run after dependency injection is performed on the class. Apply this annotation to a JAX-WS application handler, a server endpoint implementation class.	• Annotation target: Method
`javax.annotation.PreDestroy`	The **@PreDestroy** annotation marks a method that must be run when the instance is in the process of being removed by the container. Apply this annotation to a JAX-WS application handler or a server endpoint implementation class.	• Annotation target: Method

IBM proprietary annotations

Annotation class	Annotation	Properties
`com.ibm.websphere.wsaddressing.jaxws21.SubmissionAddressing`	The **@SubmissionAddressing** annotation specifies that this service wants to enable WS-Addressing support for the 2004/08 WS-Addressing specification. This annotation is part of the IBM implementation of the JAX-WS 2.1 specification. Apply this annotation to methods on a server endpoint implementation class.	• Annotation target: Type • Properties: **- required** Specifies that WS-Addressing headers must be present on incoming messages. The default value is `false`. (Boolean)

Rules for methods on classes annotated with @WebService

The following rules apply for methods on classes annotated with the @WebService annotation.

- If the @WebService annotation of an implementation class references an SEI, the implementation class must not have any @WebMethod annotations.
- All public methods for an SEI are considered exposed methods regardless of whether the @WebMethod annotation is specified or not. It is incorrect to have an @WebMethod annotation on an SEI that contains the `exclude` attribute.
- For an implementation class that does not reference an SEI, if the @WebMethod annotation is specified with a value of `exclude=true`, that method is not exposed. If the @WebMethod annotation is not specified, all public methods are exposed including the inherited methods with the exception of methods inherited from java.lang.Object.

JAX-WS application packaging:

You can package a Java Application Programming Interface (API) for XML Web Services (JAX-WS) application as a Web service. A JAX-WS Web service is contained within a Web archive (WAR) file or a WAR module within an enterprise archive (EAR) file.

A JAX-WS enabled WAR file contains:

- A WEB-INF/web.xml file
- Annotated classes that implement the Web services contained in the application module
- [Optional] Web Services Description Language (WSDL) documents that describe the Web services contained in the application module

A WEB-INF/web.xml file is similar to this example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_ID" xmlns="http://java.sun.com/xml/ns/j2ee"
         xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
         xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee
         http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd"
         version="2.4">
</web-app>
```

The web.xml might contain servlet or servlet-mapping elements. When customizations to the web.xml file are not needed, the WebSphere Application Server runtime defines them dynamically as the module is loaded. For more information on configuring the web.xml file, read about customizing Web URL patterns in the web.xml file for JAX-WS applications.

Annotated classes must contain, at a minimum, a Web service implementation class that includes the `@WebService` annotation. The definition and specification of the Web services-related annotations are provided by the JAX-WS and JSR-181 specifications. The Web service implementation classes can exist within the `WEB-INF/classes` or directory within a Java archive (JAR) file that is contained in the `WEB-INF/lib` directory of the WAR file.

You can optionally include WSDL documents in the JAX-WS application packaging. If the WSDL document for a particular Web service is omitted, then the WebSphere Application Server runtime constructs the WSDL definition dynamically from the annotations contained in the Web service implementation classes. You must include the `@WebService`, `@WebMethod`, `@WebParam`, `@WebResult`, and optionally the `@SOAPBinding` annotations if the WSDL document is omitted.

Note: In WebSphere Application Server Version 7.0, the default annotation support behavior has changed. In the Version 6.1 Feature Pack for Web services, the default behavior is to scan pre-Java EE 5 Web application modules to identify JAX-WS services and to scan pre-Java EE 5 Web application modules and EJB modules for service clients during application installation. For Version 7.0, the

default behavior is to not scan pre-Java EE 5 modules for annotations during application installation or server startup. You can preserve compatibility with feature packs from previous releases by either setting the UseWSFEP61ScanPolicy property in the META-INF/MANIFEST.MF of a Web archive (WAR) file or EJB module or by defining the Java virtual machine custom property, com.ibm.websphere.webservices.UseWSFEP61ScanPolicy, on servers to request scanning during application installation and server startup. To learn more about annotations scanning, see the JAX-WS annotations documentation.

JAXB

Java Architecture for XML Binding (JAXB) is a Java technology that provides an easy and convenient way to map Java classes and XML schema for simplified development of Web services. JAXB leverages the flexibility of platform-neutral XML data in Java applications to bind XML schema to Java applications without requiring extensive knowledge of XML programming.

JAXB is an XML to Java binding technology that supports transformation between schema and Java objects and between XML instance documents and Java object instances. JAXB consists of a runtime application programming interface (API) and accompanying tools that simplify access to XML documents. JAXB also helps to build XML documents that both conform and validate to the XML schema. Java API for XML-Based Web Services (JAX-WS) leverages the JAXB API and tools as the binding technology for mappings between Java objects and XML documents. JAX-WS tooling relies on JAXB tooling for default data binding for two-way mappings between Java objects and XML documents.

Note: WebSphere Application Server Version 7.0 supports the JAXB 2.1 specification. JAX-WS 2.1 requires JAXB 2.1 for data binding. JAXB 2.1 provides enhancements such as improved compilation support and support for the @XMLSeeAlso annotation. With JAXB 2.1, you can configure the xjc schema compiler so that it does not automatically generate new classes for a particular schema. Similarly, you can configure the schemagen schema generator to not automatically generate a new schema. This enhancement is useful when you are using a common schema and you do not want a new schema generated. JAXB 2.1 also introduces the @XMLSeeAlso annotation that enables JAXB to bind additional Java classes that it might not otherwise know about when binding a Java class with this annotation. This annotation enables JAXB to know about all classes that are potentially involved in marshalling or unmarshalling as it is not always possible or practical to list all of the subclasses of a given Java class. JAX-WS 2.1 also supports the use of the @XMLSeeAlso annotation on a service endpoint interface (SEI) or on a service implementation bean to ensure all of the classes referenced by the annotation are passed to JAXB for processing.

JAXB provides the xjc schema compiler tool, the schemagen schema generator tool, and a runtime framework. You can use the xjc schema compiler tool to start with an XML schema definition (XSD) to create a set of JavaBeans that map to the elements and types defined in the XSD schema. You can also start with a set of JavaBeans and use the schemagen schema generator tool to create the XML schema. Once the mapping between XML schema and Java classes exists, XML instance documents can be converted to and from Java objects through the use of the JAXB binding runtime API. Data stored in XML documents can be accessed without the need to understand the data structure. You can then use the resulting Java classes to assemble a Web services application.

JAXB annotated classes and artifacts contain all the information needed by the JAXB runtime API to process XML instance documents. The JAXB runtime API supports marshaling of JAXB objects to XML and unmarshaling the XML document back to JAXB class instances. Optionally, you can use JAXB to provide XML validation to enforce both incoming and outgoing XML documents to conform to the XML constraints defined within the XML schema.

JAXB is the default data binding technology used by the Java API for XML Web Services (JAX-WS) tooling and implementation within this product. You can develop JAXB objects for use within JAX-WS applications.

You can also use JAXB independently of JAX-WS when you want to leverage the XML data binding technology to manipulate XML within your Java applications.

The following diagram illustrates the JAXB architecture.

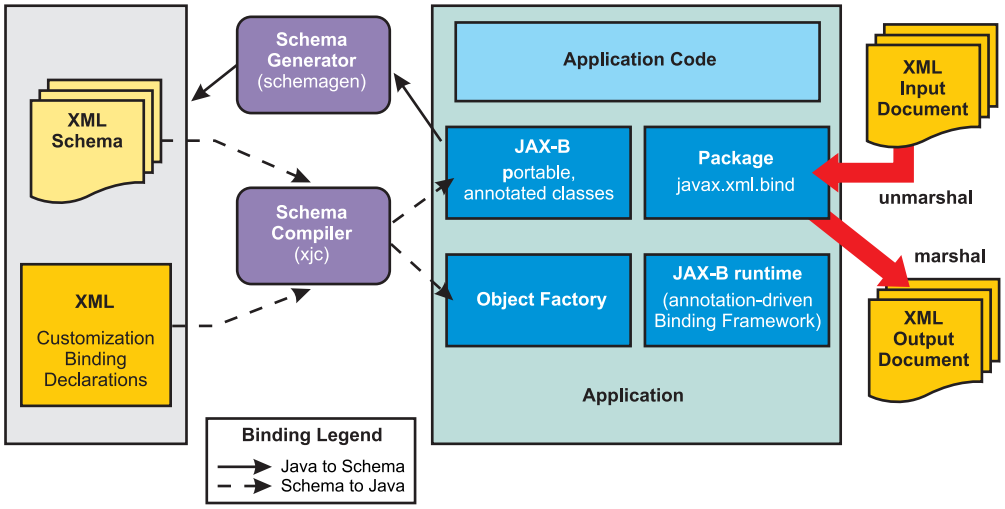

Figure 5. JAXB architecture

JAX-RPC

The *Java API for XML-based RPC (JAX-RPC)* specification enables you to develop SOAP-based interoperable and portable Web services and Web service clients. JAX-RPC 1.1 provides core APIs for developing and deploying Web services on a Java platform and is a part of the Web Services for Java Platform, Enterprise Edition (Java EE) platform. The Java EE platform enables you to develop portable Web services.

WebSphere Application Server implements JAX-RPC 1.1 standards.

The JAX-RPC standard covers the programming model and bindings for using Web Services Description Language (WSDL) for Web services in the Java language. JAX-RPC simplifies development of Web services by shielding you from the underlying complexity of SOAP communication.

On the surface, JAX-RPC looks like another instantiation of remote method invocation (RMI). Essentially, JAX-RPC enables clients to access a Web service as if the Web service was a local object mapped into the client's address space even though the Web service provider is located in another part of the world. The JAX-RPC is done by using the XML-based protocol SOAP, which typically rides on top of HTTP.

JAX-RPC defines the mappings between the WSDL port types and the Java interfaces, as well as between Java language and Extensible Markup Language (XML) schema types.

A JAX-RPC Web service can be created from a JavaBean or a enterprise bean implementation. You can specify the remote procedures by defining remote methods in a Java interface. You only need to code one or more classes that implement the methods. The remaining classes and other artifacts are generated by the Web service vendor's tools. The following is an example of a Web service interface:

```
package com.ibm.mybank.ejb;
import java.rmi.RemoteException;
import com.ibm.mybank.exception.InsufficientFundsException;
/**
 * Remote interface for Enterprise Bean: Transfer
 */
public interface Transfer_SEI extends java.rmi.Remote {
```

```
   public void transferFunds(int fromAcctId, int toAcctId, float amount)
      throws java.rmi.RemoteException;

}
```

The interface definition in JAX-RPC must follow specific rules:

- The interface must extend `java.rmi.Remote` just like RMI.
- Methods must create `java.rmi.RemoteException`.
- Method parameters cannot be remote references.
- Method parameter must be one of the parameters supported by the JAX-RPC specification. The following list are examples of method parameters that are supported. For a complete list of method parameters see the JAX-RPC specification.
  - Primitive types: `boolean`, `byte`, `double`, `float`, `short`, `int` and `long`
  - Object wrappers of primitive types: `java.lang.Boolean`, `java.lang.Byte`, `java.lang.Double`, `java.lang.Float`, `java.lang.Integer`, `java.lang.Long`, `java.lang.Short`
  - `java.lang.String`
  - `java.lang.BigDecimal`
  - `java.lang.BigInteger`
  - `java.lang.Calendar`
  - `java.lang.Date`
- Methods can take value objects which consist of a composite of the types previously listed, in addition to aggregate value objects.

A client creates a stub and invokes methods on it. The stub acts like a proxy for the Web service. From the client code perspective, it seems like a local method invocation. However, each method invocation gets marshaled to the remote server. Marshaling includes encoding the method invocation in XML as prescribed by the SOAP protocol.

The following are key classes and interfaces needed to write Web services and Web service clients:

- **Service interface**: A factory for stubs or dynamic invocation and proxy objects used to invoke methods
- **ServiceFactory class**: A factory for Services.
- **`loadService`**

  The `loadService` method is provided in WebSphere Application Server Version 6.0 to generate the service locator which is required by a JAX-RPC implementation. If you recall, in previous versions there was no specific way to acquire a generated service locator. For managed clients you used a JNDI method to get the service locator and for non-managed clients, you were required to instantiate IBM's specific service locator `ServiceLocator service=new ServiceLocator(...);` which does not offer portability. The `loadService` parameters include:
  - **`wsdlDocumentLocation:`** A URL for the WSDL document location for the service or null.
  - **`serviceName`**: A qualified name for the service
  - **`properties`**: A set of implementation-specific properties to help locate the generated service implementation class.
- **`isUserInRole`**

  The `isUserInRole` method returns a boolean indicating whether the authenticated user for the current method invocation on the endpoint instance is included in the specified logical role.
  - **`role`**: The role parameter is a String specifying the name of the role.
- **Service**
- **Call interface**: Used for dynamic invocation
- **Stub interface**: Base interface for stubs

If you are using a stub to access the Web service provider, most of the JAX-RPC API details are hidden from you. The client creates a ServiceFactory (`java.xml.rpc.ServiceFactory`). The client instantiates a Service (`java.xml.rpc.Service`) from the ServiceFactory. The service is a factory object that creates the port. The port is the remote service endpoint interface to the Web service. In the case of DII, the Service object is used to create Call objects, which you can configure to call methods on the Web service's port.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

RMI-IIOP using JAX-RPC:

Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) can be used with JAX-RPC to support non-SOAP bindings.

Java API for XML-based Remote Procedure Call (JAX-RPC) is the Java standard API for invoking Web services through remote procedure calls. A transport is used by a programming language to communicate over the Internet. You can use protocols with the transport such as SOAP and Remote Method Invocation (RMI). You can use Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) with JAX-RPC to support non-SOAP bindings.

Using RMI-IIOP with JAX-RPC, enables WebSphere Java clients to invoke enterprise beans using a WSDL file and the JAX-RPC programming model instead of using the standard Web Services for Java Platform, Enterprise Edition (Java EE) programming model. When a enterprise JavaBeans implementation is used to invoke a Web service, multiprotocol JAX-RPC permits the Web service invocation path to be optimized for WebSphere Java clients. To learn more this optimization, read about using enterprise bean bindings to invoke an EJB from a Web services client.

Benefits of using the RMI/IIOP protocol instead of a SOAP- based protocol are:

- XML processing is not required to send and receive messages; Java serialization is used instead.
- The client JAX-RPC call can participate in a user transaction, which is not the case when SOAP is used.

Web Services-Interoperability Basic Profile

The Web Services-Interoperability (WS-I) Basic Profile is a set of non-proprietary Web services specifications that promote interoperability. WebSphere Application Server conforms to the WS-I Basic Profile Version 1.1 and WS-I Basic Security Profile Version 1.0.

The WS-I Basic Profile is governed by a consortium of industry-leading corporations, including IBM, under direction of the WS-I Organization. The profile consists of a set of principles that relate to bringing about open standards for Web services technology. All organizations that are interested in promoting interoperability among Web services are encouraged to become members of the Web Services Interoperability Organization.

Several technology components are used in the composition and implementation of Web services, including messaging, description, discovery, and security. Each of these components are supported by specifications and standards, including SOAP 1.1, Extensible Markup Language (XML) 1.0, HTTP 1.1, Web Services Description Language (WSDL) 1.1, and Universal Description, Discovery and Integration (UDDI). The WS-I Basic Profile specifies how these technology components are used together to achieve interoperability, and mandates specific use of each of the technologies when appropriate. You can read more about the WS-I Basic Profile at the WS-I Organization Web site.

As technology components are updated, these components are also used in the composition and implementation of Web Services. One example is that both SOAP 1.1 and SOAP 1.2 are now supported.

Note: Building on the support for WS-I Basic Profile Version 1.0, WS-I Basic Profile V1.1, Attachment Profile V1.0, and Basic Security Profile (BSP) V1.0, you can implement Web services with WebSphere Application Server Version 7.0 using the following current emerging standard WS-I profiles:

- *WS-I Basic Profile V1.2* builds on WS-I Basic Profile V1.0 and WS-I Basic Profile V1.1 and adds support for WS-Addressing (WS-A) and SOAP Message Transmission Optimization Mechanism (MTOM). The WS-Addressing specification enables the asynchronous message exchange pattern so that you can decouple the service request from the service response. The SOAP header of the sender's request contains the wsa:ReplyTo value that defines the endpoint reference to which the provider's response is sent. Decoupling the request from the response enables long running Web services interactions. Leveraging the asynchronous programming model support in JAX-WS Version 2.1 in combination with WS-Addressing, you can now take advantage of the ability to create Web services invocations where the client can continue to process work without waiting for a response to return. This provides for a more dynamic and efficient model to invoke Web services. Using MTOM, you can send and receive binary data optimally within a SOAP message.
- *WS-I Basic Profile V2.0* builds on top of Basic Profile V1.2 with the addition of support for SOAP 1.2.
- *WS-I Basic Security Profile V1.1* extends the WS-I Basic Security Profile V1.0 standard by profiling the latest WS-Security V1.1 specification.
- *WS-I Reliable Secure Profile 1.0* builds on WS-I Basic Profile V1.2, WS-I Basic Profile V2.0, WS-I Basic Security Profile V1.0, and WS-I Basic Security Profile V1.1 and adds support for WS-Reliable Messaging 1.1, WS-Make Connection 1.0, and WS-Secure Conversation 1.3. WS-Reliable Messaging 1.1 is a session-based protocol that provides message level reliability for Web services interactions. WS-Make Connection 1.0 was developed by the WS-Reliable Messaging workgroup to address scenarios where a Web services endpoint is behind a firewall or the endpoint has no visible endpoint reference. If a Web services endpoint loses connectivity during a reliable session, WS-Make Connection provides an efficient method to re-establish the reliable session. Additionally, WS-Secure Conversation V1.3 is a session-based security protocol that uses an efficient symmetric key based encryption algorithm for message level security. WS-I Reliable Secure Profile V1.0 provides secure reliable session-oriented Web services interactions.

Each of the technology components has requirements that you can read about in more detail at the WS-I Organization Web site. For example, support for Universal Transformation Format (UTF)-16 encoding is required by WS-I Basic Profile. UTF-16 is a kind of Unicode encoding scheme that uses 16-bit values to store Universal Character Set (UCS) characters. UTF-8 is the most common encoding that is used on the Internet; UTF-16 encoding is typically used for Java and Windows product applications; and UTF-32 is used by various Linux and UNIX systems. Unlike UTF-8, UTF-16 has issues with big-endian and little-endian, and often involves Byte Order Mark (BOM) to indicate the endian. BOM is mandatory for UTF-16 encoding and it can be used in UTF-8.

The application server only supports UTF-8 and UTF-16 encoding of SOAP messages.

The following table summarizes some of the properties of each UTF:

Bytes	Encoding form
EF BB BF	UTF-8
FF FE	UTF-16, little-endian
FE FF	UTF-16, big-endian
00 00 FE FF	UTF-32, big-endian
FF FE 00 00	UTF-32, little-endian

BOM is written prior to the XML text, and it indicates to the parser how the XML is encoded. The XML declaration contains the encoding, for example: <?xml version=*xxx* encoding="utf-*xxx*"?>. BOM is used with the encoding to determine how to interpret the XML. Here is an example of a SOAP message and how BOM and UTF encoding are used:

```
POST http://www.whitemesa.net/soap12/add-test-rpc HTTP/1.1
Content-Type: application/soap+xml; charset=utf-16; action=""
SOAPAction:
Host: localhost: 8080
Content-Length: 562

0xFF0xFE<?xml version="1.0" encoding="utf-16"?>
<soap:Envelope xmlns:soap="http://www.w3.org/2002/12/soap-envelope"
 xmlns:soapenc="http://www.w3.org/2002/12/soap-encoding
 xmlns:tns="http://whitemesa.net/wsdl/soap12-test"
 xmlns:types="http://whitemesa.net/wsdl/soap12-test/encodedTypes"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
 <soap:Body>
  <q1:echoString xmlns:q1="http://soapinterop.org/">
   <inputString soap:encodingStyle="http://example.org/unknownEncoding"
   xsi:type="xsd:string">
    Hello SOAP 1.2
   </inputString>
  </q1:echoString>
 </soap:Body>
</soap:Envelope>
```

In the example code, 0xFF0xFE represents the byte codes, while the *<?xml>* declaration is the textual representation.

Support for styleEncoding is not supported in SOAP 1.2 so here is the same example of the SOAP message but without the encoding information:

```
OxFF0xFE<?xml version="1.0" encoding="utf-16"?>
<soap:Envelope xmlns:soap="http://www.w3.org/2002/12/soap-envelope"
   xmlns:soapenc="http://www.w3.org/2002/12/soap-encoding
 xmlns:tns="http://whitemesa.net/wsdl/soap12-test"
 xmlns:types="http://whitemesa.net/wsdl/soap12-test/encodedTypes"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
 <soap:Body>
  <q1:echoString xmlns:q1="http://soapinterop.org/">
   <inputString xsi:type="xsd:string">
    Hello SOAP 1.2
   </inputString>
  </q1:echoString>
 </soap:Body>
</soap:Envelope>
```

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

WS-I Attachments Profile

The *Web Services-Interoperability (WS-I) Attachments Profile* is a set of non-proprietary Web services specifications that promote interoperability. This profile compliments the WS-I Basic Profile 1.1 to add support for interoperable SOAP messages with attachments-based Web services.

WebSphere Application Server conforms to the WS-I Attachments Profile 1.0.

Attachments are typically used to send binary data, for example, data that is mapped in Java code to java.awt.Image and javax.activation.DataHandler. The raw data can be sent in the SOAP message, however, this approach is inefficient because an XML parser has to scan the data as it parses the message.

The WS-I Attachments Profile provides a solution to the limitations that are presented by Web Services Description Language (WSDL) 1.1. Because WSDL 1.1 attachments are not part of the XML schema type space, they can be message parts only. As message parts, the attachments cannot be arrays or properties of Java beans. The profile defines the wsi:swaRef XML schema type.Use the wsi:swaRef XML schema type to overcome the limitations of WSDL 1.1 attachments.

The wsi:swaRef type is an extension of the xsd:anyURI type, where its value contains the content-ID of the attachment.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

Web services migration scenarios: JAX-RPC to JAX-WS and JAXB

This topic explains scenarios for migrating your Java API for XML-based RPC (JAX-RPC) Web services to Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) Web services.

Changes in the tooling can be largely hidden from the user by a development environment like the assembly tools available with WebSphere Application Server. Also, depending on the data specified in the XML, some methods that were used for the JAX-RPC service can be used with little or no change in a JAX-WS service. There are also conditions that do require changes to be made in the JAX-WS service.

Because Java EE environments emphasize compatibility, most application servers that offer support for the newer JAX-WS and JAXB specifications continue to support the previous JAX-RPC specification. A consequence of this is that existing Web services are likely to remain JAX-RPC based while new Web services are developed using the JAX-WS and JAXB programming models.

However, as time passes and applications are revised and rewritten, there might be times when the best strategy is to migrate a JAX-RPC based Web service to one that is based on the JAX-WS and JAXB programming models. This might result from a vendor choosing to provide enhancements to qualities of service that are only available in the new programming models. For example, SOAP 1.2 and SOAP Message Transmission Optimization Mechanism (MTOM) support are only available within the JAX-WS 2.x and JAXB 2.x programming models and not JAX-RPC.

The following information includes issues that you might have while migrating from JAX-RPC to JAX-WS and JAXB.

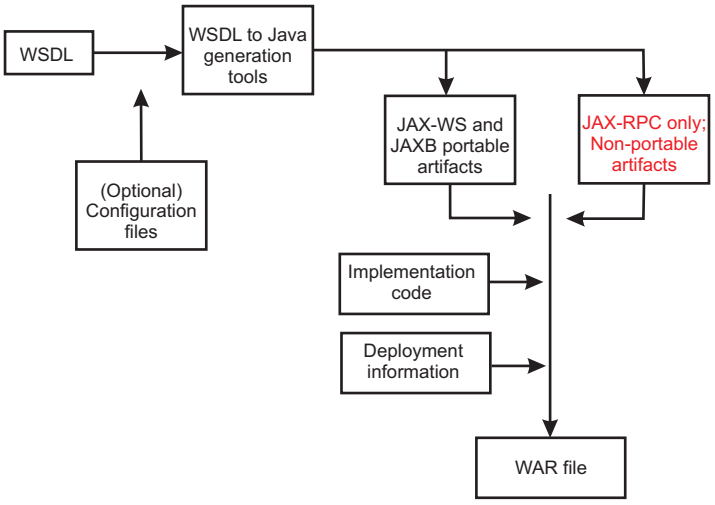
Note: When the terms *migrate*, *migrating*, and *migration* are used in this topic, unless there is some statement to indicate otherwise, the move from a JAX-RPC to a JAX-WS and JAXB environment is being described.

Comparison of JAX-RPC to JAX-WS and JAXB programming models

If you are looking for additional information that describes the changes between the JAX-RPC and JAX-WS and JAXB programming models, IBM developerWorks has published several Web services hints and tips topics.

Development models

The high level combined development models for JAX-RPC and JAX-WS and JAXB are shown the following image:



At a high level, the models are very similar. The only difference is that the JAX-RPC model produces both portable and non-portable artifacts; the JAX-WS and JAXB model does not produce non-portable artifacts.

The image displays the following components:

- **Web Services Description Language (WSDL) file:** A document conforming to the WSDL recommendation as published by the W3C organization.
- **(Optional) Configuration files**
- **WSDL to Java generation tool:** The specifications describe the mappings required, not the name of the tools. Typically, the tool for JAX-WS and JAXB is wsimport, and for JAX-RPC the tools are wscompile and wsdeploy.
- **Portable artifacts:** These are files generated by the WSDL to Java generation tool that have well-defined mappings in the JAX-RPC or JAX-WS and JAXB, whichever is applicable, specifications. These artifacts can be used without modification between different implementations of JAX-RPC or JAX-WS and JAXB.
- **Non-portable artifacts:** These are files generated by the WSDL to Java generation tool that do not have well-defined mappings in the JAX-RPC or JAX-WS and JAXB, whichever is applicable, specifications. These artifacts generally require modification between different implementations of JAX-RPC or JAX-WS/JAXB.
- **Implementation code:** This is the code that you need to meet particular requirements for implementation.
- **Deployment information:** Additional information that is needed to run the application in a particular environment.
- **Web archive (WAR) file:** In the context of the SampleService image, a WAR file is an archive file that contains all items needed to deploy a Web service into a particular environment. This is sometimes called a *cooked WAR file*.

The Development and runtime environments

A specialized development environment simplifies Web services migration by automating many of the tasks. For development of WebSphere-based applications, including Web services, you can use the assembly tools. You can read more about the use of the assembly tools in the assembly tool information center.

The following sample code in this topic was tested in the following runtime environment:

- IBM WebSphere Application Server V6.1, which includes support for the JAX-RPC specification.
- IBM WebSphere Application Server V6.1 Feature Pack for Web Services, which includes support for the JAX-WS and JAXB specifications.

Examples

The following examples show some of the code changes that you might need to migrate your JAX-RPC Web services to JAX-WS and JAXB Web services. In particular, there is an emphasis on the changes in the implementation code that you must write, from both the client and the server side. If no new function is to be introduced, the changes required to move from JAX-RPC to JAX-WS and JAXB might be few.

Sample Web service

The first example is a sample JAX-RPC-based Web Service that was created from a WSDL file (top-down development); the same WSDL file is used to generate the JAX-WS and JAXB-based service. The WSDL file describes the Web service, SampleService, with these operations described by the following image:

As shown in the image, the five operations offered are:

- xsd:int calcShippingCost(xsd:int, xsd:int)
- xsd:string getAccountNumber(xsd:string)
- xsd:dateTime calculateShippingDate(xsd:dateTime)
- xsd:string ckAvailability(xsd:int) creates invalidDateFault
- Person findSalesRep(xsd:string)

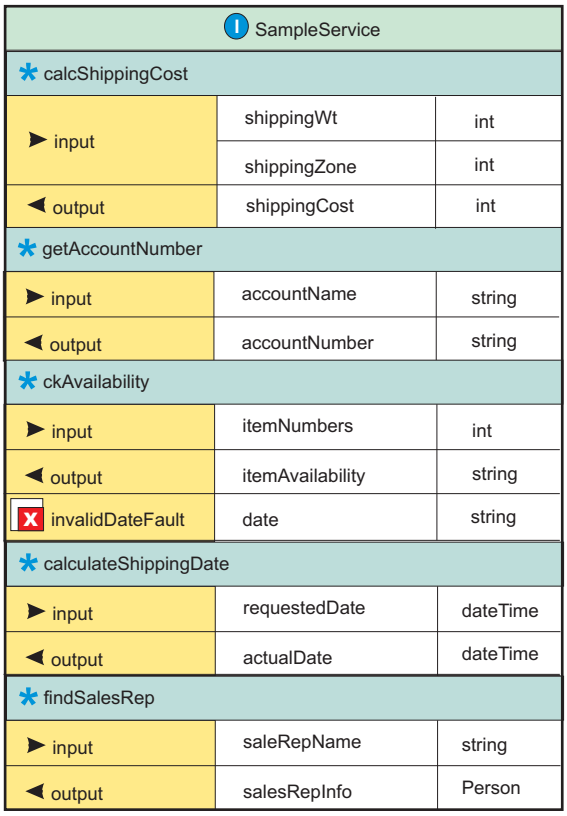
Also assume that Person is defined by the following schema fragment in the WSDL file:

```
<complexType name="Person">
 <sequence>
  <element name="name" type="xsd:string"/>
  <element name="age" type="xsd:int"/>
  <element name="location" type="impl:Address/>
 </sequence>
</complexType>
```

Address is defined by:

```
<complexType name="Address">
 <sequence>
  <element name="street" type="xsd:string"/>
  <element name="city" type="xsd:string"/>
  <element name ="state" type="xsd:string"/>
  <element name="zip" type="xsd:int"/>
 </sequence>
</complexType>
```

The following image also shows that the operation, ckAvailability(xsd:int), which produces an invalidDateFault exception.



Service operations

Review the service code created by the tooling. The following information includes examining what is created for a JAX-RPC runtime and also for a JAX-WS and JAXB runtime.

JAX-RPC

For JAX-RPC, the tooling accepts the WSDL file as input, and, amongst other files, generates the SampleService.java and SampleServiceImpl.java interfaces. The SampleService.java interface defines an interface and the generated code can be review in the following code block. The SampleServiceSoapBindingImpl.java interface provides the skeleton of an implementation, and you typically modify to add your own logic.

JAX-RPC version of SampleService.java:

```
/**
* SampleService.java
*
* This file was auto-generated from WSDL  * by the IBM Web services WSDL2Java emitter.  * cf20633.22 v82906122346
*/
package simple;
public interface SampleService extends java.rmi.Remote {
 public java.lang.Integer calcShippingCost(java.lang.Integer shippingWt,
  java.lang.Integer shippingZone) throws java.rmi.RemoteException;
 public java.lang.String getAccountNumber(java.lang.String accountName)
  throws java.rmi.RemoteException;
 public java.lang.String[] ckAvailability(int[] itemNumbers)
  throws java.rmi.RemoteException, simple.InvalidDateFault;
 public java.util.Calendar calculateShippingDate(
  java.util.Calendar requestedDate)
  throws java.rmi.RemoteException;
 public simple.Person findSalesRep(java.lang.String saleRepName)
  throws java.rmi.RemoteException; }
```

JAX-WS and JAXB

For JAX-WS and JAXB, the tooling accepts the WSDL file as input, and as in the case of JAX-RPC, generates SampleService.java and SampleServiceImpl.java interfaces. As with JAX-RPC, the SampleService.java interface also defines an interface as shown in the following code block. The SampleServiceImpl.java interface provides the skeleton of an implementation, and you typically modify to add your own logic.

Note: The code has been annotated by the tooling.
JAX-WS and JAXB version of the SampleService.java interface:

```
package simple;
 import java.util.List;
 import javax.jws.WebMethod;
 import javax.jws.WebParam;
 import javax.jws.WebResult;
 import javax.jws.WebService;
 import javax.xml.datatype.XMLGregorianCalendar;
 import javax.xml.ws.RequestWrapper;
 import javax.xml.ws.ResponseWrapper;

/**
* This class was generated by the JAX-WS SI.  * JAX-WS RI IBM 2.0_03-06/12/2007 07:44 PM(Raja)-fcs  *
Generated source version: 2.0
*
*/
@WebService(name = "SampleService", targetNamespace = "http://simple") public interface SampleService {

 /**
 *
 * @param shippingWt
 * @param shippingZone
 * @return
 * returns java.lang.Integer
 */
 @WebMethod
 @WebResult(name = "shippingCost", targetNamespace = "")
 @RequestWrapper(localName = "calcShippingCost", targetNamespace = "http://simple",
className = "simple.CalcShippingCost")
 @ResponseWrapper(localName = "calcShippingCostResponse", targetNamespace = "http://simple",
className = "simple.CalcShippingCostResponse")
 public Integer calcShippingCost(
 @WebParam(name = "shippingWt", targetNamespace = "")
 Integer shippingWt,
 @WebParam(name = "shippingZone", targetNamespace = "")
 Integer shippingZone);

 /**
 *
 *
 @param accountName
 * @return
 *     returns java.lang.String
 */
 @WebMethod
 @WebResult(name = "accountNumber", targetNamespace = "")
 @RequestWrapper(localName = "getAccountNumber", targetNamespace = "http://simple",
className = "simple.GetAccountNumber")
 @ResponseWrapper(localName = "getAccountNumberResponse", targetNamespace = "http://simple",
className = "simple.GetAccountNumberResponse")
 public String getAccountNumber(
  @WebParam(name = "accountName", targetNamespace = "")
  String accountName);
 /**
 *
 * @param requestedDate
 * @return
 *     returns javax.xml.datatype.XMLGregorianCalendar
 */
 @WebMethod
 @WebResult(name = "actualDate", targetNamespace = "")
 @RequestWrapper(localName = "calculateShippingDate", targetNamespace = "http://simple",
className = "simple.CalculateShippingDate")
 @ResponseWrapper(localName = "calculateShippingDateResponse", targetNamespace = "http://simple",
className = "simple.CalculateShippingDateResponse")
```

```
 public XMLGregorianCalendar calculateShippingDate(
  @WebParam(name = "requestedDate", targetNamespace = "")
  XMLGregorianCalendar requestedDate);
 /**
 *
 * @param itemNumbers
 * @return
 *     returns java.util.List<java.lang.String>
 * @throws InvalidDateFault_Exception
 */
 @WebMethod
 @WebResult(name = "itemAvailability", targetNamespace = "")
 @RequestWrapper(localName = "ckAvailability", targetNamespace = "http://simple", className = "simple.CkAvailability")
 @ResponseWrapper(localName = "ckAvailabilityResponse", targetNamespace = "http://simple",
className = "simple.CkAvailabilityResponse")
 public List<String> ckAvailability(
  @WebParam(name = "itemNumbers", targetNamespace = "")
  List<Integer> itemNumbers)
  throws InvalidDateFault_Exception
 ;
 /**
 *
 * @param saleRepName
 * @return
 *     returns simple.Person
 */
 @WebMethod
 @WebResult(name = "salesRepInfo", targetNamespace = "")
 @RequestWrapper(localName = "findSalesRep", targetNamespace = "http://simple", className = "simple.FindSalesRep")
 @ResponseWrapper(localName = "findSalesRepResponse", targetNamespace = "http://simple",
className = "simple.FindSalesRepResponse")
 public Person findSalesRep(
 @WebParam(name = "saleRepName", targetNamespace = "")
 String saleRepName);

}
```

Comparing the code examples

At first glance, it might seem that there is little similarity between the interfaces. If you disregard the additional information added by the annotations for JAX-WS and JAXB, the code samples are similar. For example, the calcShippingCost method in the JAX-WS and JAXB version the following lines of code exist:

```
@WebMethod
 @WebResult(name = "shippingCost", targetNamespace = "")
 @RequestWrapper(localName = "calcShippingCost", targetNamespace = "http://simple",
className = "simple.CalcShippingCost")
 @ResponseWrapper(localName = "calcShippingCostResponse", targetNamespace = "http://simple",
className = "simple.CalcShippingCostResponse")
 public Integer calcShippingCost(
  @WebParam(name = "shippingWt", targetNamespace = "")
  Integer shippingWt,
  @WebParam(name = "shippingZone", targetNamespace = "")
  Integer shippingZone);
```

But, if you discard the annotations, the following lines of code are:

```
public Integer calcShippingCost(
        Integer shippingWt,
        Integer shippingZone);
```

These lines are almost identical to what was generated for JAX-RPC. The only difference is that the JAX-RPC code can produce the java.rmi.RemoteException error as follows:

```
public java.lang.Integer calcShippingCost(java.lang.Integer shippingWt,
   java.lang.Integer shippingZone) throws java.rmi.RemoteException;
```

Following this logic, three of the methods have essentially the same signatures:

```
public Integer calcShippingCost(Integer shippingWt, Integer shippingZone)
 public String getAccountNumber(String accountName)
 public Person findSalesRep(String saleRepName)
```

This means that migrating from JAX-RPC to JAX-WS does not directly affect these methods and the original implementation code that is successfully running in the JAX-RPC based environment can probably be used without modification for these methods.

However two of the methods do have different signatures:

For JAX-RPC:

```
public java.util.Calendar calculateShippingDate(
 java.util.Calendar requestedDate)
public java.lang.String[] ckAvailability(int[] itemNumbers)
 throws java.rmi.RemoteException,
 simple.InvalidDateFault
```

JAX-WS and JAXB:

```
public XMLGregorianCalendar calculateShippingDate(
 XMLGregorianCalendar requestedDate)
public List<String> ckAvailability(List<Integer> itemNumbers)
 throws InvalidDateFault_Exception
```

Note:

You might find it easier to compare the skeleton implementation files since the annotations are not present in SampleServiceImpl.java.:

- SampleServiceSoapBindingImpl.java
- SampleServiceImpl.java

The differences in signatures are due to the following reasons:

- Differences mappings from XML names to Java names

  For the calculateShippingDate method, both the input parameter and the return parameter have changed from type java.util.Calendar to type XMLGregorianCalendar. This is because the WSDL specified these parameters to be of type, xsd:dateTime, JAX-RPC maps this data type to java.util.Calendar, while JAX-WS and JAXB maps it to XMLGregorianCalendar.
- Different mappings of arrays from XML to Java

  For the ckAvailability method, the change is due to the data mappings for XML arrays.

  JAX-RPC maps the following WSDL elements:

  ```
  <element maxOccurs="unbounded" name="itemNumbers" type="xsd:int"/>
  <element maxOccurs="unbounded" name="itemAvailability" type="xsd:string"/>
  ```

  The previous elements are mapped to the following Java source:

  ```
  int[] itemNumbers
  java.lang.String[] itemAvailability
  ```

  JAX-WS and JAXB map the following WSDL elements:

  ```
  List<Integer> itemNumbers
  List<String> ckAvailability
  ```
- Different mappings of exceptions

  For the ckAvailability method, the JAX-RPC code generated the following error:

  ```
  simple.InvalidDateFault
  ```

  The JAX-WS code generates the following error:

  ```
  InvalidDateFault_Exception
  ```

  Except for the names, the constructors for these exceptions are different. Therefore, the actual JAX-RPC code that produces the error might be displayed as:

```
throw new InvalidDateFault("this is an InvalidDateFault");
```

For JAX-WS, the code uses a command similar to the following example::

```
throw new InvalidDateFault_Exception( "this is an InvalidDateFault_Exception", new InvalidDateFault());
```

In cases that use exceptions, the code that uses it needs to change.

Migrating the code

Now that the differences between code have been explained, review the original code for the methods that need changing and how to change this code so that it works in a JAX-WS and JAXB environment.

Assume that the original (JAX-RPC) implementation code is similar to following:

```
public java.util.Calendar calculateShippingDate(
     java.util.Calendar requestedDate) throws java.rmi.RemoteException {
// Set the date to the date that was sent to us and add 7 days.
requestedDate.add(java.util.Calendar.DAY_OF_MONTH, 7);

// . . .

return requestedDate;
}
```

You can write the new code to directly use the new types as in the following examples:

```
public XMLGregorianCalendar calculateShippingDate(
XMLGregorianCalendar requestedDate) {
try {
// Create a data type factory.
DatatypeFactory df = DatatypeFactory.newInstance();
// Set the date to the date that was sent to us and add 7 days.
Duration duration = df.newDuration("P7D");
requestedDate.add(duration);

} catch (DatatypeConfigurationException e) {
// TODO Auto-generated catch block
e.printStackTrace();
}

// . . .

return requestedDate;
}
```

Migrating the code for the ckAvailability method

When migrating the code for the ckAvailability method, changes were required because of the way that arrays and exceptions are mapped from XML is different between JAX-RPC and JAX-WS. Assume that the original JAX-RPC Web service code is similar to the following example:

```
public java.lang.String[] ckAvailability(int[] itemNumbers)
{

    String[] myString = new String[itemNumbers.length];
    for (int j = 0; j < myString.length; j++) {

            . . .
             if ( ... )

    throw new simple.InvalidDateFault("InvalidDateFault");

            . . .
            if ( . . .)
               myString[j] = "available:  " + jitemNumbers[j] ;
```

```
            else
               myString[j] = "not available:  " + jitemNumbers[j];

    }
    return myString;
}
```

The previous code accepts an int[] as input and returns a String[]. For the JAX-WS and JAXB version, these are List<Integer> and List<String> elements respectively. Processing for these arrays, and discarding the Exception code, the JAX-RPC code is similar to the following:

```
public java.lang.String[] ckAvailability(int[] itemNumbers)
{

    String[] myString = new String[itemNumbers.length];
    for (int j = 0; j < jitemNumbers.length; j++) {

            . . .
            if ( . . .)
               myString[j] = "available:  " + itemNumbers.get(j);
            else
               myString[j] = "not available:  " + itemNumbers.get(j);
    }
    return myString;
}
```

The following JAX-WS and JAXB equivalent code exists using Lists instead of arrays:

```
List <String> ckAvailability(List <Integer> itemNumbers)
{

    ArrayList<String> retList = new ArrayList<String>();
    for (int count = 0; count < itemNumbers.size(); count++) {

            . . .
            if ( . . .)
               retList.add("available:  " + itemNumbers.get(j));
            else
               retList.add("not available:  " + itemNumbers.get(j));
    }
    return retList;
}
```

The differences in the mappings of exceptions from XML to Java forces the JAX-WS code to use. InvalidDateFault_Exception instead of InvalidDateFault.

This means that you must replace `throw new simple.InvalidDateFault("InvalidDateFault");` with some other code. Therefore, the following line is used for the new code:

```
throw new InvalidDateFault_Exception( "test InvalidDateFault_Exception", new InvalidDateFault());
```

The final JAX-WS and JAXB implementation of the method might be similar to the following code:

```
List <String> ckAvailability(List <Integer> itemNumbers)
{

    ArrayList<String> retList = new ArrayList<String>();
    for (int count = 0; count < itemNumbers.size(); count++) {

if ( . . . ) {
   throw new InvalidDateFault_Exception(
   "test InvalidDateFault_Exception",
   new InvalidDateFault());
}
```

```
. . .
if ( . . .)
   retList.add("available:  " + itemNumbers.get(count));
else
   retList.add("not available:  " + itemNumbers.get(count));
   }
   return retList;
}
```

There are multiple ways that you might choose to migrate the code. With practice and an effective development environment, migrating from JAX-RPC to JAX-WS can be straightforward.

Web services migration best practices

Use these Web services migration best practices when migrating Web services applications.

If you have used the Apache SOAP support to develop Web services client applications in WebSphere Application Server Versions 4, 5, or 5.1, you might need to migrate your applications or the security files for your applications. The following table summarizes the Web services specifications supported by the WebSphere products.

WebSphere Application Server Version	Web services specifications supported
4.0	Apache SOAP 2.2
5.0 and 5.0.1	Apache SOAP 2.3
5.0.2 or later	Java 2 Platform, Enterprise Edition (J2EE), also known as (JSR 109)
6.0.x and 6.1	J2EE (JSR 109)
7.0 or later	Web Services for Java Platform, Enterprise Edition (Java EE) 5 also known as JSR 109

Note: The Apache SOAP 2.2 and Apache SOAP 2.3-based implementations that were available in WebSphere Application Server Version 4.0.*x*, 5.0 and 5.0.1 have been deprecated. It is recommended that applications that are using these SOAP implementations migrate to Web Services for Java EE (JSR 109) support that is provided in current WebSphere Application Server versions.

For more information on migrating your Web services, see Migrating Apache SOAP Web services to Web Services to J2EE standards .

It is recommended that new Web services be developed using the Web services for Java EE specification. For more information, read about implementing Web services applications.

Security cannot be directly migrated from SOAP 2.3 to the Java EE standards. After you have migrated your Web services to the Java EE standards, read about securing Web services for Version 6 applications based on WS-Security.

Follow these best practices for the most optimal migration experience:

The application server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation Web services programming model extending the foundation provided by the JAX-RPC programming model.

Note: Existing JAX-RPC applications wanting to use JAX-WS features must be rewritten using the JAX-WS programming model.

Redeploy existing JAX-RPC Web services after migrating to a new release of the application server

When migrating to a new release of the application server, it is recommended that you redeploy your Web services applications. You should redeploy your Web services application in the new application server environment because of possible changes to the supported levels of Web services specifications and Web services deployment descriptors in each release. To redeploy your Web service, select **Deploy Web Services** in the Install New Application wizard or use the wsdeploy command. To learn more about this process, see the deploying Web services applications onto application servers documentation.

Migrating a Version 5 Java API for XML-based remote procedure call (JAX-RPC) client that uses SOAP over Java Message Service (JMS) to invoke a Web service

A JAX-RPC client that is run on WebSphere Application Server Version 5, can use SOAP over JMS to invoke a Web service that is run on a Version 5 Application Server.

A user ID and password are not required on the target WebSphere MQ queue. After the application server is migrated to Version 6.*x*, and uses the Version 6.*x* default messaging feature, client requests can fail because basic authentication is enabled. The following error message displays when this migration problem occurs:

```
SibMessage W [:] CWSIT0009W: A client request failed in the application server with
endpoint <endpoint name> in bus <bus_name> with reason: CWSIT0016E: The user
ID null failed authentication in bus <bus_name>.
```

When the application server is migrated to Version 6.*x*, and the default messaging provider (service integration technologies) is used, and administrative and application security is enabled for the server or the cell, the service integration bus queue destination inherits the security characteristics of the server or the cell by default. If the server or the cell has basic authentication enabled, the client request fails.

The following options are available to solve this problem. The solutions are listed by the level of security that they impose:

- Disable administrative and application security on the main security panel within the administrative console. To disable administrative and application security, click **Security > Global security**. Deselect the **Enable administrative security** and **Enable application security** options.
- Modify the settings for the service integration bus that hosts the queue destination so that the bus security is disabled and the bus does not inherit security characteristics from the server or the cell. This option is equivalent to the level of security that you can configure in Version 5.
- Configure the basic authentication on each client that uses the service.

Migrating Apache SOAP Web services

See Migrating Apache SOAP Web services to Web Services for J2EE standards to learn how to migrate Apache SOAP Web services. This topic explains how to migrate Web services that were developed using Apache SOAP to Web services that are developed based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification.

Migrating Web services assembled with early versions of the Application Server Toolkit or Assembly Toolkit

If you are migrating your Web service or Web service components from earlier versions of the Application Server Toolkit or Assembly Toolkit, refer to the following hints and tips to improve your success:

- Secure Web services are not migrated by the J2EE Migration Wizard when Web services are migrated from J2EE 1.3 to J2EE 1.4.
- The migration of secure Web services requires manual steps.

- After the J2EE migration, the secure binding and extension files must be migrated manually to J2EE 1.4 as follows:
  1. Double click on the `webservices.xml` file to open the Web Services editor.
  2. Select the **Binding Configurations** tab to edit the binding file.
  3. Add all the necessary binding configurations under the new sections **Request Consumer Binding Configuration Details** and **Response Generator Binding Configuration Details**.
  4. Select the **Extension** tab to edit the extension file.
  5. Add all the necessary extension configurations under the new sections **Request Consumer Service Configuration Details** and **Response Generator Service Configuration Details**.
  6. Save and exit the editor.

.

WebSphere Application Server roles and goals

A description of several computing roles that members of your organization might perform when working with WebSphere Application Server.

Enterprise architect

The enterprise architect provides overall leadership for all architectural and technological matters with respect to the company's IT environment.

Solution architect

The solution architect designs and coordinates a new solution, application or component with end-to-end responsibility including both hardware and software elements.

The main goal of the solution architect is to design a solution that supports the specification set by the enterprise architect.

System administrator

The system administrator is responsible for managing systems and software, and for installing operating system upgrades and middleware products in many accounts.

The system administrator installs and configures appropriate hardware and software (including middleware) to implement the design provided by the solution architect. Additionally the system administrator monitors and maintains the configured system, modifying and removing previously configured objects as and when required.

Application developer

The application developer creates business applications.

The goal of the application developer is to develop applications that provide the business services described by the solution architect.

Deploying Web services applications onto application servers

After assembling the artifacts required to enable the Web module for Web services into an enterprise archive (EAR) file, you can deploy the EAR file into the application server.

Before you begin

To deploy Java-based Web services, you need an enterprise application, also known as an EAR file that is configured and enabled for Web services.

A Java API for XML-Based Web Services (JAX-WS) application does not require additional bindings and deployment descriptors for deployment whereas a Java API for XML-based RPC (JAX-RPC) Web services application requires you to add additional bindings and deployment descriptors for application deployment. JAX-WS is much more dynamic, and does not require any of the static data generated by the deployment step required for deploying JAX-RPC applications.

For JAX-WS Web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

Note: In a mixed node cell, you can only target a JAX-WS enabled enterprise beans module to a server using WebSphere Application Server Version 7.0. However, you can target a JAX-WS enabled Web application archives (WAR) module to a server using either WebSphere Application Server Version 7.0 or WebSphere Application Server Version 6.1 Feature Pack for Web Services

You can use the wsdeploy command with JAX-RPC applications to add WebSphere product-specific deployment classes to a Web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file.

To install or deploy a JAX-WS application, you only need to install the JAX-WS enabled EAR file. If your Web services application contains only JAX-WS endpoints, you do not need to run the wsdeploy command, as this command is used to process only JAX-RPC endpoints.

Ensure that you have installed the HTTP or Java Message Service (JMS) router module that was generated with the endptEnabler command onto the same target as your Web services enterprise bean JAR files. These HTTP or JMS router modules are included in your Web services application and they need to use the runtime libraries of the application server.

About this task

This task is one of the steps in developing and implementing Web services.

You can use either the administrative console or the **wsadmin** scripting tool to deploy an EAR file. If you are installing an containing Web services by using the **wsadmin** command, specify the **-deployws** option for JAX-RPC applications. If you are installing an application containing Web services by using the administrative console, select **Deploy WebServices** in the Install New Application wizard. For more information about installing applications using the administrative console see Installing a new application.

If your JAX-RPC Web services application was previously deployed with the **wsdeploy** command, it is not necessary to specify Web services deployment during installation.

The following actions deploy the EAR file with the **wsadmin** command:

1. Start *install_root*/bin/wsadmin from a command prompt.
2. Deploy the EAR file.
   - For JAX-WS Web service applications, enter the **$AdminApp install *EARfile* "-usedefaultbindings"** command at the **wsadmin** prompt.
   - For JAX-RPC Web service applications, enter the **$AdminApp install *EARfile* "-usedefaultbindings -deployws"** command at the **wsadmin** prompt.

Results

You have a Web service installed onto your application server.

Note: While installing Web services applications that contain a large number of enterprise beans onto the application server, you might receive out of memory errors. If you receive out of memory errors, increase the heap size of your Java Virtual Machine (JVM). Read about tuning the IBM virtual machine for Java documentation to learn more about tuning the application server environment.

What to do next

You can confirm that the Web services application was deployed by entering the Web service endpoint URL in a browser, then viewing an informative page. The information page contains the following information:

```
{http://webservice.pli.tc.wssvt.ibm.com}RetireWebServices
Hello! This is an Axis2 Web service!
```

The first line of this information is variable, depending on your Web service. The URI in the brackets is the namespace and the string that follows, in this example RetireWebServices, is the name of the port used to access the Web service.

The next step you might want to consider is to apply security to your Web service.

Provide options to perform the Web services deployment settings

Use this panel to specify options for Web services deployment.

This administrative console panel is a step in the application installation and update wizards.

To view this panel, you must select **Deploy Web services** on the **Select installation options** panel.

To view this administrative console page, complete the following steps:

1. Click **Applications > New application >** ***application_path*** .
2. Select the option to **Show all installation options and parameters** .
3. Click **Next** to get to the **Step: Select installation options** panel.
4. Select **Deploy Web service**.
5. Click **Next** to get to the **Step: Provide options to perform the Web services deployment** panel.

You can specify the Web services deployment options on this panel only when installing or updating an application that uses Web services.

The wsdeploy command is supported by Java API for XML-based RPC (JAX-RPC) applications. The Java API for XML-Based Web Services (JAX-WS) programming model that is implemented by the application server does not support the wsdeploy command. If your Web services application contains only JAX-WS endpoints, you do not need to run the wsdeploy command, as this command is used to process only JAX-RPC endpoints.

The options that you specify set parameter values for the **wsdeploy** command. The **wsdeploy** command adds product-specific deployment classes to a Web services-compatible enterprise archive (EAR) file or an application client Java archive (JAR) file. These classes include:

- Stubs
- Serializers and deserializers
- Implementations of service interfaces

The **wsdeploy** command is run during installation after you click **Finish** on the **Summary** panel of the wizard.

Related tasks

Installing enterprise application files with the console
Installing Java Platform, Enterprise Edition (Java EE) application files consists of placing assembled enterprise application, Web, enterprise bean (EJB), or other installable modules on a server or cluster configured to hold the files. Installed files that start and run properly are considered *deployed*.

Related reference

"wsdeploy command"
This topic explains how to use the **wsdeploy** command-line tool with Web services. The **wsdeploy** command adds WebSphere product-specific deployment classes to a Web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file.

Enterprise application settings
Use this page to configure an enterprise application.

Deploy Web services option - Classpath

Specifies entries to add to the CLASSPATH when the generated classes are compiled.

To specify the class paths of multiple entries, you need to separate the entries with a semicolon on Windows platforms and on Linux, Unix, and z/OS platforms, you need to use a colon to separate the entries. This is the same separator that is used with the CLASSPATH environment variable.

This option is the same as the **wsdeploy** command parameter `-cp` *`class_path`*.

Data type	String
Default	null

Deploy Web services option - Extension Directories

Specifies a directory that contains zipped or Java archive (JAR) files. All zipped and JAR files in this directory are added to the CLASSPATH used to compile the generated files.

This option is the same as the **wsdeploy** command parameter `-jardir` *`directory`*.

Data type	String
Default	null

wsdeploy command

This topic explains how to use the **wsdeploy** command-line tool with Web services. The **wsdeploy** command adds WebSphere product-specific deployment classes to a Web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file.

The wsdeploy command is supported by Java API for XML-based RPC (JAX-RPC) applications. The Java API for XML-Based Web Services (JAX-WS) programming model that is implemented by the application server does not support the wsdeploy command. If your Web services application contains only JAX-WS endpoints, you do not need to run the wsdeploy command, as this command is used to process only JAX-RPC endpoints.

The deployment classes that are added by the wsdeploy tool to a Web services-compatible EAR file or a JAR file include:
- Stubs
- Serializers and deserializers
- Implementations of service interfaces

This deployment step must be performed at least once, and can be performed more often. Deployment can be performed separately using the **wsdeploy** command, assembly tools, or when the application is installed. When using the **wsadmin** command for installation, specify the **-deployws** option.

The **wsdeploy** command operates as noted in the following list:
- Each module in the enterprise application or JAR file is examined.
- If the module contains Web services implementations, indicated by the presence of the `webservices.xml` deployment descriptor, the associated Web Services Description Language (WSDL) files are located and the **WSDL2Java** command is run with the role deploy-server option.
- If the module contains Web services clients, indicated by the presence of the client deployment descriptor, the associated WSDL files are located and the **WSDL2Java** command is run with the role deploy-client option.
- The files generated by the **WSDL2Java** command are compiled and repackaged.

See **WSDL2Java** command for more information about the files that are generated for deployment.

When the generated files are compiled, they can reference application-specific classes outside the EAR or JAR file, if the EAR or JAR file is not self-contained. In this case, use either the -jardir or -cp option to specify additional JAR or zip files to be added to CLASSPATH variable when the generated files are compiled.

wsdeploy command syntax

The command syntax is noted in the following example:

`wsdeploy` *`Input_filename Output_filename`* `[options]`

Required options:
- ***Input_filename***

  Specifies the path to the EAR or JAR file to deploy.
- ***Output_filename***

  Specifies the path of the deployed EAR or JAR file. If *output_filename* already exists, it is silently overwritten. The *output_filename* can be the same as the *input_filename*.

Other options:
- **-jardir** *directory*

  Specifies a directory that contains JAR or zip files. All JAR and zip files in this directory are added to the CLASSPATH used to compile the generated files. This option can be specified zero or more times.
- **-cp** *entries*

  Specifies entries to add to the CLASSPATH when the generated classes are compiled. Multiple entries are separated the same as they are in the CLASSPATH environment variable.
- **-codegen**

  Specifies to generate but not compile deployment code. This option implicitly specifies the -keep option.
- **-debug**

  Includes debugging information when compiling, that is, use javac -g to compile.
- **-help**

  Displays a help message and exit.
- **-ignoreerrors**

  Do not stop deployment if validation or compilation errors are encountered.
- **-keep**

  Do not delete working directories containing generated classes. A message is displayed indicating the name of the working directory that is retained.
- **-novalidate**

  Do not validate the Web services deployment descriptors in the input file.
- **-trace**

Displays processing information, including the names of the generated files.

Example The following example illustrates how the options are used with the **wsdeploy** command:

```
wsdeploy x.ear x_deployed.ear -trace -keep
Processing web service module x_client.jar.
Keeping directory: f:\temp\Base53383.tmp for module: x_client.jar.
Parsing XML file:f:\temp\Base53383.tmp\WarDeploy.wsdl
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java.
Done processing module x_client.jar.
```

Messages

- Flag *-f* is not valid.

  Option *f* was not recognized as a valid option.
- Flag *-c* is ambiguous.

  Options can be abbreviated, but the abbreviation must be unique. In this case, the **wsdeploy** command cannot determine which option was intended.
- Flag *-c* is missing parameter *-p*.

  A required parameter for an option is omitted.
- Missing *p* parameter.

  A required option is omitted.

JAX-WS application deployment model

The administration function of the product is enhanced to support installing and deploying Java Application Programming Interface (API) for XML Web Services (JAX-WS) applications like any other WebSphere Application Server applications.

A JAX-WS application is packaged as a Web archive (WAR) file or a WAR module within an Enterprise Archive (EAR) file. The JAX-WS application deployment model is similar to the Java API for XML Remote Protocol Call (JAX-RPC) Web services application model. The main difference between them is that JAX-RPC Web services application requires you to add additional bindings and deployment descriptors for application deployment. A JAX-WS application does not require additional bindings and deployment descriptors for deployment. You can deploy your JAX-WS applications as you would deploy any other WebSphere Application Server application.

JAX-WS Web services is a rewrite of JAX-RPC Web services. The table compares the Web services stack for both JAX-WS and JAX-RPC Web services.

JAX-RPC Web services	JAX-WS Web services
Bindings are proprietary	Bindings are based on the open source Java API for XML Bindings (JAXB)
Parsing is proprietary	Parsing is based on the open source Java Specification Request (JSR) 173
No Java annotations support	Support for Java annotations such as `@WebService`, `@WebMethod`, `@WebParam`, `@WebResult`, and `@SOAPBinding`

JAX-RPC Web services	JAX-WS Web services
During deployment, some deployment descriptor files are created in a JAX-RPC based service and client. The following files are created on the services side, when it is an EJB based Web service and EJB based module: • webservices.xml • <name_of_service>_mapping.xml • ibm-webservices-bnd.xmi • ibm-webservices-ext.xmi When the service is a JavaBeans-based or Web module-based service, the following files and deployment descriptors are required: • webservices.xml • <name_of_service>_mapping.xml • In the web.xml, there is no additional content • ibm-webservices-bnd.xmi • ibm-webservices-ext.xmi The web.xml exists in both EJB and JavaBeans based services. However, there is no additional content added to the file during deployment of a Web service application or module.	For JAX-WS Web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

Note: In WebSphere Application Server Version 7.0, the default annotation support behavior has changed. In the Version 6.1 Feature Pack for Web services, the default behavior is to scan pre-Java EE 5 Web application modules to identify JAX-WS services and to scan pre-Java EE 5 Web application modules and EJB modules for service clients during application installation. For Version 7.0, the default behavior is to not scan pre-Java EE 5 modules for annotations during application installation or server startup. You can preserve compatibility with feature packs from previous releases by either setting the UseWSFEP61ScanPolicy property in the META-INF/MANIFEST.MF of a Web archive (WAR) file or EJB module or by defining the Java virtual machine custom property, com.ibm.websphere.webservices.UseWSFEP61ScanPolicy, on servers to request scanning during application installation and server startup. To learn more about annotations scanning, see the JAX-WS annotations documentation.

Deploying Web services applications onto application servers

After assembling the artifacts required to enable the Web module for Web services into an enterprise archive (EAR) file, you can deploy the EAR file into the application server.

Before you begin

To deploy Java-based Web services, you need an enterprise application, also known as an EAR file that is configured and enabled for Web services.

A Java API for XML-Based Web Services (JAX-WS) application does not require additional bindings and deployment descriptors for deployment whereas a Java API for XML-based RPC (JAX-RPC) Web services application requires you to add additional bindings and deployment descriptors for application deployment. JAX-WS is much more dynamic, and does not require any of the static data generated by the deployment step required for deploying JAX-RPC applications.

For JAX-WS Web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file.

You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

Note: In a mixed node cell, you can only target a JAX-WS enabled enterprise beans module to a server using WebSphere Application Server Version 7.0. However, you can target a JAX-WS enabled Web application archives (WAR) module to a server using either WebSphere Application Server Version 7.0 or WebSphere Application Server Version 6.1 Feature Pack for Web Services

You can use the wsdeploy command with JAX-RPC applications to add WebSphere product-specific deployment classes to a Web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file.

To install or deploy a JAX-WS application, you only need to install the JAX-WS enabled EAR file. If your Web services application contains only JAX-WS endpoints, you do not need to run the wsdeploy command, as this command is used to process only JAX-RPC endpoints.

Ensure that you have installed the HTTP or Java Message Service (JMS) router module that was generated with the endptEnabler command onto the same target as your Web services enterprise bean JAR files. These HTTP or JMS router modules are included in your Web services application and they need to use the runtime libraries of the application server.

About this task

This task is one of the steps in developing and implementing Web services.

You can use either the administrative console or the **wsadmin** scripting tool to deploy an EAR file. If you are installing an containing Web services by using the **wsadmin** command, specify the **-deployws** option for JAX-RPC applications. If you are installing an application containing Web services by using the administrative console, select **Deploy WebServices** in the Install New Application wizard. For more information about installing applications using the administrative console see Installing a new application.

If your JAX-RPC Web services application was previously deployed with the **wsdeploy** command, it is not necessary to specify Web services deployment during installation.

The following actions deploy the EAR file with the **wsadmin** command:

1. Start *install_root*/bin/wsadmin from a command prompt.
2. Deploy the EAR file.
   - For JAX-WS Web service applications, enter the **$AdminApp install *EARfile* "-usedefaultbindings"** command at the **wsadmin** prompt.
   - For JAX-RPC Web service applications, enter the **$AdminApp install *EARfile* "-usedefaultbindings -deployws"** command at the **wsadmin** prompt.

Results

You have a Web service installed onto your application server.

Note: While installing Web services applications that contain a large number of enterprise beans onto the application server, you might receive out of memory errors. If you receive out of memory errors, increase the heap size of your Java Virtual Machine (JVM). Read about tuning the IBM virtual machine for Java documentation to learn more about tuning the application server environment.

What to do next

You can confirm that the Web services application was deployed by entering the Web service endpoint URL in a browser, then viewing an informative page. The information page contains the following information:

```
{http://webservice.pli.tc.wssvt.ibm.com}RetireWebServices
Hello! This is an Axis2 Web service!
```

The first line of this information is variable, depending on your Web service. The URI in the brackets is the namespace and the string that follows, in this example RetireWebServices, is the name of the port used to access the Web service.

The next step you might want to consider is to apply security to your Web service.

Provide options to perform the Web services deployment settings

Use this panel to specify options for Web services deployment.

This administrative console panel is a step in the application installation and update wizards.

To view this panel, you must select **Deploy Web services** on the **Select installation options** panel.

To view this administrative console page, complete the following steps:

1. Click **Applications > New application >** ***application_path*** .
2. Select the option to **Show all installation options and parameters** .
3. Click **Next** to get to the **Step: Select installation options** panel.
4. Select **Deploy Web service**.
5. Click **Next** to get to the **Step: Provide options to perform the Web services deployment** panel.

You can specify the Web services deployment options on this panel only when installing or updating an application that uses Web services.

The wsdeploy command is supported by Java API for XML-based RPC (JAX-RPC) applications. The Java API for XML-Based Web Services (JAX-WS) programming model that is implemented by the application server does not support the wsdeploy command. If your Web services application contains only JAX-WS endpoints, you do not need to run the wsdeploy command, as this command is used to process only JAX-RPC endpoints.

The options that you specify set parameter values for the **wsdeploy** command. The **wsdeploy** command adds product-specific deployment classes to a Web services-compatible enterprise archive (EAR) file or an application client Java archive (JAR) file. These classes include:

- Stubs
- Serializers and deserializers
- Implementations of service interfaces

The **wsdeploy** command is run during installation after you click **Finish** on the **Summary** panel of the wizard.

This topic explains how to use the **wsdeploy** command-line tool with Web services. The **wsdeploy** command adds WebSphere product-specific deployment classes to a Web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file.

Enterprise application settings
Use this page to configure an enterprise application.

Deploy Web services option - Classpath

Specifies entries to add to the CLASSPATH when the generated classes are compiled.

To specify the class paths of multiple entries, you need to separate the entries with a semicolon on Windows platforms and on Linux, Unix, and z/OS platforms, you need to use a colon to separate the entries. This is the same separator that is used with the CLASSPATH environment variable.

This option is the same as the **wsdeploy** command parameter `-cp` *`class_path`*.

Data type	String
Default	null

Deploy Web services option - Extension Directories

Specifies a directory that contains zipped or Java archive (JAR) files. All zipped and JAR files in this directory are added to the CLASSPATH used to compile the generated files.

This option is the same as the **wsdeploy** command parameter `-jardir` *`directory`*.

Data type	String
Default	null

wsdeploy command

This topic explains how to use the **wsdeploy** command-line tool with Web services. The **wsdeploy** command adds WebSphere product-specific deployment classes to a Web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file.

The wsdeploy command is supported by Java API for XML-based RPC (JAX-RPC) applications. The Java API for XML-Based Web Services (JAX-WS) programming model that is implemented by the application server does not support the wsdeploy command. If your Web services application contains only JAX-WS endpoints, you do not need to run the wsdeploy command, as this command is used to process only JAX-RPC endpoints.

The deployment classes that are added by the wsdeploy tool to a Web services-compatible EAR file or a JAR file include:
- Stubs
- Serializers and deserializers
- Implementations of service interfaces

This deployment step must be performed at least once, and can be performed more often. Deployment can be performed separately using the **wsdeploy** command, assembly tools, or when the application is installed. When using the **wsadmin** command for installation, specify the **-deployws** option.

The **wsdeploy** command operates as noted in the following list:
- Each module in the enterprise application or JAR file is examined.
- If the module contains Web services implementations, indicated by the presence of the `webservices.xml` deployment descriptor, the associated Web Services Description Language (WSDL) files are located and the **WSDL2Java** command is run with the role deploy-server option.
- If the module contains Web services clients, indicated by the presence of the client deployment descriptor, the associated WSDL files are located and the **WSDL2Java** command is run with the role deploy-client option.
- The files generated by the **WSDL2Java** command are compiled and repackaged.

See **WSDL2Java** command for more information about the files that are generated for deployment.

When the generated files are compiled, they can reference application-specific classes outside the EAR or JAR file, if the EAR or JAR file is not self-contained. In this case, use either the -jardir or -cp option to specify additional JAR or zip files to be added to CLASSPATH variable when the generated files are compiled.

wsdeploy command syntax

The command syntax is noted in the following example:

`wsdeploy` *`Input_filename Output_filename`* `[options]`

Required options:
- ***Input_filename***

  Specifies the path to the EAR or JAR file to deploy.
- ***Output_filename***

  Specifies the path of the deployed EAR or JAR file. If *output_filename* already exists, it is silently overwritten. The *output_filename* can be the same as the *input_filename*.

Other options:
- **-jardir** *directory*

  Specifies a directory that contains JAR or zip files. All JAR and zip files in this directory are added to the CLASSPATH used to compile the generated files. This option can be specified zero or more times.
- -**cp** *entries*

  Specifies entries to add to the CLASSPATH when the generated classes are compiled. Multiple entries are separated the same as they are in the CLASSPATH environment variable.
- **-codegen**

  Specifies to generate but not compile deployment code. This option implicitly specifies the -keep option.
- **-debug**

  Includes debugging information when compiling, that is, use javac -g to compile.
- **-help**

  Displays a help message and exit.
- **-ignoreerrors**

  Do not stop deployment if validation or compilation errors are encountered.
- **-keep**

  Do not delete working directories containing generated classes. A message is displayed indicating the name of the working directory that is retained.
- **-novalidate**

  Do not validate the Web services deployment descriptors in the input file.
- **-trace**

  Displays processing information, including the names of the generated files.

Example The following example illustrates how the options are used with the **wsdeploy** command:

```
wsdeploy x.ear x_deployed.ear -trace -keep
Processing web service module x_client.jar.
Keeping directory: f:\temp\Base53383.tmp for module: x_client.jar.
Parsing XML file:f:\temp\Base53383.tmp\WarDeploy.wsdl
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java.
Done processing module x_client.jar.
```

JAX-WS application deployment model

The administration function of the product is enhanced to support installing and deploying Java Application Programming Interface (API) for XML Web Services (JAX-WS) applications like any other WebSphere Application Server applications.

A JAX-WS application is packaged as a Web archive (WAR) file or a WAR module within an Enterprise Archive (EAR) file. The JAX-WS application deployment model is similar to the Java API for XML Remote Protocol Call (JAX-RPC) Web services application model. The main difference between them is that JAX-RPC Web services application requires you to add additional bindings and deployment descriptors for application deployment. A JAX-WS application does not require additional bindings and deployment descriptors for deployment. You can deploy your JAX-WS applications as you would deploy any other WebSphere Application Server application.

JAX-WS Web services is a rewrite of JAX-RPC Web services. The table compares the Web services stack for both JAX-WS and JAX-RPC Web services.

JAX-RPC Web services	JAX-WS Web services
Bindings are proprietary	Bindings are based on the open source Java API for XML Bindings (JAXB)
Parsing is proprietary	Parsing is based on the open source Java Specification Request (JSR) 173
No Java annotations support	Support for Java annotations such as `@WebService`, `@WebMethod`, `@WebParam`, `@WebResult`, and `@SOAPBinding`

JAX-RPC Web services	JAX-WS Web services
During deployment, some deployment descriptor files are created in a JAX-RPC based service and client. The following files are created on the services side, when it is an EJB based Web service and EJB based module: • webservices.xml • <name_of_service>_mapping.xml • ibm-webservices-bnd.xmi • ibm-webservices-ext.xmi When the service is a JavaBeans-based or Web module-based service, the following files and deployment descriptors are required: • webservices.xml • <name_of_service>_mapping.xml • In the web.xml, there is no additional content • ibm-webservices-bnd.xmi • ibm-webservices-ext.xmi The web.xml exists in both EJB and JavaBeans based services. However, there is no additional content added to the file during deployment of a Web service application or module.	For JAX-WS Web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

Note: In WebSphere Application Server Version 7.0, the default annotation support behavior has changed. In the Version 6.1 Feature Pack for Web services, the default behavior is to scan pre-Java EE 5 Web application modules to identify JAX-WS services and to scan pre-Java EE 5 Web application modules and EJB modules for service clients during application installation. For Version 7.0, the default behavior is to not scan pre-Java EE 5 modules for annotations during application installation or server startup. You can preserve compatibility with feature packs from previous releases by either setting the UseWSFEP61ScanPolicy property in the META-INF/MANIFEST.MF of a Web archive (WAR) file or EJB module or by defining the Java virtual machine custom property, com.ibm.websphere.webservices.UseWSFEP61ScanPolicy, on servers to request scanning during application installation and server startup. To learn more about annotations scanning, see the JAX-WS annotations documentation.

Using the UDDI registry

The Universal Description, Discovery, and Integration (UDDI) registry is a directory for Web services that is implemented using the UDDI specification. It is a component of WebSphere Application Server.

About this task

Throughout this information, the term *UDDI registry* refers to the UDDI registry component that is supplied as part of WebSphere Application Server.

This section describes the UDDI registry and how to use it. An administrator can install, configure, and manage the UDDI registry. A user can use the UDDI registry user interface and the UDDI Application Programming Interfaces (APIs).

1. To learn about the UDDI registry, see the following topics:
   - “Overview of the Version 3 UDDI registry” on page 410
   - “UDDI registry terminology” on page 412
2. To use the UDDI registry, see the following topics:

- "Getting started with the UDDI registry" on page 977
- Using the UDDI registry user interface
- UDDI registry client programming
- "Java API for XML Registries (JAXR) provider for UDDI" on page 448

3. To install, configure, or manage a UDDI registry, see the following topics:
   - "Getting started with the UDDI registry" on page 977
   - "Setting up and deploying a new UDDI registry" on page 460
   - Configuring UDDI registry security
   - "Managing the UDDI registry" on page 988
   - "UDDI registry management interfaces" on page 415
   - "Configuring SOAP API and GUI services for the UDDI registry" on page 986
   - "Applying an upgrade to the UDDI registry" on page 986
   - "Removing and reinstalling the UDDI registry" on page 978
   - Migrating the UDDI registry
4. To resolve any problems with the UDDI registry, see the following topic:
   - UDDI registry troubleshooting

Overview of the Version 3 UDDI registry

The Universal Description, Discovery, and Integration (UDDI) specification defines a way to publish and discover information about Web services. The term *Web service* describes specific business functionality that is exposed by a company, usually through an Internet connection, to allow another company, its subsidiaries, or software program, to use the service.

You can find the UDDI specification on the OASIS UDDI Web page.

The UDDI specification defines a standard for the visibility, reusability, and manageability that are essential for a service-oriented architecture (SOA) registry service.

The UDDI registry is a directory for Web services that is implemented using the UDDI specification. It is a component of WebSphere Application Server.

A critical component of IBM's on-demand service-oriented architecture, the UDDI registry solves the problem of discovery of technical components for an enterprise and its partners by:

- Providing control, flexibility, and confidentiality so that an enterprise can protect its e-business investments
- Increasing efficiency by making it easier to identify technical assets
- Leveraging existing infrastructures

The following example shows how the UDDI registry can be used in a larger enterprise.

A company has a legacy application that provides telephone numbers and human resources (HR) information about employees. This application is turned into a Web service and published to the registry. A developer in the same company wants to write an application for a procurement function that also needs to provide HR information to the supplier. The application needs to give the supplier access to the employee account codes after the employee provides a name or serial number. Before Web services, the developer might be in one of the following situations:

- The developer does not know about the similar application
- The developer knows about the application, but cannot reuse it because of technical barriers
- The developer knows about the application and reuses it, but only after significant time and negotiation

With UDDI, the developer can search for the Web service and reuse the existing technical component in their new application for the supplier in minutes. The developer saves time and gets the application running sooner, thereby increasing efficiency and saving the company time and money. The UDDI registry was the first version 2 standard-compliant UDDI registry for private enterprise work. The UDDI registry in this version has the following characteristics:

- It supports the UDDI Version 3.0 specification, in addition to the Version 1.0 and Version 2.0 standard APIs.
- It leverages the proven, reliable WebSphere Application Server technology.
- It uses a relational database, such as DB2, for its persistent store.

What is new in UDDI Version 3

The main aspects of the UDDI Version 3 specification that are provided with this version of WebSphere Application Server are as follows:

Improved recognition of the importance of private UDDI registries
Private UDDI registries are registries that are installed, owned, managed, and controlled by a separate body such as a department within a company, a company, an industry consortium, or an e-marketplace.

Publisher-assigned keys
The publisher of a UDDI entity can specify its key, rather than the registry automatically assigning a unique key. This means that more human-friendly, URI-based keys can be used, and it makes it easier to manage multiple registries.

UDDI information model improvements
The UDDI data structures are extended, which improves the ability of UDDI to represent businesses and services through metadata.

Security enhancements
Digital signatures provide additional security. Each of the main UDDI entities can be digitally signed, which improves the integrity and trustworthiness of UDDI data.

Ownership transfer APIs
These APIs support the transfer of the ownership of a UDDI entity from one publisher to another.

UDDI policy
You can set policy to define the behavior of a UDDI registry and therefore recognize the different environments in which a UDDI registry is used.

HTTP GET support for UDDI entities
You can use HTTP GET to access XML representations of each of the UDDI data structures. This extends the HTTP GET service beyond the scope for discovery URLs in the UDDI Version 2 specification.

Additional UDDI registry capabilities

The Version 3 UDDI registry in this version of WebSphere Application Server provides the following capabilities that are additional to support for the UDDI Version 3 specification:

Version 2 UDDI inquiry and publish SOAP API compatibility
There is backward compatibility for the Version 1 and Version 2 SOAP inquiry and publish APIs.

UDDI administrative console extension
The WebSphere Application Server administrative console includes a section that administrators can use to manage UDDI-specific aspects of their WebSphere environment. This management includes the ability to set defaults for initialization of the UDDI node, such as its node ID, and to set the UDDI Version 3 policy values.

UDDI registry administrative interface
The Java Management Extensions (JMX) administrative interface enables administrators to manage UDDI-specific aspects of the WebSphere environment programmatically.

Multidatabase support
The UDDI data is persisted to a registry database. The following database products that are supported by WebSphere Application Server are also supported for use as the persistence store for the UDDI registry. For specific details on supported levels, see Detailed system requirements page.

- Apache Derby Version 10.2
- DB2 for iSeries Versions 5.2 and 5.3
- Oracle Versions 9i and 10g

User-defined value set support
You can create your own categorization schemes or value sets. These are in addition to the standard schemes, such as North American Industry Classification System (NAICS), that are provided with the UDDI registry.

UDDI utility tools
You can use UDDI utility tools to import or export entities that use the UDDI Version 2 API.

UDDI user interface
The UDDI user console supports the UDDI Version 3 inquiry and publish APIs.

UDDI Version 3 client
The Java client for UDDI Version 3 handles the construction of raw SOAP requests for the client application. It is a JAX-RPC client and uses Version 3 data types, which are generated from the UDDI Version 3 Web Services Description Language (WSDL) and schema. These data types are serialized or deserialized to the XML, which constitutes the raw UDDI requests.

UDDI Version 2 clients
The following clients for UDDI Version 2 requests are provided:

- UDDI4J. A Java class library for issuing UDDI requests. This client is provided in WebSphere Application Server Version 5 for both UDDI Version 1 requests (uddi4j.jar) and Version 2 requests (uddi4jv2.jar). These class libraries are still supported, as part of the com.ibm.uddi.jar file, but are now both deprecated.
- JAXR. The Java API for XML Registries (JAXR) is a Java client API for accessing UDDI and ebXML registries. WebSphere Application Server provides a JAXR provider for accessing the UDDI registry that conforms to the JAXR 1.0 specification.
- EJB. An Enterprise JavaBeans (EJB) interface for issuing UDDI Version 2 requests. This client is still supported, but is now deprecated.

UDDI registry terminology

Some terms specific to the UDDI registry are explained. Also, the relationship between the versions of the UDDI registry, the Organization for the Advancement of Structured Information (OASIS) specification, and the WebSphere Application Server level are shown.

Throughout the UDDI information in this information center, the directory locations of WebSphere Application Server are referred to as *app_server_root* and *profile_root*.

UDDI Definitions

bindingTemplate
AbindingTemplate is technical information about a service entry point and construction specifications.

businessEntity
A businessEntity is information about the party who publishes information about a family of services.

businessService
A businessService is descriptive information about a particular service.

customized UDDI node
A customized UDDI node is a UDDI node that is initialized with customized settings for the UDDI properties and UDDI policies. In particular, this type kind of node does not have default values for those properties that are read-only after initialization.

Use a customized UDDI node for anything other than simple testing purposes (for which a default UDDI node is enough). To set up a customized UDDI node, see Setting up a customized UDDI node.

When you first start a customized UDDI node, you must set values for certain properties, and then initialize the node (using the administrative console or UDDI administrative interface), before the node is ready to accept UDDI requests. The properties that you must set control characteristics of the UDDI node that cannot be changed after initialization.

An advantage of using a customized UDDI node is that can set these properties to values that are suitable for your environment and usage of UDDI.

After a customized UDDI node is initialized, it is the same as a default UDDI node except that it uses customized UDDI property and policy values.

default UDDI node
A default UDDI node is a UDDI node that is initialized with default settings for the UDDI properties and UDDI policies, including the properties that are read-only after initialization. A default UDDI node is intended for use for testing and to provide a simple way to become familiar with the behavior of the UDDI registry.

You can set up a default UDDI node in two ways. The first is to run the uddiDeploy.jacl script, specifying the 'default' option, in which case the UDDI database will be an Apache Derby database that is created for you automatically.

The second is to create the database yourself, specifying the default option, which for Apache Derby is the DEFAULT parameter when using the UDDIDerbyCreate.jar file, and for DB2 or Oracle the SQL script insert_default_database_indicator.

After a default UDDI node is initialized, it is the same as a customized UDDI node except that it uses default UDDI property and policy values.

policy profile
A policy profile is set of UDDI policies. The default policy profile is the profile created when the default UDDI node is created. In the default policy profile, the nodeID and root key generator are set to read-only and cannot be changed after installation.

publisherAssertion
A publisherAssertion is information about a relationship between two parties, asserted by one or both.

tModel
A tModel (short for technical model) is a data structure representing a reusable concept, such as a Web service type, a protocol used by Web services, or a category system.

tModel keys in a service description are a technical ″fingerprint″ that you can use to trace the compatibility origins of a given service. They provide a common point of reference so that you can identify compatible services.

tModels are used to establish the existence of a variety of concepts and to point to their technical definitions. tModels that represent value sets such as category, identifier, and relationship systems

are used to provide additional data to the UDDI core entities to facilitate discovery along a number of dimensions. This additional data is captured in keyedReferences that reside in categoryBags, identifierBags, or publisherAssertions. The tModelKey attributes in these keyedReferences refer to the value set that relates to the concept or namespace being represented. The keyValues contain the actual values from that value set. In some cases, keyNames are significant, for example, to describe relationships and when using the general keywords value set. In all other cases, keyNames provide a version of the keyValue that people can read.

UDDI application
The UDDI application is the UDDI registry enterprise application.

UDDI entitlement
A UDDI entitlement is an entitlement that a UDDI user or publisher has in a UDDI registry, such as the capability to publish keyGenerators, or the tier to which the publisher is assigned (in other words, the number of entities that the publisher is entitled to publish). Each UDDI publisher has a range of settings for the various UDDI entitlements. A UDDI entitlement is sometimes referred to as a 'user entitlement', or as the UDDI publisher's set of 'user entitlements'.

UDDI node
A UDDI node is a set of Web Services that support at least one of the UDDI API sets, which supports interaction with UDDI data through the UDDI APIs. There is no direct mapping between a UDDI node and a WebSphere Application Server node. A UDDI node consists of an instance of the UDDI application running in an application server (or a cluster of UDDI application instances running in a cluster of application servers), together with an instance of the UDDI database containing UDDI data.

UDDI node initialization
UDDI node initialization is the process that sets up values in the UDDI database, and establishes the ″personality″ of the UDDI node. A UDDI node cannot accept UDDI API requests until it is initialized.

UDDI node state
The UDDI node state describes the current state of the UDDI node, as opposed to the state of the UDDI application (which is either stopped or started). A UDDI node can be in one of the following states:

- not initialized
- initialization pending
- initialization in progress
- migration pending
- migration in progress
- value set creation pending
- value set creation in progress
- activated
- deactivated

UDDI NodeId
The UDDI NodeId is a unique identifier of a UDDI node.

UDDI policy
A UDDI policy is a statement of required and expected behavior of a UDDI registry, specified using policy values for the various policies that are defined in the UDDI Version specification.

UDDI property
A UDDI property is a value for a property that controls the personality or behavior of a UDDI node.

UDDI publisher
A UDDI publisher is a WebSphere user who is entitled to publish UDDI entities to a specified UDDI registry. A UDDI publisher is sometimes referred to as a 'UDDI user', or simply as a 'publisher' when used in a UDDI context.

UDDI registry
A UDDI registry comprises one or more UDDI nodes. The UDDI registry in this version of WebSphere Application Server supports single-node UDDI registries only.

UDDI tier
A UDDI tier determines the number of UDDI entities of each type (business, services per business, bindings per service, tModel, publisher assertion) that a UDDI publisher is entitled to publish. Each UDDI publisher is assigned (either by default or explicitly by a UDDI administrator) to a particular tier, and cannot publish more entities than are allowed for that tier. There are some predefined tiers supplied with the UDDI registry, and a UDDI administrator can create additional tiers. A UDDI tier is often referred to simply as a 'tier' when used in a UDDI context.

Version 2 UDDI registry
A Version 2 UDDI registry is a UDDI registry implementation that supports Version 2 of the UDDI specification and also Version 1. A Version 2 UDDI registry is included in WebSphere Application Server Network Deployment Version 5.x.

Version 3 UDDI registry
A Version 3 UDDI registry is a UDDI registry implementation that supports Version 3 of the UDDI specification, and also Versions 1 and 2. A Version 3 UDDI registry is included in WebSphere Application Server. Note that Version 3 UDDI registry does not indicate a UDDI registry implementation that supports only UDDI Version 3 requests.

The following table shows how the various versions of the UDDI registry relate to the relevant OASIS specification and WebSphere Application Server level:

UDDI registry Version	OASIS UDDI specification levels supported	Supported on WebSphere Application Server version
1.1	• UDDI Version 1 • UDDI Version 2	4.0.2
1.1.1	• UDDI Version 1 • UDDI Version 2	4.0.3 and later
2.0.x	• UDDI Version 1 • UDDI Version 2	5.0.x
2.1.x	• UDDI Version 1 • UDDI Version 2	5.1.x
3.0.2	• UDDI Version 1 • UDDI Version 2.0.4 (APIs), Version 2.0.3 (data structures) • UDDI Version 3.0.2	6.0 and later

UDDI registry management interfaces

This topic explains interfaces and tools that you can use to manage UDDI nodes programmatically.

UDDI registry Administrative (JMX) Interface

The UDDI registry Administrative (JMX) Interface provides a Java API that allows you to manage runtime configuration settings to control UDDI registry runtime behavior, such as setting the maximum number of

results that UDDI users can receive for inquiry requests, or creating publish limits for UDDI publishers. Sample client code is provided for you to build on.

User Defined Value Set Support in the UDDI registry

User Defined Value Set Support in the UDDI registry explains the tooling provided to manage your own categorization value sets, including loading value set data into a UDDI registry node.

UDDI Utility Tools

UDDI Utility Tools explains the tooling and Java API for promoting version 2 entities from one UDDI registry to another while retaining entity keys. This is particularly useful for publishing canonical tModels with a predefined key.

UDDI registry Administrative (JMX) Interface

You can use the UDDI registry Administrative Interface to inspect and manage the runtime configuration of a UDDI application. You can manage the information and the activation state about a UDDI node, update properties and policies, set publish tier limits, register UDDI publishers, and control value set support.

The operations of the UDDI registry Administrative Interface can be read and invoked using standard JMX (Java Management Extensions) interfaces. The use of JMX is explained in Using administrative programs (JMX).

Each WebSphere UDDI registry application registers an MBean with an MBean identifier of 'UddiNode'. This MBean may be used by client applications to inspect and manage the runtime configuration of a UDDI application. This includes managing the activation state of and information about a UDDI node, updating properties and policies, setting publish tier limits, registration of UDDI publishers, and controlling value set support.

You can read and invoke the UddiNode attributes and operations using standard JMX interfaces. A client utility class UddiNodeProxy.java provides a ready-made application to connect to a UddiNode MBean and perform all the available operations. Example classes are also provided to drive UddiNodeProxy and demonstrate how to use the various UDDI management data types.

When WebSphere Application Server security is enabled, you can only invoke the operations of the UddiNode MBean if you are a user in an administrative role. The operations which make updates require the Administrator or Operator role, while get operations can be performed by Administrator, Operator, Configurator and Monitor roles.

UddiNodeProxy Usage

The following .jar files are required for compilation:

- *app_server_root*/plugins/com.ibm.uddi.jar
- *app_server_root*/runtimes/com.ibm.ws.admin.client.jar

The UddiNodeProxy class provides a utility method to programmatically interrogate the UddiNode MBean and output all the available attributes, operations and notifications to System.out. For each operation, the return type, operation name and parameter types are output as well as the impact property which indicates how the operation changes the state of the UddiNode MBean (and the UDDI node). As for all MBeans, the value for the impact property can be one of:

ACTION:
state of MBean will be changed

INFO: of the MBean remains unchanged and will return information

ACTION_INFO:
state of the MBean will change and return some information

UNKNOWN:
the impact of invoking the operation is not known

1. Invoke outputMBeanInterface:`uddiNode.outputMBeanInterface();`

   Expected output:

```
java.lang.String getNodeID() [INFO]
(getter for attribute nodeID)
java.lang.String getNodeState() [INFO]
(getter for attribute nodeState)
java.lang.String getNodeDescription() [INFO]
(getter for attribute nodeDescription)

uddi.node.event
notificationInfo: description=null,descriptorType=notification,severity=(6),name=jmx.attribute.
changed
```

See ManageNodeInfoSample class for sample code that demonstrates the attributes and operations described in this section.

Managing UDDI Node States and Attributes

UDDI nodes can be in one of several states, depending on the way the UDDI application was installed (as a default configuration or one where the administrator controls when initialization occurs). The UddiNode MBean provides four read only attributes: nodeID, nodeState, nodeDescription and nodeApplicationName. In addition the following MBean operations change UDDI node state: activateNode, deactivateNode and initNode.

nodeID

The node ID is the unique identifier for a UDDI node. If the UDDI application is installed as a default configuration the node ID is automatically generated. If the UDDI application is set up manually, the node ID is set by the administrator. It must be a valid UDDI key.

```
String nodeID = uddiNode.getNode();

System.out.println("node ID: " + nodeId);
```

nodeState

The nodeState attribute can have one of the following values:

nodeState value	English text associated with state
node.state.uninitialized	Not initialized

node.state.initialized	Initialized
node.state.initPending	Initialization pending
node.state.initInProgress	Initialization in progress
node.state.initMigrationPending	Migration pending
node.state.initMigration	Migration in progress
node.state.initValueSetCreationPending	Value set creation pending
node.state.initValueSetCreation	Value set creation in progress
node.state.activated	Activated
node.state.deactivated	Deactivated
node.state.unknown	Unknown

After installing a UDDI application using the default configuration, the UDDI node will be in activated state, that is, ready to receive and process UDDI API requests. The node ID and root key generator and some other properties are generated and cannot be changed. For a manually installed UDDI application where you want to specify the UDDI node ID and root key generator values, starting the UDDI application will put the UDDI node into initPending state. In this state, you can update all writable values up until the point you invoke the initNode operation. The initNode operation loads base tModels and value set data and writes all the configuration data to the UDDI node's database. During initialization the state is initInProgress. When initialization completes, the state changes momentarily to initialized and settles at activated. At this point the state can only be switched between activated and deactivated using deactivateNode and activateNode MBean operations.

Each node state value is in fact a message key which can be looked up in the messages.properties resource bundle. The attribute value can be retrieved using the getNodeState method of UddiNodeProxy:

1. Invoke getNodeState:

```
String nodeStateKey = uddiNode.getNodeState();
```

2. Look up translated text from ResourceBundle and output:

```
String messages = "com.ibm.uddi.v3.management.messages";

ResourceBundle bundle = ResourceBundle.getBundle(messages,
                                                 Locale.ENGLISH);

String nodeStateText =  bundle.getString(nodeStateKey);

System.out.println("node state: " + nodeStateText);
```

nodeDescription

You can get the administrator assigned description for the UDDI node using the getNodeDescription method of UddiNodeProxy:

1. Invoke getNodeDescription and output:

```
String nodeDescription = uddiNode.getNodeDescription();
System.out.println("node description: " + nodeDescription);
```

nodeApplicationName

The nodeApplicationName attribute is useful for discovering where the UDDI application that corresponds to the UDDI node is installed. The value will be a concatenation of the cell, node and server names, separated by colons. Retrieve the application location using the getApplicationId method of UddiNodeProxy:

1. Invoke getApplicationId and output:

```
String nodeApplicationId = uddiNode.getApplicationId();

System.out.println("node application location: " +
                                        nodeApplicationId);
```

activateNode

Changes the state of the UDDI node to activated, if the UDDI node was previously deactivated.

1. . Invoke activateNode:

```
uddiNode.activateNode();
```

deactivateNode

Changes the state of the UDDI node to deactivated, if the UDDI node was previously activated.

1. Invoke deactivateNode:

```
uddiNode.deactivateNode();
```

initNode

Causes UDDI node initialization, and when this completes the state of the UDDI node is 'activated'.

1. Invoke initNode:

```
uddiNode.initNode();
```

Managing Configuration Properties

UDDI node runtime behavior is affected by the setting of several configuration properties. The UddiNode MBean provides operations to inspect and update their values, as follows: getProperties, getProperty, updateProperty and updateProperties.

See ManagePropertiesSample class for sample code that demonstrates the operations described in this section.

getProperties

Returns collection of all configuration properties as ConfigurationProperty objects.

1. Invoke getProperties:

```
List properties = uddiNode.getProperties();
```

2. Cast each collection member to ConfigurationProperty:

```
if (properties != null) {
  for (Iterator iter = properties.iterator(); iter.hasNext();) {
       ConfigurationProperty property =
                         (ConfigurationProperty) iter.next();
       System.out.println(property);
  }
}
```

Once you have the ConfigurationProperty objects you can inspect attributes like the ID, value, type, whether the property is read only, required for initialization, and get name and description message keys. For example, invoking the toString method returns results similar to:

```
ConfigurationProperty
id: operatorNodeIDValue
nameKey: property.name.operatorNodeIDValue
descriptionKey: property.desc.operatorNodeIDValue
type: java.lang.String
value: uddi:capnscarlet:capnscarlet:server1:default
unitsKey:
```

```
readOnly: true
required: true
usingMessageKeys: false
validValues: none
```

You can use the nameKey and descriptionKey values to look up the translated name and description for a given locale, using the messages.properties resource in the sample package.

getProperty

Returns ConfigurationProperty object with the specified ID. Available property IDs are specified in PropertyConstants together with descriptions of the purpose of the corresponding properties.

1. Invoke getProperty:

```
ConfigurationProperty property =
uddiNode.getProperty(PropertyConstants.DATABASE_MAX_RESULT_COUNT);
```

2. To retrieve the value of the property you could use the getValue method which returns an Object, but in this case, the property is of type integer, so it's easier to retrieve the value using the convenience method getIntegerValue:

```
int maxResults = property.getIntegerValue();
```

updateProperty

Updates the value of the ConfigurationProperty object with the specified ID. Available property IDs are specified in PropertyConstants together with descriptions of the purpose of the corresponding properties. Although you can invoke the setter methods in a ConfigurationProperty object, the only value that is updated in the UDDI node is the value. So to update a property, the steps are typically:

1. Create a ConfigurationProperty object and set its ID:

```
ConfigurationProperty defaultLanguage = new ConfigurationProperty();
defaultLanguage.setId(PropertyConstants.DEFAULT_LANGUAGE);
```

2. Set the value:

```
defaultLanguage.setStringValue("ja");
```

3. Invoke updateProperty:

```
uddiNode.updateProperty(defaultLanguage);
```

updateProperties

Updates several ConfigurationProperty objects in a single request. Set up the ConfigurationProperty objects as for the updateProperty operation.

1. Add updated properties to a List:

```
List updatedProperties = new ArrayList();

updatedProperties.add(updatedProperty1);
updatedProperties.add(updatedProperty2);
```

2. Invoke updateProperties:

```
uddiNode.updateProperties(updatedProperties);
```

Managing Policies

Policies affecting behavior of the UDDI API are managed using the following UddiNode operations: getPolicyGroups, getPolicyGroup, getPolicy, updatePolicy and updatePolicies.

See ManagePoliciesSample class for sample code that demonstrates the attributes and operations described in this section.

getPolicyGroups

Returns collection of all policy groups as PolicyGroup objects.

1. Invoke getPolicyGroups:

```
List policyGroups = uddiNode.getPolicyGroups();
```

2. Cast each collection member to PolicyGroup:

```
if (policyGroups != null) {
for (Iterator iter = policyGroups.iterator(); iter.hasNext();) {
  PolicyGroup policyGroup = (PolicyGroup) iter.next();
  System.out.println(policyGroup);
}
}
```

Each policy group has an ID, name and description key, which you can look up in the messages.properties resource in the sample package. Although the PolicyGroup class does have a getPolicies method, PolicyGroup objects that are returned by the getPolicyGroups operation do not contain any Policy objects. Because of this behavior, clients can determine the known policy groups, and their IDs, without retrieving the entire set of policies in one request. To retrieve the policies within a policy group, use the getPolicyGroup operation.

getPolicyGroup

Returns the PolicyGroup object with the supplied ID.

1. Convert policy group ID to a String:

```
String groupId = Integer.toString(PolicyConstants.REG_APIS_GROUP);
```

2. Invoke getPolicyGroup:

```
PolicyGroup policyGroup = uddiNode.getPolicyGroup(groupId);
```

getPolicy

Returns the Policy object for the specified ID. Like a ConfigurationProperty, a Policy object has an ID, name and description keys, type, value and indicators specifying if the policy is read only or required for node initialization.

1. Convert policy ID to a String:

```
String policyId = Integer.toString(
            PolicyConstants.REG_AUTHORIZATION_FOR_INQUIRY_API);
```

2. Invoke getPolicy:

```
Policy policy = uddiNode.getPolicy(policyId);
```

updatePolicy

Updates the value of the Policy object with the specified ID. Available policy IDs are specified in PolicyConstants together with descriptions of the purpose of the corresponding policies. Although you can invoke the setter methods in a Policy object, the only value that is updated in the UDDI node is the value. So to update a policy, the steps are typically:

1. Create a Policy object and set its ID:

```
Policy updatedPolicy = new Policy();
String policyId =
      Integer.toString(PolicyConstants.REG_SUPPORTS_UUID_KEYS);
updatedPolicy.setId(policyId);
```

2. Set the value:

```
updatedPolicy.setBooleanValue(true);
```

3. Invoke updatePolicy:

```
uddiNode.updatePolicy(updatedPolicy);
```

updatePolicies

Updates several Policy objects in a single request. Set up the Policy objects as for the updatePolicy operation.

1. Add updated policies to a List:

```
List updatedPolicies = new ArrayList();

updatedPolicies.add(updatedPolicy1);
updatedPolicies.add(updatedPolicy2);
```

2. Invoke updatePolicies:

```
uddiNode.updatePolicies(updatedPolicies);
```

Managing Tiers

Tiers control how many of each type of UDDI entities a publisher can save in the UDDI registry. A tier has an ID, an administrator defined name and description, and a set of limits, one for each type of entity. Tiers are managed using the following UddiNode operations: createTier, getTierDetail, getTierInfos, getLimitInfos, setDefaultTier, updateTier, deleteTier and getUserCount.

See ManageTiersSample class for sample code that demonstrates the attributes and operations described in this section.

createTier

Creates a new tier, with specified publish limits for each UDDI entity.

1. Set tier name and description in a TierInfo object.

```
String tierName = "Tier 100";
String tierDescription = "A tier with all limits set to 100.";

TierInfo tierInfo = new TierInfo(null, tierName, tierDescription);
```

2. Define Limit objects for each UDDI entity:

```
List limits = new ArrayList();

Limit businessLimit = new Limit();
businessLimit.setIntegerValue(100);

businessLimit.setId(LimitConstants.BUSINESS_LIMIT);

Limit serviceLimit = new Limit();
serviceLimit.setIntegerValue(100);
serviceLimit.setId(LimitConstants.SERVICE_LIMIT);

Limit bindingLimit = new Limit();
bindingLimit.setIntegerValue(100);
bindingLimit.setId(LimitConstants.BINDING_LIMIT);

Limit tModelLimit = new Limit();
tModelLimit.setIntegerValue(100);
tModelLimit.setId(LimitConstants.TMODEL_LIMIT);

Limit assertionLimit = new Limit();
assertionLimit.setIntegerValue(100);

assertionLimit.setId(LimitConstants.ASSERTION_LIMIT);
limits.add(businessLimit);
limits.add(serviceLimit);
limits.add(bindingLimit);
limits.add(tModelLimit);
limits.add(assertionLimit);
```

3. Create Tier object:

```
Tier tier = new Tier(tierInfo, limits);
```

4. Invoke create Tier and retrieve created tier:

```
Tier createdTier = uddiNode.createTier(tier);
```

5. Inspect generated tier ID of created tier:

```
tierId = createdTier.getId();
System.out.println("created tier has ID: " + tierId);
```

getTierDetail

Returns the Tier object for the given tier ID. The Tier class has getter methods for the tier ID, tier name and description (as set by the administrator), and the collection of Limit objects which specify how many of each UDDI entity type may be published by UDDI publishers allocated to the tier. The isDefault method indicates whether the tier is the default tier, that is, the tier that is allocated to UDDI publishers when auto registration is enabled.

1. Invoke getTierDetail:

```
Tier tier = uddiNode.getTierDetail("2");
```

updateTier

Updates tier contents with the supplied Tier object.

1. Update an existing Tier object (which may have been newly instantiated, or returned by the getTierDetail or createTier operations). This example retains the tier name and description, and all the limit values except the limit being updated:

```
modifiedTier.setName(tier.getName());
modifiedTier.setDescription(tier.getDescription());

Limit tModelLimit = new Limit();
tModelLimit.setId(LimitConstants.TMODEL_LIMIT);
tModelLimit.setIntegerValue(50);

List updatedLimits = new ArrayList();
updatedLimits.add(tModelLimit);

modifiedTier.setLimits(updatedLimits);
```

2. Invoke updateTier:

```
uddiNode.updateTier(modifiedTier);
```

getTierInfos

Returns collection of lightweight tier descriptor objects (TierInfo) which contain the tier ID, and tier name and description values, and whether the tier is the default tier.

1. Invoke getTierInfos:

```
List tierInfos = uddiNode.getTierInfos();
```

2. Output content of each TierInfo:

```
if (tierInfos != null) {

  for (Iterator iter = tierInfos.iterator(); iter.hasNext();) {
     TierInfo tierInfo = (TierInfo) iter.next();
     System.out.println(tierInfo);
  }
}
```

setDefaultTier

Specifies the tier with the given tier ID is the default tier. The default tier is the tier that is allocated to UDDI publishers when auto registration is enabled. Typically this would be set to a tier with low publish limits to prevent casual users publishing too many entities.

1. Invoke setDefaultTier:

```
uddiNode.setDefaultTier("4");
```

deleteTier

Removes the tier with the given tier ID. Tiers can only be removed if they have no UDDI publishers assigned to them, and the tier is not the default tier.

1. Invoke deleteTier:

```
uddiNode.deleteTier("4");
```

getUserCount

Returns the number of UDDI publishers assigned to tier specified by the tier ID.

1. Invoke getUserCount:

```
Integer userCount = uddiNode.getUserCount("4");
System.out.println("users in tier 4: " + userCount.intValue());
```

getLimitInfos

Returns collection of Limit objects representing the limit values for each type of UDDI entity. Limits are used in Tier objects.

1. Invoke getLimitInfos:

```
List limits = uddiNode.getLimitInfos();
```

2. Output the ID and limit value for each Limit object:

```
for (Iterator iter = limits.iterator(); iter.hasNext();) {
  Limit limit = (Limit) iter.next();

  System.out.println("limit ID: "
                     + limit.getId()
                     + ", limit value: "
                     + limit.getIntegerValue());
}
```

Managing UDDI Publishers

UDDI publishers are managed using the UddiNode MBean operations createUddiUser, createUddiUsers, updateUddiUser, deleteUddiUser, getUddiUser, getUserInfos, getEntitlementInfos, assignTier, getUserTier. An example is provided for each, making use of the UddiNodeProxy client class.

See ManagePublishersSample class for sample code that demonstrates the attributes and operations described in this section.

createUddiUser

Registers a single UDDI publisher, in a specified tier, with specified entitlements. The UddiUser class represents the UDDI publisher, and this is constructed using a user ID, a TierInfo object which specifies the tier ID to allocate the UDDI publisher to, and a collection of Entitlement objects which specify what the UDDI publisher is permitted to do.

Tip: to allocate the UDDI publisher default entitlements, set the entitlements parameter to null.

1. Create the UddiUser object:

```
UddiUser user = new UddiUser("user1", new TierInfo("3"), null);
```

2. Invoke createUddiUser:

```
uddiNode.createUddiUser(user);
```

createUddiUsers

Registers multiple UDDI publishers. This example shows how to register 7 UDDI publishers in one call, with default entitlements.

1. Create TierInfo objects for tiers that publishers will be allocated to:

```
TierInfo tier1 = new TierInfo("1");
TierInfo tier4 = new TierInfo("4");
```

2. Create UddiUser objects for each UDDI publisher, specifying tier to allocate to:

```
UddiUser publisher1 = new UddiUser("Publisher1", tier4, null);
UddiUser publisher2 = new UddiUser("Publisher2", tier4, null);
UddiUser publisher3 = new UddiUser("Publisher3", tier4, null);
UddiUser publisher4 = new UddiUser("Publisher4", tier1, null);
UddiUser publisher5 = new UddiUser("Publisher5", tier1, null);
UddiUser cts1 = new UddiUser("cts1", tier4, null);
UddiUser cts2 = new UddiUser("cts2", tier4, null);
```

3. Add the UddiUser objects to a List:

```
List uddiUsers = new ArrayList();

uddiUsers.add(publisher1);
uddiUsers.add(publisher2);
uddiUsers.add(publisher3);
uddiUsers.add(publisher4);
uddiUsers.add(publisher5);
uddiUsers.add(cts1);
uddiUsers.add(cts2);
```

4. Invoke createUddiUsers:

```
uddiNode.createUddiUsers(uddiUsers);
```

updateUddiUser

Updates a UDDI publisher with the details in the supplied UddiUser object. This is typically used to change the tier of one UDDI publisher or update their entitlements. Tip: only supply the entitlements you want to update – the remainder of available entitlements will retain their existing value.

1. Create Entitlement objects with appropriate permission. (the entitlement IDs are found in EntitlementConstants:

```
Entitlement publishUuiDKeyGenerator =
    new Entitlement(PUBLISH_UUID_KEY_GENERATOR, true);
Entitlement publishWithUuidKey =
    new Entitlement(PUBLISH_WITH_UUID_KEY, true);
```

2. Add Entitlement objects to a List:

```
List entitlements = new ArrayList();
entitlements.add(publishUuiDKeyGenerator);
entitlements.add(publishWithUuidKey);
```

3. Update a UddiUser object with the updated entitlements:

```
user.setEntitlements(entitlements);
```

4. Invoke updateUddiUser:

```
uddiNode.updateUddiUser(user);
```

getUddiUser

Retrieves details about a UDDI publisher in the form of a UddiUser object. This specifies the UDDI publisher ID, information about the tier they are assigned to and the entitlements they possess.

1. Invoke getUddiUser:

```
UddiUser user1 = uddiNode.getUddiUser("user1");
```

2. Output the contents of UddiUser:

```
System.out.println("retrieved user: " + user1);
```

getUserInfos

Returns a collection of UserInfo objects. Each UserInfo represents a UDDI publisher known to the UDDI node, and the name of the tier they are allocated to. To get details about a specific UDDI publisher, including the tier ID, and entitlements, use the getUddiUser operation.

1. Invoke getUserInfos:

```
List registeredUsers = uddiNode.getUserInfos();
```

2. Output the UserInfo objects:

```
System.out.println("retrieved registered users: ");
System.out.println(registeredUsers);
```

getEntitlementInfos

Returns a collection of Entitlement objects. Each entitlement is a property that controls whether permission is granted to a UDDI publisher to perform a specified action.

1. Invoke getEntitlementInfos:

```
List entitlementInfos = uddiNode.getEntitlementInfos();
```

2. Specify where to find message resources:

```
String messages = "com.ibm.uddi.v3.management.messages";
ResourceBundle bundle = ResourceBundle.getBundle(
                                    messages, Locale.ENGLISH);
```

3. Iterate through the Entitlement objects, displaying the ID, name and description:

```
for (Iterator iter = entitlementInfos.iterator(); iter.hasNext();) {
  Entitlement entitlement = (Entitlement) iter.next();

  StringBuffer entitlementOutput = new StringBuffer();

  String entitlementId = entitlement.getId();
  String entitlementName =
              bundle.getString(entitlement.getNameKey());
String entitlementDescription =
              bundle.getString(entitlement.getDescriptionKey());

  entitlementOutput.append("Entitlement id: ");
  entitlementOutput.append(entitlementId);
  entitlementOutput.append("\n  name: ");
  entitlementOutput.append(entitlementName);
  entitlementOutput.append("\n  description: ");
  entitlementOutput.append(entitlementDescription);

  System.out.println(entitlementOutput.toString());
}
```

deleteUddiUser

Removes the UDDI publisher with the specified user name (ID) from the UDDI registry.

1. Invoke deleteUddiUser:

```
uddiNode.deleteUddiUser("user1");
```

assignTier

Assigns UDDI publishers with supplied IDs to the specified tier. This is useful when you want to restrict several UDDI publishers, perhaps by assigning them all to a tier that doesn't allow publishing of any entities.

1. Create list of publisher IDs:

```
List uddiUserIds = new ArrayList();

uddiUserIds.add("Publisher1");
uddiUserIds.add("Publisher2");
uddiUserIds.add("Publisher3");
uddiUserIds.add("Publisher4");
uddiUserIds.add("Publisher5");
uddiUserIds.add("cts1");
uddiUserIds.add("cts2");
```

2. Invoke assignTier:

```
uddiNode.assignTier(uddiUserIds, "0");
```

getUserTier

Returns information about the tier a UDDI publisher is assigned to. The returned TierInfo has getters methods for retrieving the tier ID, tier name, tier description, and whether the tier is the default tier.

1. Invoke getUserTier:

```
TierInfo tierInfo = getUserTier("Publisher3");
```

2. Output the contents of the TierInfo object:

```
System.out.println(tierInfo);
```

Managing Value Sets

Value sets are represented in a UDDI registry as value set tModels, with a UDDI types keyedReference with value 'categorization'. Such value sets are backed with a set of valid values and for user defined value sets, this data is loaded into the UDDI registry using UddiNode MBean operations (although it is more convenient to use the User defined value set tool for this purpose). Each value set can be controlled by policy as being supported or not supported. When a value set is supported by policy, it can be referenced within UDDI publish requests. The UddiNode operations available to manage value sets and their data are: getValueSets, getValueSetDetail, getValueSetProperty, updateValueSet, updateValueSets, loadValueSet, changeValueSetTModelKey, unloadValueSet and isExistingValueSet.

See ManageValueSetsSample class for sample code that demonstrates the attributes and operations described in this section.

getValueSets

Returns collection of ValueSetStatus objects.

1. Invoke getValueSets:

```
List valueSets = uddiNode.getValueSets();
```

2. Cast each element to ValueSetStatus and output contents:

```
for (Iterator iter = valueSets.iterator(); iter.hasNext();) {

  ValueSetStatus valueSetStatus = (ValueSetStatus) iter.next();
  System.out.println(valueSetStatus);
}
```

getValueSetDetail

Returns ValueSetStatus object for the given value set tModel key.

1. Invoke getValueSetDetail:

```
uddiNode.getValueSetDetail(
                "uddi:uddi.org:ubr:categorization:naics:2002");
```

2. Retrieve and display details:

```
String name = valueSetStatus.getName();
String displayName = valueSetStatus.getDisplayName();
boolean supported = valueSetStatus.isSupported();

System.out.println("name: " + name);
System.out.println("display name: " + displayName);
System.out.println("supported: " + supported);
```

3. Display value set properties:

```
List properties = valueSetStatus.getProperties();

for (Iterator iter = properties.iterator(); iter.hasNext();) {

  ValueSetProperty property = (ValueSetProperty) iter.next();
  System.out.println(property);
}
```

getValueSetProperty

Returns a property of a value set as a ValueSetProperty object. This is mainly for use by the administrative console to render properties of a value set as a row in a table. For example, one such property is the keyedReference which indicates whether the value set is checked.

1. Invoke getValueSetProperty:

```
uddiNode.getValueSetProperty(
                "uddi:uddi.org:ubr:categorization:naics:2002",
                ValueSetPropertyConstants.VS_CHECKED);
```

2. Read and display boolean value of the property:

```
boolean checked = valueSetProperty.getBooleanValue();

System.out.println("checked: " + checked);
```

updateValueSet

Updates value set status. Only the supported attribute can be updated (all other setter methods are used by the UDDI application).

1. Create a ValueSetStatus object specifying the tModel key and the updated supported value:

```
ValueSetStatus updatedStatus = new ValueSetStatus();
updatedStatus.setTModelKey(
                "uddi:uddi.org:ubr:categorization:naics:2002");
updatedStatus.setSupported(true);
```

2. Invoke updateValueSet:

```
uddiNode.updateValueSet(updatedStatus);
```

updateValueSets

Updates value set status for multiple value sets. As for the updateValueSet operation, only the supported attribute is updated.

1. Populate List with updated ValueSetStatus objects:

```
List valueSets = new ArrayList();

ValueSetStatus valueSetStatus = new ValueSetStatus();
valueSetStatus.setTModelKey(
                "uddi:uddi.org:ubr:categorization:naics:2002");
valueSetStatus.setSupported(false);
valueSets.add(valueSetStatus);
```

```
valueSetStatus = new ValueSetStatus();
 valueSetStatus.setTModelKey(
                "uddi:uddi.org:ubr:categorizationgroup:wgs84");
valueSetStatus.setSupported(false);
valueSets.add(valueSetStatus);

valueSetStatus = new ValueSetStatus();
valueSetStatus.setTModelKey(
                "uddi:uddi.org:ubr:identifier:iso6523:icd");
valueSetStatus.setSupported(false);
valueSets.add(valueSetStatus);
```

2. Invoke updateValueSets:

```
uddiNode.updateValueSets(valueSets);
```

loadValueSet

Loads values for a value set from a UDDI registry V3/V2 taxonomy data file on the local file system. Note: there is also a loadValueSet operation that takes a ValueSetData object but this is only for use by the user defined value set tool.

1. Invoke loadValueSet:

```
uddiNode.loadValueSet(
                      "/valuesets/myvalueset.txt",
                      "uddi:cell:node:server:myValueSet");
```

changeValueSetTModelKey

Any value set values that were allocated to one value set tModel are allocated to the new value set tModel.

1. Invoke changeValueSetTModelKey with old and new tModel keys:

```
uddiNode.changeValueSetTModelKey(
             "uddi:cell:node:server:myValueSet",
             "uddi:cell:node:server:myNewValueSet");
```

unloadValueSet

Unloads values for a value set with the given tModel key.

1. Invoke unloadValueSet:

```
uddiNode.unloadValueSet("uddi:myValueSet");
```

isExistingValueSet

Determines if value set data exists for the given tModel key.

1. Invoke isExistingValueSet and display result:

```
boolean exists = uddiNode.isExistingValueSet(
                "uddi:uddi.org:ubr:categorization:naics:2002");
System.out.println("NAICS 2002 is a value set: " + exists);
```

User-defined value set support in the UDDI registry

The UDDI Version 3 registry provides the structure and modeling tools to find information within a registry effectively. Users can define multiple value sets and add custom value sets. In UDDI Version 2, this functionality was called custom taxonomy support.

Data is worthless if it is lost within a mass of other data and cannot be distinguished or discovered. If a client of UDDI cannot effectively find information within a registry, the purpose of UDDI is considerably compromised. Providing the structure and modeling tools to address this problem is at the heart of UDDI's design. The verification of data within UDDI is core to its mission of description, discovery and integration. It achieves this by several means.

It allows users to define multiple value sets that can be used in UDDI. In such a way, multiple classification schemes can be overlaid on a single UDDI entity. This capability allows organizations to extend the set of such systems UDDI registries support. One is not tied to a single system, but can rather employ several different classification systems simultaneously.

While default value sets are shipped with the product, the UDDI Version 3 registry provides tools enabling 'custom' value sets to be added, potentially enabling UDDI entities to be more specifically categorized when published and further enhancing the capability of client to find specific data.

These value sets can be either checked or unchecked, and this is indicated via a keyedReference in the categoryBag of the tModel that represents a value set (a ″categorization tModel″). These keyedReferences have the tModel key for uddi-org:types and are added to the categoryBag to further describe the behavior of the categorization tModel, as follows:

checked
: Marking a tModel with this classification asserts that it represents a categorization, identifier, or namespace tModel that has a validation service to check that category values are present in a specified value set.

unchecked
: Marking a tModel with this classification asserts that it represents a categorization, identifier, or namespace tModel that does not have a validation service.

The procedure defined below describes how to add additional user-defined value sets, and display their allowed values in the UDDI user console value set tree display. Rational Application Developer has a Web Services Explorer user interface that also allows addition and display of custom checked value sets. The publisher of a value set categorization tModel may specify a 'display name' for use in UDDI user console implementations.

Procedure for adding a user defined value set

To add a user defined value set to the UDDI registry, perform the following tasks:

1. Publish a categorization tModel
2. Load the user defined value set data
3. Set the value set to **supported** status using the Administrative console. To do this you must be a user in an administrative role. This means that user defined value sets cannot be added to the UDDI registry without administrator permission.

The checked value set will only be referenced when the above tasks are complete. Value set data must be provided for validating checked value sets.

Value set data may also be used by user consoles for unchecked value sets, but it is not a requirement and is usually only used for presentation of deprecated value sets, such as unspc-org:unspc and back-level compatibility.

If the value set is checked, any publish requests that have a categoryBag containing keyedReferences with the new categorization tModel will be validated. If there is value set data corresponding to the categorization tModel in the registry database, only valid values will be accepted. If there is no value set data in the database **all** values will be rejected, and the publish request will fail. If the categorization tModel is unchecked, all values will be allowed, regardless of whether there is a corresponding value set present in the UDDI registry database. The value set tModel is not available for use until the administrator enables support for it using the administrative console, or the JMX interface.

Suggested approach

To introduce a new value set:

1. Publish the categorization tModel with a keyedReference of type 'uddi-org:categorization:types' with a key value of **categorization**, a keyedReference of type 'uddi-org:categorization:types' with a Key

Name of **'Checked value set'** and a Key Value of **'checked'**, or a Key Name of **'Unchecked value set'** and a Key Value of **'unchecked'** and a keyedReference of type 'uddi-org:categorization:general_keywords' supplying the value set display name (as described below).
2. Load user defined value set data into the UDDI registry database using the UDDIUserDefinedValueSet utility (described below).
3. Use the administrative Console to set the status of the value set to supported (as described in Value set settings). This can also be achieved directly using the JMX interface.

Note: The SOAP and EJB interfaces will be able to make use of categorization tModels as soon as they are published. However, the UDDI registry user console will require a restart of the UDDI application because it currently gathers its list of categorizations for use in the value set tree display when the application starts.

Publishing a Checked Categorization tModel

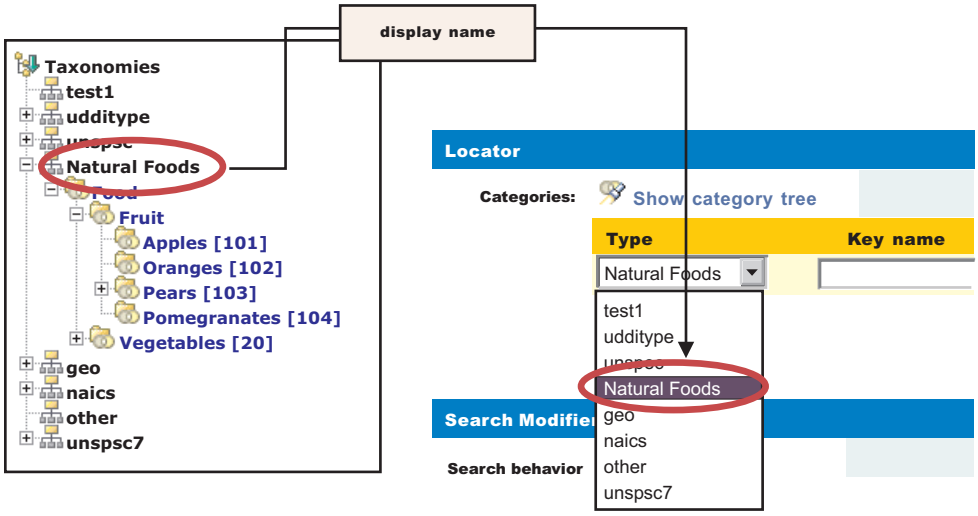
This section describes how to publish a checked categorization tModel with the **'Checked value set'** Key Name for use by a user defined value set.

Publish a tModel to the UDDI registry with a categoryBag containing keyedReferences as follows:

Note	tModelKey	KeyName	KeyValue
1	uddi:uddi-org:categorization:types In the UDDI registry user interface this tModelKey can be chosen by selecting the category type of **UDDI Types**	**categorization**	**categorization**
2	uddi:uddi-org:categorization:types In the UDDI registry user interface this tModelKey can be chosen by selecting the category type of **UDDI Types**	**Checked value set**	**checked**
3	uddi:uddi-org:categorization:general_keywords In the UDDI registry user interface this tModelKey can be chosen by selecting the category type of **categorization:general_keywords**	**urn:x-ibm:uddi:customTaxonomy:displayName**	*<User Defined Value Set displayName>*

1. Indicates this tModel is a categorization tModel (required).
2. Indicates use of the tModel will be checked against a list of valid data (required). (Omitting this keyedReference, or explicitly specifying a value of 'unchecked' will indicate this categorization is unchecked).
3. Indicates special use of the general keywords value set, with a proprietary uniform resource name (URN) as the keyName value, defines a name for the user-defined value set that is intended for use in user console implementations where the full tModel name might be too long. The value can be 1-255 characters (inclusive) long.

The displayName is intended to provide a way to label a value set such that, when the UDDI user console displays it in a value set tree or in a pull-down list of available value sets, the meaning is clear to the user without being restricted to 8 characters and without needing to be the same as the published tModelName, which could be as long as 255 characters. An example is shown below:



The urn:x-ibm:customTaxonomy:displayName should be unique if only to avoid confusion when displayed in user interfaces but this is not validated.

To publish a new categorization tModel using SOAP, the message would be:

```
<save_tModel generic="3.0" xmlns="urn:uddi-org:api_v3">
  <authInfo></authInfo>>
  <tModel tModelKey="">
    <name>Natural Foods tModel</name>
    <categoryBag>
      <keyedReference tModelKey="uddi:uddi.org:categorization:types" keyName="categorization"
                      keyValue="categorization"/>
      <keyedReference tModelKey="uddi:uddi.org:categorization:types" keyName="Checked value set"
                      keyValue="checked"/>
      <keyedReference tModelKey="uddi:uddi.org:categorization:general_keywords"
                      keyName="urn:x-ibm:uddi:customTaxonomy:displayName" keyValue="Natural Foods"/>
    </categoryBag>
  </tModel>
</save_tModel>
```

Note: to specify an unchecked categorization substitute the key name **'Checked value set'** with **'Unchecked value set'** and **'checked'** Key Value with **'unchecked'** or, more simply, omit the keyedReference completely.

Loading User Defined Value Set Data

User Defined Value Set Data File Format

Value set data is identified by a unique code value, an optional description and a parent code that specifies its relationship with other code values. Value set data must adhere to this format:

Column name	Maximum length	Description of use
Code	765	Unique value within the value set used for validation
description	765	Typically used by UDDI user consoles and optionally in the keyedReference as the keyName value
parentcode	765	Indicates which existing **code** is the logical parent of this one, and is used in tree displays

Typically columns are delimited in the value set data file by '#' characters as in this example:

```
00#Food#00
10#Fruit#00
101#Apples#10
102#Oranges#10
103#Pears#10
1031#Anjou#103
1032#Conference#103
1033#Bosc#103
104#Pomegranates#10
20#Vegetables#00
201#Carrots#20
202#Potatoes#20
203#Peas#20
204#Sprouts#20
```

In the example, 'Food' is the description for the root node with child nodes of 'Fruit' and 'Vegetables' (both of these have parentcode values the same as the code value for 'Food').

The value set data in the example file could then be rendered in a tree like this:

```
Food
  Fruit
    Apples
    Oranges
    Pears
      Anjou
      Conference
      Bosc
    Pomegranates
  Vegetables
    Carrots
    Potatoes
    Peas
    Sprouts
```

The file must be saved in UTF-8 format.

Custom Taxonomy files used in UDDI Version 2 are also supported by the utility.

UDDIUserDefinedValueSet

A utility is provided to load value set data into the UDDI registry, assign existing value set data to another tModel and unload existing value set data. This utility uses the UDDI registry's JMX interface and therefore requires a number of connection parameters.

```
Usage: UDDIUserDefinedValueSet '{'function'}' [options]

function:
-load <path> <key>         Load value set data from specified file
-newKey <oldKey> <newKey>  Move value set to a new tModel
-unload <key>              Unload existing value set

options:
-properties <path>         Specify location of configuration file
-host <host name>          Application Server host
-port <port>               SOAP Lister port number
-node <node name>          Node running a UDDI server
-server <server name>      Server with UDDI deployed
-columnDelimiter <delim>   Character delimiter to denote field end
-stringDelimiter <delim>   Character delimiter to denote strings

Connector security parameters

-userName <name>
-password <password>
```

```
-trustStore <path>
-trustStorePassword <password>
-keyStore <name>
-keyStorePassword <password>
```

Note: Ensure that the command window from which the UDDIUserDefinedValueSet is run is using a suitable codepage and font for displaying the characters contained in the value set name. Use of an incorrect codepage/font may result in unclear messages on a successful load, and create difficulty using the -unload and -newKey options.

The UDDIUserDefinedValueSet script is located in the *app_server_root*/bin directory.

If no connection parameters are supplied a connection is sought on the local host using the default Application Server SOAP port number.

Command arguments are case insensitive.

Usage examples

Load a value set data for a tModel on the local UDDI registry using the percent sign as a column marker in the valuesetdata.txt file.

Move value set data from one checked tModel to another on a UDDI registry in a network deployment configuration.

Unload a value set from a tModel from a server with security turned on supplying the connection and security parameters in myproperties.properties file, but supplying the server and password arguments on the command line (which augment or override those contained in the properties file).

The configuration file, if specified by the optional **-properties** parameter, determines a number of optional parameters. These parameters can be specified on the command line and, if so, override the values in the properties file. These parameters are largely JMX connection parameters and security parameters.

The string.delimiter is typically used where a description value contains the same character as the column delimiter character. For example, if the column.delimiter was set to ',' (a comma), and there was a value set description value of 'Fruits, citrus', you could include this in the value set data file by setting the string.delimiter to ″ (double quote) and enclosing the description in quotes: 'Fruits, citrus'. Note that the quote character is escaped with a backslash ('\') to indicate the literal character is to be used.

If an attempt is made to load a value set to a tModel that has existing value set data, a warning message is given. To override this error provide the **-override** argument. This argument is also required if moving value set data to a new tModel using **-newKey** where the tModel is **checked**, and also unloaded value set data for a **checked** tModel.

Command line arguments and example data	Property and example data	Comments
-columnDelimiter #	column.delimiter=#	The column delimiter that is used in value set data files
-stringDelimiter \″	string.delimiter=\″	The field delimiter (this value must be different to the column.delimiter value)
-host ibm.com®	host=ibm.com	The host name of the system that is running the application server
-port 8880	port=8880	The SOAP port number of the application server

-node ibmNode	node=ibmNode	The name of the node that is running the server with the UDDI registry
-server server1	server=server1	The server that is running the UDDI registry
-userName ibmuser	security.username=ibmuser	The user name. This value is required if WebSphere Application Server security is turned on
-password mypassword	security.password=mypassword	The password
-trustStore /TrustStoreLocation	security.truststore=/TrustStoreLocation	The truststore file location
-keyStore ibmkeystore	security.keystore=ibmkeystore	The keystore name
-trustStorepassword trustpass	security.truststore.password=trustpass	The truststore password
-keyStorePassword keypass	security.keystore.password=keypass	The keystore password

Set the value set to supported

Use the administrative console to set the value set to **supported** by:

- Click *UDDI Nodes* > *<node>* and *Value Sets* (under Additional Properties on the right of the screen)
- Select the Value Set (by checking the box next to it)
- Click *Enable Support* above the list of Value Sets

Validation and Error Handling

The UDDI registry user console performs validation while a save tModel request is being built, that is, before the publish occurs. For example, if the user tries to add two customTaxonomy:displayName keyedReferences the following message is displayed:

```
Advice: Only one 'urn:x-ibm:uddi:customTaxonomy:displayName' key name is allowed for the 'Other' taxonomy.
```

If a keyedReference containing a keyName value that starts with 'urn:x-ibm:uddi:customTaxonomy:' is followed by anything other than 'displayName', the following message is displayed:

```
Advice: Only key name values of 'urn:x-ibm:uddi:customTaxonomy:displayName' are supported.
```

For requests where the save_tModel message may have multiple tModels, if any one of the tModels is a categorization tModel and it fails validation, the request fails with a UDDIInvalidValueException (plus additional information explaining the likely cause), and none of the tModels is published. For example:

```
E_invalidValue (20200) A value that was passed in a keyValue attribute did not pass validation.
This applies to checked categorizations, identifiers and other validated code lists. The error
text will clearly indicate the key and value combination that failed validation. Invalid 'custo
mTaxonomy:dbKey' keyValue [naics] in keyedReference. KeyValue already in use by tModelKey[UUID:
C0B9FE13-179F-413D-8A5B-5004DB8E5BB2]
```

UDDI Utility Tools

The UDDI Utility Tools is a suite of functions that you can use to migrate, move, or copy UDDI Version 2 entities, including child entities and their respective Version 2 entity keys, into a Version 3 UDDI registry.

Note: The UDDI Version 3 publish API supports publisher assigned keys (the Version 2 API did not) and promotion of entities between Version 3 registries can be achieved using normal API functions. UDDI Utility Tools supplied in this release is functionally equivalent to the version supplied in WebSphere Application Server 5.1. However, it is important to know that all UDDI Utility Tools functions in this release are performed using the UDDI Version 2 API. You can export from Version 2 and 3 registries (supplying only the Version 2 representation of the UDDI Entity key) and import into the Version 3 registry, using Version 2 API types. Entities from a Version 3 registry are exported

as Version 2 entities and, as such, elements such as digital signatures will not be present. See section Saving Version 3 entities with a supplied key for an example on how to use the Version 3 API to assign your own keys to Version 3 entities.

Other uses of the tool include:

- Search and select entities from a source UDDI registry by specifying Version 2 keys or search criteria
- Publishing canonical tModels in a UDDI registry, including child entities
- Persist UDDI (Version 2) entities in an intermediate XML representation that can be used to customize and copy those entities to multiple target UDDI Registries, by specifying Version 2 Keys
- Update existing entities in a target UDDI registry, including child entities
- Delete selected entities from a target UDDI registry by specifying Version 2 keys

Use the UDDI Utility Tools by running the UDDIUtilityTools.jar file. This file is located in the *app_server_root*/UDDIReg/scripts directory. Alternatively, you can invoke all of the functions of UDDI Utility Tools through the supplied public Java API.

There are five main functions in UDDI Utility Tools:

Export

Given an entity type and key, or a list of entity types and keys, UDDI Utility Tools gets the UDDI entities from the specified registry and writes them to the UDDI Entity Definition File. The entity type for each key can be one of business, service, bindingTemplate or tModel. The Entity Definition File contains XML that exactly describes each of the specified entities, according to the UDDI Utility Tools schema (which includes the UDDI Version 2 schema). The UDDI Entity Definition File separates entities by type, and automatically detects and records tModels referenced by the specified entities. You can use the 'referenced tModels' section of the file to ensure a target registry includes any referenced tModels before you try to import new entities to that registry.

Import

Given a list of UDDI entities (which can be supplied using the UDDI Entity Definition File generated by the export function, possibly with additional editing, or programmatically in a container object), the import function detects if the entities already exist in the target registry and, if they do not, creates a minimal entity (″stub″) with the specified key. The entities are then published updating the stubs with the supplied data and overwriting, or ignoring, existing entities as specified by the user. Note that the original key is maintained throughout.

Promote

Combines the export and import steps such that the specified entities are extracted (by key) from the source registry and then imported into the target registry in a single logical step. The generation of a UDDI Entity Definition File is optional for this function.

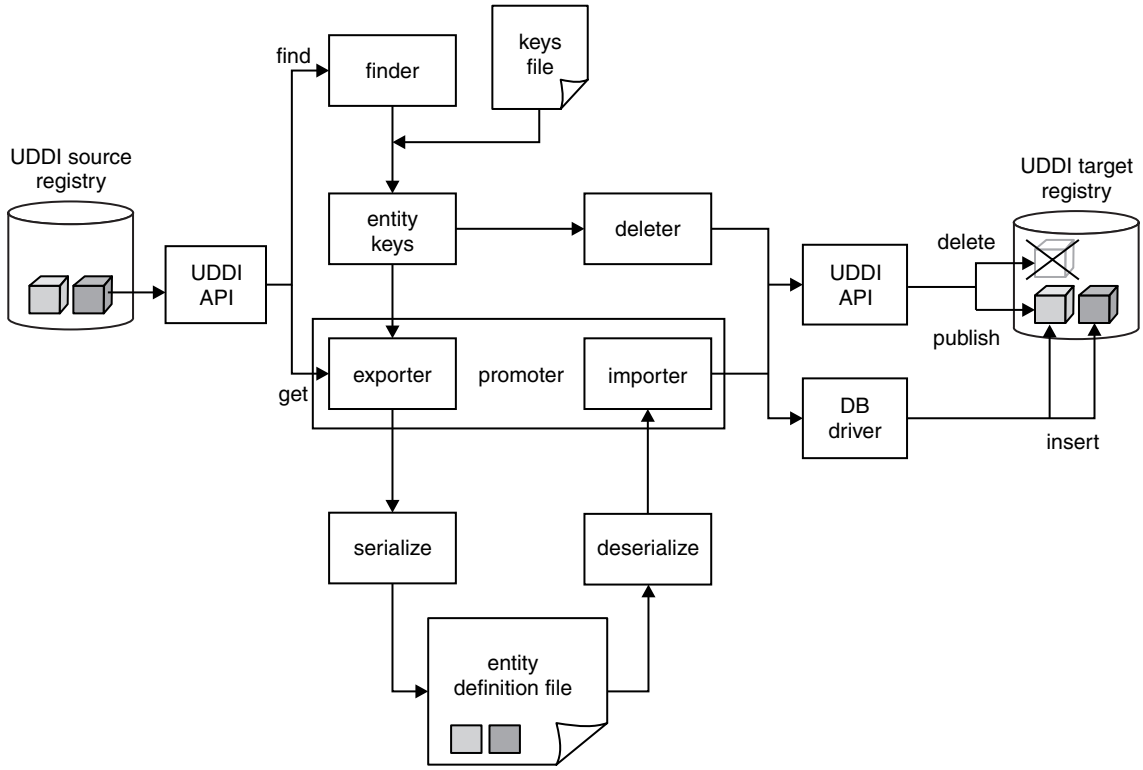
Delete Deletes the specified entities from the target UDDI registry. The entities to delete are specified as an entity type, or a list of entity types, and keys, in the same way as for the export function.

Find Matching Entities

Takes as input search criteria in the form of UDDI Inquiry API objects for each of the various entity types. The set of entities that match the search criteria are used to generate a list of entity keys, and this in turn can be used as input to the export, promote and delete functions.

Note: This function is available only through the programmatic API.

The relationship between the functions, their input and output, and the source and target UDDI Registries is shown in this conceptual overview diagram:



Setting up the configuration file

Configuration data for UDDI Utility Tools resides in a configuration properties file, which describes the runtime environment, UDDI and database locations and access information, logging information, security configuration, entity definition file location, and other flags to control whether referenced entities are to be imported and/or overwritten.

UDDI Utility Tools is distributed with a sample configuration properties file (UDDIUtilityTools.properties) and this is searched for by default in the current directory if no properties path is specified. By default, this file is located in the *app_server_root*/UDDIReg/scripts directory. Modify the file, according to the following list, and specify this modified file when running the utility tools.

- Set the classpath, which should include the current directory (.) and the UDDIUtilityTools.jar itself, plus all the dependent jars, which are listed in the Prerequisites section later on in this topic. The classpath must include the database driver jar (for example db2java.zip).

  If you are configuring a JSSE provider, add the .jar file which contains the provider to the classpath. The configuration of a JSSE provider is optional and is performed by setting the `jsse.provider` property. The default value is com.ibm.jsse.IBMJSSEProvider. To specify the FIPS JSSE provider set the value of the `jsse.provider` property to com.ibm.fips.jsse.IBMJSSEFIPSProvider.
- Set other properties, which are commented in the sample UDDIUtilityTools.properties file as shown below.
- Change localhost to the name of your server.
- Change the port number 9080 to your internal HTTP port.

```

```

Prerequisites

Ensure that the following .jar files are available to the UDDI Utility Tools. The locations of the .jar files should be specified in the classpath property in the UDDI Utility Tools properties file:

UDDIUtilityTools.jar
This is the tools JAR itself and is located in *app_server_root*/UDDIReg/scripts.

com.ibm.uddi.jar
This file contains the UDDI4J classes and is located in *app_server_root*/plugins.

j2ee.jar
This file contains some required Java platform for enterprise applications classes, and is located in *app_server_root*/lib.

com.ibm.ws.runtime.jar
This is the Apache SOAP implementation and is located in *app_server_root*/plugins.

DbDriver
This is the driver needed to allow the UDDIUtilityTool to connect to your target database. See the table below for the values you need to specify for your chosen database:

	DB2	Apache Derby	Oracle
DBDriverLocation for classpath on distributed, Windows and i5/OS platforms	*DB2_HOME*/db2java.zip	*app_server_root*/derby/lib/derbyclient.jar	*ORACLE_HOME*/jdbc/lib/ojdbc6.jar
Driver on distributed, Windows and i5/OS platforms	com.ibm.db2.jdbc.app.DB2Driver, or com.ibm.db2.jcc.DB2Driver if you are using a remote DB2 database (you can also set up a local alias to the remote database using the DB2 client)	com.ibm.db2.jcc.DB2Driver	oracle.jdbc.OracleDriver
URL on distributed, Windows and i5/OS platforms	jdbc:db2://host:*database_name*	jdbc:db2j:net://host:1527/*database_name* (see note below)	jdbc:oracle:thin:@host:1521:*database_name*

where

- *app_server_root* is the directory location of WebSphere Application Server.
- *DB2_HOME* is the directory location of DB2, for example c:\Program Files\SQLLIB\java12\
- *ORACLE_HOME* is the directory location of Oracle, for example c:\oracle\ora92\

- *database_name* is the name of the database. For Apache Derby, make sure that *database_name* includes the path to the database, for example *profile_root*/databases/com.ibm.uddi/UDDI30

Note:

- If you are using Apache Derby, make the database network enabled so that it can handle multiple connections. For further details, refer to the section about managing the Derby Network Server in the Derby Server and Administration Guide.
- If you are using DB2, add DB2_HOME/sqllib/lib to your LD_LIBRARY_PATH and LIBPATH environment variables.

The Security provider configuration section in the above properties file shows the location of the default DummyClientTrustFile.jks file. If you are using your own truststore, ensure that the location is placed here.

The UDDI Utility Tools use UDDI Version 2 SOAP inquiry and publish interfaces. These APIs are protected as described in Access control for UDDI registry interfaces. The UDDI Utility Tools also access the UDDI registry database through the database driver, and access to the database is controlled by the database management system.

The UDDI Entity Definition File

You generate this file by the export and promote functions, or you can choose to create it (either by hand, or by modifying a version of the file output by UDDI Utility Tools specifying the export function). It is the input to the import function.

Note: The extension to the uddi:tModel type to add a 'deleted' attribute is not currently used in UDDI Utility Tools.

The file is validated for well formedness and that it complies with the UDDI Utility Tools schema, shown here.

```
<?xml version="1.0" encoding="UTF-8" ?>

```

UDDI Entity Definition File example for canonical tModels

The example Entity Definition File following shows the five main sections for tModels, businesses, services, bindings and referencedTModels:

UDDI Utility Tools can be used to create new UDDI entities in a target UDDI registry. A typical example of this is to introduce a new canonical tModel, which has a publicly known tModel key.

```
<?xml version="1.0" encoding="UTF-8"?>
<promote:uddiEntities xmlns="urn:uddi-org:api_v2" xmlns:promote="http://www.ibm.com/xmlns/prod/WebSphere/
                      UDDIUtilityTools">

  <!-- tModels -->
  <promote:tModels>

    <tModel tModelKey="uuid:ee3966a8-faa5-416e-9772-128554343571" >
      <name>http://schemas.xmlsoap.org/ws/2002/07/policytmodel</name>
      <description>WS-PolicyAttachment policy expression</description>
    </tModel>
```

```
    <tModel tModelKey="uuid:ad61de98-4db8-31b2-a299-a2373dc97212" >
      <name>uddi-org:wsdl:address</name>
 <description xml:lang="en">
This tModel is used to specify the URL fact that the address must be obtained from the WSDL deployment
file.
      </description>
      <overviewDoc>
        <overviewURL>
http://www.oasis-open.org/committees/uddi-spec/doc/tn/uddi-spec-tc-tn-wsdl-v2.htm#Address
        </overviewURL>
      </overviewDoc>
    </tModel>

  </promote:tModels>

  <!-- businesses -->
  <promote:businesses>
  </promote:businesses>

  <!-- services -->
  <promote:services>
  </promote:services>

  <!-- bindings -->
  <promote:bindings>
  </promote:bindings>

  <!-- referenced tModels -->
  <promote:referencedTModels>
  </promote:referencedTModels>

</promote:uddiEntities>
```

Starting UDDI Utility Tools at a command prompt

Ensure that you are using the correct level of Java code by setting the PATH statement to include the Java code that is supplied with WebSphere Application Server. For example, from the command line, type:

UDDI Utility Tools can be started using:

java - jar UDDIUtilityTools.jar <function> [options]
: using a specified properties file that sets up classpath and other parameters, or it can be called using:

java CommandLineProcessor
: where CommandLineProcessor is the class which processes command line arguments for UDDI Utility Tools, sets up configuration and invokes the appropriate function.

Note: Before you run UDDIUtilityTools.jar from the command line, ensure that you have edited the UDDIUtilityTools.properties file. If you have saved this properties file in a different directory from the directory containing the UDDIUtilityTools.jar file, make sure you specify the location of the properties file as part of the command line arguments. See the Setting up the configuration file section earlier in this topic for more details.

The usage is as follows:

```
Usage: java -jar UDDIUtilityTools.jar {function} [options]

function:
  -promote <entity source>   Promote entities between registries
  -export <entity source>    Extract entities from registry to XML
  -delete <entity source>    Delete entities from registry
  -import                    Create entities from XML to registry

where <entity source> is one of:
  -tmodel|-business|-service|-binding <key> Specify single entity type and key
```

```
  -keysFile | -f <filename>  Specify file containing entity types and keys

options:
  -properties <filename>     Specify path to configuration file
  -overwrite | -o            Overwrite an entity if it already exists
  -log | -v                  Output verbose messages
  -definitionFile <filename> Specify path to UDDI entity definition file
  -importReferenced          Import entities referenced by source entities

The following options override property settings in configuration file:
  -overwrite
  -log
  -definitionFile
  -importReferenced

Example: java -jar UDDIUtilityTools.jar -promote -keysFile /uddikeys.txt
```

Below are a set of UDDI Utility Tools command line examples:

To export a single business to the EDF file specified in a properties file in the current directory.

```
java -jar UDDIUtilityTools.jar -export -business 28B8B928-2B2E-4EC9-A647-1E40651E4752
```

As above but this time using a keys file to specify the entities to be exported

```
java -jar UDDIUtilityTools.jar -export -keysFile /myKeyFiles/keyFile01.txt
```

As above but also specifying verbose output to appear on the command line.

```
java -jar UDDIUtilityTools.jar -export -keysFile /myKeyFiles/keyFile02.txt -v
```

To import the contents of the default EDF specified in a UDDIUtilitiyTools.properties file in the current directory.

```
java -jar UDDIUtilityTools.jar -import
```

As above but also specifying that referenced tModels should be imported into the target registry.

```
java -jar UDDIUtilityTools.jar -import -importReferenced
```

To import the entities from an EDF at the specified location.

```
java -jar UDDIUtilityTools.jar -import -definitionFile /myEDFs/entities01.xml
```

To import the entities from the default EDF including referenced tModels. Overwrite specifies that any entities excluding referenced tModels that are found in the target registry should be overwritten.

```
java -jar UDDIUtilityTools.jar -import -overwrite -importReferenced
```

To promote a single service from a source to a target registry using the properties file at a specified location.

```
java -jar UDDIUtilityTools.jar -promote -service 67961D67-330F-4F14-8210-E74A58E710F3
-properties /UUT/myUUTProps.properties
```

To promote a set of entities specified in a keys file.

```
java -jar UDDIUtilityTools.jar -promote -keysFile /myKeyFiles/keyFile03.txt
```

As above but specifying that existing entities in the target registry get overwritten.

```
java -jar UDDIUtilityTools.jar -promote -keysFile /myKeyFiles/keyFile04.txt -overwrite
```

To promote a set of entities specified in a keys file including referenced tModels.

```
java -jar UDDIUtilityTools.jar -promote -keysFile /myKeyFiles/keyFile05.txt -importReferenced
```

To promote a set of entities specified in a keys file but also create an EDF containing the promoted entities.

```
java -jar UDDIUtilityTools.jar -promote -keysFile /myKeyFiles/keyFile06.txt
-definitionFile /myEDFs/entities02.xml
```

To logically delete a single tModel. Note that it is not possible to physically delete tModels.

```
java -jar UDDIUtilityTools.jar -delete -tModel UUID:1E2B9D1E-E53D-4D36-9D46-6CCC176C466A
```

To delete all the entities specified in the keys file. Note that with the exception tModels all other entities will be physically deleted from the target registry.

```
java -jar UDDIUtilityTools.jar -delete -keysFile /myKeyFiles/keyFile04.txt
```

A keys file example

The following example shows the keys that are to be exported, promoted, or deleted from the target registry:

```
#
# Keys of entities to be exported, promoted from source registry or deleted from target registry
#
# Note: keys must be comma separated and on SAME line
# Note: property names are case sensitive. ('tmodels=' will be ignored)

businesses=97C77097-AC6C-4CA0-A6C4-452F7045C470, 4975E949-581F-4FCA-AD5F-E08280E05F9F
services=BB3864BB-1578-4833-8179-14391F14791F
bindings=
tModels=273F1727-7BFF-4FB5-A1FD-BA5C45BAFD9C
```

Note: If the importReferenced property is set to true, the list of tModels in the referencedTModels section is imported to the target registry. Minimal entities are created if the referencedTModel is new. If the referencedTModel already exists it is never overwritten, regardless of the overwrite property value. This is so that commonly referenced tModels such as categorization tModels do not keep being updated unnecessarily.

Should you need to update a referencedTModel, you must manually move the referencedTModel definition to the tModels section in the entity definition file and set overwrite to true.

Content of the log files

The following examples show the contents of two of the log files that are produced by running the tool. Some comments have been added in square brackets and in italic to highlight important points in the log file. The first is the messages.log, which shows successful and unsuccessful operations for export, import and delete functions:

```

```

Starting UDDI Utility Tools through the API

UDDI Utility Tools provides a public API to functions for exporting, importing, promoting, finding and deleting UDDI entities. All of these functions can be invoked by using the PromoterAPI class. Usage of this class to perform these functions is typically to:

1. Create a Configuration object and populate it from a Properties object or from a configuration properties file.
2. Create a PromoterAPI object passing the Configuration in the constructor.
3. For keys based functions (export, delete and promote), set the keys by supplying a UDDIEntityKeys object, the location of the keys file, or, for one entity, by specifying an entity type and a key value.
4. Invoke the corresponding method for the function required: exportEntities, promoteEntities(boolean), importEntities, deleteEntities or extractKeysFromInquiry(FindTModel, FindBusiness, FindService, FindBinding, FindRelatedBusinesses).

There is some sample code for UDDI Utility Tools, demonstrating usage of the API classes, available from Samples Central.

The ″low-level″ API classes and methods have been deprecated in this release. Refer to the API documentation for details.

Known limitations with UDDI Utility Tools and workarounds

There are some known limitations with UDDI Utility Tools and a workaround for each. See UDDI troubleshooting tips for more information.

Embedded Apache Derby Restriction

The ’export’ and ’delete’ functions when referencing a source registry with an embedded Apache Derby database are supported. However, the ’import’ and ’promote’ functions are not supported when referencing a target registry because of a limitation with the UDDI registry when working with an embedded Apache Derby database. To allow the ’promote’ and ’import’ functions to work, the embedded Apache Derby database needs to be made network enabled. For information about configuring network Apache Derby, refer to the section about managing the Derby Network Server in the Derby Server and Administration Guide.

Saving Version 3 entities with a supplied key

An example of saving a Version 3 business with a defined key is shown below.

```
<?xml version="1.0" encoding="UTF-8"?>
<Envelope xmlns="http://schemas.xmlsoap.org/soap/envelope/">
  <Body>
    <save_business xmlns="urn:uddi-org:api_v3">
      <authInfo>a399c4a3-6387-47cd-a1bd-91f7bb91bdd7</authInfo>
      <businessEntity businessKey="uddi:mycompany-p1.com:computers">
        <name xml:lang="en">WithKey</name>
      </businessEntity>
    </save_business>
  </Body>
</Envelope>
```

Known limitations with UDDI Utility Tools and workarounds

There are known limitations with the UDDI Utility Tools and a workaround for each:

- PublisherAssertions are not supported and will not be promoted.

  Workaround: After the user has promoted the businesses that are related, he must recreate the publisherAssertion relationship.
- Referenced businesses in service projections are not added automatically to the EDF in the same manner as referenced tModels.

  Workaround: Add the referenced business that will 'own' the projected service to the EDF. If the business is not present in the target registry, it should be placed before the service's owning business in the EDF.
- Cycle detection for service projections are not detected in the same manner as for referenced tModels.

  Workaround: If a circular reference is present between two or more service projections, break the cycle by removing one of the projections temporarily, perform the import and update the changed entity to reestablish the cycle in the target registry.
- tModels that were deleted (in the logical sense) in the source registry are imported and promoted as undeleted in the target registry. This is because, in the UDDI Version 2 specification, the deleted state of tModels is not exposed as API calls.

  Workaround: After importing the tModel, perform a delete. This is done using the UDDI Utility Tools delete function, or any other UDDI registry API access method.
- BindingTemplates referenced by hostingRedirectors are not added automatically to the EDF in the same manner as referenced tModels.

  Workaround: Add the referenced bindingTemplate to the EDF.
- Businesses referenced by an 'owningBusiness' keyedReference are not automatically added to the EDF.

  Workaround: Import the referenced business into the target registry before importing the tModel that references it.
- A few combinations of command line arguments are not validated and prevented, for example, it is possible to specify -import with -keysFile <path to file> in the same command, although the -keysFile is ignored.

Java API for XML Registries (JAXR) provider for UDDI

The Java API for XML Registries (JAXR) is a Java client API for accessing both UDDI (Version 2 only) and ebXML registries. It is part of the Java EE specification.

The JAXR API comprises the Java Platform, Enterprise Edition (Java EE) packages javax.xml.registry and javax.xml.registry.infomodel. There is Java EE API documentation at Web Services Reference.

The preferred UDDI Java client APIs are:

- UDDI4J Version 2, for UDDI Version 2
- UDDI Version 3 Client for Java, for UDDI Version 3

JAXR provider

The current JAXR specification (Version 1.0) defines a JAXR provider as an implementation of the JAXR API. Generally, a JAXR provider can be a JAXR provider for UDDI, a JAXR provider for ebXML, or a pluggable provider that supports both UDDI and ebXML. The JAXR provider for UDDI is a provider for UDDI only.

UDDI versions

A JAXR provider for UDDI accesses a UDDI registry using the UDDI Version 2 SOAP APIs only. The UDDI registry for UDDI Version 3 in this version of WebSphere Application Server supports the UDDI Version 1, 2 and 3 SOAP APIs. Therefore you can use the JAXR provider for UDDI to access this registry. You can also use the JAXR provider to access the UDDI registry for UDDI Version 2 in WebSphere Application Server Version 5.x.

To work with the UDDI Version 3 SOAP APIs, use the UDDI Version 3 Client for Java; you cannot use JAXR.

Capability level

The JAXR specification defines two capability profiles, capability level 0 and capability level 1. The JAXR API documentation categorizes each JAXR method as either level 0 or level 1. Generally, a JAXR provider for UDDI has capability level 0 and supports all level 0 methods, while A JAXR provider for ebXML has capability level 1 and supports all level 0 and level 1 methods. The JAXR provider for UDDI is a capability level 0 provider, and supports only level 0 methods.

JAXR for UDDI - getting started and further information

A sample program demonstrates how to get started with the Java API for XML Registries (JAXR). This topic also discusses class libraries, authentication and security, internal taxonomies, and logging and messages.

A simple sample

The following sample program shows how to obtain the ConnectionFactory instance, create a Connection to the registry and save an Organization in the registry.

Replace all references to ″localhost″ with references to the specific iSeries machine on which the UDDI registry is running.

```
import java.net.PasswordAuthentication;
import java.util.ArrayList;
import java.util.Collection;
import java.util.HashSet;
import java.util.Properties;
import java.util.Set;

import javax.xml.registry.BulkResponse;
import javax.xml.registry.BusinessLifeCycleManager;
import javax.xml.registry.Connection;
import javax.xml.registry.ConnectionFactory;
import javax.xml.registry.JAXRException;
import javax.xml.registry.RegistryService;
import javax.xml.registry.infomodel.Key;
import javax.xml.registry.infomodel.Organization;

public class JAXRSample
{
    public static void main(String[] args) throws JAXRException
    {
        //Tell the ConnectionFactory to use the JAXR Provider for UDDI
        System.setProperty("javax.xml.registry.ConnectionFactoryClass",
                                                    "com.ibm.xml.registry.uddi.ConnectionFactoryImpl");
```

```
        ConnectionFactory connectionFactory = ConnectionFactory.newInstance();

        //Set the URLs for the UDDI inquiry and publish APIs.
        //These must be the URLs of the UDDI version 2 APIs.
        Properties props = new Properties();
        props.setProperty("javax.xml.registry.queryManagerURL", "http://localhost:9080/uddisoap/inquiryapi");
        props.setProperty("javax.xml.registry.lifeCycleManagerURL", "http://localhost:9080/uddisoap/publishapi");
        connectionFactory.setProperties(props);

        //Create a Connection to the UDDI registry accessible at the above URLs.
        Connection connection = connectionFactory.createConnection();

        //Set the user ID and password used to access the UDDI registry.
        PasswordAuthentication pa = new PasswordAuthentication("Publisher1", new char[] { 'p', 'a', 's',
                                                                                          's', 'w', 'o', 'r', 'd' });
        Set credentials = new HashSet();
        credentials.add(pa);
        connection.setCredentials(credentials);

        //Get the javax.xml.registry.BusinessLifeCycleManager interface, which contains
        //methods corresponding to UDDI publish API calls.
        RegistryService registryService = connection.getRegistryService();
        BusinessLifeCycleManager lifeCycleManager = registryService.getBusinessLifeCycleManager();

        //Create an Organization (UDDI businessEntity) with name "Organization 1".
        Organization org = lifeCycleManager.createOrganization("Organization 1");

        //Add the Organization to a Collection, ready to be saved in the UDDI registry.
        Collection orgs = new ArrayList();
        orgs.add(org);

        //Save the Organization in the UDDI registry.
        BulkResponse bulkResponse = lifeCycleManager.saveOrganizations(orgs);

        //Obtain the Organization's Key (the UDDI businessEntity's businessKey) from the response.
        if (bulkResponse.getExceptions() == null)
        {
            //1 Organization was saved, so 1 key will be returned in the response collection
            Collection responses = bulkResponse.getCollection();
            Key organizationKey = (Key)responses.iterator().next();
            System.out.println("\nOrganization Key = " + organizationKey.getId());
        }
    }
}
```

Classpath

The class libraries of the JAXR Provider for UDDI are contained within the com.ibm.uddi_1.0.0.jar file, located in the *app_server_root*/plugins directory. When using the JAXR API from within a J2EE application running under WebSphere Application Server, all required classes will automatically be on the classpath. When using the JAXR API from outside this environment, the following jars must be on the Java classpath:

- *app_server_root*/lib/bootstrap.jar
- *app_server_root*/lib/j2ee.jar
- *app_server_root*/plugins/com.ibm.uddi_1.0.0.jar
- *app_server_root*/plugins/com.ibm.ws.runtime_6.1.0

javax.xml.registry.ConnectionFactory

To use the JAXR Provider for UDDI, the name of the ConnectionFactory implementation class must first be specified by setting the System Property “javax.xml.registry.ConnectionFactoryClass” to “com.ibm.xml.registry.uddi.ConnectionFactoryImpl”. Failure to specify this will result in the value defaulting to “com.sun.xml.registry,common.ConnectionFactoryImpl”, which will not be found. This will result in a JAXRException when the ConnectionFactory.newInstance() method is called. The JAXR Provider for UDDI does not support lookup of the ConnectionFactory via JNDI.

javax.xml.registry.Connection Properties

Connection specific properties must be specified by setting a java.util.Properties object on the JAXR ConnectionFactory before obtaining a Connection. The JAXR specification defines the full list of these properties. The table below lists the three most important properties, and what values they should take in order to use the JAXR Provider for UDDI to access the UDDI registry. The only required Connection property is “javax.xml.registry.queryManagerURL”, however it is recommended that “javax.xml.registry.lifeCycleManagerURL” is also set, and that the default value of “javax.xml.registry.security.authenticationMethod” is understood. The rest of the Connection properties defined in the JAXR specification are optional, and their values are not specific to the UDDI registry. The JAXR Provider for UDDI does not define any additional provider-specific properties.

Property	Description
javax.xml.registry.queryManagerURL	The URL of the UDDI registry’s inquiry API for UDDI Version 2. Typically this will be of the form: “http://<hostname>:<port>/uddisoap/inquiryapi”. This property is required.
javax.xml.registry.lifeCycleManagerURL	The URL of the UDDI registry’s publish API for UDDI v2. Typically this will be of the form: “http://<hostname>:<port>/uddisoap/publishapi”. If this property is not specified, it defaults to the value of the javax.xml.registry.queryManagerURL property, however the UDDI registry will typically have different URLs for the inquiry and publish APIs, and it is recommended to specifiy both properties.
javax.xml.registry.authenticationMethod	The method of authentication to use when authenticating with the registry. This may take one of two values, “UDDI_GET_AUTHTOKEN” and “HTTP_BASIC”. The default value is “UDDI_GET_AUTHTOKEN” if none is specified. See section Authentication and Security below for more information.

Authentication and security

Authentication

The javax.xml.registry.authenticationMethod Connection property tells the JAXR Provider which method to use when authenticating with the UDDI registry. The two supported values of this property are “UDDI_GET_AUTHTOKEN” and “HTTP_BASIC”. The JAXR Provider for UDDI does not support the “CLIENT_CERTIFICATE” or “MS_PASSPORT” methods of authentication. If this property is not set, the default authentication method is “UDDI_GET_AUTHTOKEN”.

UDDI_GET_AUTHTOKEN

The JAXR Provider uses the UDDI V2 get_authToken API to authenticate with the registry. The get_authToken call is made automatically by the JAXR Provider when the Connection credentials are set, and the UDDI V2 authToken returned by the call is saved by the JAXR Provider for use on subsequent UDDI publish API calls.

HTTP_BASIC

The JAXR Provider uses HTTP basic authentication to authenticate with the registry. This is supported by WebSphere Application Server when security is on. No UDDI V2 get_authToken API call is made, instead the username and password are sent in the HTTP headers using HTTP basic authentication every time a UDDI API call is made (both inquiry and publish). If the UDDI registry does not require HTTP basic authentication, the credentials are ignored.

The JAXR Provider uses UDDI Version 2 SOAP inquiry and publish APIs. These APIs are protected as described in Access control for UDDI registry interfaces.

USING SSL (Secure Sockets Layer)

SSL can be used to encrypt HTTP traffic between the JAXR Provider for UDDI and the UDDI registry. To use SSL, the JAXR client program should do the following:

1. When setting the “javax.xml.registry.queryManagerURL” and “javax.xml.registry.lifeCycleManagerURL” Connection properties, specify a URL with the protocol “https” and the correct port for using SSL to access the UDDI registry. The UDDI registry’s default port for HTTPS is 9443. Often only the lifeCycleManager URL (the UDDI Publish API URL) will require SSL.
2. Add a new Security Provider to the java.security.Security object, according to the JSSE (Java Secure Sockets Extension) implementation being used. If running under the JVM provided in WebSphere Application Server, the JSSE provided by IBM will automatically be on the classpath. Add the IBM Security Provider as follows:

   ```
   java.security.Security.addProvider(new com.ibm.jsse.JSSEProvider());
   ```
3. Set the System property “javax.net.ssl.trustStore” to be the file name of the client trust store file. The client trust store file is a Java key store (.jks) file and must contain the server certificate of the UDDI registry. Key store files can be managed using the ikeyman tool
4. Set the System property “javax.net.ssl.trustStorePassword”. This is the password used to open the client trust store file.
5. If using an IBM version of JVM that is older than the level provided in this version of WebSphere Application Server, it may be necessary to set the System property “java.protocol.handler.pkgs” to “com.ibm.net.ssl.internal.www.protocol”. For more information on SSL and the ikeyman tool refer to SSL and IKEYMAN within this Information Center.

Internal taxonomies

The JAXR Provider for UDDI supplies the following internal taxonomies:

Taxonomy	ClassificationScheme name (UDDI tModel name)	ClassificationScheme id (UDDI Version 2 tModelKey)
NAICS 1997	ntis-gov:naics:1997	UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2
NAICS 2002	ntis-gov:naics:2002	UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2
UNSPSC 3.1	unspsc-org:unspsc:3-1	UUID:DB77450D-9FA8-45D4-A7BC-04411D14E384
UNSPSC 7	unspsc-org:unspsc	UUID:CD153257-086A-4237-B336-6BDCBDCC6634
ISO3166 2003	ubr-uddi-org:iso-ch:3166-2003	UUID:4E49A8D6-D5A2-4FC2-93A0-0411D8D19E88

The tModels corresponding to all of these taxonomies are available in the UDDI Version 3 registry. If using the JAXR Provider to access a UDDI Version 2 registry, only the tModels corresponding to NAICS 1997, UNSPSC 3.1 and ISO3166 are available.

Custom internal taxonomies

A user may supply their own custom internal taxonomies. To create a new custom internal taxonomy and make it available to the JAXR provider, follow these steps:

1. Create a text file containing the taxonomy element data. As an example, look at the file iso3166-2003-data.txt in plugins/com.ibm.uddi_1.0.0. This is the taxonomy data file for the supplied ISO 3166 taxonomy. The first few lines are:

   ```
   iso3166#--#World#--
   iso3166#AD#Andorra#--
   iso3166#AE#United Arab Emirates#--
   ```

```
iso3166#AE-AJ#'Ajm?n#AE
iso3166#AE-AZ#Ab? Z?aby[Abu Dhabi]#AE
iso3166#AE-DU#Dubayy [Dubai]#AE
iso3166#AE-FU#Al Fujayrah#AE
iso3166#AE-RK#Ra's al Khaymah#AE
iso3166#AE-SH#Ash Sh?riqah [Sharjah]#AE
iso3166#AE-UQ#Umm al Qaywayn#AE
iso3166#AF#Afghanistan#--
iso3166#AF-BAL#Balkh#AF
iso3166#AF-BAM#B?m??n#AF
```

Each line represents one element of the taxonomy, or one Concept in the taxonomy Concept tree. Each line has the form:

```
<taxonomy ID>#<element value>#<element name>#<parent element value>
```

Token	Description
<taxonomy ID>	The taxonomy ID is the same for every element of a taxonomy.
<element value>	The Concept value (UDDI keyValue).
<element name>	The Concept name (UDDI keyName).
<parent element value>	This defines the element's parent element in the taxonomy tree. For every element (except the root element) in the data file, there should be another line which defines the element's parent element. The root element is denoted by defining itself as its own parent. There should be only one root element, and no parentless elements.
#	The delimiter character. This does not have to be "#" and can be defined for each taxonomy in the taxonomyConfig.properties file.

2. Save a ClassificationScheme (UDDI tModel) in the UDDI registry to represent the new internal taxonomy. This can be done using the javax.xml.registry.BusinessLifeCycleManager.saveClassificationSchemes() method.
3. Add the new taxonomy to the taxonomyConfig.properties file:
   a. Copy the supplied taxonomyConfig.properties file from the root of the com.ibm.uddi_1.0.0.jar file.

      The content of the supplied taxonomyConfig.properties file is:

      ```
      naics-1997 = UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2, naics-1997-data.txt, #
      naics-2002 = UUID:1FF729F2-1948-46CF-B660-31EC107F1663, naics-2002-data.txt, #
      unspsc  = UUID:DB77450D-9FA8-45D4-A7BC-04411D14E384, unspsc-data.txt,     #
      unspsc7_data = UUID:CD153257-086A-4237-B336-6BDCBDCC6634, unspsc7-data.txt,    #
      iso3166-2003 = UUID:4E49A8D6-D5A2-4FC2-93A0-0411D8D19E88, iso3166-2003-data.txt,#
      ```

      This file has one line per supplied internal taxonomy, which is of the form:

      ```
      <taxonomy ID> = <tModelKey>,<data filename>,<data file delimiter>
      ```

Token	Description
<taxonomy ID>	This is used internally by the JAXR provider to identify each taxonomy. It does not have to be the same as the taxonomy ID in the corresponding taxonomy data file.
<tModelKey>	The tModelKey of the corresponding UDDI tModel. (The id of the corresponding JAXR ClassificationScheme).
<data filename>	The name of the corresponding taxonomy data file.
<data file delimiter>	The delimiter character used in the taxonomy data file. All supplied internal taxonomies use "#", but user-supplied internal taxonomies may use different delimiters.

   b. Add a new line for the new taxonomy to the copy of the taxonomyConfig.properties file. Do not remove any existing taxonomies from the file as this will make them unavailable to the JAXR provider.
4. Add the copied taxonomyConfig.properties file to the Java classpath ahead of jaxruddi.jar.

5. If any JAXR client programs are still running that were started before the new taxonomy was added to the taxonomyConfig.properties file, a new Connection must be created in order to pick up the new taxonomy.

Important notes on internal taxonomies

Each internal taxonomy is loaded into memory once per JAXR Connection. The taxonomy's ClassificationScheme is created when the Connection is created. At this time the associated UDDI tModel is obtained from the registry and used to populate the ClassificationScheme attributes. The taxonomy's Concept object tree is not created until the first time the ClassificationScheme is requested by the user. All subsequent requests for the same internal taxonomy using the same Connection will return the same object tree.

Modification of the Concept object tree

Because there is only one ClassificationScheme and Concept object tree per internal taxonomy per Connection, a user should not attempt to modify programmatically any part of the Concept tree, because all future requests for this taxonomy using the same Connection will return the modified (and now possibly invalid) objects. Programmatic modification of the Concept tree will not result in any changes to the associated taxonomy data file. If a user wishes to make a change to the values in a user-defined internal taxonomy, they must first make the changes in the taxonomy data file, and then create a new Connection to pick up the changes in a new Concept tree.

Modification of the ClassificationScheme

Similarly, a user should not attempt to modify programmatically an internal ClassificationScheme, except in the case where a user wishes to modify and then save a user-defined internal ClassificationScheme. A new Connection is not required to pick up programmatic changes.

Logging and messages

UDDI4J Logging

The JAXR Provider for UDDI uses UDDI4J Version 2 to communicate with the UDDI registry. UDDI4J has its own logging which can be switched on by setting the value of the System property "org.uddi4j.logEnabled" to "true". This outputs to the standard error log the XML request and response bodies of every UDDI request.

Trace

Entry, exit, exception, warning and debug trace is provided using commons-logging. See http://jakarta.apache.org/commons/logging/ for more information on commons-logging. Trace will only be created if the JAXR client configures it. Entry, exit and debug trace uses the debug level of logging. Exception and warning trace uses the info level of logging. Additionally, info level logging is provided before each UDDI4J request is made.

Standard error log messages

The InternalTaxonomyManager, EnumerationManager and PostalSchemeManager send warning messages to System.err if error conditions occur that do not warrant an exception, but that the user should be informed of. Examples of these are if a taxonomy data file contains an invalid line, or if a tModel corresponding to an internal taxonomy could not be found in the registry.

Planning to use Web services

You can plan to develop and implement Web services based on a variety of Java programming models.

Before you begin

The Samples Gallery includes Samples that demonstrate JAX-WS-based Web services. The JAX-WS Web services Samples demonstrate the simple message exchange patterns using both synchronous and asynchronous invocation of Web services in SOAP 1.1 and SOAP 1.2 environments. The Samples are composed with Web service standards such as WS-Addressing (WS-A) , WS-Reliable Messaging (WS-RM), and WS-Secure Conversation (WS-SC), which you can use to complete a broad range of interoperability tests. The samples demonstrate the use of JavaBeans artifacts and static service endpoints and proxy-based clients. Additionally, a Sample is provided that demonstrates Message Transmission Optimization Mechanism (MTOM).

About this task

Note: IBM WebSphere Application Server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation Web services programming model extending the foundation provided by the JAX-RPC programming model. Using the strategic JAX-WS programming model, development of Web services and clients is simplified through support of a standards-based annotations model. Although the JAX-RPC programming model and applications are still supported, take advantage of the easy-to-implement JAX-WS programming model to develop new Web services applications and clients.

You must re-write existing JAX-RPC applications if you want to take advantage of the features of the JAX-WS programming model.

Web services reflect the service-oriented architecture approach to programming. This approach is based on the idea of building applications by discovering and implementing network-available services, or by invoking the available applications to accomplish a task. Web services deliver interoperability, for example, Web services applications provide a way for components created in different programming languages to work together as if they were created using the same language. Web services rely on existing transport technologies, such as HTTP, and standard data encoding techniques, such as Extensible Markup Language (XML), for invoking the implementation.

1. Identify your goals and design Web services to fit your e-business solution. Consider what you want to accomplish by using Web services. Decide how Web services fit into your current topology, applications and programming model. Determine how the Web services process requests on the server and how the clients manage and use the Web service.
2. Design your Web services for reliability, availability, manageability and security. For example, you want your Web services to process a transaction in a reasonable time at all hours of the day and provide users with optimal security, such as authentication for buyers. Planning to use Web services to work with WebSphere Application Server helps to meet these requirements.
3. Review the standards used in developing and deploying Web services onto WebSphere Application Server. Development and deployment are based on a variety of Java programming models.
4. Decide what development and implementation tools to use. You can use a variety of manual development and implementation tasks. Whether you have an existing Web service to implement or you want to develop your own from a JavaBeans implementation or from an Enterprise JavaBeans (EJB) module, you can choose different tasks respective to your resources. You can also use assembly tools to complete development and implementation tasks.
5. Install the application server. For detailed information on installing the application server, read about installing your application serving environment.
6. Review Web services Samples.

Results

You have a design plan for implementing Web services applications into your business architecture.

Learning about the Web Services Invocation Framework (WSIF)

The Web Services Invocation Framework (WSIF) is a WSDL-oriented Java API. You use this API to invoke Web services dynamically, regardless of the service implementation format (for example enterprise bean) or the service access mechanism (for example Java Message Service (JMS)).

About this task

Using WSIF, you can move away from the usual Web services programming model of working directly with the SOAP APIs, towards a model where you interact with representations of the services. You can therefore work with the same programming model regardless of how the service is implemented and accessed.

To learn about WSIF, see the following topics:

- "Goals of WSIF."
- "WSIF Overview" on page 458.
  1. "WSIF architecture" on page 458.
  2. "WSIF and WSDL" on page 459.
  3. "WSIF usage scenarios" on page 459.

Goals of WSIF

WSIF aims to extend the flexibility provided by SOAP services into a general model for invoking Web services, irrespective of the underlying binding or access protocols.

SOAP bindings for Web services are part of the WSDL specification, therefore when most developers think of using a Web service, they immediately think of assembling a SOAP message and sending it across the network to the service endpoint, using a SOAP client API. For example: using Apache SOAP the client creates and populates a Call object that encapsulates the service endpoint, the identification of the SOAP operation to invoke, the parameters to send, and so on.

While this process works for SOAP, it is limited in its use as a general model for invoking Web services for the following reasons:

- "Web services are more than just SOAP services."
- "Tying client code to a particular protocol implementation is restricting" on page 457.
- "Incorporating new bindings into client code is hard" on page 457.
- "Multiple bindings can be used in flexible ways" on page 457.
- "A freer Web services environment enables intermediaries" on page 457.

The goals of the Web Services Invocation Framework (WSIF) are therefore:

- To give a binding-independent mechanism for Web service invocation.
- To free client code from the complexities of any particular protocol used to access a Web service.
- To enable dynamic selection between multiple bindings to a Web service.
- To help the development of Web service intermediaries.

Web services are more than just SOAP services

You can deploy as a Web service any application that has a WSDL-based description of its functional aspects and access protocols. If you are using the Java Platform, Enterprise Edition (Java EE) environment, then the application is available over multiple transports and protocols.

For example, you can take a database-stored procedure, expose it as a stateless session bean, then deploy it into a SOAP router as a SOAP service. At each stage, the fundamental service is the same. All that changes is the access mechanism: from Java DataBase Connectivity (JDBC) to Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) and then to SOAP.

The WSDL specification defines a SOAP binding for Web services, but you can add binding extensions to the WSDL so that, for example, you can offer an enterprise bean as a Web service using RMI-IIOP as the access protocol. You can even treat a single Java class as a Web service, with in-thread Java method invocations as the access protocol. With this broader definition of a Web service, you need a binding-independent mechanism for service invocation.

Tying client code to a particular protocol implementation is restricting

If your client code is tightly bound to a client library for a particular protocol implementation, it can become hard to maintain.

For example, if you move from Apache SOAP to Java Message Service (JMS) or enterprise bean, the process can take a lot of time and effort. To avoid these problems, you need a protocol implementation-independent mechanism for service invocation.

Incorporating new bindings into client code is hard

If you want to make an application that uses a custom protocol work as a Web service, you can add extensibility elements to WSDL to define the new bindings. But in practice, achieving this capability is hard.

For example you have to design the client APIs to use this protocol. If your application uses just the abstract interface of the Web service, you have to write tools to generate the stubs that enable an abstraction layer. These tasks can take a lot of time and effort. What you need is a service invocation mechanism that allows you to update existing bindings, and to add new bindings.

Multiple bindings can be used in flexible ways

To take advantage of Web services that offer multiple bindings, you need a service invocation mechanism that can switch between the available service bindings at run time, without having to generate or recompile a stub.

Imagine that you have successfully deployed an application that uses a Web service which offers multiple bindings. For example, imagine that you have a SOAP binding for the service and a local Java binding that lets you treat the local service implementation (a Java class) as a Web service.

The local Java binding for the service can only be used if the client is deployed in the same environment as the service. In this case, it is more efficient to communicate with the service by making direct Java calls than by using the SOAP binding.

If your clients could switch the actual binding used based on run-time information, they could choose the most efficient available binding for each situation.

A freer Web services environment enables intermediaries

Web services offer application integrators a loosely-coupled paradigm. In such environments, intermediaries can be very powerful.

Intermediaries are applications that intercept the messages that flow between a service requester and a target Web service, and perform some mediating task (for example logging, high-availability or transformation) before passing on the message. The Web Services Invocation Framework (WSIF) is designed to make building intermediaries both possible and simple. Using WSIF, intermediaries can add value to the service invocation without needing transport-specific programming.

WSIF Overview

The Web Services Invocation Framework (WSIF) provides a Java API for invoking Web services, independent of the format of the service or the transport protocol through which it is invoked.

This framework addresses all of the issues identified in “Goals of WSIF” on page 456.

WSIF provides the following features:
- An API that provides binding-independent access to any Web service.
- A close relationship with WSDL, so it can invoke any service that you can describe in WSDL.
- A stubless and completely dynamic invocation of a Web service.
- The capability to plug a new or updated implementation of a binding into WSIF at run time.
- The option to defer the choice of a binding until run time.

WSIF provides runtime support for Web services, and for WSDL extensions and bindings, that were not known at build time. This capability is known as *dynamic invocation*. Using WSIF, a client application can choose dynamically the optimal binding to use for invoking Web service operations. For example, a Web service might offer a SOAP binding, and also a local Java binding so that you can treat the local service implementation (a Java class) as a Web service. If a client application is deployed in the same environment as the service, then this client can use the local Java binding for the service. This provides more efficient communication between the client and the service by making direct Java calls rather than indirect calls using the SOAP binding. WSIF provides this runtime support through the use of providers. The providers support Web services, WSDL extensions and bindings that were not known at build time by using the WSDL description to access the target service.

WSIF is designed to work both in an unmanaged environment (stand-alone) and inside a managed container. You can use the Java Naming and Directory Interface (JNDI) to find the WSIF service, or you can use the location described in the WSDL.

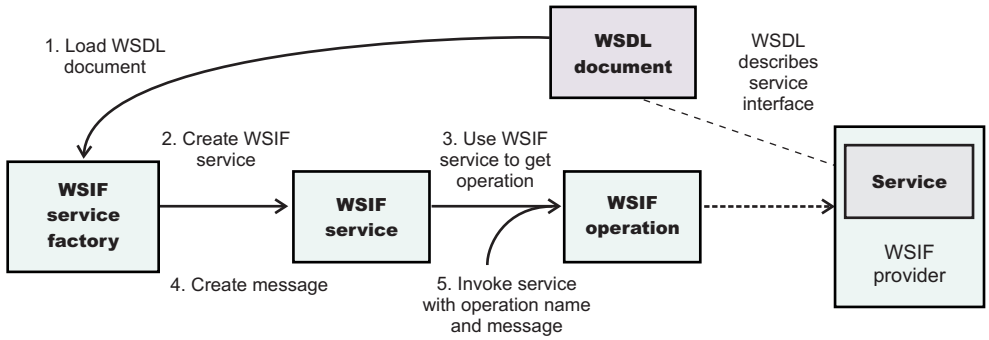
For more conceptual information about WSIF and WSDL, see the following topics:
- WSIF and WSDL
- WSIF architecture
- WSIF usage scenarios

WSIF supports Internet Protocol Version 6, and Java API for XML-based Remote Procedure Calls (JAX-RPC) Version 1.1 for SOAP.

WSIF architecture

A diagram depicting the Web Services Invocation Framework (WSIF) architecture, and a description of each of the major components of the architecture.

The Web Services Invocation Framework (WSIF) architecture is shown in the figure.



The components of this architecture include:

WSDL document
The Web service WSDL document contains the location of the Web service. The binding document defines the protocol and format for operations and messages defined by a particular portType.

WSIF service
The WSIFService interface is responsible for generating an instance of the WSIFOperation interface to use for a particular invocation of a service operation. For more information, see the WSIFService interface topic.

WSIF operation
The run-time representation of an operation, called *WSIFOperation* is responsible for invoking a service based on a particular binding. For more information, see the WSIFOperation interface topic.

WSIF provider
A WSIF provider is an implementation of a WSDL binding that can run a WSDL operation through a binding-specific protocol. WSIF includes SOAP providers, JMS providers, Java providers and EJB providers. For more information, see Linking a WSIF service to the underlying implementation of the service.

WSIF and WSDL

There is a close relationship between the metadata-based Web Services Invocation Framework (WSIF) and the evolving semantics of Web Services Description Language (WSDL).

In WSDL, a service is defined in three distinct sections:
- The **portType**. This section defines the abstract interface offered by the service. A portType defines a set of *operations*. Each operation can be In-Out (request-response), In-Only, Out-Only and Out-In (Solicit-Response). Each operation defines the input and/or output *messages*. A message is defined as a set of *parts*, and each part has a schema-defined type.
- The **binding**. This section defines how to map between the abstract portType and a real service format and protocol. For example the SOAP binding defines the encoding style, the SOAPAction header, the namespace of the body (the targetURI), and so on.
- The **port**. This section defines the actual location (endpoint) of the available service. For example, the HTTP Web address at which a SOAP service is available.

Currently in WSDL, each port has one and only one binding, and each binding has a single portType. But (more importantly) each service (portType) can have multiple ports, each of which represents an alternative location and binding for accessing that service.

The Web Services Invocation Framework (WSIF) follows the semantics of WSDL as much as possible:
- The WSIF dynamic invocation API directly exposes run-time equivalents of the model from WSDL. For example, invocation of an operation involves executing an operation with an input message.
- WSDL has extension points that support the addition of new ports and bindings. This enables WSDL to describe new systems. The equivalent concept in WSIF is a provider, that enables WSIF to understand a class of extensions and thereby to support a new service implementation type.

As a metadata-based invocation framework, WSIF follows the design of the metadata. As WSDL is extended, WSIF is updated to follow.

The primary type system of WSIF is XML schema. WSIF supports invocation using dynamic proxies, which in turn support Java type systems, but when you use the WSIFMessage interface it is your responsibility to populate WSIFMessage objects with data based on the XML schema types as defined in the WSDL document. You should define your object types by a canonical and fixed mapping from schema types into the run-time environment.

WSIF usage scenarios

This topic describes two brief scenarios that illustrate the role WSIF plays in the emerging Web services environment.

Scenario: Redevelopment and redeployment

When you first implement a Web service, you create a simple prototype. When you want to move a prototype Web service into production, you often need to redevelop and redeploy it.

The Web Services Invocation Framework (WSIF) uses the same API calls irrespective of the underlying technologies, therefore if you use WSIF:

- You can reimplement and redeploy your services without changing the client code.
- You can use existing reliable and high-performance infrastructures like Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) and Java Message Service (JMS) without sacrificing the location-independence that the Web service model offers.

Scenario: Service Flow composition

A service flow typically invokes a Web service, then passes the response from one Web service to the next Web service, perhaps performing some transformation in the middle.

There are two key aspects to this flow that WSIF provides:

- A representation of the service invocation based on the metadata in WSDL.
- The ability to build invocations based solely on the portType, which can therefore be used in any implementation.

For example, imagine that you build a meta-service that uses a number of services to build a process. Initially, several of those services are simple Java bean prototypes that are written and exposed through SOAP, but you plan to reimplement some of them as EJB components, and to out-source others.

If you use SOAP, it ties up multiple threads for every onward invocation, because they pass through the Web server and servlet engine and on to the SOAP router. If you use WSIF to call the beans directly, you get much better performance compared to SOAP and you do not lose access or location transparency. Using WSIF, you can replace the Java bean implementations with EJB implementations without changing the client code. To move some of the Web services from local implementations to external SOAP services, you just update the WSDL.

Setting up and deploying a new UDDI registry

A UDDI registry node consists of the UDDI registry application (an enterprise application that is supplied as part of WebSphere Application Server), a store of data (using a relational database management system) referred to as the UDDI database, and a means to connect the application to the data (a datasource and related elements). To set up a new UDDI registry you create the UDDI database and datasource, and deploy the supplied application.

Before you begin

Start WebSphere Application Server, and create a server to host the UDDI registry. Use Starting and stopping quick reference for information about starting WebSphere Application Server using either commands or the administrative console.

About this task

The subtopics describe how to create the UDDI database (which can be local or remote) and datasource, and how to deploy the UDDI registry application.

You can create either a *default* UDDI node or a *customized* UDDI node. The main difference between default and customized, in the context of these set up tasks, refers to a number of mandatory UDDI registry properties such as the UDDI node ID and description, and the prefix to be used for generated discovery URLs.

Default UDDI node
The mandatory properties are automatically set to default values and cannot be changed. A default UDDI node is a suitable option for initial evaluation of the UDDI registry, and for development and test purposes.

Customized UDDI node
You must set the mandatory properties, but once set they cannot be changed for this configuration. With a customized UDDI node you have more control over the database management system used for the UDDI database, and the properties used to set up the UDDI database. With a customized UDDI node, you create the UDDI database and datasource to your own specifications before deploying the UDDI registry application. A customized node is a suitable option for production purposes. To move from a default UDDI node to a customized node, see "Changing the UDDI registry application environment after deployment" on page 483.

- If you want to quickly set up a UDDI registry for test or development purposes, follow the instructions in "Setting up a default UDDI node with a default datasource" on page 462. The database, datasource and UDDI registry application are created or deployed by a single script. Note that the database type is embedded Apache Derby.
- If you want to create a default UDDI registry with a database other than embedded Apache Derby, or if you want an embedded Apache Derby database but you want to create the datasource manually, follow the instructions in "Setting up a default UDDI node" on page 463.
- If you want to create a customized UDDI registry, follow the instructions in "Setting up a customized UDDI node" on page 472.

Database considerations for production use of the UDDI registry

The UDDI registry fully supports a number of databases and can be used for development and test purposes. However, there are factors to consider when you decide which database is appropriate for your anticipated UDDI registry production use.

It is important to consult the information that is supplied by your chosen database vendor, but you also need to consider the likely size and volume of requests, and whether the general performance and scalability of the UDDI registry is important.

For example, the Apache Derby database supports the full function of the UDDI registry, but it is not an enterprise level database and it does not have the same characteristics, for example, scaling or performance, as enterprise databases such as DB2.

Note: Apache Derby is not supported for production use.

If you need multiple connections to the UDDI registry database (for example to use the UDDI registry in a cluster configuration) and Apache Derby is your preferred database, you need to use the network option for Apache Derby. This is because embedded Apache Derby has a limitation that allows only one Java virtual machine to access or load a database instance at any one time. That is, two application servers cannot access the same Apache Derby database instance at the same time.

Note: The UDDI registry can support multiple users, even if a single database connection exists.

Related concepts

"Overview of the Version 3 UDDI registry" on page 410
The Universal Description, Discovery, and Integration (UDDI) specification defines a way to publish and discover information about Web services. The term *Web service* describes specific business functionality that is exposed by a company, usually through an Internet connection, to allow another company, its subsidiaries, or software program, to use the service.

Related reference

"About Apache Derby" on page 1538
Use Apache Derby as a test and development database only. Apache Derby must run at a minimal version of v10.3 or Cloudscape® v10.1x. The Apache Derby package that is bundled with the application server is backed by full IBM Quality Assurance (QA).

"Data source minimum required settings for Apache Derby" on page 1436
These properties vary according to the database vendor requirements for JDBC driver implementations. You must set the appropriate properties on every data source that you configure. These settings are for Apache Derby and Cloudscape data sources.

Setting up a default UDDI node with a default datasource

Use this task to create a UDDI node with predetermined property values and an embedded Apache Derby database.

About this task

You cannot change the mandatory node properties, such as node ID, either during the creation of the node, or afterward. Such a node is suitable for initial evaluation of the UDDI registry and for development and test purposes. If you want to choose the mandatory node properties yourself, set up a customized node as detailed in "Setting up a customized UDDI node" on page 472.

The UDDI database and datasource are automatically created by running a single script, which also deploys the UDDI registry application. If you want to have more control over the datasource, refer to "Setting up a default UDDI node" on page 463.

1. Create the UDDI node by running the wsadmin script uddiDeploy.jacl from the *app_server_root*/bin directory. The syntax of the command is shown below.

```
wsadmin [-conntype none] [-profileName profile_name] -wsadmin_classpath app_server_root/derby/lib
               -f uddiDeploy.jacl
               node_name
               server_name
               default
```

   where

   - '-profileName *profile_name*' is optional, and is the name of the profile in which the UDDI application is deployed. If you do not specify a profile, the default profile will be used.
   - '-conntype none' is optional, and is only needed if the application server is not running.
   - *app_server_root* is the directory name of the WebSphere Application Server installation location.
   - *node_name* is the name of the WebSphere node on which the target server runs. Note that the node name is case sensitive.
   - *server_name* is the name of the target server on which you wish to deploy the UDDI registry, such as server1. Note the server name entered is case sensitive.
   - 'default' causes the command to create a UDDI node, with default policies, within an Apache Derby database and datasource. This is a special case only for Apache Derby and creates everything required to run a UDDI node.

     If the Apache Derby database already exists, you are asked if you want to recreate it. If you choose to recreate the database, your existing database is deleted and a new one is created in its place. If you choose not to recreate the database, the command exits and a new database is not created.

Note: If the application server has already accessed the existing Apache Derby database, the uddiDeploy.jacl script cannot recreate the database. Use the uddiRemove.jacl script to remove the database, as described in “Removing a UDDI registry node” on page 978, restart the server, and run the uddiDeploy.jacl script again.

For example, to create a UDDI node called ’MyNode’ on server ’server1’, you might enter the following (this assumes server1 is started):

```
wsadmin -profileName myProfile -wsadmin_classpath /QIBM/ProdData/WebSphere/
AppServer/V61/Base/derby/lib -f uddiDeploy.jacl MyNode server1 default
```

If the server is not started, the command is:

```
wsadmin -conntype none -profileName myProfile -wsadmin_classpath /QIBM/ProdData/
WebSphere/AppServer/V61/Base/derby/lib -f uddiDeploy.jacl MyNode server1 default
```

(Enter these commands as one command on a single line.)

2. Click **Applications** → **Application Types** → **WebSphere enterprise applications** to display the installed applications. Start the UDDI registry application by selecting the check box next to it and clicking **Start**. Alternatively, if the application server is not already running, start the application server. This action automatically starts the UDDI registry application. The UDDI node is now active.

   Note: Restarting the UDDI application, or the application server, always reactivates the UDDI node, even if the node was previously deactivated.

3. Click **UDDI** → **UDDI Nodes** → *UDDI_node_id* to display the properties page for the UDDI registry node. Set **Prefix for generated discoveryURLs** to a valid URL for your configuration. This property specifies the URL prefix that is applied to generated discovery URLs that are used by the HTTP GET service for UDDI Version 2.

What to do next

Follow the instructions in “Using the UDDI registry Installation Verification Program (IVP)” on page 482 to verify that you have successfully set up the UDDI node.

Setting up a default UDDI node

Use this task to create a UDDI node with predetermined property values. This UDDI node is suitable for initial evaluation of the UDDI registry and for development and test purposes.

About this task

You cannot change the mandatory node properties, such as node ID, either during the creation of the node, or afterward. If you want to choose your own mandatory node properties, set up a customized node, as detailed in “Setting up a customized UDDI node” on page 472.

1. Create a database schema to hold the UDDI registry by completing one of the following tasks, ensuring that you use the default node options where specified:
   - “Creating a DB2 distributed database for the UDDI registry” on page 464
   - “Creating a DB2 for iSeries database for the UDDI registry” on page 465
   - “Creating an Apache Derby database for the UDDI registry” on page 467
   - “Creating an Oracle database for the UDDI registry” on page 468
2. Set up a data source for the UDDI registry application to use to access the database, as described in “Creating a data source for the UDDI registry” on page 469.
3. Deploy the UDDI registry application, as described in “Deploying the UDDI registry application” on page 471.
4. Click **Applications** → **Application Types** → **WebSphere enterprise applications** to display the installed applications. Start the UDDI registry application by selecting the check box next to it and clicking **Start**. Alternatively, if the application server is not already running, start the application server. This action automatically starts the UDDI registry application. The UDDI node is now active.

Note: Restarting the UDDI application, or the application server, always reactivates the UDDI node, even if the node was previously deactivated.

5. Click **UDDI** → **UDDI Nodes** → *UDDI_node_id* to display the properties page for the UDDI registry node. Set **Prefix for generated discoveryURLs** to a valid URL for your configuration. This property specifies the URL prefix that is applied to generated discovery URLs that are used by the HTTP GET service for UDDI Version 2.

What to do next

Because you have chosen to use a default UDDI node, the node will be initialized when the UDDI application is started for the first time. Follow the instructions in "Using the UDDI registry Installation Verification Program (IVP)" on page 482 to verify that you have successfully set up the UDDI node.

Creating a DB2 distributed database for the UDDI registry

Perform this task if you want to use DB2 on the Windows, Linux or UNIX operating systems, as the database store for your UDDI registry data.

Before you begin

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

<DataBaseName>
The name of the UDDI registry database. A recommended value is UDDI30, and this name is assumed throughout the UDDI information. If you use another name, substitute that name when UDDI30 is used in the information center.

<DB2UserID>
A DB2 userid with administrative privileges.

<DB2Password>
The password for the DB2 userid.

<BufferPoolName>
The name of a buffer pool to be used by the UDDI registry database. A suggested name is uddibp, but any name can be used, because the buffer pool is created as part of this task.

<TableSpaceName>
The name of a table space. A suggested value is uddits, but any name can be used.

<TempTableSpaceName>
The name of a temporary table space. A suggested value is udditstemp, but any name can be used, because the temporary table space is created as part of this task.

About this task

You need to perform this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

If you want to create a remote database, refer first to the database product documentation about the relevant capabilities of the product.

1. Change directory to *app_server_root*/UDDIReg/databaseScripts.
2. Start the DB2 Command Line Processor by entering `db2` at the command prompt.
3. Run the following command to setup the DB2 environment variables:
   ```
   set DB2CODEPAGE=1208
   ```
4. Create the DB2 database by entering the following command:
   ```
   create database <DataBaseName> using codeset UTF-8 territory en
   ```

where <DataBaseName> is the name of the database being created.

5. Configure the DB2 database by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `update db cfg for <DataBaseName> using applheapsz 2048`
   c. `update db cfg for <DataBaseName> using logfilsiz 8192`
   d. `connect reset`
   e. `terminate`
6. Create additional database structures by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `create bufferpool <BufferPoolName> size 250 pagesize 32K`
   c. `connect reset`
   d. `terminate`
   e. `force application all`
   f. `terminate`
   g. `stop`
   h. `start`
7. Create further database structures by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `create regular tablespace uddits pagesize 32K managed by system using ('<TableSpaceName>') extentsize 64 prefetchsize 32 bufferpool <BufferPoolName>`
   c. `create system temporary tablespace <TempTableSpacename> pagesize 32K managed by system using ('<TempTableSpacename>') extentsize 32 overhead 14.06 prefetchsize 32 transferrate 0.33 bufferpool <BufferPoolName>`
8. Exit the DB2 Command Line Processor and enter the following commands exactly as shown, noting that one step uses -vf rather than -tvf (on Windows platforms, run the commands from the db2cmd window). These commands define the database structures needed to store the UDDI data:
   a. `db2 -tvf uddi30crt_10_prereq_db2.sql`
   b. `db2 -tvf uddi30crt_20_tables_generic.sql`
   c. `db2 -tvf uddi30crt_25_tables_db2udb.sql`
   d. `db2 -tvf uddi30crt_30_constraints_generic.sql`
   e. `db2 -tvf uddi30crt_35_constraints_db2udb.sql`
   f. `db2 -tvf uddi30crt_40_views_generic.sql`
   g. `db2 -tvf uddi30crt_45_views_db2udb.sql`
   h. `db2 -vf uddi30crt_50_triggers_db2udb.sql`
   i. `db2 -tvf uddi30crt_60_insert_initial_static_data.sql`
9. [Optional] Enter the following command if you want the database to be used as a default UDDI node:
   `db2 -tvf uddi30crt_70_insert_default_database_indicator.sql`

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating a DB2 for iSeries database for the UDDI registry

Perform this task if you want to use DB2 for iSeries as the database store for your UDDI registry data.

Before you begin

IBMUDI30 and IBMUDS30 are the default names of the UDDI registry schema in the SQL scripts mentioned below. These default names are the recommended values and are assumed throughout the UDDI documentation. If you want to use different names, modify the SQL files listed below, then substitute your own names whenever you see 'IBMUDI30' or 'IBMUDS30' in other sections of the documentation.

About this task

You need to perform this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

1. Use iSeries Navigator to run SQL scripts.
   a. Open iSeries Navigator.
   b. Expand **My Connections** → **iSeriesName** → **Databases**.
   c. Select **iSeriesName**.
   d. Right-click **Run SQL Scripts...**.

   A **Run SQL Scripts** window opens.
2. Open the i5/OS DB2 SQL files.
   a. Map a network drive to the root directory of your i5/OS server's integrated file system.
   b. In Windows Explorer, expand the `WAS_HOME/UDDIReg/databaseScripts` directory.
   c. Open the following SQL files with a text editor (such as Notepad):
      - uddi30crt_10_prereq_db2_iSeries.sql
      - uddi30crt_20_tables_generic_iSeries.sql
      - uddi30crt_25_tables_db2udb_iSeries.sql
      - uddi30crt_30_constraints_generic_iSeries.sql
      - uddi30crt_35_constraints_db2udb_iSeries.sql
      - uddi30crt_40_views_generic_iSeries.sql
      - uddi30crt_45_views_db2udb_iSeries.sql
      - uddi30crt_50_triggers_db2udb_iSeries.sql
      - uddi30crt_60_insert_initial_static_data_iSeries.sql
3. Copy the text to the **Run SQL Scripts** window.
   a. In the text editor of the file `uddi30crt_10_prereq_db2_iSeries.sql`, click **Edit** → **Select All**.
   b. Click **Edit** → **Copy**.
   c. In the **Run SQL Scripts** window, click **Edit** → **Paste**.
   d. Click **Run** → **All**.
   e. After the script completes running, select all the SQL text and delete it from the **Run SQL Scripts** window.
   f. Repeat the above steps for all the SQL scripts listed in step 2.

   Note: iSeries Navigator for i5/OS V5R2 will encounter an error on the last line of the SQL script when running the `uddi30crt_25_tables_db2udb_iSeries.sql` script. This error can be ignored. i5/OS V5R2 does support running UDDI in a clustered high availability environment. For more information, see the WebSphere Application Server for i5/OS tech notes.
4. This step should only be run if you want your database to be used as a default UDDI node.
   a. Open `uddi30crt_70_insert_default_database_indicator.sql` as described in Step 2 above.
   b. Copy and run `uddi30crt_70_insert_default_database_indicator.sql` as described in Step 3 above.

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating an Apache Derby database for the UDDI registry

Perform this task to use Apache Derby (embedded or network) as the database store (either local or remote) for your UDDI registry.

Before you begin

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

arg1 The path of the SQL files. On a standard installation, this is *app_server_root*/UDDIReg/databasescripts

arg2 The path to the location where you want to install the Apache Derby database.

For example, *profile_root*/databases/com.ibm.uddi

arg3 The name of the Apache Derby database. A recommended value is UDDI30, and this name is assumed throughout the UDDI information. If you use another name, substitute that name when UDDI30 is used in the information center.

arg4 An optional argument, which must either be the string 'DEFAULT', or be omitted. Specify DEFAULT if you want the database to be used as a default UDDI node. This argument is case sensitive.

If you want to create a remote database, refer first to the database product documentation about the relevant capabilities of the product.

About this task

You need to perform this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

1. Start a Qshell session by entering the STRQSH command from the i5/OS command line.
2. Run the following Java -jar command from the *app_server_root*/UDDIReg/databaseScripts directory, to create a UDDI Apache Derby database using UDDIDerbyCreate.jar.

   ```
   java -Djava.ext.dirs=app_server_root/derby/lib:app_server_root/java/jre/lib/ext -jar UDDIDerbyCreate.jar
   arg1 arg2 arg3 arg4
   ```

   If the Apache Derby database already exists, you are asked if you want to recreate it. If you choose to recreate the database, your existing database is deleted and a new one is created in its place. If you choose not to recreate the database, the command exits and a new database is not created.

   Note: If the application server has already accessed the existing Apache Derby database, the uddiDeploy.jacl script cannot recreate the database. Use the uddiRemove.jacl script to remove the database, as described in "Removing a UDDI registry node" on page 978, restart the server, and run the uddiDeploy.jacl script again.
3. If you are using a remote database (which requires network Apache Derby), or you want to use network Apache Derby for other reasons, for example, if you want to use Apache Derby with a cluster, configure the Apache Derby Network Server framework. For details, see the section about managing the Derby Network Server in the Derby Server and Administration Guide.

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating an Oracle database for the UDDI registry

Perform this task if you want to use Oracle as the database store for your UDDI registry data. You need only do this once for each UDDI registry, as part of setting up and deploying a UDDI registry.

About this task

The supported versions of Oracle are Version 9i[1] and Version 10g[2]

You can create a remote database using Oracle, but not a local database. Because the database is remote, use the database product documentation to familiarize yourself with the relevant capabilities of the product before proceeding with this task.

Before you begin

This task creates three new schemas: ibmuddi, ibmudi30 and ibmuds30. You will be unable to complete this task if you already have existing schemas with these names.

The steps below use a number of variables for which you need to enter appropriate values. You should decide the values that you will use before you start. The variables used are:

<OracleUserID>
is the Oracle userid to be used to create the database.

<OraclePassword>
is the password for the Oracle userid.

1. Run the following commands:
   a. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_10_prereq_oracle.sql`
   b. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_20_tables_generic.sql`
   c. Complete one of the following actions depending on your level of Oracle:
      - For Oracle 9i:

```
sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_25_tables_oracle_pre10g.sql
```

      - For Version 10g and later:

```
sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_25_tables_oracle.sql
```

   d. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_30_constraints_generic.sql`
   e. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_35_constraints_oracle.sql`
   f. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_40_views_generic.sql`
   g. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_45_views_oracle.sql`
   h. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_50_triggers_oracle.sql`
   i. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_60_insert_initial_static_data.sql`

1.

Restrictions:
discoveryURL (Business) maximum 4000 bytes, UDDI specification 4096 characters; accessPoint (bindingTemplate) maximum 4000 bytes, UDDI Specification 4096 characters; instanceParms (tModelInstanceInfo) maximum 4000 bytes, UDDI specification 8192 characters; overviewURL (tModelInstanceInfo) maximum 4000 bytes, UDDI specification 4096 characters; Digital Signature maximum 4000 bytes.

2.

Restrictions:
discoveryURL (Business) maximum 4000 bytes, UDDI specification 4096 characters; accessPoint (bindingTemplate) maximum 4000 bytes, UDDI Specification 4096 characters.

2. This last command should only be run if you want the database to be used as a default UDDI node.

```
sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_70_insert_default_database_indicator.sql
```

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating a data source for the UDDI registry

You create a data source so that the UDDI registry can use it to access the UDDI database.

Before you begin

You must have already created the database for the UDDI registry.

About this task

Perform this task as part of setting up and deploying a new UDDI registry. The data source is used by the UDDI registry to access the UDDI database.

1. Create a J2C Authentication Data Entry. This is not required for embedded Apache Derby, but is required for network Apache Derby.
   a. Click **Security** → **Global security** → **[Authentication] Java Authentication and Authorization Service** → **J2C authentication data**.
   b. Click **New** to create a new J2C authentication data entry.
   c. Enter the following details:

      Alias A suitable short name, for example UDDIAlias.

      Userid

      The database user ID (for example db2admin for DB2, or IBMUDDI for Oracle), which is used to read and write to the UDDI registry database. For network Apache Derby, the user ID can be any value.

      Password

      The password associated with the user ID specified earlier. For network Apache Derby, the password can be any value.

      Description

      A description of the user ID.

      Click **Apply**, then save the changes to the master configuration.
2. Create a JDBC Provider, if a suitable one does not already exist, using the following table to determine the provider type and implementation type for your chosen database:

Database	Provider type	Implementation type
DB2	DB2 UDB for iSeries (Native)	Connection Pool data source
Oracle	Oracle JDBC Driver	Connection Pool data source
Embedded Apache Derby	Derby JDBC Driver	Connection Pool data source
Network Apache Derby	Derby Network Server JDBC Driver provider	Connection Pool data source
Microsoft SQL Server	DataDirect Connect JDBC Driver Microsoft SQL Server JDBC Driver	Connection Pool data source

   For details on how to create a JDBC provider, see Creating and configuring a JDBC provider using the administrative console.
3. Use the following steps to create the data source for the UDDI registry:
   a. Click **Resources** → **JDBC** → **JDBC Providers**.

b. Select the scope of the JDBC provider that you selected or created earlier, that is, the level at which the JDBC provider is defined. For example, for a JDBC provider that is defined at the level of server1, select the following:

```
Node=Node01, Server=server1
```

All the JDBC providers that are defined at the selected scope are displayed.

c. Select the JDBC provider that you created earlier.

d. Under **Additional Properties**, select **Data sources**. Do not select the **Data sources (WebSphere Application Server V4)** option.

e. Click **New** to create a new data source.

f. In the **Create a data source** wizard, enter the following data:

Name A suitable name, for example UDDI Datasource.

JNDI name
Set this value to **datasources/uddids**. This is a mandatory field.

You must not have any other data sources that use this JNDI name. If you have another data source that uses this JNDI name, you must either remove it or change its JNDI name. For example, if you created a default UDDI node previously using an Apache Derby database, before you continue, use the uddiRemove.jacl script with the default option to remove the data source and the UDDI application instance.

Component-managed authentication alias

- For DB2, Oracle, or network Apache Derby, select the alias that you created in step 2. It is prefixed by the node name, for example MyNode/UDDIAlias.
- for embedded Apache Derby leave this set to (none).

g. Click **Next**.

h. On the database-specific properties page of the wizard, enter the following data:

- for DB2:

Database name
For example:

```
*LOCAL
```

- For Oracle - **URL** - for example:

```
jdbc:oracle:oci8:@<Oracle database name>
```

- For Apache Derby (embedded or network) - **Database name** - for example:

```
profile_root/databases/com.ibm.uddi/UDDI30
```

For network Apache Derby, also make sure that the **Server name** and **Port number** match the network server.

Use this Data Source in container-managed persistence (CMP)
Ensure that the check box is cleared.

i. Click **Next**, then check the summary and click **Finish**.

j. Click the data source to display its properties, and add the following information:

Description
A description of the data source.

Category
Set this value to uddi.

Data store helper class name
This value is provided automatically:

Database	Data store helper class name
DB2	com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper
Oracle 9i or 10g	com.ibm.websphere.rsadapter.Oracle10gDataStoreHelper
Oracle 11g	com.ibm.websphere.rsadapter.Oracle11gDataStoreHelper
Embedded Apache Derby	com.ibm.websphere.rsadapter.DerbyDataStoreHelper
Network Apache Derby	com.ibm.websphere.rsadapter.DerbyNetworkServerDataStoreHelper

Mapping-configuration alias
Set this option to DefaultPrincipalMapping.

k. Click **Apply**.

l. Select **Additional Properties** → **Custom Properties** → **libraries**.

m. Enter `IBMUDI30,IBMUDS30` in the **Value** field and click **OK**.

n. Save the changes to the master configuration.

4. Test the connection to your UDDI database by selecting the check box next to the data source and clicking **Test connection**. A message similar to "Test Connection for datasource UDDI Datasource on server server1 at node Node01 was successful" is displayed. If a different message is displayed, use the information in that message to investigate and resolve the problem.

What to do next

Continue with setting up and deploying your UDDI registry node.

Deploying the UDDI registry application

You deploy a UDDI registry application as part of setting up a UDDI node. You can either use the supplied script, or use the administrative console.

Before you begin

Before you deploy a UDDI registry application, you must create the database and data source for the UDDI registry.

About this task

Use this task as part of "Setting up a default UDDI node" on page 463 or "Setting up a customized UDDI node" on page 472.

1. Start a Qshell session by entering the STRQSH command from the i5/OS command line.
2. Run the uddiDeploy.jacl script as shown, from the *app_server_root*/bin directory.

   This script deploys the UDDI registry to a server that you specify.

   ```
   wsadmin [-conntype none] [-profileName profile_name] -f uddiDeploy.jacl
                  node_name
                  server_name
   ```

   where:

   - '-conntype none' is optional, and is needed only if the application server is not running.
   - '-profileName *profile_name*' is optional, and is the name of the profile in which the UDDI application is deployed. If you do not specify a profile, the default profile is used.
   - *node_name* is the name of the WebSphere Application Server node on which the target server runs. The node name is case sensitive.
   - *server_name* is the name of the target server on which you wish to deploy the UDDI registry, for example, server1. The server name is case sensitive.

For example, to deploy UDDI on node 'MyNode' and server 'server1', (assuming that server1 is already started):

```
wsadmin -f uddiDeploy.jacl MyNode server1
```

You can also deploy the UDDI application (the uddi.ear file) using the administrative console, in the normal way. However, if you use the administrative console, some steps that the uddiDeploy.jacl script performs automatically do not occur. If you use the administrative console to install the UDDI application, you must perform some actions manually. To do this, use the following steps:

a. Install the application.
b. Click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***uddi_application*** → **[Detail Properties] Class loading and update detection**.
c. Ensure that **Class loader order** is set to **Classes loaded with application class loader first**.
d. Ensure that **WAR class loader policy** is set to **Single class loader for application**.

What to do next

Continue setting up the UDDI node.

Setting up a customized UDDI node

You set up a UDDI node with your own property values so that it is suitable for production configurations.

About this task

Use this task to set up a UDDI node with property values that you choose. You cannot change the mandatory node properties, such as node ID, after the initialization of the node. Such a node is suitable for production purposes.

1. Review the information in "Database considerations for production use of the UDDI registry" on page 461 to decide which database system to use, then create a database schema to hold the UDDI registry by completing one of the following tasks. Do not use the default node options where specified.
   - "Creating a DB2 distributed database for the UDDI registry" on page 464
   - "Creating a DB2 for iSeries database for the UDDI registry" on page 465
   - "Creating an Apache Derby database for the UDDI registry" on page 467
   - "Creating an Oracle database for the UDDI registry" on page 468
2. Set up a data source for the UDDI registry application to use to access the database, as described in "Creating a data source for the UDDI registry" on page 469.
3. Deploy the UDDI registry application, as described in "Deploying the UDDI registry application" on page 471.
4. Click **Applications** → **Application Types** → **WebSphere enterprise applications** to display the installed applications. Start the UDDI registry application by selecting the check box next to it and clicking **Start**. Alternatively, if the application server is not already running, start the application server. This action automatically starts the UDDI registry application. The UDDI node is now active.

   Note: Restarting the UDDI application, or the application server, always reactivates the UDDI node, even if the node was previously deactivated.

What to do next

Because you chose a user-customized UDDI node, you need to set the properties for the UDDI node using UDDI administration, and initialize the node, before it is ready to accept UDDI requests. See "Initializing the UDDI registry node" on page 481 for details.

Creating a DB2 distributed database for the UDDI registry

Perform this task if you want to use DB2 on the Windows, Linux or UNIX operating systems, as the database store for your UDDI registry data.

Before you begin

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

<DataBaseName>
The name of the UDDI registry database. A recommended value is UDDI30, and this name is assumed throughout the UDDI information. If you use another name, substitute that name when UDDI30 is used in the information center.

<DB2UserID>
A DB2 userid with administrative privileges.

<DB2Password>
The password for the DB2 userid.

<BufferPoolName>
The name of a buffer pool to be used by the UDDI registry database. A suggested name is uddibp, but any name can be used, because the buffer pool is created as part of this task.

<TableSpaceName>
The name of a table space. A suggested value is uddits, but any name can be used.

<TempTableSpaceName>
The name of a temporary table space. A suggested value is udditstemp, but any name can be used, because the temporary table space is created as part of this task.

About this task

You need to perform this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

If you want to create a remote database, refer first to the database product documentation about the relevant capabilities of the product.

1. Change directory to *app_server_root*/UDDIReg/databaseScripts.
2. Start the DB2 Command Line Processor by entering `db2` at the command prompt.
3. Run the following command to setup the DB2 environment variables:
   ```
   set DB2CODEPAGE=1208
   ```
4. Create the DB2 database by entering the following command:
   ```
   create database <DataBaseName> using codeset UTF-8 territory en
   ```
   where <DataBaseName> is the name of the database being created.
5. Configure the DB2 database by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `update db cfg for <DataBaseName> using applheapsz 2048`
   c. `update db cfg for <DataBaseName> using logfilsiz 8192`
   d. `connect reset`
   e. `terminate`
6. Create additional database structures by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `create bufferpool <BufferPoolName> size 250 pagesize 32K`

c. `connect reset`
d. `terminate`
e. `force application all`
f. `terminate`
g. `stop`
h. `start`

7. Create further database structures by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `create regular tablespace uddits pagesize 32K managed by system using ('<TableSpaceName>') extentsize 64 prefetchsize 32 bufferpool <BufferPoolName>`
   c. `create system temporary tablespace <TempTableSpacename> pagesize 32K managed by system using ('<TempTableSpacename>') extentsize 32 overhead 14.06 prefetchsize 32 transferrate 0.33 bufferpool <BufferPoolName>`
8. Exit the DB2 Command Line Processor and enter the following commands exactly as shown, noting that one step uses -vf rather than -tvf (on Windows platforms, run the commands from the db2cmd window). These commands define the database structures needed to store the UDDI data:
   a. `db2 -tvf uddi30crt_10_prereq_db2.sql`
   b. `db2 -tvf uddi30crt_20_tables_generic.sql`
   c. `db2 -tvf uddi30crt_25_tables_db2udb.sql`
   d. `db2 -tvf uddi30crt_30_constraints_generic.sql`
   e. `db2 -tvf uddi30crt_35_constraints_db2udb.sql`
   f. `db2 -tvf uddi30crt_40_views_generic.sql`
   g. `db2 -tvf uddi30crt_45_views_db2udb.sql`
   h. `db2 -vf uddi30crt_50_triggers_db2udb.sql`
   i. `db2 -tvf uddi30crt_60_insert_initial_static_data.sql`
9. [Optional] Enter the following command if you want the database to be used as a default UDDI node:
   `db2 -tvf uddi30crt_70_insert_default_database_indicator.sql`

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating a DB2 for iSeries database for the UDDI registry

Perform this task if you want to use DB2 for iSeries as the database store for your UDDI registry data.

Before you begin

IBMUDI30 and IBMUDS30 are the default names of the UDDI registry schema in the SQL scripts mentioned below. These default names are the recommended values and are assumed throughout the UDDI documentation. If you want to use different names, modify the SQL files listed below, then substitute your own names whenever you see 'IBMUDI30' or 'IBMUDS30' in other sections of the documentation.

About this task

You need to perform this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

1. Use iSeries Navigator to run SQL scripts.
   a. Open iSeries Navigator.
   b. Expand **My Connections** → **iSeriesName** → **Databases**.
   c. Select **iSeriesName**.

d. Right-click **Run SQL Scripts...**.

A **Run SQL Scripts** window opens.

2. Open the i5/OS DB2 SQL files.
   a. Map a network drive to the root directory of your i5/OS server's integrated file system.
   b. In Windows Explorer, expand the `WAS_HOME/UDDIReg/databaseScripts` directory.
   c. Open the following SQL files with a text editor (such as Notepad):
      - uddi30crt_10_prereq_db2_iSeries.sql
      - uddi30crt_20_tables_generic_iSeries.sql
      - uddi30crt_25_tables_db2udb_iSeries.sql
      - uddi30crt_30_constraints_generic_iSeries.sql
      - uddi30crt_35_constraints_db2udb_iSeries.sql
      - uddi30crt_40_views_generic_iSeries.sql
      - uddi30crt_45_views_db2udb_iSeries.sql
      - uddi30crt_50_triggers_db2udb_iSeries.sql
      - uddi30crt_60_insert_initial_static_data_iSeries.sql
3. Copy the text to the **Run SQL Scripts** window.
   a. In the text editor of the file `uddi30crt_10_prereq_db2_iSeries.sql`, click **Edit** → **Select All**.
   b. Click **Edit** → **Copy**.
   c. In the **Run SQL Scripts** window, click **Edit** → **Paste**.
   d. Click **Run** → **All**.
   e. After the script completes running, select all the SQL text and delete it from the **Run SQL Scripts** window.
   f. Repeat the above steps for all the SQL scripts listed in step 2.

   Note: iSeries Navigator for i5/OS V5R2 will encounter an error on the last line of the SQL script when running the `uddi30crt_25_tables_db2udb_iSeries.sql` script. This error can be ignored. i5/OS V5R2 does support running UDDI in a clustered high availability environment. For more information, see the WebSphere Application Server for i5/OS tech notes.
4. This step should only be run if you want your database to be used as a default UDDI node.
   a. Open `uddi30crt_70_insert_default_database_indicator.sql` as described in Step 2 above.
   b. Copy and run `uddi30crt_70_insert_default_database_indicator.sql` as described in Step 3 above.

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating an Apache Derby database for the UDDI registry

Perform this task to use Apache Derby (embedded or network) as the database store (either local or remote) for your UDDI registry.

Before you begin

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

arg1 The path of the SQL files. On a standard installation, this is *app_server_root*/UDDIReg/databasescripts

arg2 The path to the location where you want to install the Apache Derby database.

For example, *profile_root*/databases/com.ibm.uddi

arg3 The name of the Apache Derby database. A recommended value is UDDI30, and this name is assumed throughout the UDDI information. If you use another name, substitute that name when UDDI30 is used in the information center.

arg4 An optional argument, which must either be the string 'DEFAULT', or be omitted. Specify DEFAULT if you want the database to be used as a default UDDI node. This argument is case sensitive.

If you want to create a remote database, refer first to the database product documentation about the relevant capabilities of the product.

About this task

You need to perform this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

1. Start a Qshell session by entering the STRQSH command from the i5/OS command line.
2. Run the following Java -jar command from the *app_server_root*/UDDIReg/databaseScripts directory, to create a UDDI Apache Derby database using UDDIDerbyCreate.jar.

   ```
   java -Djava.ext.dirs=app_server_root/derby/lib:app_server_root/java/jre/lib/ext -jar UDDIDerbyCreate.jar
   arg1 arg2 arg3 arg4
   ```

   If the Apache Derby database already exists, you are asked if you want to recreate it. If you choose to recreate the database, your existing database is deleted and a new one is created in its place. If you choose not to recreate the database, the command exits and a new database is not created.

   Note: If the application server has already accessed the existing Apache Derby database, the uddiDeploy.jacl script cannot recreate the database. Use the uddiRemove.jacl script to remove the database, as described in "Removing a UDDI registry node" on page 978, restart the server, and run the uddiDeploy.jacl script again.
3. If you are using a remote database (which requires network Apache Derby), or you want to use network Apache Derby for other reasons, for example, if you want to use Apache Derby with a cluster, configure the Apache Derby Network Server framework. For details, see the section about managing the Derby Network Server in the Derby Server and Administration Guide.

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating an Oracle database for the UDDI registry

Perform this task if you want to use Oracle as the database store for your UDDI registry data. You need only do this once for each UDDI registry, as part of setting up and deploying a UDDI registry.

About this task

The supported versions of Oracle are Version 9i[3] and Version 10g[4]

3.

Restrictions:

discoveryURL (Business) maximum 4000 bytes, UDDI specification 4096 characters; accessPoint (bindingTemplate) maximum 4000 bytes, UDDI Specification 4096 characters; instanceParms (tModelInstanceInfo) maximum 4000 bytes, UDDI specification 8192 characters; overviewURL (tModelInstanceInfo) maximum 4000 bytes, UDDI specification 4096 characters; Digital Signature maximum 4000 bytes.

4.

You can create a remote database using Oracle, but not a local database. Because the database is remote, use the database product documentation to familiarize yourself with the relevant capabilities of the product before proceeding with this task.

Before you begin

This task creates three new schemas: ibmuddi, ibmudi30 and ibmuds30. You will be unable to complete this task if you already have existing schemas with these names.

The steps below use a number of variables for which you need to enter appropriate values. You should decide the values that you will use before you start. The variables used are:

<OracleUserID>
is the Oracle userid to be used to create the database.

<OraclePassword>
is the password for the Oracle userid.

1. Run the following commands:
   a. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_10_prereq_oracle.sql`
   b. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_20_tables_generic.sql`
   c. Complete one of the following actions depending on your level of Oracle:
      - For Oracle 9i:

```
sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_25_tables_oracle_pre10g.sql
```

      - For Version 10g and later:

```
sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_25_tables_oracle.sql
```

   d. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_30_constraints_generic.sql`
   e. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_35_constraints_oracle.sql`
   f. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_40_views_generic.sql`
   g. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_45_views_oracle.sql`
   h. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_50_triggers_oracle.sql`
   i. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_60_insert_initial_static_data.sql`
2. This last command should only be run if you want the database to be used as a default UDDI node.

```
sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_70_insert_default_database_indicator.sql
```

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating a data source for the UDDI registry

You create a data source so that the UDDI registry can use it to access the UDDI database.

Before you begin

You must have already created the database for the UDDI registry.

Restrictions:
discoveryURL (Business) maximum 4000 bytes, UDDI specification 4096 characters; accessPoint (bindingTemplate) maximum 4000 bytes, UDDI Specification 4096 characters.

About this task

Perform this task as part of setting up and deploying a new UDDI registry. The data source is used by the UDDI registry to access the UDDI database.

1. Create a J2C Authentication Data Entry. This is not required for embedded Apache Derby, but is required for network Apache Derby.
   a. Click **Security** → **Global security** → **[Authentication] Java Authentication and Authorization Service** → **J2C authentication data**.
   b. Click **New** to create a new J2C authentication data entry.
   c. Enter the following details:

      Alias A suitable short name, for example UDDIAlias.

      Userid

      The database user ID (for example db2admin for DB2, or IBMUDDI for Oracle), which is used to read and write to the UDDI registry database. For network Apache Derby, the user ID can be any value.

      Password
      The password associated with the user ID specified earlier. For network Apache Derby, the password can be any value.

      Description
      A description of the user ID.

      Click **Apply**, then save the changes to the master configuration.
2. Create a JDBC Provider, if a suitable one does not already exist, using the following table to determine the provider type and implementation type for your chosen database:

Database	Provider type	Implementation type
DB2	DB2 UDB for iSeries (Native)	Connection Pool data source
Oracle	Oracle JDBC Driver	Connection Pool data source
Embedded Apache Derby	Derby JDBC Driver	Connection Pool data source
Network Apache Derby	Derby Network Server JDBC Driver provider	Connection Pool data source
Microsoft SQL Server	DataDirect Connect JDBC Driver Microsoft SQL Server JDBC Driver	Connection Pool data source

   For details on how to create a JDBC provider, see Creating and configuring a JDBC provider using the administrative console.
3. Use the following steps to create the data source for the UDDI registry:
   a. Click **Resources** → **JDBC** → **JDBC Providers**.
   b. Select the scope of the JDBC provider that you selected or created earlier, that is, the level at which the JDBC provider is defined. For example, for a JDBC provider that is defined at the level of server1, select the following:

```
Node=Node01, Server=server1
```

      All the JDBC providers that are defined at the selected scope are displayed.
   c. Select the JDBC provider that you created earlier.
   d. Under **Additional Properties**, select **Data sources**. Do not select the **Data sources (WebSphere Application Server V4)** option.
   e. Click **New** to create a new data source.
   f. In the **Create a data source** wizard, enter the following data:

      Name A suitable name, for example UDDI Datasource.

JNDI name

Set this value to **datasources/uddids**. This is a mandatory field.

You must not have any other data sources that use this JNDI name. If you have another data source that uses this JNDI name, you must either remove it or change its JNDI name. For example, if you created a default UDDI node previously using an Apache Derby database, before you continue, use the uddiRemove.jacl script with the default option to remove the data source and the UDDI application instance.

Component-managed authentication alias

- For DB2, Oracle, or network Apache Derby, select the alias that you created in step 2. It is prefixed by the node name, for example MyNode/UDDIAlias.
- for embedded Apache Derby leave this set to (none).

g. Click **Next**.

h. On the database-specific properties page of the wizard, enter the following data:

- for DB2:

Database name

For example:

```
*LOCAL
```

- For Oracle - **URL** - for example:

```
jdbc:oracle:oci8:@<Oracle database name>
```

- For Apache Derby (embedded or network) - **Database name** - for example:

```
profile_root/databases/com.ibm.uddi/UDDI30
```

For network Apache Derby, also make sure that the **Server name** and **Port number** match the network server.

Use this Data Source in container-managed persistence (CMP)

Ensure that the check box is cleared.

i. Click **Next**, then check the summary and click **Finish**.

j. Click the data source to display its properties, and add the following information:

Description

A description of the data source.

Category

Set this value to uddi.

Data store helper class name

This value is provided automatically:

Database	Data store helper class name
DB2	com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper
Oracle 9i or 10g	com.ibm.websphere.rsadapter.Oracle10gDataStoreHelper
Oracle 11g	com.ibm.websphere.rsadapter.Oracle11gDataStoreHelper
Embedded Apache Derby	com.ibm.websphere.rsadapter.DerbyDataStoreHelper
Network Apache Derby	com.ibm.websphere.rsadapter.DerbyNetworkServerDataStoreHelper

Mapping-configuration alias

Set this option to DefaultPrincipalMapping.

k. Click **Apply**.

l. Select **Additional Properties** → **Custom Properties** → **libraries**.

m. Enter `IBMUDI30,IBMUDS30` in the **Value** field and click **OK**.

n. Save the changes to the master configuration.

4. Test the connection to your UDDI database by selecting the check box next to the data source and clicking **Test connection**. A message similar to "Test Connection for datasource UDDI Datasource on server server1 at node Node01 was successful" is displayed. If a different message is displayed, use the information in that message to investigate and resolve the problem.

What to do next

Continue with setting up and deploying your UDDI registry node.

Deploying the UDDI registry application

You deploy a UDDI registry application as part of setting up a UDDI node. You can either use the supplied script, or use the administrative console.

Before you begin

Before you deploy a UDDI registry application, you must create the database and data source for the UDDI registry.

About this task

Use this task as part of "Setting up a default UDDI node" on page 463 or "Setting up a customized UDDI node" on page 472.

1. Start a Qshell session by entering the STRQSH command from the i5/OS command line.
2. Run the uddiDeploy.jacl script as shown, from the *app_server_root*/bin directory.

   This script deploys the UDDI registry to a server that you specify.

   ```
   wsadmin [-conntype none] [-profileName profile_name] -f uddiDeploy.jacl
                  node_name
                  server_name
   ```

   where:

   - '-conntype none' is optional, and is needed only if the application server is not running.
   - '-profileName *profile_name*' is optional, and is the name of the profile in which the UDDI application is deployed. If you do not specify a profile, the default profile is used.
   - *node_name* is the name of the WebSphere Application Server node on which the target server runs. The node name is case sensitive.
   - *server_name* is the name of the target server on which you wish to deploy the UDDI registry, for example, server1. The server name is case sensitive.

   For example, to deploy UDDI on node 'MyNode' and server 'server1', (assuming that server1 is already started):

   ```
   wsadmin -f uddiDeploy.jacl MyNode server1
   ```

   You can also deploy the UDDI application (the uddi.ear file) using the administrative console, in the normal way. However, if you use the administrative console, some steps that the uddiDeploy.jacl script performs automatically do not occur. If you use the administrative console to install the UDDI application, you must perform some actions manually. To do this, use the following steps:

   a. Install the application.
   b. Click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***uddi_application*** → **[Detail Properties] Class loading and update detection**.
   c. Ensure that **Class loader order** is set to **Classes loaded with application class loader first**.
   d. Ensure that **WAR class loader policy** is set to **Single class loader for application**.

What to do next

Continue setting up the UDDI node.

Initializing the UDDI registry node

Use this topic to initialize a UDDI registry node after set up or migration.

Before you begin

You must have already set up a UDDI registry node, either as a new node or to use for migrating a UDDI registry Version 2 node.

About this task

The UDDI registry node has various properties, some of which must be set before initializing the node. There are two categories of UDDI registry node properties:

- Mandatory node properties. These properties must be set before the UDDI node can be initialized. You may set these properties as many times as you wish before initialization. However, once the UDDI node has been initialized, these properties will become read only for the lifetime of that UDDI node. It is very important to set these properties correctly.
- All other properties. These properties may be set before, and after, initialization.

Configure these properties and initialize the node using the UDDI administrative console or JMX management interface.

1. Click **UDDI** → **UDDI Nodes** > *UDDI_node_id* to display the properties page for the UDDI registry node.
2. Set the mandatory node properties to suitable, and valid, values. These properties are indicated by the presence of a '*' next to the input field. The properties are listed below; more information on each property is given in the context help of the administrative console.

   UDDI node ID
   This must be a text string beginning with 'uddi:' that is unique to this UDDI node. The default value may be sufficient, but if you accept it you should ensure that it is unique.

   UDDI node description
   This is a text string describing the node.

   Root key generator
   This must be a text string beginning with 'uddi:' that is unique to this UDDI node. The default value may be sufficient but may contain text, such as 'keyspace_id', that you should modify to match your system. If you accept the default value, ensure that it is unique for this UDDI node.

   Prefix for generated discoveryURLs
   This should be a valid URL.
3. If you are migrating from Version 2 of the UDDI registry, use the table below to perform the following steps:
   - Set any properties from uddi.properties that **must** remain the same as Version 2.
   - Set any properties from uddi.properties that you would like to keep the same (such as dbMaxResultCount).

Version 2 UDDI property (set in uddi.property file)	Version 3 UDDI Property (set via Administrative Console or UDDI Administrative Interface)	Recommended Version 3 UDDI property setting
dbMaxResultCount	maximum inquiry response set size	You might want to retain the value from Version 2, but can safely change this (or use the default)
persister	no equivalent	Not applicable

Version 2 UDDI property (set in uddi.property file)	Version 3 UDDI Property (set via Administrative Console or UDDI Administrative Interface)	Recommended Version 3 UDDI property setting
defaultLanguage	default language code	You are recommended to retain the value from Version 2
operatorName	UDDI node ID	You must use a valid value for the UDDI node ID. This will be applied to your Version 2 data as it is migrated.
maxSearchKeys	maximum search keys	You might want to retain the value from Version 2, but can safely change this (or use the default)
getServletURLprefix	Prefix for generated discoveryURLs	You should enter a valid value for your configuration, which should therefore be the same as the value used for Version 2.
getServletName	no equivalent	Not applicable

4. Set any other properties, such as policy values, that you wish to change from the default settings (or these can be changed at a later time). For an explanation of policies and properties see “UDDI node settings” on page 989.
5. Click **Apply** to save your changes.

   Note: You cannot change mandatory node properties after initialization. If you do not save your changes before proceeding to the initialize step, you will have to delete and recreate the database.
6. After saving your changes, initialize the UDDI node by clicking **Initialize**, at the top of the pane.

   If you are migrating from Version 2 of the UDDI registry, the Version 2 data is migrated now. The initialization may take some time to complete; to track its progress, return to the node collection page and click the refresh icon at the top of the **Status** column. Alternatively, open a second administrative console window, and use the refresh icon in the same manner. The UDDI node passes through the following states
   a. Initialization pending.
   b. Initialization in progress.
   c. Migration in progress. (This state will only occur if you are migrating.)
   d. Value set creation in progress.
   e. Activated.

What to do next

If you have migrated the node from a previous version, return to Migrating to Version 3 of the UDDI registry to verify that the migration was successful. If you have created a new node, follow the instructions in “Using the UDDI registry Installation Verification Program (IVP)” to verify that you have successfully set up the UDDI node.

Using the UDDI registry Installation Verification Program (IVP)

Use the Installation Verification Program (IVP) to verify that you have successfully deployed a UDDI registry.

Before you begin

This topic describes a simple test that you can carry out as an Installation Verification Program (IVP) to verify that you have deployed a UDDI registry successfully. You should perform this task *after* you have followed the instructions in Setting up and Deploying a new UDDI registry.

1. Open a browser window and enter the URL that accesses the UDDI registry User Interface (see Using the UDDI registry user interface).

2. Under the **Quick Find** heading on the **Find** tab, click the **Business** radio button and enter % in the **Starting with** field.
3. Click **Find**. If you have deployed your UDDI registry successfully, the detail frame displays the business entity which represents this UDDI node. You can click on the business entity to see its detail.

What to do next

As a further installation verification test, you can publish and find more UDDI entities by using the UDDI registry User Interface, or you can compile and run one or more of the UDDI registry samples available through the UDDI registry link on the Samples for WebSphere Application Server page of the IBM developerWorks® WebSphere Web site.

Changing the UDDI registry application environment after deployment

You can change the environment of the UDDI registry application after you deploy it. This means you can evaluate a UDDI registry using one database, then put it into production using a different database, or you can move from a standalone application server to a network deployment cell.

About this task

After you deploy the UDDI registry application, you might want to change its environment. For example, you might perform initial evaluation of the UDDI registry using an Apache Derby database, and then want to put the UDDI registry into production using a DB2 database, or you might want to move from a standalone application server to a network deployment cell.

1. Optional: To move from a default UDDI node to a customized UDDI node, delete the UDDI registry database and recreate it by completing one of the following tasks, ensuring that you do NOT use the default node options where specified:
   - “Creating a DB2 distributed database for the UDDI registry” on page 464
   - “Creating a DB2 for iSeries database for the UDDI registry” on page 465
   - “Creating an Apache Derby database for the UDDI registry” on page 467
   - “Creating an Oracle database for the UDDI registry” on page 468

   Note: Any data saved in the default node (policies, properties and user data) will be lost when you delete the database. If you do not want to delete the database, you can instead create an entirely new customized UDDI node in a separate application server. The default UDDI node will still exist for you to use for test purposes.
2. Optional: To change the database type for the UDDI registry, perform the following steps:
   a. Stop the UDDI registry application (click **Applications** → **Application Types** → **WebSphere enterprise applications**, select the relevant check box and click **Stop**).
   b. Either change the JNDI name of the existing datasource from datasources/uddids to another value, or delete the datasource. To display the datasource properties click **Resources** → **JDBC** → **JDBC providers >** *database_type* **JDBC Provider > [Additional Properties] Data sources >** *uddi_datasource*.
   c. Create the new database by referring to one of the following topics:
      - “Creating a DB2 distributed database for the UDDI registry” on page 464
      - “Creating a DB2 for iSeries database for the UDDI registry” on page 465
      - “Creating an Apache Derby database for the UDDI registry” on page 467
      - “Creating an Oracle database for the UDDI registry” on page 468
   d. To transfer your UDDI data, use the standard capabilities of the database products to export the data from the old database, and import it into the new one.
   e. Create the new datasource. See “Creating a data source for the UDDI registry” on page 469.
   f. Restart the UDDI registry application.

g. Check that you can access your UDDI data, then delete the old database.

Creating a DB2 distributed database for the UDDI registry

Perform this task if you want to use DB2 on the Windows, Linux or UNIX operating systems, as the database store for your UDDI registry data.

Before you begin

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

<DataBaseName>
The name of the UDDI registry database. A recommended value is UDDI30, and this name is assumed throughout the UDDI information. If you use another name, substitute that name when UDDI30 is used in the information center.

<DB2UserID>
A DB2 userid with administrative privileges.

<DB2Password>
The password for the DB2 userid.

<BufferPoolName>
The name of a buffer pool to be used by the UDDI registry database. A suggested name is uddibp, but any name can be used, because the buffer pool is created as part of this task.

<TableSpaceName>
The name of a table space. A suggested value is uddits, but any name can be used.

<TempTableSpaceName>
The name of a temporary table space. A suggested value is udditstemp, but any name can be used, because the temporary table space is created as part of this task.

About this task

You need to perform this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

If you want to create a remote database, refer first to the database product documentation about the relevant capabilities of the product.

1. Change directory to *app_server_root*/UDDIReg/databaseScripts.
2. Start the DB2 Command Line Processor by entering `db2` at the command prompt.
3. Run the following command to setup the DB2 environment variables:
   ```
   set DB2CODEPAGE=1208
   ```
4. Create the DB2 database by entering the following command:
   ```
   create database <DataBaseName> using codeset UTF-8 territory en
   ```
   where <DataBaseName> is the name of the database being created.
5. Configure the DB2 database by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `update db cfg for <DataBaseName> using applheapsz 2048`
   c. `update db cfg for <DataBaseName> using logfilsiz 8192`
   d. `connect reset`
   e. `terminate`
6. Create additional database structures by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`

b. `create bufferpool <BufferPoolName> size 250 pagesize 32K`
c. `connect reset`
d. `terminate`
e. `force application all`
f. `terminate`
g. `stop`
h. `start`

7. Create further database structures by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `create regular tablespace uddits pagesize 32K managed by system using ('<TableSpaceName>') extentsize 64 prefetchsize 32 bufferpool <BufferPoolName>`
   c. `create system temporary tablespace <TempTableSpacename> pagesize 32K managed by system using ('<TempTableSpacename>') extentsize 32 overhead 14.06 prefetchsize 32 transferrate 0.33 bufferpool <BufferPoolName>`
8. Exit the DB2 Command Line Processor and enter the following commands exactly as shown, noting that one step uses -vf rather than -tvf (on Windows platforms, run the commands from the db2cmd window). These commands define the database structures needed to store the UDDI data:
   a. `db2 -tvf uddi30crt_10_prereq_db2.sql`
   b. `db2 -tvf uddi30crt_20_tables_generic.sql`
   c. `db2 -tvf uddi30crt_25_tables_db2udb.sql`
   d. `db2 -tvf uddi30crt_30_constraints_generic.sql`
   e. `db2 -tvf uddi30crt_35_constraints_db2udb.sql`
   f. `db2 -tvf uddi30crt_40_views_generic.sql`
   g. `db2 -tvf uddi30crt_45_views_db2udb.sql`
   h. `db2 -vf uddi30crt_50_triggers_db2udb.sql`
   i. `db2 -tvf uddi30crt_60_insert_initial_static_data.sql`
9. [Optional] Enter the following command if you want the database to be used as a default UDDI node:
   `db2 -tvf uddi30crt_70_insert_default_database_indicator.sql`

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating a DB2 for iSeries database for the UDDI registry

Perform this task if you want to use DB2 for iSeries as the database store for your UDDI registry data.

Before you begin

IBMUDI30 and IBMUDS30 are the default names of the UDDI registry schema in the SQL scripts mentioned below. These default names are the recommended values and are assumed throughout the UDDI documentation. If you want to use different names, modify the SQL files listed below, then substitute your own names whenever you see 'IBMUDI30' or 'IBMUDS30' in other sections of the documentation.

About this task

You need to perform this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

1. Use iSeries Navigator to run SQL scripts.
   a. Open iSeries Navigator.
   b. Expand **My Connections** → **iSeriesName** → **Databases**.

c. Select **iSeriesName**.
d. Right-click **Run SQL Scripts...**.

A **Run SQL Scripts** window opens.

2. Open the i5/OS DB2 SQL files.
   a. Map a network drive to the root directory of your i5/OS server's integrated file system.
   b. In Windows Explorer, expand the `WAS_HOME/UDDIReg/databaseScripts` directory.
   c. Open the following SQL files with a text editor (such as Notepad):
      - uddi30crt_10_prereq_db2_iSeries.sql
      - uddi30crt_20_tables_generic_iSeries.sql
      - uddi30crt_25_tables_db2udb_iSeries.sql
      - uddi30crt_30_constraints_generic_iSeries.sql
      - uddi30crt_35_constraints_db2udb_iSeries.sql
      - uddi30crt_40_views_generic_iSeries.sql
      - uddi30crt_45_views_db2udb_iSeries.sql
      - uddi30crt_50_triggers_db2udb_iSeries.sql
      - uddi30crt_60_insert_initial_static_data_iSeries.sql
3. Copy the text to the **Run SQL Scripts** window.
   a. In the text editor of the file `uddi30crt_10_prereq_db2_iSeries.sql`, click **Edit** → **Select All**.
   b. Click **Edit** → **Copy**.
   c. In the **Run SQL Scripts** window, click **Edit** → **Paste**.
   d. Click **Run** → **All**.
   e. After the script completes running, select all the SQL text and delete it from the **Run SQL Scripts** window.
   f. Repeat the above steps for all the SQL scripts listed in step 2.

   Note: iSeries Navigator for i5/OS V5R2 will encounter an error on the last line of the SQL script when running the `uddi30crt_25_tables_db2udb_iSeries.sql` script. This error can be ignored. i5/OS V5R2 does support running UDDI in a clustered high availability environment. For more information, see the WebSphere Application Server for i5/OS tech notes.
4. This step should only be run if you want your database to be used as a default UDDI node.
   a. Open `uddi30crt_70_insert_default_database_indicator.sql` as described in Step 2 above.
   b. Copy and run `uddi30crt_70_insert_default_database_indicator.sql` as described in Step 3 above.

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating an Apache Derby database for the UDDI registry

Perform this task to use Apache Derby (embedded or network) as the database store (either local or remote) for your UDDI registry.

Before you begin

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

arg1 The path of the SQL files. On a standard installation, this is *app_server_root*/UDDIReg/databasescripts

arg2 The path to the location where you want to install the Apache Derby database.

For example, *profile_root*/databases/com.ibm.uddi

arg3 The name of the Apache Derby database. A recommended value is UDDI30, and this name is assumed throughout the UDDI information. If you use another name, substitute that name when UDDI30 is used in the information center.

arg4 An optional argument, which must either be the string 'DEFAULT', or be omitted. Specify DEFAULT if you want the database to be used as a default UDDI node. This argument is case sensitive.

If you want to create a remote database, refer first to the database product documentation about the relevant capabilities of the product.

About this task

You need to perform this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

1. Start a Qshell session by entering the STRQSH command from the i5/OS command line.
2. Run the following Java -jar command from the *app_server_root*/UDDIReg/databaseScripts directory, to create a UDDI Apache Derby database using UDDIDerbyCreate.jar.

   ```
   java -Djava.ext.dirs=app_server_root/derby/lib:app_server_root/java/jre/lib/ext -jar UDDIDerbyCreate.jar
   arg1 arg2 arg3 arg4
   ```

   If the Apache Derby database already exists, you are asked if you want to recreate it. If you choose to recreate the database, your existing database is deleted and a new one is created in its place. If you choose not to recreate the database, the command exits and a new database is not created.

   Note: If the application server has already accessed the existing Apache Derby database, the uddiDeploy.jacl script cannot recreate the database. Use the uddiRemove.jacl script to remove the database, as described in "Removing a UDDI registry node" on page 978, restart the server, and run the uddiDeploy.jacl script again.
3. If you are using a remote database (which requires network Apache Derby), or you want to use network Apache Derby for other reasons, for example, if you want to use Apache Derby with a cluster, configure the Apache Derby Network Server framework. For details, see the section about managing the Derby Network Server in the Derby Server and Administration Guide.

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating an Oracle database for the UDDI registry

Perform this task if you want to use Oracle as the database store for your UDDI registry data. You need only do this once for each UDDI registry, as part of setting up and deploying a UDDI registry.

About this task

The supported versions of Oracle are Version 9i[5] and Version 10g[6]

5.

Restrictions:

discoveryURL (Business) maximum 4000 bytes, UDDI specification 4096 characters; accessPoint (bindingTemplate) maximum 4000 bytes, UDDI Specification 4096 characters; instanceParms (tModelInstanceInfo) maximum 4000 bytes, UDDI specification 8192 characters; overviewURL (tModelInstanceInfo) maximum 4000 bytes, UDDI specification 4096 characters; Digital Signature maximum 4000 bytes.

6.

You can create a remote database using Oracle, but not a local database. Because the database is remote, use the database product documentation to familiarize yourself with the relevant capabilities of the product before proceeding with this task.

Before you begin

This task creates three new schemas: ibmuddi, ibmudi30 and ibmuds30. You will be unable to complete this task if you already have existing schemas with these names.

The steps below use a number of variables for which you need to enter appropriate values. You should decide the values that you will use before you start. The variables used are:

<OracleUserID>
is the Oracle userid to be used to create the database.

<OraclePassword>
is the password for the Oracle userid.

1. Run the following commands:
   a. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_10_prereq_oracle.sql`
   b. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_20_tables_generic.sql`
   c. Complete one of the following actions depending on your level of Oracle:
      - For Oracle 9i:

```
sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_25_tables_oracle_pre10g.sql
```

      - For Version 10g and later:

```
sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_25_tables_oracle.sql
```

   d. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_30_constraints_generic.sql`
   e. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_35_constraints_oracle.sql`
   f. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_40_views_generic.sql`
   g. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_45_views_oracle.sql`
   h. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_50_triggers_oracle.sql`
   i. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_60_insert_initial_static_data.sql`
2. This last command should only be run if you want the database to be used as a default UDDI node.

```
sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_70_insert_default_database_indicator.sql
```

What to do next

Continue with setting up and deploying your UDDI registry node.

Configuring Web services applications using scripting

You can use the wsadmin scripting tool to complete the several tasks for a Web services application.

Before you begin

Develop a Web services application.

Restrictions:
discoveryURL (Business) maximum 4000 bytes, UDDI specification 4096 characters; accessPoint (bindingTemplate) maximum 4000 bytes, UDDI Specification 4096 characters.

About this task

The WebSphere Application Server wsadmin tool provides the ability to run scripts. You can use the wsadmin tool to manage a WebSphere Application Server installation, as well as configuration, application deployment, and server run-time operations. The WebSphere Application Server only supports the Jacl and Jython scripting languages.

To use the wsadmin tool to configure a Web services application, publish a Web Services Description Language (WSDL) file, or to configure policy sets:

1. Launch a scripting command.
2. Follow the steps in one of the following topics, depending on what task you want to complete:
   - Publish WSDL files.
   - Configure Web service client deployed WSDL file names.
   - Configure Web service client bindings.
   - Configure Web service client preferred port mappings .
   - Configure Web service client port information .
   - Configure the scope of a Web service port .

Results

You have configured Web services applications with the wsadmin tool.

Querying Web services with the wsadmin tool

You can use the Jython or Jacl scripting language to query for Web services properties with the wsadmin tool. Use the commands in the WebServicesAdmin group to list all Web services and attributes, find attributes of a specific Web service, determine the Web service endpoint, and determine the operation name of a Web service.

Before you begin

The wsadmin administrative scripting program supports two scripting languages, Jacl and Jython. The Jacl syntax is deprecated. This topic includes examples written only in the Jython scripting language.

Before you can complete the procedure for the commands in the WebServicesAdmin group, you must launch the wsadmin tool.

About this task

Use the following commands to query for Web services and Web service attributes. If you receive a NoItemFoundException error, the specified application, module, service, or endpoint cannot be found. Verify that all input parameters are correct.

You can optionally specify the client parameter for any command in the WebServicesAdmin command group. The client parameter indicates whether to return service providers or service clients. Specify `false` to request service providers and `true` to request service clients.

- Query the configuration for all installed Web services for all enterprise applications.

  Enter the following command. You do not need to specify the application parameter for this command.

```
AdminTask.listWebServices()
```

  This command returns all installed Web services. The command also returns the application name, module name, service name, and service type for each Web service.

  Sample output:

```
'[ [service {http://www.ibm.com}service1] [client false] [application
application1] [module webapp1.war] [type JAX-WS] ]'
```

- Query the configuration for all installed Web services for a specific enterprise application.

  Enter the following command, and specify the name of the application you want to query:

```
AdminTask.listWebServices('[–application application_name -client false]')
```

  This command returns all installed Web services for the *application_name* that you specify. The command also returns the application name, module name, service name, and service type for each Web service.

  Sample output:

```
'[ [service {http://www.ibm.com}service1] [client false] [application
application1] [module webapp1.war] [type JAX-WS] ]'
```

- Query the configuration for the Web service name and type for a enterprise application.

  Enter the following command, and specify the application name, module name, and Web service name. The **client** parameter is optional.

```
AdminTask.getWebService('[–application application_name
-module module_name -service webservice_name -client false]')
```

  The command returns the Web service name and Web service type.

  Sample output:

```
'[ [service {http://www.ibm.com}service1] [client false] [type JAX-WS] ]'
```

- Query the configuration for the Web service endpoints for a enterprise application.

  The logical endpoint name is the port name in the Web Services Description Language (WSDL) document. Enter the following command, and specify the application name, module name, and Web service name. The **client** parameter is optional.

```
AdminTask.listWebServiceEndpoints('[–application application_name
 -module module_name -service webservice_name -client false]')
```

  This command returns the port on which the Web service is installed.

  Sample output:

```
'[logicalEndpoint QuotePort01]'
```

- Query the configuration for the Web service operation names for a enterprise application.

  Enter the following command, and specify the application name, module name, Web service name, and endpoint name. The logical endpoint name is the port name in the Web Services Description Language (WSDL) document. The **client** parameter is optional.

```
AdminTask.listWebServiceOperations('[–application application_name -module module_name
-service webservice_name -logicalEndpoint endpoint_name -client false]')
```

  This command returns all Web service operations.

  Sample output:

```
'[operation ivt_app_op1] [operation ivt_app_op2]'
```

- Query the configuration for the service providers, endpoints, and operations from each deployed asset.

  The listServices command provides generic query functions. Use the following command to display information about service providers, endpoints, and operations for enterprise applications and Web Services Notification (WSN) clients. Each parameter is optional. If you do not specify the queryProps parameter, the command returns each service provider in your configuration. If you do not specify the expandResources parameter, the command does not return the logical endpoints or operations for each service. The following command example returns each service provider and the corresponding endpoints for the `myApplication` application:

```
AdminTask.listServices('-queryProps "[[CompositionUnit=myApplication][client=false]" -expandResources endpoint']
```

  The following command example returns each JAX-WS service provider and the corresponding endpoints and operations within a cell:

```
AdminTask.listServices('[-queryProps "[[serviceType JAX-WS][client false]]"]')
```

  This command returns the service providers that match the search query.

Sample output:

```
'[ [service {http://com/ibm/was/wssample/sei/echo/}EchoService] [assetType [J2EE Application]] [client false] [application WSSampleServicesSei]
 [module SampleServicesSei.war] [serviceType JAX-WS] ]

[ [service {http://com/ibm/was/wssample/sei/echo/}EchoService12] [assetType [J2EE Application]] [client false] [application WSSampleServicesSei]
 [module SampleServicesSei.war] [serviceType JAX-WS] ]

[service {http://com/ibm/was/wssample/sei/ping/}PingService] [assetType [J2EE Application]] [client false] [application WSSampleServicesSei]
 [module SampleServicesSei.war] [serviceType JAX-WS] ]

[ [service {http://com/ibm/was/wssample/sei/ping/}PingService12] [assetType [J2EE Application]] [client false] [application WSSampleServicesSei]
 [module SampleServicesSei.war] [serviceType JAX-WS]]'
```

The following command example returns each WSN service client and the corresponding endpoints and operations within a cell:

```
AdminTask.listServices('[-queryProps "[[serviceType [JAX-WS (WSN)]][clie
nt true]]" -expandResource logicalEndpoint]')
```

This command returns the service providers that match the search query.

Sample output:

```
'[ [service {http://www.ibm.com/websphere/wsn/out/remote-publisher}OutboundRemotePublisherService] [assetType [WSN Service]] [client true]
 [bus bus1] [WSNService wsn1] [serviceType [JAX-WS (WSN)]] ]

[ [assetType [WSN Service]] [service {http://www.ibm.com/websphere/wsn/out/remote-publisher}OutboundRemotePublisherService]
 [bus bus1] [client true] [WSNService wsn1] [serviceType [JAX-WS (WSN)]] [logicalEndpoint OutboundRemotePublisherPort] ]

[ [service {http://www.ibm.com/websphere/wsn/out/notification}OutboundNotificationService] [assetType [WSN Service]] [client true]
 [bus bus1] [WSNService wsn1] [serviceType [JAX-WS (WSN)]] ]

[ [assetType [WSN Service]] [service {http://www.ibm.com/websphere/wsn/out/notification}OutboundNotificationService]
 [bus bus1] [client true] [WSNService wsn1] [serviceType [JAX-WS (WSN)]] [logicalEndpoint OutboundNotificationPort] ]'
```

Starting the wsadmin scripting client
You can use the wsadmin tool to configure and administer application servers, application deployment, and server run-time operations.

“Configuring application and system policy sets for Web services using scripting” on page 497
Use the wsadmin tool, which supports the Jython and Jacl scripting languages, to configure application or system policy sets for Web services. You can manage the policies for the Quality of Service (QoS) by creating policy sets and managing associated policies.

Using scripting (wsadmin)
The WebSphere administrative (wsadmin) scripting program is a powerful, non-graphical command interpreter environment enabling you to run administrative operations in a scripting language.

WebServicesAdmin command group for the AdminTask object

Use this topic as a reference for the commands for the WebServicesAdmin group of the AdminTask object. Use these commands with your administrative scripts to list available Web services, list web services attributes, determine the endpoint configuration for a Web service, and determine a specific operation name.

Use the commands in the WebServicesAdmin group to query information for installed web services. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the WebServicesAdmin group of the AdminTask object.

- “getWebService” on page 492
- “listServices” on page 492
- “listWebServices” on page 494
- “listWebServicesEndpoints” on page 495
- “listWebServicesOperations” on page 496

getWebService

The getWebService command retrieves the attributes for a Web service. This command applies to enterprise applications only.

Target object

None.

Required parameters

-application
Specifies the name of the deployed enterprise application. (String, required)

-module
Specifies the name of the module. (String, required)

-service
Specifies the name of the Web service. (String, required)

Optional parameters

-client
Specifies whether the Web service is a provider or a client. The default value is `false` (service provider). When set to `true`, the command only returns Web service clients. (Boolean, optional)

Return value

Returns a list of attributes, including service name, whether the service is a provider or client, and service type. The service type attribute is only applicable for service providers.

Batch mode example usage

Using Jython string:

```
AdminTask.getWebService('[–application application_name -module module_name -service webservice_name -client false]')
```

Sample output:

```
'[[service {http://www.ibm.com}service1][type JAX-WS][client false]]'
```

Interactive mode example usage

Using Jython:

```
AdminTask.getWebService ('-interactive')
```

listServices

The listServices command queries the configuration for services, endpoints, and operations. This command provides more generic query functions than the rest of commands in this command group. It is applicable to Java™ applications as well as other assets such as Web Services Notification (WSN) clients.

Target object

None.

Optional parameters

-queryProps

Specifies properties used to locate the service provider or client of interest. For example, if you specify `[[type=JAX-WS][client=true]]`, the command returns each JAX-WS reference in the enterprise applications. (Properties, optional)

The -queryProps parameter accepts the several properties. You can use one or multiple properties to specify your query criteria. Do not mix the query properties between different asset types. For example, if you specify `application` and `bus`, the command reports an error.

- Specify the following properties with the -queryProps parameter to query enterprise applications:

Property and value	Description
`assetType=J2EE Application`	Queries each Java EE application.
`application=`*`application_name`*	Queries a specific Java EE application.
`module=`*`module_name`*	Queries a specific Java EE application module. You must specify the `application` and `module` properties to query for application modules.

- Specify the following properties with the -queryProps parameter to query for WSN clients:

Property and value	Description
`assetType=WSN Service`	Queries each WSN service client.
`bus=`*`bus_name`*	Queries a specific bus.
`WSNService=`*`WSN_service_name`*	Queries a specific WSN service. You must specify the `bus` and `WSNService` properties to query for a specific WSN service.

- Specify the following properties with the -queryProps parameter to query all assets:

Property and value	Description
`serviceType=`*`service_type`*	Queries by service type. Specify `JAX-WS` to query for Java™ API for XML-Based Web Services assets. Specify `JAX-WS (WSN)` to query for Web Services Notification assets.
`client=`*`Boolean`*	Queries for clients or providers. Specify `true` to query for clients. Specify `false` to query for providers.
`service=`*`service_name`*	Queries for the logical endpoints and operations for a specific service.

-expandResource

Specifies whether to return service names only or services and detailed resource information. Specify `logicalEndpoint` or `operation`. If you specify the `logicalEndpoint` value, the command returns the matching services and each endpoint in the services. If you specify the `operation` value, the command returns the matching services and the corresponding endpoints and operations. (String, optional)

Return value

The command returns a list of properties for each service, as well as detailed endpoint and operation information if you query for endpoints and operations.

Batch mode example usage

The following examples query each service provider in the `myApplication` application. The examples return the logical endpoints for each service because the -expandResources parameter is set as `logicalEndpoint`, as the following example output demonstrates:

```
[ [service {http://com/ibm/was/wssample/sei/echo/}EchoService] [assetType [J2EE Application]]
 [client false] [application MyWSApplication] [module ServicesModule.war] [serviceType JAX-WS] ]
[ [assetType [J2EE Application]] [service {http://com/ibm/was/wssample/sei/echo/}EchoService]
 [client false] [application MyWSApplication] [module ServicesModule.war] [serviceType JAX-WS] [logicalEndpoint EchoServicePort] ]

[ [service {http://com/ibm/was/wssample/sei/ping/}PingService] [assetType [J2EE Application]]
 [client false] [application MyWSApplication] [module ServicesModule.war] [serviceType JAX-WS] ]
[ [assetType [J2EE Application]] [service {http://com/ibm/was/wssample/sei/ping/}PingService]
 [client false] [application MyWSApplication] [module ServicesModule.war] [serviceType JAX-WS]
 [logicalEndpoint PingServicePort] ]
```

Using Jython string:

```
AdminTask.listServices('[-queryProps [[application MyWSApplication][client false]] -expandResource logicalEndpoint]')
```

Using Jython list:

```
AdminTask.listServices(['–queryProps', '[[application myApplication][client false]]', '-expandResource', 'logicalEndpoint'])
```

The following examples query each service client under the myBus bus. The examples do not return logical endpoints or operations for each service client because it does not specify the -expandResource parameter.

Using Jython string:

```
AdminTask.listServices('[–queryProps [[bus myBus][client true]] ]')
```

Using Jython list:

```
AdminTask.listServices(['–queryProps', '[[bus myBus][client true]]'])
```

Interactive mode example usage

Using Jython:

```
AdminTask.listServices('-interactive')
```

listWebServices

The listWebServices command retrieves a list of available Web services for one or all applications. If an application name is not supplied, the command lists all of the Web services. This command applies to enterprise applications only.

Target object

None.

Required parameters

None.

Optional parameters

-application
Specifies the name of the deployed enterprise application. If you do not specify this parameter, the command returns all Web services in the cell. (String, optional)

-client
Specifies whether the Web service is a provider or a client. The default value is false (service provider). When set to true, the command only returns Web service clients. (Boolean, optional)

Return value

All Web services for the application specified. For each Web service, the command returns the following attributes and corresponding values: application name, module name, service name, whether the Web service is a service provider or client, and service type. The service type is only specified if the Web service is a service provider.

Batch mode example usage

Using Jython string:

```
AdminTask.listWebServices('[–application application1 -client false]')
```

Using Jython list:

```
AdminTask.listWebServices(['–application', 'application1', '-client', 'false'])
```

Sample output:

```
'[[service {http://www.ibm.com}service1][application application1][module webapp1.war][type JAX-WS][client false]]'
```

Interactive mode example usage

Using Jython:

```
AdminTask.listWebServices('-interactive')
```

listWebServicesEndpoints

The listWebServicesEndpoints command returns a list of logical endpoints for a Web service. The logical endpoint name is the port name in the Web Services Description Language (WSDL) document. This command applies to enterprise applications only.

Target object

None.

Required parameters

-application
Specifies the name of the deployed enterprise application. (String, required)

-module
Specifies the name of the module. (String, required)

-service
Specifies the name of the Web service. (String, required)

Optional parameters

-client
Specifies whether the Web service is a provider or a client. The default value is `false` (service provider). When set to `true`, the command only returns Web service clients. (Boolean, optional)

Return value

Returns the logical endpoint name for the Web service specified.

Batch mode example usage

Using Jython string:

```
AdminTask.listWebServiceEndpoints('[–application application_name -module module_name -service webservice_name -client false]')
```

Using Jython list:

```
AdminTask.listWebServiceEndpoints(['–application', 'application_name', '-module', 'module_name', '-service', 'webservice_name', '-client', 'false'])
```

Sample output:

```
'[[logicalEndpoint QuotePort01]]'
```

Interactive mode example usage

Using Jython:

```
AdminTask.listWebServicesEndpoints('-interactive')
```

listWebServicesOperations

The listWebServicesOperations command returns a list of Web service operations. This command applies to enterprise applications only.

Target object

None.

Required parameters

-application
Specifies the name of the deployed enterprise application. (String, required)

-module
Specifies the name of the module. (String, required)

-service
Specifies the name of the Web service. (String, required)

-logicalEndpoint
The port name in the Web Services Description Language (WSDL) document. (String, required)

Optional parameters

-client
Whether the Web service is a provider or a client. The default value is `false` (service provider). When set to `true`, the command only returns Web service clients. (Boolean, optional)

Return value

Returns the operation name for the Web service specified.

Batch mode example usage

Using Jython string:

```
AdminTask.listWebServiceOperations('[–application application_name -module module_name -service webservice_name -client false
 -logicalEndpoint endpoint_name]')
```

Using Jython list:

```
AdminTask.listWebServiceOperations(['–application', 'application_name', '-module', 'module_name', '-service', 'webservice_name', '-client',
 'false', '-logicalEndpoint', 'endpoint_name'])
```

Sample output:

```
'[[operation ivt_app_op1][operation ivt_app_op2]]'
```

Interactive mode example usage

Using Jython:

```
AdminTask.listWebServicesOperations('-interactive')
```

Configuring application and system policy sets for Web services using scripting

Use the wsadmin tool, which supports the Jython and Jacl scripting languages, to configure application or system policy sets for Web services. You can manage the policies for the Quality of Service (QoS) by creating policy sets and managing associated policies.

Before you begin

Develop a Web services application. For additional information, see the Web services applications topics in the information center.

If you develop an application that uses a custom policy set, the custom policy set configuration is not included in the application enterprise archive (EAR) file. Install the application and import the custom policy set separately.

About this task

The commands in the PolicySetManagement group for the AdminTask object configure both application and system policy sets. Use the following tasks to configure and manage policy sets for your Web services.

Note: In WebSphere Application Server Version 7.0, the security model is enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

To support a mixed-cell environment, WebSphere Application Server supports Version 7.0 and Version 6.1 bindings. General cell-level bindings are specific to Version 7.0 Application-specific bindings remain at the version that the application requires. When the user creates an application-specific binding, the application server determines the required binding version to use for application.

Use the following guidelines to manage bindings in your environment:

- To display or modify default Version 6.1 bindings, Version 7.0 trust service bindings, or to reference bindings by attachment for an application, specify the attachmentId and bindingLocation parameters with the getBinding or setBinding commands.
- To use or modify general Version 7.0 bindings, specify the bindingName parameter with the getBinding or setBinding commands.
- To display the version of a specific binding, specify the **version** attribute for the getBinding command.

Use a Version 6.1 binding for an application in a Version 7.0 environment if:

- The module in the application is installed on at least one Web Services Feature Pack server.
- The application contains at least one Version 6.1 application-specific binding. The application server does not assign general bindings to resource attachments for applications that are installed on a Web Services Feature Pack server. All application-specific bindings for an application must be at the same level.

General service provider and client bindings are not linked to a particular policy set and they provide configuration information that you can reuse across multiple applications. You can create and manage general provider and client policy set bindings and then select one of each binding type to use as the

default for an application server. Setting the server default bindings is useful if you want the services that are deployed to a server to share binding configuration. You can also accomplish this sharing of binding configuration by assigning the binding to each application deployed to the server or by setting default bindings for a security domain and assigning the security domain to one or more servers. You can specify default bindings for your service provider or client that are used at the global security (cell) level, for a security domain, for a particular server. The default bindings are used in the absence of an overriding binding specified at a lower scope. The order of precedence from lowest to highest that the application server uses to determine which default bindings to use is as follows:

1. Server level default
2. Security domain level default
3. Global security (cell) default

The sample general bindings that are provided with the product are initially set as the global security (cell) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. For trust service attachments, the default bindings are used when no trust specific bindings are assigned. If you do not want to use the provided Provider sample as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided Client sample as the default service client binding, you can select an existing general client binding or create a new general client binding.

- Use the PolicySetManagement group of commands to configure application and client policy sets:
  - Create a new policy set or copy an existing policy set.
  - Add policies to your policy set.
  - Attach your policy set to an application, Web service, endpoint, or operation.
  - Customize cell-wide, server-specific, or application binding configurations.
  - Manage and edit your policy set configurations.
    - Edit, enable, disable, or remove policies.
    - Add, edit, or remove policy set attachments.
    - Export and import policy sets.
    - Delete policy sets.
- Use the PolicySetManagement group of commands to configure system policy sets.
  - Create a new system policy set or copy an existing system policy set.
  - Add policy types for your policy set.
  - Add trust service attachments.
  - Customize binding configurations.
  - Manage and edit your policy set configurations.
    - Edit, enable, disable or remove policies.
    - Add, edit, or remove policy set attachments.
    - Export and import policy sets.
    - Delete policy sets.

Creating policy sets using the wsadmin tool

Create policy sets to centrally manage policies that are customized for your Web services. Use the wsadmin tool, which supports the Jython and Jacl scripting languages, to create new policy sets, copy existing policy sets, or import a policy set configuration. You can also query for an existing policy set and respective attributes.

Before you begin

In order to complete this task, you must use the Administrator role with cell-wide access when administrative security is enabled.

About this task

There are three ways to create a new policy set using the wsadmin tool. You can create a new policy set and its configuration, copy an existing policy set, or import a policy set.

When you create a new policy set, you must add policies. If you copy an existing policy set, you can transfer the policies and attachments that are configured on the existing policy set. The command examples in this topic use batch mode syntax. You can use the -interactive option with all commands in the PolicySetManagement group.

- Create a new policy set using the Jython scripting language.
  1. Launch the wsadmin scripting tool using the Jython scripting language.
  2. Determine the policy requirements for your Web services.
  3. Enter the command syntax to create a new policy set with a given name.

     Based on your configuration, there are two types of policy sets to create. You can use both application and system policy sets with Java API for XML-Based Web Services (JAX-WS) applications. Use the -policySetType parameter to specify the type of policy set. To create an application policy set, specify `application` for the value of the -policySetType parameter. To create a policy set for the trust service, specify `system` or `system/trust` for the -policySetType parameter. For WS-MetadataExchange attachments, specify `system` for the -policySetType parameter. The -policySetType parameter is optional. The wsadmin tool creates an application policy set if the -policySetType parameter is not specified.

     Enter the following command to create an application policy set:

```
AdminTask.createPolicySet('[-policySet PolicySet1 -description policySet_description]')
```

     Enter the following command to create a policy set for the trust service:

```
AdminTask.createPolicySet('[-policySet PolicySet1 -description policySet_description -policySetType system]')
```

     The command returns a success or failure message.
  4. Add policies for your new policy set. Use this step to add a policy with default values for the specified policy set.

     Enter the following command to add and enable a policy:

```
AdminTask.addPolicyType('[-policySet PolicySet1 -policyType policyType_name]')
```

     Enter the following command to add and disable a policy. Your configuration changes are contained within the policy set, but will have no effect on the system if the -enabled parameter is set to `false`.

```
AdminTask.addPolicyType('[-policySet PolicySet1 -policyType policyType_name -enabled false]')
```

     The command returns a success or failure message. Repeat this step to create additional policies for your configuration.
  5. Save the configuration changes.

     Enter the following command to save your changes:

```
AdminConfig.save()
```

- Copy an existing policy set using the Jython scripting language.
  1. Launch the wsadmin scripting tool using the Jython scripting language.
  2. Determine the policy requirements for your Web services.
  3. Enter the command syntax to copy an existing policy set:

     Set the -transferAttachments parameter to `true` to transfer the attachments from the existing policy set to the new policy set. The default value for the -transferAttachments parameter is `false`.

Enter the following command to create the new policy set and to transfer the attachments of the existing policy set:

```
AdminTask.copyPolicySet('[-sourcePolicySet existingPolicySet_name -newPolicySet PolicySet1 -newDescription PolicySet1_description -transferAttachments true]')
```

The command returns a success or failure message.

4. Save the configuration changes.

   Enter the following command to save your changes:

```
AdminConfig.save()
```

- Import a policy set from an archive file or import a default policy set using the Jython scripting language.
  1. Launch the wsadmin scripting tool using the Jython scripting language.
  2. Determine the policy requirements for your Web services.
  3. Import a policy set.

     Use the importPolicySet command to import the archive file containing the policy set configuration of interest to the destination environment. Specify the verifyPolicySetType parameter to verify that the policy set to import matches a specific type. Set the value as `application`, `system`, or `system/trust` to specify the policy set type. You cannot import a policy set onto a server or client environment if the policy set already exists in the destination environment.

     For example, the following command creates a customSecureConversation policy set from the customSC.zip archive file:

```
AdminTask.importPolicySet('[-importFile /IBM/WebSphere/AppServer/bin/customSC.zip -verifyPolicySetType system/trust]')
```

     Additionally, you can also use the importPolicySet command to import a default policy set onto a server environment, as the following example demonstrates:

```
AdminTask.importPolicySet('[-defaultPolicySet SecureConversation -policySet copyOfdefaultSC -verifyPolicySetType system]')
```

     The command returns a success or failure message.

  4. Save the configuration changes.

     Enter the following command to save your changes:

```
AdminConfig.save()
```

Results

If you receive a success message after entering the commands, you can now manage a policy set that is customized for your Web services applications. You can further configure the policy set and policies.

What to do next

Use the **validatePolicySet** command to validate your policy set configurations after modifying attributes for policies. For example, enter the following command to validate the *PolicySet1* policy set:

```
AdminTask.validatePolicySet('-policySet PolicySet1')
```

“PolicySetManagement command group for the AdminTask object” on page 573
You can use the Jython or Jacl scripting languages to manage policy set configurations with the wsadmin tool. Use the commands and parameters in the PolicySetManagement group to create, delete, and manage policy set, policy, and policy set attachment configurations.

Updating policy set attributes using the wsadmin tool

Use policy sets to centrally manage policies that are customized for your Web services. Use the Jython or Jacl scripting language with the wsadmin tool to update policy set attributes. You can also query the configuration for an existing policy set and respective attributes.

Before you begin

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to update policy sets.
Configurator	The Configurator role cannot update policy sets.
Deployer	The Deployer role cannot update policy sets.
Operator	The Operator role cannot update policy sets.
Monitor	The Monitor role cannot update policy sets.

About this task

After creating a new policy set, you can update your policy set configuration with the updatePolicySet command. The command uses a properties object to update all attributes or a subset of attributes for the specified policy set.

1. Launch the wsadmin scripting tool using the Jython scripting language.
2. View the current attribute values for the policy set of interest.

   Enter the following command to display the attribute values of the *policySet1* policy set:

```
AdminTask.getPolicySet('[-policySet policySet1]')
```

3. Modify attributes for the policy set of interest.

   Enter the following command to modify the `type` and `description` attributes for the *policySet1* policy set.

```
AdminTask.updatePolicySet('-policySet policySet1 -attributes "[ [type application] [description [my custom policy set to manage WSSecurity]] ]"')
```

   You can also use the -interactive option to update a policy set. To start -interactive mode, enter this command:

```
AdminTask.updatePolicySet('-interactive')
```

4. Save the configuration changes.

   Enter the following command to save your changes:

```
AdminConfig.save()
```

Results

If you received a success message after entering the commands, manage and customize the policy set for your Web services applications.

What to do next

After updating policy set attributes, you can further configure policies and policy set attachments using the commands and parameters for the PolicySetManagement group of the AdminTask object.

“PolicySetManagement command group for the AdminTask object” on page 573
You can use the Jython or Jacl scripting languages to manage policy set configurations with the wsadmin tool. Use the commands and parameters in the PolicySetManagement group to create, delete, and manage policy set, policy, and policy set attachment configurations.

Adding and removing policies using the wsadmin tool

You can use the Jython or Jacl scripting language and the wsadmin tool to query, add, and remove policies for your policy sets.

Before you begin

Before you use the commands in this topic, verify that you are using the most recent version of the wsadmin tool. The policy set management commands that accept a properties object as the value for the **attributes** or **bindingLocation** parameters are not supported on previous versions of the wsadmin tool. For example, the commands do not run on a Version 6.1.0.x node.

Additionally, if administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to create and remove policies.
Configurator	The Configurator role cannot create or remove policies.
Deployer	The Deployer role cannot create or remove policies.
Operator	The Operator role cannot create or remove policies.
Monitor	The Monitor role cannot create or remove policies.

About this task

Policies define which Qualities of Service (QoS) to manage within a policy set. Policy definitions are based on the standards set by the Organization for the Advancement of Structured Information (OASIS) and Web Services Security specifications.

For application policy sets, you can add the following policies:

- WSSecurity
- WSReliableMessaging
- WSAddressing
- HTTPTransport
- SSLTransport
- WSTransaction
- JMSTransport

For system policy sets, you can add the following policies:

- WSSecurity
- WSAddressing
- HTTPTransport
- SSLTransport
- WS-MetadataExchange

Use the following steps to add or remove policy types from your policy set configurations:

- Add a policy to a policy set. Use this section to add a policy with default values to the specified policy set. You can create and enable or create and disable the policy.
  1. Launch the wsadmin scripting tool using the Jython scripting language.
  2. List all policies for a specified policy set.

     Enter the following command and specify the policy set of interest to list all policies that have been added to the policy set:

     ```
     AdminTask.listPolicyTypes('[-policySet PolicySet1]')
     ```

     Enter the following command to list all the available policies:

     ```
     AdminTask.listPolicyTypes()
     ```
  3. Add the policy to your configuration.

     Enter the following command to add and enable a policy:

     ```
     AdminTask.addPolicyType('[-policySet PolicySet1
     -policyType policyType_name]')
     ```

     Enter the following command to add and disable a policy. Your configuration changes are contained within the policy set, these changes do not effect the system if the -enabled parameter is set to `false`.

     ```
     AdminTask.addPolicyType('[-policySet PolicySet1
     -policyType policyType_name -enabled false]')
     ```
  4. Enter the following command to save your changes:

     ```
     AdminConfig.save()
     ```
  5. For your configuration changes to take effect, restart all applications with attachments to the policy set.

  The command returns a success or failure message. Repeat this step to create additional policies for your configuration.
- Remove a policy from the policy set configuration. The deletePolicyType command removes the specified policy from the policy set. Applications with attachments to the policy set are not affected until the application restarts.

1. Launch the wsadmin scripting tool using the Jython scripting language.
2. Enter the following command to list all policies for the policy set of interest:

   ```
   AdminTask.listPolicyTypes('[-policySet PolicySet1]')
   ```

3. Enter the following command to remove the policy:

   ```
   AdminTask.deletePolicyType('[-policySet PolicySet1
   -policyType policyType_name]')
   ```

   The command returns a success or failure message.
4. Save the configuration changes.

   Enter the following command to save your changes:

   ```
   AdminConfig.save()
   ```

5. For your configuration changes to take effect, restart all applications with attachments to the policy set.

What to do next

Use the validatePolicySet command to validate your policy set configurations after modifying attributes for policies. For example, enter the following command to validate the *PolicySet1* policy set:

```
AdminTask.validatePolicySet('-policySet PolicySet1')
```

Editing policy configurations using the wsadmin tool

Use the wsadmin tool, which supports the Jython and Jacl scripting languages, to edit policy configurations for your policy sets.

Before you begin

Before you use the commands in this topic, verify that you are using the most recent version of the wsadmin tool. The policy set management commands that accept a properties object as the value for the **attributes** or **bindingLocation** parameters are not supported on previous versions of the wsadmin tool. For example, the commands do not run on a Version 6.1.0.x node.

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to modify policies.
Configurator	The Configurator role cannot modify policies.
Deployer	The Deployer role cannot modify policies.
Operator	The Operator role cannot modify policies.
Monitor	The Monitor role cannot modify policies.

About this task

Policies define the type of policy to manage within a policy set. Policies are based on the Quality of Services (QoS), such as Web Services Security (WS-Security) and Web Services Addressing (WS-Addressing). Policy definitions are based on the standards set by the Organization for the Advancement of Structured Information (OASIS) and WS-Security specifications.

Use the following steps to edit existing policies in your policy set configurations:

1. Launch the wsadmin scripting tool using the Jython scripting language.
2. Determine which policy set to edit.

   To view a list of policies on a policy set, enter the listPolicyTypes command, specifying the policy set of interest.

```
AdminTask.listPolicyTypes('[-policySet PolicySet1]')
```

   Enter the listPolicyTypes command without the policySet parameter to view a list of available policies for all policy sets in your configuration:

```
AdminTask.listPolicyTypes()
```

3. Review the policy attributes to edit.

   Enter the getPolicyType command, specifying the policy and associated policy set of interest.

```
AdminTask.getPolicyType('[-policySet PolicySet1 -policyType myPolicyType]')
```

4. Modify the policy set attributes.

   Use the setPolicyType command to update the policy configuration. Update one or multiple attributes by passing a properties object for the -attributes parameter. The following example modifies the `enabled` and `provides` properties:

```
AdminTask.setPolicyType('[-policySet PolicySet1 -policyType myPolicyType
 -attributes "[[enabled true][provides security]]"')
```

5. Save the configuration changes.

   Enter the following command to save your changes:

```
AdminConfig.save()
```

6. For your configuration changes to take effect, restart all applications with attachments to the policy set.

What to do next

Use the validatePolicySet to validate your policy set configurations after modifying attributes for policies. For example, enter the following command to validate the *PolicySet1* policy set:

```
AdminTask.validatePolicySet('-policySet PolicySet1')
```

Related concepts

You can use the Jython or Jacl scripting language and the wsadmin tool to query, add, and remove policies for your policy sets.

“Creating policy sets using the wsadmin tool” on page 498
Create policy sets to centrally manage policies that are customized for your Web services. Use the wsadmin tool, which supports the Jython and Jacl scripting languages, to create new policy sets, copy existing policy sets, or import a policy set configuration. You can also query for an existing policy set and respective attributes.

“Managing policy sets using the administrative console” on page 803
You can use policy sets, or assertions that define services, to simplify your Web services configuration because policy sets group security and other Web services settings into reusable units. You can use the administrative console to create, modify, and delete custom policy sets.

“Enabling policies for policy sets using the administrative console” on page 950
Policies can be listed in a policy set in the disabled state so that they are not currently included in the policy set. You can enable a policy to be included in a policy set using the administrative console.

“Adding policies to policy sets using the administrative console” on page 903
You can use the administrative console to add policies to policy sets. Adding and configuring policies to a policy set further defines the rules governing the policy set.

“Managing policies in a policy set using the administrative console” on page 902
When working with policy sets in the administrative console, you can customize the included policies to ensure message security. You can enable, disable, customize, add, or delete policies from a policy set. With your policy sets, you can define policies for WS-Addressing, WS-Security, WS-ReliableMessaging, WS-Transaction, HTTP transport, Java Messaging Service (JMS) transport, and Secure Sockets Layer (SSL) transport. The policies for all but WS-Security are relatively straightforward to define.

Related reference

“Policy configuration properties for all policies” on page 549
You can use the **attributes** parameter with the setPolicyType and setBinding commands to specify various properties for each quality of service (QoS) within a policy set. You can use the properties in this topic with each QoS within application and system policy sets.

“PolicySetManagement command group for the AdminTask object” on page 573
You can use the Jython or Jacl scripting languages to manage policy set configurations with the wsadmin tool. Use the commands and parameters in the PolicySetManagement group to create, delete, and manage policy set, policy, and policy set attachment configurations.

Enabling secure conversation using the wsadmin tool

Use this topic and the commands in the SecureConversation group of the AdminTask object to enable secure conversation client cache by creating a new policy set and bindings to attach to your applications.

Before you begin

Verify that the SecureConversation policy set is available in your configuration. By default, the SecureConversation policy set is not available. Use the importPolicySet command to import the SecureConversation policy to your configuration, as the following example demonstrates:

```
AdminTask.importPolicySet('-defaultPolicySet SecureConversation')
```

Before you use the commands in this topic, verify that you are using the most recent version of the wsadmin tool. The policy set management commands that accept a properties object as the value for the **attributes** or **bindingLocation** parameters are not supported on previous versions of the wsadmin tool. For example, the commands do not run on a Version 6.1.0.x node.

About this task

This topic uses the default SecureConversation policy set and default WS-Security and TrustServiceSecurityDefault bindings to enable secure conversation.

The default SecureConversation policy set contains an application policy with the symmetric binding, and a bootstrap policy with the asymmetric binding. The application policy secures application messages. The bootstrap policy secures RequestSecurityToken (RST) messages. The trust service, which issues security context token providers, uses the TrustServiceSecurityDefault system policy and the TrustServiceSecurityDefault bindings. The trust policy secures RequestSecurityTokenResponse (RSTR) messages. If you modify the bootstrap policy, you must also modify the trust policy so that both of the configurations match.

Note: Use the following steps in development and test environments only. The WS-Security bindings in this procedure contain sample key files that you must customize before using the bindings in a production environment. Create custom bindings for your production environment.

1. Launch the wsadmin scripting tool using the Jython scripting language.
2. Copy the existing SecureConversation policy set.

   Use the following command example to create a new policy set by copying the existing SecureConversation policy set:

```
AdminTask.copyPolicySet('[-sourcePolicySet SecureConversation -newPolicySet CopyOfSCPolicySet]')
```

3. Change the binding for the global security domain. If you chose the **Create the server using the development template** option when you created your profile with the Profile Management Tool or the manageprofiles command utility, you can optionally skip this step.
   a. List each WS-Security policy attribute.

      To modify the binding for the global security domain, use the getDefaultBindings command to determine the binding that is set as the default for the provider or client, as the following example demonstrates:

```
AdminTask.getDefaultBinding('-bindingType provider')
```

   b. Display the attributes for the binding.

      Use the getBinding command to display the current attributes for the binding, as the following example demonstrates:

```
AdminTask.getBinding('-bindingLocation "" -bindingName myBinding')
```

   c. Modify the outbound configuration for the protection token.

      Use the following commands to modify the outbound configuration for the protection token:

```
cmd1_attributes_value = "[ [application.securityoutboundbindingconfig.tokengenerator_5.callbackhandler
.key.name [CN=Bob,O=IBM, C=US]] [application.securityoutboundbindingconfig.tokengenerator_5.callbackhandler
.keystore.storepass storepass] [application.securityoutboundbindingconfig.tokengenerator_5.callbackhandler
.keystore.type JCEKS] [application.securityoutboundbindingconfig.tokengenerator_5.callbackhandler.key.alias bob]
[application.securityoutboundbindingconfig.tokengenerator_5.callbackhandler.keystore.path ${USER_INSTALL_ROOT}
/etc/ws-security/samples/enc-sender.jceks] ]"

AdminTask.setBinding('[-policyType WSSecurity -bindingLocation "" -attributes cmd1_attributes_value
-attachmentType application]')

cmd2_attributes_value = "[ [application.securityoutboundbindingconfig.tokengenerator_0.callbackhandler.keystore
.path ${USER_INSTALL_ROOT}/etc/ws-security/samples/dsig-sender.ks] [application.securityoutboundbindingconfig
.tokengenerator_0.callbackhandler.keystore.storepass client] [application.securityoutboundbindingconfig
.tokengenerator_0.callbackhandler.key.name [CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP]] [application
.securityoutboundbindingconfig.tokengenerator_0.callbackhandler.key.keypass client] [application
.securityoutboundbindingconfig.tokengenerator_0.callbackhandler.key.alias soaprequester]
```

```
[application.securityoutboundbindingconfig.tokengenerator_0.callbackhandler.keystore.type JKS] ]"

AdminTask.setBinding('[-policyType WSSecurity -bindingLocation "" -attributes cmd2_attributes_value
-attachmentType application]')
```

4. Optional: Modify the TrustDefaultBindings binding. If you chose the **Create the server using the development template** option when you created your profile with the Profile Management Tool or the manageprofiles command utility, you can optionally skip this step.

   If the TrustDefaultBindings are not yet customized, use the following commands to modify the TrustDefaultBindings binding:

```
cmd3_attributes_value = "[  [application.securityoutboundbindingconfig.tokengenerator_1.callbackhandler.keystore
.storepass storepass] [application.securityoutboundbindingconfig.tokengenerator_1.callbackhandler.key.alias bob]
[application.securityoutboundbindingconfig.tokengenerator_1.callbackhandler.keystore.type JCEKS] [application
.securityoutboundbindingconfig.tokengenerator_1.callbackhandler.keystore.path ${USER_INSTALL_ROOT}/etc
/ws-security/samples/enc-sender.jceks] [application.securityoutboundbindingconfig.tokengenerator_1.callbackhandler
.key.name [CN=Bob, O=IBM, C=US]] ]"

AdminTask.setBinding('[-policyType WSSecurity -bindingLocation "[attachmentId 2]"
-attributes cmd3_attributes_value -attachmentType system/trust]')

cmd4_attributes_value = "[ [application.securityoutboundbindingconfig.tokengenerator_0.callbackhandler.keystore.path
${USER_INSTALL_ROOT}/etc/ws-security/samples/dsig-sender.ks] [application.securityoutboundbindingconfig.tokengenerator_0
.callbackhandler.keystore.storepass client] [application.securityoutboundbindingconfig.tokengenerator_0.callbackhandler
.key.name [CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP]] [application.securityoutboundbindingconfig.tokengenerator_0
.callbackhandler.key.keypass client] [application.securityoutboundbindingconfig.tokengenerator_0.callbackhandler.key
.alias soaprequester] [application.securityoutboundbindingconfig.tokengenerator_0.callbackhandler.keystore.type JKS] ]"

AdminTask.setBinding('[-policyType WSSecurity -bindingLocation "[attachmentId 2]"
-attributes cmd4_attributes_value -attachmentType system/trust]')
```

5. Attach the policy set and binding to the application.

   Use the attachmentType parameter for the createPolicySetAttachment command to specify if your application is a service client or a service provider. Use the following commands to attach the *CopyOfSCPolicySet* policy set to the *myTestApp* service client application:

```
AdminTask.createPolicySetAttachment('[-applicationName myTestApp -policySet CopyOfSCPolicySet
-resources WebService:/ -attachmentType client]')
```

   Use the following commands to attach the *CopyOfSCPolicySet* policy set to the *myTestApp* service provider application:

```
AdminTask.createPolicySetAttachment('[-applicationName myTestApp -policySet CopyOfSCPolicySet
-resources WebService:/ -attachmentType application]')
```

   This step automatically assigns the bindings.

Results

Your secure conversation configuration is updated in the WSSCCache.xml file located in the cell level directory.

What to do next

Manage your secure conversation configurations with the SecureConversation command group for the AdminTask object.

Related concepts

Secure conversation client cache
For both distributed and local clients, the WebSphere Application Server secure conversation client cache stores tokens on the client.

"SecureConversation default policy sets" on page 810
The SecureConversation default policy sets are based on the Web Services Secure Conversation Language (SecureConversation) standard that establishes a secure context, based on shared keys for the client and server to use for a series of messages. This standard provides a framework to define how to secure the message exchange across organizations. The SecureConversation default policy sets include the SecureConversation policy set, the Lightweight Third-Party Authentication (LTPA) SecureConversation policy set, and the Username SecureConversation policy set.

Related tasks

Configuring the Web services security distributed cache using the administrative console
You can configure the Web services security runtime to use the security distributed cache to store security tokens.

Example: Installing a Web Services Sample with the console
The product provides a Web Services sample application that you can install on a Version 7.x application server.

Managing WS-Security distributed cache configurations using the wsadmin tool

The distributed cache stores tokens on the client. Use this topic and the commands in the WSSCacheManagement group of the AdminTask object to query, update, and remove custom and non-custom properties for the distributed cache configuration.

Before you begin

Configure a policy set with WS-Security enabled.

About this task

The distributed cache stores tokens on both distributed and local clients. WebSphere Application Server supports only the security context token for the WS-Trust security token service client and the security trust service components.

You can use the administrative console or the wsadmin tool to manage your secure conversation distributed cache configuration. You can use the wsadmin tool and the Jython scripting language syntax to:

- Query your current distributed cache configuration settings.
- Set the value for the renewal time after token expiration.
- Enable or disable distributed cache for clustered servers.
- Add custom properties to your configuration.
- Remove custom properties from your configuration.
- Query the configuration for your existing distributed cache configuration.

  You can retrieve a list of your current distributed cache configuration settings and custom properties with the queryWSSDistributedCacheConfig and queryWSSDistributedCacheCustomConfig commands. There are no required or optional parameters for the query commands.

  To list all non-custom configuration settings, run the following Jython command:

```
AdminTask.queryWSSDistributedCacheConfig()
```

  To list all distributed cache custom properties, enter the following Jython command:

```
AdminTask.queryWSSDistributedCacheCustomConfig()
```

- Update your secure conversation distributed cache configuration settings and custom properties.

Use the following steps to update all non-custom distributed cache configuration settings:

1. Review your existing configuration settings by running the queryWSSDistributedCacheConfig command, as the following example demonstrates:

```
AdminTask.queryWSSDistributedCacheConfig()
```

   The command returns a properties object that contains the configuration properties and values for the distributed cache configuration. The following table displays the configuration properties that the command returns:

Property	Description
tokenRecovery	Specifies whether token recovery is enabled or disabled. If the tokenRecovery property is set to `true`, the Datasource property specifies the shared data source that is assigned to the distributed cache.
distributedCache	Specifies whether distributed caching is enabled or disabled.
Datasource	Specifies the name of the shared data source that is assigned to the distributed cache if token recovery is enabled.
renewIntervalBeforeTimeoutMinutes	Specifies the amount of time, in minutes, that the client waits before it attempts to renew the token.
synchronousClusterUpdate	Specifies whether the system performs a synchronous update of distributed caches on cluster members. By default, synchronous cluster updating is enabled.
minutesInCacheAfterTimeout	Specifies the amount of time that the token remains in the cache after the token times out.

2. Use the updateWSSDistributedCacheConfig command to enable or disable distributed cache and to modify the amount of time after token expiration when downstream calls are allowed to complete.

   The following command example enables distributed cache, and sets the `mySharedDataSource` as the shared data source for token recovery:

```
AdminTask.updateWSSDistributedCacheConfig('[-tokenRecovery true -Datasource
 mySharedDataSource -distributedCache true')
```

3. Enter the following command to save your configuration changes:

```
AdminConfig.save()
```

Use the following steps to update custom properties for your distributed cache configuration:

1. Review your existing configuration settings by executing the queryWSSDistributedCacheCustomConfig command. For example:

```
AdminTask.queryWSSDistributedCacheCustomConfig()
```

   The command returns a properties object that contains the name and value pairs that correspond to each custom property.

2. Use the updateWSSDistributedCacheCustomConfig command to add custom properties for your distributed cache configuration. Specify and define each custom property by passing a properties object with the -customProperties parameter using the following Jython format:

```
-customProperties [[property1 value1][property2 value2]]
```

   For example, the following command adds the `cancelActionRST` custom property and defines the value as `http://schemas.xmlsoap.org/ws/2005/02/trust/RST/SCT/Cancel`:

```
AdminTask.updateWSSDistributedCacheCustomConfig('[-customProperties [[cancelActionRST
 http://schemas.xmlsoap.org/ws/2005/02/trust/RST/SCT/Cancel]]]')
```

3. Enter the following command to save your configuration changes:

```
AdminConfig.save()
```

- Remove custom properties from your distributed cache configuration. Use the following steps to remove custom properties from your distributed cache configuration:

  1. Review your existing configuration settings by executing the queryWSSDistributedCacheCustomConfig command. For example:

```
AdminTask.queryWSSDistributedCacheCustomConfig()
```

2. Use the deleteWSSDistributedCacheConfigCustomProperties command to remove custom properties for your distributed cache configuration. Specify the custom properties to delete by passing a string array with the -propertyNames parameter. For example, the following command removes the `cancelActionRST` custom property:

```
AdminTask.deleteWSSDistributedCacheConfigCustomProperties('[-propertyNames
 [cancelActionRST]]')
```

3. Enter the following command to save your configuration changes:

```
AdminConfig.save()
```

Results

Your WS-Security distributed cache configuration is updated.

Related concepts

Secure conversation client cache
For both distributed and local clients, the WebSphere Application Server secure conversation client cache stores tokens on the client.

"SecureConversation default policy sets" on page 810
The SecureConversation default policy sets are based on the Web Services Secure Conversation Language (SecureConversation) standard that establishes a secure context, based on shared keys for the client and server to use for a series of messages. This standard provides a framework to define how to secure the message exchange across organizations. The SecureConversation default policy sets include the SecureConversation policy set, the Lightweight Third-Party Authentication (LTPA) SecureConversation policy set, and the Username SecureConversation policy set.

Related tasks

Configuring the Web services security distributed cache using the administrative console
You can configure the Web services security runtime to use the security distributed cache to store security tokens.

Example: Installing a Web Services Sample with the console
The product provides a Web Services sample application that you can install on a Version 7.x application server.

Configuring custom policies and bindings for security tokens using the wsadmin tool

Use the setPolicyType and setBinding commands for the AdminTask object to specify security tokens for custom policy and binding configurations.

Before you begin

Create a new custom policy set.

About this task

The following scenarios configure the custom policy and bindings to use a Kerberos token based on the Oasis Kerberos Token Profile V1.1 specification. You can also use the setPolicyType and setBinding commands to configure other binary security tokens, such as username tokens, Lightweight Third-Party Authentication (LTPA) and SecureConversation.

- Configure custom policies for security tokens.
  1. Launch the wsadmin scripting tool using the Jython scripting language.
  2. Display the properties of the policy of interest.

     Use the getPolicyType command to display detailed property information for the WS-Security policy type, as the following command demonstrates:

```
AdminTask.getPolicyType('-policySet AuthenticationTokenService -policyType
 WSSecurity')
```

The getPolicyType command returns a properties object that contains name and value pairs for each property, as the following sample output displays:

```
'[ [SupportingTokens.request:krb_token.CustomToken.IncludeToken
 http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200512/IncludeToken/AlwaysToRecipient] [enabled true] [type WSSecurity]
 [description [Policies for sending security tokens and providing message confidentiality and integrity, based on the OASIS Web
 Service Security and Token Profiles specifications.]] [SupportingTokens.request:krb_token.CustomToken.WssCustomToken.uri ]
 [provides ] [SupportingTokens.request:krb_token.CustomToken.WssCustomToken.localname
 http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ] ]'
```

3. Specify the authentication token for the policy type.

   Use the setPolicyType command to specify the Uniform Resource Identifier (URI) of the authentication token for services as the value for the `SupportingTokens.request:krb_token.CustomToken.WssCustomToken.uri` property. Use the `[ ]` syntax to specify an empty string. The following example specifies an empty string as the value for the authentication token:

```
AdminTask.setPolicyType('-policySet AuthenticationTokenService -policyType
 WSSecurity -attributes "[ [SupportingTokens.request:krb_token.CustomToken.IncludeToken
 http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200512/IncludeToken/AlwaysToRecipient] [enabled true] [type
 WSSecurity] [description  [Policies for sending security tokens and providing message confidentiality and integrity,
 based on the OASIS Web Service Security and Token Profiles specifications.]]
 [SupportingTokens.request:krb_token.CustomToken.WssCustomToken.uri []] [provides []]
 [SupportingTokens.request:krb_token.CustomToken.WssCustomToken.localname
 http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ] ]"')
```

- Configure custom bindings for security tokens.
  1. Launch the wsadmin scripting tool using the Jython scripting language.
  2. Display the properties of the bindings of interest.

     Use the getBinding command to display detailed property information for the binding of interest, as the following command demonstrates:

```
AdminTask.getBinding('-policyType WSSecurity -bindingLocation "" -bindingName
 AuthenticationTokenService')
```

     The getBinding command returns a properties object that contains name and value pairs for each property, as the following sample output displays:

```
'[ [application.securityinboundbindingconfig.tokenconsumer_0.properties_0.name
 com.ibm.wsspi.wssecurity.krbtoken.serviceSPN]  [application.securityinboundbindingconfig.tokenconsumer_0.valuetype.localname
 http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ]
 [application.securityinboundbindingconfig.tokenconsumer_0.valuetype.uri ]
 [application.securityinboundbindingconfig.tokenconsumer_0.callbackhandler.classname
 com.ibm.websphere.wssecurity.callbackhandler.KRBTokenConsumeCallbackHandler]  [application.name
 application][application.securityinboundbindingconfig.tokenconsumer_0.properties_0.value HTTP/derekho1.firehorse.austin.ibm.com]
 [application.securityinboundbindingconfig.tokenconsumer_0.jaasconfig.configname system.wss.consume.KRB5BST]
 [application.securityinboundbindingconfig.tokenconsumer_0.name
 con_krbtoken][application.securityinboundbindingconfig.tokenconsumer_0.classname
 com.ibm.ws.wssecurity.wssapi.token.impl.CommonTokenConsumer]
 [application.securityinboundbindingconfig.tokenconsumer_0.securitytokenreference.reference request:krb_token] ]'
```

  3. Specify the authentication token for the policy type.

     Use the setBinding command to specify the Uniform Resource Identifier (URI) of the authentication token for services as the value for the `application.securityinboundbindingconfig.tokenconsumer_0.valuetype.uri` property. Use the `[ ]` syntax to specify an empty string. The following example specifies an empty string as the value for the authentication token:

```
AdminTask.setBinding('-policyType WSSecurity -bindingLocation ""
 -bindingName AuthenticationTokenService -attributes  "[
 [application.securityinboundbindingconfig.tokenconsumer_0.properties_0.name com.ibm.wsspi.wssecurity.krbtoken.serviceSPN]
 [application.securityinboundbindingconfig.tokenconsumer_0.valuetype.localname
 http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ]
 [application.securityinboundbindingconfig.tokenconsumer_0.valuetype.uri []]
 [application.securityinboundbindingconfig.tokenconsumer_0.callbackhandler.classname
 com.ibm.websphere.wssecurity.callbackhandler.KRBTokenConsumeCallbackHandler] [application.name
 application][application.securityinboundbindingconfig.tokenconsumer_0.properties_0.value
 HTTP/derekho1.firehorse.austin.ibm.com] [application.securityinboundbindingconfig.tokenconsumer_0.jaasconfig.configname
 system.wss.consume.KRB5BST][application.securityinboundbindingconfig.tokenconsumer_0.name
 con_krbtoken][application.securityinboundbindingconfig.tokenconsumer_0.classname
 com.ibm.ws.wssecurity.wssapi.token.impl.CommonTokenConsumer]
 [application.securityinboundbindingconfig.tokenconsumer_0.securitytokenreference.reference request:krb_token]
 ]"')
```

Results

If the setPolicyType and setBinding commands return a 'true' value, the system successfully updated the policy and binding configurations.

"PolicySetManagement command group for the AdminTask object" on page 573
You can use the Jython or Jacl scripting languages to manage policy set configurations with the wsadmin tool. Use the commands and parameters in the PolicySetManagement group to create, delete, and manage policy set, policy, and policy set attachment configurations.

"WSSecurity policy and binding properties" on page 549
Use the **attributes** parameter for the setPolicyType and setBinding commands to specify additional configuration information for the WSSecurity policy and binding configurations. Application and system policy sets can use the WSSecurity policy and binding configuration.

Creating policy set attachments using the wsadmin tool

Use the wsadmin tool, which supports the Jython and Jacl scripting languages, to define the policy set configuration for your Web services applications. You can attach policy sets to an application, Web service, endpoint, or specific operation.

Before you begin

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to create policy set attachments. If you have access to a specific resource only, you can create policy set attachments for the resource for which you have access.
Configurator	The Configurator role must have cell-wide access to create policy set attachments. If you have access to a specific resource only, you can create policy set attachments for the resource for which you have access.
Deployer	The Deployer role with cell-wide or resource specific access can create policy set attachments for application resources only.
Operator	The Operator role cannot create policy set attachments.
Monitor	The Monitor role cannot create policy set attachments.

Before you use the commands in this topic, verify that you are using the most recent version of the wsadmin tool. The policy set management commands that accept a properties object as the value for the **attributes** or **bindingLocation** parameters are not supported on previous versions of the wsadmin tool. For example, the commands do not run on a Version 6.1.0.x node.

About this task

To use a new policy set to manage policies for your application, you must attach the policy set to an application artifact or artifacts. When the application restarts, the application uses the policies from the newly attached policy set.

1. Launch a scripting command.
2. Select an application with Web services to update. Use the listWebServices command to list all Web services and the associated applications. Enter the following command to list all Web services and attributes:

```
AdminTask.listWebServices()
```

   For each Web service, the command returns the associated application name, module name, service name, and service type. For example, the following information is returned:

```
'[ [service {http://www.ibm.com}service1] [client false] [application  application1]
 [module webapp1.war] [type JAX-WS] ]'
```

3. Create a policy set attachment for an application.

   For the commands in the PolicySetManagement group, the term **resource** refers to a Web service artifact. For application and service client policy sets, the artifacts use the application hierarchy. The application hierarchy includes a Web service, module name, endpoint, or operation. Enter the value for the -resource parameter as a string, with a backslash (/) character as a delimiter.

   Note: When attempting to connect to a Web service from a thin client, verify that the resources you are specifying are valid before running the updatePolicySetAttachment command. No configuration changes are made if the requested resource does not match a resource in the attachment file for the application.

   Use the following format for application and client policy set attachments:

   - `WebService:/`

     Attaches all artifacts in the application to the policy set.
   - `WebService:/webapp1.war:{http://www.ibm.com}myService`

     Attaches all artifacts within the Web service `{http://www.ibm.com}myService` to the policy set. You must provide a fully qualified name (QName) for the service.
   - `WebService:/webapp1.war:{http://www.ibm.com}myService/endpointA`

     Attaches all operations for the `endpointA` endpoint to the policy set.
   - `WebService:/webapp1.war:{http://www.ibm.com}myService/endpointA/operation1`

     Attaches only the `operation1` operation to the policy set.

   The format for the -resource string differs for system policy set attachments for the trust service. Use the following format for system policy set attachments:

   - `Trust.opName:/`

     The `opName` attribute can be issue, renew, cancel, or validate.
   - `Trust.opName:/url`

     The `opName` attribute can be issue, renew, cancel, or validate. You can specify any valid URL for the `url` attribute.

   a. Enter the command to attach the policy set to the application. This command attaches the `policyset1` application policy set to all artifacts in the `WebService` application.

      Note: The `application` and `system/trust` values for the -attachmentType parameter are deprecated. Specify the `provider` value in place of the `application` value. For system policy

set attachments, specify the `provider` value for the attachmentType parameter and the `"[systemType trustService]"` value for the -attachmentProperties parameter. For WSNClient attachments, specify the `client` value for the attachmentType parameter and the `bus` and `WSNService` properties with the -attachmentProperties parameter.

To attach a policy set to a Web service application, specify the `provider` value for the -attachmentType parameter:

```
AdminTask.createPolicySetAttachment('[-policySet policyset1 -resources
 "WebService:/" -applicationName WebService -attachmentType provider]')
```

To attach a policy set to a service client application, specify the `client` value for the -attachmentType parameter, as the following example demonstrates:

```
AdminTask.createPolicySetAttachment('[-policySet policyset1 -resources
 "WebService:/" -applicationName WebService -attachmentType client]')
```

To create a trust service attachment for a system policy set, specify the `provider` value for the -attachmentType parameter and the `[systemType trustService]` value for the -attachmentProperties parameter, as the following example demonstrates:

```
AdminTask.createPolicySetAttachment('[-policySet policyset1 -resources
 "WebService:/" -applicationName WebService -attachmentType client -attachmentProperties "[systemType
 trustService]"]')
```

This command returns an attachment ID number that you must use to reference this attachment. In the next step, use the attachment ID number to set the binding configuration. For this example, the attachment ID number is `124`.

4. Run the command to set the binding. The following example demonstrates how to set the timestamp expiration attribute on the `SecureConversation123binding` binding for the `WSSecurity` policy, on the `WebService` Web service application. To attach a policy set to a Web services application, specify the `provider` value for the -attachmentType parameter.

```
AdminTask.setBinding('-policyType WSSecurity -bindingLocation "[ [application WebService] [attachmentId 124] ]" -attachmentType provider
 -bindingName SecureConversation123binding -attributes "[application.securityoutboundbindingconfig.timestampexpires.expires 5]"')
```

5. Save the configuration changes.

   Enter the following command to save your changes:

```
AdminConfig.save()
```

Results

Your have attached the policy set to the application artifact or artifacts specified. Restart your application to use the policies from the newly attached policy set.

What to do next

Manage and update your attachments.

Related tasks

Configuring attachments for the trust service using the administrative console
You can attach the trust service operations for a service endpoint to a system policy set and binding. Each new endpoint that is specified initially has the following four operations: issue, renew, cancel, and validate. By default, all endpoints inherit the policy set and binding that are attached to the respective trust service operation under Trust Service Defaults. However, you can explicitly attach a different policy set.

"Managing policy set attachments using the wsadmin tool"
Use the wsadmin tool to manage your policy set attachment configurations. You can use the Jython or Jacl scripting language to list all attachments and attachment properties, add or remove resources for an existing attachment, and transfer attachments across policy sets.

"Configuring application and system policy sets for Web services using scripting" on page 497
Use the wsadmin tool, which supports the Jython and Jacl scripting languages, to configure application or system policy sets for Web services. You can manage the policies for the Quality of Service (QoS) by creating policy sets and managing associated policies.

"Creating policy sets using the wsadmin tool" on page 498
Create policy sets to centrally manage policies that are customized for your Web services. Use the wsadmin tool, which supports the Jython and Jacl scripting languages, to create new policy sets, copy existing policy sets, or import a policy set configuration. You can also query for an existing policy set and respective attributes.

"Adding and removing policies using the wsadmin tool" on page 503
You can use the Jython or Jacl scripting language and the wsadmin tool to query, add, and remove policies for your policy sets.

"Removing policy set attachments using the wsadmin tool" on page 543
You can use the Jython or Jacl scripting language to remove and transfer policy sets from application artifacts. You can also remove resources that apply to a policy set attachment without deleting the policy set attachment.

"Managing policy sets using the administrative console" on page 803
You can use policy sets, or assertions that define services, to simplify your Web services configuration because policy sets group security and other Web services settings into reusable units. You can use the administrative console to create, modify, and delete custom policy sets.

Use this topic as a reference for the commands for the WebServicesAdmin group of the AdminTask object. Use these commands with your administrative scripts to list available Web services, list web services attributes, determine the endpoint configuration for a Web service, and determine a specific operation name.

Managing policy set attachments using the wsadmin tool

Use the wsadmin tool to manage your policy set attachment configurations. You can use the Jython or Jacl scripting language to list all attachments and attachment properties, add or remove resources for an existing attachment, and transfer attachments across policy sets.

Before you begin

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to manage policy set attachments. If you have access to a specific resource only, you can manage policy set attachments for the resource for which you have access.
Configurator	The Configurator role must have cell-wide access to manage policy set attachments. If you have access to a specific resource only, you can manage policy set attachments for the resource for which you have access.
Deployer	The Deployer role with cell-wide or resource specific access can manage policy set attachments for application resources only.
Operator	The Operator role cannot manage policy set attachments.
Monitor	The Monitor role cannot manage policy set attachments.

About this task

Policy set attachments define how a policy set is attached to resources and binding configurations.

- Query the configuration for policy set attachments and attachment properties.

  Before making configuration changes to your policy set attachments, use the listAttachmentsForPolicySet and getPolicySetAttachments commands to view current configuration information about your policy set attachments.

  1. Launch the wsadmin scripting tool using the Jython scripting language.
  2. Use the listAttachmentsForPolicySet command to view all applications to which a specific policy set is attached, for example:

     ```
     AdminTask.listAttachmentsForPolicySet('[-policySet PolicySet1]')
     ```

     Use the -attachmentType parameter to narrow your query. You can query for `provider` or `client` attachments.

     Note: The `application` and `system/trust` values for the -attachmentType parameter are deprecated. Specify the `provider` value in place of the `application` value. For system policy set attachments, specify the `provider` value for the attachmentType parameter and the `"[systemType trustService]"` value for the -attachmentProperties parameter. For WSNClient attachments, specify the `client` value for the attachmentType parameter and the `bus` and `WSNService` properties with the -attachmentProperties parameter.
  3. Use the getPolicySetAttachments command to view the properties for all policy set attachments in a specified application, for example:

     ```
     AdminTask.getPolicySetAttachments('[-applicationName application1]')
     ```

     Use the -attachmentType parameter to narrow your query. You can query for `provider` or `client` attachments.
- Determine the assets to which a specific policy set is attached.

  Use the listAssetsAttachedToPolicySet command to display the assets that are attached to the policy set of interest, as the following example demonstrates:

  ```
  AdminTask.listAssetsAttachedToPolicySet('[-policySet SecureConversation]')
  ```

  The command returns a list of properties that describe each asset. Each properties object contains the assetType property, which specifies the type of asset.
- Modify resources that apply to a policy set attachment.
  1. Launch the wsadmin scripting tool using the Jython scripting language.

2. Determine the resource of interest and review the command syntax for the updatePolicySetAttachment command.

   For the commands in the PolicySetManagement group, the term **resource** refers to a Web service artifact. For application and service client policy sets, the artifacts use the application hierarchy. The application hierarchy includes a Web service, module name, endpoint, or operation. Enter the value for the -resource parameter as a string, with a backslash (/) character as a delimiter.

   Note: When attempting to connect to a Web service from a thin client, verify that the resources you are specifying are valid before running the updatePolicySetAttachment command. No configuration changes are made if the requested resource does not match a resource in the attachment file for the application.

   Use the following format for application and client policy set attachments:

   – `WebService:/`

     Attaches all artifacts in the application to the policy set.

   – `WebService:/webapp1.war:{http://www.ibm.com}myService`

     Attaches all artifacts within the Web service `{http://www.ibm.com}myService` to the policy set. You must provide a fully qualified name (QName) for the service.

   – `WebService:/webapp1.war:{http://www.ibm.com}myService/endpointA`

     Attaches all operations for the `endpointA` endpoint to the policy set.

   – `WebService:/webapp1.war:{http://www.ibm.com}myService/endpointA/operation1`

     Attaches only the `operation1` operation to the policy set.

   The format for the -resource string differs for system policy set attachments for the trust service. Use the following format for system policy set attachments:

   – `Trust.opName:/`

     The `opName` attribute can be issue, renew, cancel, or validate.

   – `Trust.opName:/url`

     The `opName` attribute can be issue, renew, cancel, or validate. You can specify any valid URL for the `url` attribute.

3. Modify the attachment.

   For example, the policy set attachment is connected to the operation1 operation, which is a specific single operation. To attach the 124 attachment to all operations for the endpointA endpoint, enter the following command:

   ```
   AdminTask.updatePolicySetAttachment('[-attachmentId 124 -resources
   "WebService:/webapp1.war:{http://www.ibm.com}myService/endpointA" -applicationName application1]')
   ```

   Note: The updatePolicySetAttachment command replaces all existing resources for an attachment with the resources specified in the command. You can also update your policy set attachments using the addToPolicySetAttachment command to add resources to an existing attachment or the createPolicySetAttachment command to create an attachment for a specific resource. For more information about these commands reference the commands for the PolicySetManagement group for the AdminTask object.

4. Save the configuration changes.

   Enter the following command to save your changes:

   ```
   AdminConfig.save()
   ```

- Remove resources that apply to a policy set attachment.
  1. Launch the wsadmin scripting tool using the Jython scripting language.
  2. Determine which resources to remove with the command. You can remove a resource for each Web service artifact, each operation for an endpoint, or for a specific operation. In the following example, the command removes the `newAttach` attachment from `operation1`, which is associated with the `plantShop` application.

```
AdminTask.removeFromPolicySetAttachment('[-attachmentId newAttach -resources
"WebService:/webapp1.war:{http://www.ibm.com}myPlantService/endpointA/operation1" -applicationName plantShop]')
```

The command returns a success or failure message.

3. Save the configuration changes.

   Enter the following command to save your changes:

   ```
   AdminConfig.save()
   ```

- Transfer attachments from one policy set to another policy set. This command detaches each Web service from the source policy set and attaches those Web services to the destination policy set. The destination policy set must have the same set of enabled policy types as the source policy set.

  1. Enter the following command to transfer all attachments:

     ```
     AdminTask.transferAttachmentsForPolicySet('[-sourcePolicySet PolicySet1
     -destinationPolicySet PolicySet2]')
     ```

     The command returns a success or failure message.

  2. Save the configuration changes.

     Enter the following command to save your changes:

     ```
     AdminConfig.save()
     ```

Configuring general, cell-wide bindings for policies using the wsadmin tool

You can use the Jython or Jacl scripting language to customize your cell-wide default binding configuration. Create multiple cell-wide general bindings that you can attach to applications.

Before you begin

Before you use the commands in this topic, verify that you are using the most recent version of the wsadmin tool. The policy set management commands that accept a properties object as the value for the **attributes** or **bindingLocation** parameters are not supported on previous versions of the wsadmin tool. For example, the commands do not run on a Version 6.1.0.x node.

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to configure bindings. If you have access to a specific resource only, you can configure bindings for the resource for which you have access. Only the Administrator role can edit binding attributes.
Configurator	The Configurator role with cell-wide or resource specific access can assign or unassign bindings, but cannot edit attributes.
Deployer	The Deployer role with cell-wide or resource specific access can assign or unassign bindings, but cannot edit attributes.
Operator	The Operator role can view, but cannot configure bindings.
Monitor	The Monitor role can view, but cannot configure bindings.

.

About this task

Bindings are environment and platform-specific information such as key store information, keys used for signature and encryption, or authentication information.

Note: In WebSphere Application Server Version 7.0, the security model is enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

To support a mixed-cell environment, WebSphere Application Server supports Version 7.0 and Version 6.1 bindings. General cell-level bindings are specific to Version 7.0 Application-specific bindings remain at the version that the application requires. When the user creates an application-specific binding, the application server determines the required binding version to use for application.

Use the following guidelines to manage bindings in your environment:

- To display or modify default Version 6.1 bindings, Version 7.0 trust service bindings, or to reference bindings by attachment for an application, specify the attachmentId and bindingLocation parameters with the getBinding or setBinding commands.
- To use or modify general Version 7.0 bindings, specify the bindingName parameter with the getBinding or setBinding commands.
- To display the version of a specific binding, specify the **version** attribute for the getBinding command.

Use a Version 6.1 binding for an application in a Version 7.0 environment if:

- The module in the application is installed on at least one Web Services Feature Pack server.
- The application contains at least one Version 6.1 application-specific binding. The application server does not assign general bindings to resource attachments for applications that are installed on a Web Services Feature Pack server. All application-specific bindings for an application must be at the same level.

General service provider and client bindings are not linked to a particular policy set and they provide configuration information that you can reuse across multiple applications. You can create and manage general provider and client policy set bindings and then select one of each binding type to use as the default for an application server. Setting the server default bindings is useful if you want the services that

are deployed to a server to share binding configuration. You can also accomplish this sharing of binding configuration by assigning the binding to each application deployed to the server or by setting default bindings for a security domain and assigning the security domain to one or more servers. You can specify default bindings for your service provider or client that are used at the global security (cell) level, for a security domain, for a particular server. The default bindings are used in the absence of an overriding binding specified at a lower scope. The order of precedence from lowest to highest that the application server uses to determine which default bindings to use is as follows:

1. Server level default
2. Security domain level default
3. Global security (cell) default

The sample general bindings that are provided with the product are initially set as the global security (cell) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. For trust service attachments, the default bindings are used when no trust specific bindings are assigned. If you do not want to use the provided Provider sample as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided Client sample as the default service client binding, you can select an existing general client binding or create a new general client binding.

1. Launch the wsadmin scripting tool using the Jython scripting language.
2. Determine the policy to update.

   To view a list of all available policies for a specific policy set, use the listPolicyType command. For example:

```
AdminTask.listPolicyTypes('[-policySet PolicySet1]')
```

3. Retrieve the current binding configuration for the policy to determine the attributes to update.

   Use the getBinding command to display a Properties object containing all configuration attributes for a specific policy binding. Specify a Properties object for the -bindingLocation parameter using an empty Properties object. For example:

```
AdminTask.getBinding('-policyType WSAddressing -bindingLocation "" -bindingName cellWideBinding1')
```

   To return a specific configuration attribute for the policy, use the -attributes parameter. For example, enter this command to determine if the WSAddressing policy has workload management enabled:

```
AdminTask.getBinding('-policyType WSAddressing -bindingLocation "" -bindingName cellWideBinding1 -attributes "[preventWLM]"')
```

   The command returns a properties object which contains the value of the requested attribute, preventWLM.

4. Edit the binding configuration.

   Use the setBinding command to update your binding configuration for a policy. To specify that you are editing a cell-wide binding, set the -bindingLocation parameter by passing a null or empty Properties object and specify the name of the binding with the -bindingName parameter. You can further customize your binding with the following parameters:

Parameter	Description	Data type
-policyType	Specifies the policy of interest.	String, optional
-attributes	Specifies the attribute values to update. This parameter can include all binding attributes for the policy or a subset to update.	Properties, optional
-replace	Specifies whether to replace all of the existing binding attributes with the attributes specified in the command. Use this parameter to remove optional parts of the configuration for policies with complex data. The default value is false.	Boolean, optional

Parameter	Description	Data type
-remove	Use this parameter to remove a specific policy from the binding configuration. The default value for the remove parameter is false. If the policyType parameter is not specified, the command removes the custom binding from the attachment. To delete the binding configuration, provide a value for the bindingName parameter and an asterisk character (*) for the attachmentId.	Boolean, optional
-domainName	Specifies the domain name for the binding. Use this parameter to scope a binding to a domain other than the global security domain.	String, optional

You must use the -attributes parameter when editing your binding configuration for cell-wide bindings. The following example disables workload management within the cell-wide default binding for the `WSAddressing` policy:

```
AdminTask.setBinding('-policyType WSAddressing -bindingLocation "" -bindingName cellWideBinding1 -attributes "[preventWLM false]"')
```

5. Save your configuration changes.

```
AdminConfig.save()
```

Configuring Version 6.1 server-specific default bindings for policies using the wsadmin tool

You can use the Jython or Jacl scripting language to customize WebSphere Application Server Version 6.1 server-specific default bindings for policies to match your installation environment or requirements.

Before you begin

Server-specific default bindings use the WebSphere Application Server Version 6.1 namespace.

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to configure bindings. If you have access to a specific resource only, you can configure bindings for the resource for which you have access. Only the Administrator role can edit binding attributes.
Configurator	The Configurator role with cell-wide or resource specific access can assign or unassign bindings, but cannot edit attributes.

Administrative role	Authorization
Deployer	The Deployer role with cell-wide or resource specific access can assign or unassign bindings, but cannot edit attributes.
Operator	The Operator role can view, but cannot configure bindings.
Monitor	The Monitor role can view, but cannot configure bindings.

About this task

Note: In WebSphere Application Server Version 7.0, the security model is enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

To support a mixed-cell environment, WebSphere Application Server supports Version 7.0 and Version 6.1 bindings. General cell-level bindings are specific to Version 7.0 Application-specific bindings remain at the version that the application requires. When the user creates an application-specific binding, the application server determines the required binding version to use for application.

Use the following guidelines to manage bindings in your environment:

- To display or modify default Version 6.1 bindings, Version 7.0 trust service bindings, or to reference bindings by attachment for an application, specify the attachmentId and bindingLocation parameters with the getBinding or setBinding commands.
- To use or modify general Version 7.0 bindings, specify the bindingName parameter with the getBinding or setBinding commands.
- To display the version of a specific binding, specify the **version** attribute for the getBinding command.

Use a Version 6.1 binding for an application in a Version 7.0 environment if:

- The module in the application is installed on at least one Web Services Feature Pack server.
- The application contains at least one Version 6.1 application-specific binding. The application server does not assign general bindings to resource attachments for applications that are installed on a Web Services Feature Pack server. All application-specific bindings for an application must be at the same level.

General service provider and client bindings are not linked to a particular policy set and they provide configuration information that you can reuse across multiple applications. You can create and manage general provider and client policy set bindings and then select one of each binding type to use as the default for an application server. Setting the server default bindings is useful if you want the services that are deployed to a server to share binding configuration. You can also accomplish this sharing of binding configuration by assigning the binding to each application deployed to the server or by setting default bindings for a security domain and assigning the security domain to one or more servers. You can specify default bindings for your service provider or client that are used at the global security (cell) level, for a security domain, for a particular server. The default bindings are used in the absence of an overriding binding specified at a lower scope. The order of precedence from lowest to highest that the application server uses to determine which default bindings to use is as follows:

1. Server level default
2. Security domain level default
3. Global security (cell) default

The sample general bindings that are provided with the product are initially set as the global security (cell) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. For trust service attachments, the default bindings are used when no trust specific bindings are assigned. If you do not want to use the provided Provider sample as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided Client sample as the default service client binding, you can select an existing general client binding or create a new general client binding.

1. Launch the wsadmin scripting tool using the Jython scripting language.
2. Determine the policy to update.

   To view a list of all available policies for a specific policy set, use the listPolicyTypes command, as the following example demonstrates:

```
AdminTask.listPolicyTypes('[-policySet WSAddressing]')
```

3. Retrieve the current binding configuration for the policy to determine the attributes to update.

   Use the getBinding command to display a Properties object containing all configuration attributes for a specific policy binding. Specify a Properties object for the -bindingLocation parameter using the property names `node` and `server`. For example:

```
AdminTask.getBinding('-policyType WSAddressing -bindingLocation "[[node node1]
[server server1]]"')
```

   To return a specific configuration attribute for the policy, use the -attributes parameter. For example, enter this command to determine if the policy is enabled:

```
AdminTask.getBinding('-policyType WSAddressing -bindingLocation "[[node node1]
[server server1]]" -attributes "[[preventWLM]]"')
```

   The command returns a properties object which contains the value of the requested attribute, `preventWLM`.

4. Edit the binding configuration.

   Use the setBinding command to update your binding configuration for a policy. To specify that you are editing a server-specific default binding, set the -bindingLocation parameter using the `node` and `server` property names in a Properties object. You can further customize your binding with the following optional parameters:

Parameter	Description	Data type
-policyType	Specifies the policy of interest.	String, optional
-remove	Use this parameter to remove a server-level binding configuration. The default value for the -remove parameter is `false`.	Boolean, optional
-attributes	Specifies the attribute values to update. This parameter can include all binding attributes for the policy or a subset to update. The -attributes parameter is not required if you are removing your server-level binding.	Properties, optional
-replace	Specifies whether to replace all of the existing binding attributes with the attributes specified in the command. Use this parameter to remove optional parts of the configuration for policies with complex data. The default value is `false`.	Boolean, optional
-domainName	Specifies the domain name for the binding. Use this parameter to scope a binding to a domain other than the global security domain.	String, optional

   You should always specify the -attributes parameter when editing your configuration. The following example disables workload management within the server-specific default binding for the `WSAddressing` policy:

```
AdminTask.setBinding('-policyType WSAddressing -bindingLocation "[ [server server1] [node node01] ]" -attributes "[preventWLM false]"')
```

5. Save your configuration changes.

```
AdminConfig.save()
```

Configuring application-specific and system bindings using the wsadmin tool

Use the Jython or Jacl scripting language to edit custom application bindings and system bindings for policies to match your installation environment or system requirements.

Before you begin

Before you use the commands in this topic, verify that you are using the most recent version of the wsadmin tool. The policy set management commands that accept a properties object as the value for the **attributes** or **bindingLocation** parameters are not supported on previous versions of the wsadmin tool. For example, the commands do not run on a Version 6.1.0.x node.

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to configure bindings. If you have access to a specific resource only, you can configure bindings for the resource for which you have access. Only the Administrator role can edit binding attributes.
Configurator	The Configurator role with cell-wide or resource specific access can assign or unassign bindings, but cannot edit attributes.
Deployer	The Deployer role with cell-wide or resource specific access can assign or unassign bindings, but cannot edit attributes.
Operator	The Operator role can view, but cannot configure bindings.
Monitor	The Monitor role can view, but cannot configure bindings.

About this task

Binding configurations are environment- and platform-specific information such as keystore information, keys used for signature and encryption, or authentication information. You can use the default binding for each policy set or define application-specific bindings within an application.

There are three types of bindings to use with your policy sets, including cell-level, application server level, and application-level. Default bindings are used at the cell-level or application server level. This topic refers to system binding information or bindings that are defined at the application level, which overrides the cell-level or application server level definition.

Use default bindings only to develop and test applications. You must change signing and encryption keys before using your bindings in a production environment.

Note: In WebSphere Application Server Version 7.0, the security model is enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

To support a mixed-cell environment, WebSphere Application Server supports Version 7.0 and Version 6.1 bindings. General cell-level bindings are specific to Version 7.0 Application-specific bindings remain at the version that the application requires. When the user creates an application-specific binding, the application server determines the required binding version to use for application.

Use the following guidelines to manage bindings in your environment:

- To display or modify default Version 6.1 bindings, Version 7.0 trust service bindings, or to reference bindings by attachment for an application, specify the attachmentId and bindingLocation parameters with the getBinding or setBinding commands.
- To use or modify general Version 7.0 bindings, specify the bindingName parameter with the getBinding or setBinding commands.
- To display the version of a specific binding, specify the **version** attribute for the getBinding command.

Use a Version 6.1 binding for an application in a Version 7.0 environment if:

- The module in the application is installed on at least one Web Services Feature Pack server.

- The application contains at least one Version 6.1 application-specific binding. The application server does not assign general bindings to resource attachments for applications that are installed on a Web Services Feature Pack server. All application-specific bindings for an application must be at the same level.

General service provider and client bindings are not linked to a particular policy set and they provide configuration information that you can reuse across multiple applications. You can create and manage general provider and client policy set bindings and then select one of each binding type to use as the default for an application server. Setting the server default bindings is useful if you want the services that are deployed to a server to share binding configuration. You can also accomplish this sharing of binding configuration by assigning the binding to each application deployed to the server or by setting default bindings for a security domain and assigning the security domain to one or more servers. You can specify default bindings for your service provider or client that are used at the global security (cell) level, for a security domain, for a particular server. The default bindings are used in the absence of an overriding binding specified at a lower scope. The order of precedence from lowest to highest that the application server uses to determine which default bindings to use is as follows:

1. Server level default
2. Security domain level default
3. Global security (cell) default

The sample general bindings that are provided with the product are initially set as the global security (cell) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. For trust service attachments, the default bindings are used when no trust specific bindings are assigned. If you do not want to use the provided Provider sample as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided Client sample as the default service client binding, you can select an existing general client binding or create a new general client binding.

1. Launch the wsadmin scripting tool using the Jython scripting language.
2. Retrieve the current binding data for the attachment of interest.

   Use the getPolicySetAttachments command to determine the attachment ID. You will need to specify the attachment ID in the getBinding and setBinding commands to specify that this is a application-specific binding configuration. Use the following command to retrieve the attachment ID:

   ```
   AdminTask.getPolicySetAttachments('-applicationName application1')
   ```

   Use the getBinding command to display a properties object that contains each configuration attribute for a specific policy binding configuration. For application and client policy set attachments, specify a properties object for the -bindingLocation parameter using the `application` and `attachmentId` property names. For a system policy set attachment for the trust service, specify only the `attachmentId` property name. The following example queries for an application policy set binding configuration:

   ```
   AdminTask.getBinding('-policyType WSAddressing -bindingLocation "[[application application1][attachmentId 123]]"')
   ```

   To return a specific configuration attribute for the policy, use the -attributes parameter.
3. Edit the binding configuration.

   Use the setBinding command to update your binding configuration for a policy. To specify that you are editing a application-specific binding configuration, set the -bindingLocation parameter by specifying the `application` and `attachmentId` property names in a properties object. You can additionally specify the -attachmentType parameter as `provider` or `client`.

   Note: The `application` and `system/trust` values for the -attachmentType parameter are deprecated. Specify the `provider` value in place of the `application` value. For system policy set attachments, specify the `provider` value for the attachmentType parameter and the `"[systemType trustService]"` value for the -attachmentProperties parameter. For WSNClient attachments, specify the `client` value for the attachmentType parameter and the `bus` and `WSNService` properties with the -attachmentProperties parameter.

Customize your binding configuration with the following optional parameters:

Parameter	Description	Data type
-policyType	Specifies the policy of interest.	String, optional
-remove	Use this parameter to remove a specific policy from the binding configuration. The default value for the -remove parameter is false. If the -policyType parameter is not specified, the command removes the application-specific binding from the attachment. To delete the binding configuration, provide a value for the -bindingName parameter and an asterisk character (*) for the -attachmentId parameter.	Boolean, optional
-attributes	Specifies the attribute values to update. This parameter can include each binding configuration attribute for the policy or a subset of attributes to update. If you do not specify the attributes parameter, the command only updates the binding configuration location that the specified attachment uses.	Properties, optional
-bindingName	Specifies the name for the binding configuration. Use this parameter to specify a name for the binding when you create a new application-specific binding. You can also use this parameter to switch an attachment to use a different, existing application-specific binding configuration. Lastly, you must specify a value for this parameter to delete a binding configuration.	String, optional
-replace	Specifies whether to replace all of the existing binding configuration attributes with the attributes specified in the command. Use this parameter to remove optional parts of the configuration for policies with complex data. The default value is `false`.	Boolean, optional
-domainName	Specifies the domain name for the binding. Use this parameter to scope a binding to a domain other than the global security domain.	String, optional

The following example disables workload management for the `myApplication` application's binding configuration for the `WSAddressing` policy:

```
AdminTask.setBinding('[-policyType WSAddressing -bindingLocation "[ [application myApplication] [attachmentId 123] ]"
 -attributes "[preventWLM false]" -attachmentType provider]')
```

4. Save the configuration changes.

   Enter the following command to save your changes.

   ```
   AdminConfig.save()
   ```

Creating application-specific and trust service-specific bindings using the wsadmin tool

You can use the Jython or Jacl scripting language to create application-specific and trust service-specific bindings to match your installation environment or requirements.

Before you begin

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to configure bindings. If you have access to a specific resource only, you can configure bindings for the resource for which you have access. Only the Administrator role can configure binding attributes.
Configurator	The Configurator role with cell-wide or resource specific access can assign or unassign bindings, but cannot edit attributes.
Deployer	The Deployer role with cell-wide or resource specific access can assign or unassign bindings, but cannot edit attributes.
Operator	The Operator role can view, but cannot configure bindings.
Monitor	The Monitor role can view, but cannot configure bindings.

About this task

Policy set bindings specify the details about how your quality of service (QoS) is configured. For example, a policy set attachment determines that sign, encrypt, or reliable messaging should be enabled. The policy set binding specifies how the protection is configured, for example, the path of the keystore file, the class name of the token generator, or the Java™ Authentication and Authorization Service (JAAS) configuration name.

For application policy sets, you can specify the policy set bindings at the cell-level using default binding configurations, at the application level using application-specific binding configurations, or at the cell-level with general bindings. Server-level default bindings are deprecated. If no binding information is specified during policy set attachment, the policy set inherits the default binding. In WebSphere Application Server Version 7.0, you can specify a general binding as the default for a server instead of server-default bindings.

For system policy sets, you can specify the bindings at the cell-level and the server-level. The available bindings for system policy sets are the TrustServiceSymmetricDefault and TrustServiceSecurityDefault bindings. If no custom binding information is specified by the attachment, the resources inherit the TrustServiceSymmetricDefault or TrustServiceSecurityDefault binding.

Note: Only use default binding for development and testing. You must customize the signing and encryption keys in your binding configurations for a production environment.

Note: In WebSphere Application Server Version 7.0, the security model is enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

To support a mixed-cell environment, WebSphere Application Server supports Version 7.0 and Version 6.1 bindings. General cell-level bindings are specific to Version 7.0 Application-specific bindings remain at the version that the application requires. When the user creates an application-specific binding, the application server determines the required binding version to use for application.

Use the following guidelines to manage bindings in your environment:

- To display or modify default Version 6.1 bindings, Version 7.0 trust service bindings, or to reference bindings by attachment for an application, specify the attachmentId and bindingLocation parameters with the getBinding or setBinding commands.
- To use or modify general Version 7.0 bindings, specify the bindingName parameter with the getBinding or setBinding commands.
- To display the version of a specific binding, specify the **version** attribute for the getBinding command.

Use a Version 6.1 binding for an application in a Version 7.0 environment if:

- The module in the application is installed on at least one Web Services Feature Pack server.
- The application contains at least one Version 6.1 application-specific binding. The application server does not assign general bindings to resource attachments for applications that are installed on a Web Services Feature Pack server. All application-specific bindings for an application must be at the same level.

General service provider and client bindings are not linked to a particular policy set and they provide configuration information that you can reuse across multiple applications. You can create and manage general provider and client policy set bindings and then select one of each binding type to use as the default for an application server. Setting the server default bindings is useful if you want the services that are deployed to a server to share binding configuration. You can also accomplish this sharing of binding configuration by assigning the binding to each application deployed to the server or by setting default bindings for a security domain and assigning the security domain to one or more servers. You can specify default bindings for your service provider or client that are used at the global security (cell) level, for a security domain, for a particular server. The default bindings are used in the absence of an overriding binding specified at a lower scope. The order of precedence from lowest to highest that the application server uses to determine which default bindings to use is as follows:

1. Server level default
2. Security domain level default
3. Global security (cell) default

The sample general bindings that are provided with the product are initially set as the global security (cell) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. For trust service attachments, the default bindings are used when no trust specific bindings are assigned. If you do not want to use the provided Provider sample as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided Client sample as the default service client binding, you can select an existing general client binding or create a new general client binding.

1. Launch the wsadmin scripting tool using the Jython scripting language.
2. Determine the type of binding to create.

   You can create application policy set bindings at the cell-level, server-level, or application-level, and trust service policy set bindings at the cell-level or server-level.
3. Retrieve the current binding configuration for the policy of interest.

   Use the getBinding command to display a Properties object containing all configuration attributes for a specific binding. Specify the location of the binding by passing a properties object using the -bindingLocation parameter and the following reference table:

Type of binding	**-bindingLocation parameter value**
Cell-level	`-bindingLocation ""`
Server-level (deprecated)	`-bindingLocation "[[node node1][server server1]]"`
Application	`-bindingLocation "[[application application1][attachmentId 123]]"`
Trust service	`-bindingLocation "[[systemType trustService] [attachmentId 123]]"`

Type of binding	-bindingLocation parameter value
WS-Notification client	-bindingLocation "[[bus myBus][WSNService myService][attachmentId 123]"

For this example, the command displays the current binding configuration for the WSAddressing policy, with the 123 attachment ID, for the application1 application:

```
AdminTask.getBinding('-policyType WSAddressing -bindingLocation "[[application application1][attachmentId 123]]"')
```

To return a specific configuration attribute for the policy, use the -attributes parameter. For example, enter this command to determine if workload management is enabled:

```
AdminTask.getBinding('-policyType WSaddressing -bindingLocation "[[application application1][attachmentId 123]]" -attributes "[preventWLM]"')
```

The command returns a properties object which contains the value of the requested attribute, preventWLM. You might receive an error message if the binding does not exist in your configuration.

4. Create a new application-specific binding for the policy of interest.

   Use the setBinding command to create a binding configuration for a policy. To specify that you are creating an application-specific binding, set the -bindingLocation parameter by passing the application and attachmentId property names in a properties object. If you are creating a system policy set binding for the trust service, you only need to specify the attachmentId property name. You can further customize your binding with the following parameters:

Parameter	Description	Data type
-policyType	Specifies the policy of interest.	String, optional
-attachmentType	Specifies the type of policy set attachment. If the attachment is for an application, you do not need to specify this parameter. **Note:** The application and system/trust values for the -attachmentType parameter are deprecated. Specify the provider value in place of the application value. For system policy set attachments, specify the provider value for the attachmentType parameter and the "[systemType trustService]" value for the -attachmentProperties parameter. For WSNClient attachments, specify the client value for the attachmentType parameter and the bus and WSNService properties with the -attachmentProperties parameter.	String, optional
-attributes	Specifies the attribute values to update. This parameter can include all binding attributes for the policy or a subset of attributes.	Properties, optional
-bindingName	Specifies the name for your new application-specific binding. A name is generated if it is not specified.	String, optional
-domainName	Specifies the domain name for the binding. Use this parameter to scope a binding to a domain other than the global security domain.	String, optional

The following example creates the WSAddressing1234binding attachment-specific binding for the WSAddressing policy, assigned to the application1 application attachment 123, and enables workload management:

```
AdminTask.setBinding('-policyType WSAddressing -bindingName
 WSAddressing123binding -bindingLocation "[ [application application1] [attachmentId 123] ]" -attributes
 "[preventWLM false]"')
```

5. Optional: Add application-specific binding properties.

   Use the setBinding command to add any additional custom properties for your application-specific binding. The application server provides custom properties that are specific to each quality of service. Use the following format to specify custom properties for the binding:

```
AdminTask.setBinding('[-bindingLocation "[ [application application1] [attachmentId 123]
 ]" -policyType WSAddressing -attributes "[[properties_x:name key_value] [properties_x:value
 value]"]')
```

6. Save your configuration changes.

```
AdminConfig.save()
```

Deleting application-specific bindings from your configuration using the wsadmin tool

You can use the Jython or Jacl scripting language to delete a custom application or system policy set binding from your configuration. You cannot delete cell-level default bindings.

Before you begin

Before you use the commands in this topic, verify that you are using the most recent version of the wsadmin tool. The policy set management commands that accept a properties object as the value for the **attributes** or **bindingLocation** parameters are not supported on previous versions of the wsadmin tool. For example, the commands do not run on a Version 6.1.0.x node.

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to modify bindings. If you have access to a specific resource only, you can modify bindings for the resource for which you have access.
Configurator	The Configurator role cannot modify bindings.
Deployer	The Deployer role cannot modify bindings.
Operator	The Operator role cannot modify bindings.
Monitor	The Monitor role cannot modify bindings.

About this task

Policy set bindings specify the details about how your quality of service (QoS) is configured. For example, a policy set attachment determines that sign, encrypt, or reliable messaging is enabled. The policy set binding specifies how the protection is configured, for example, the path of the keystore file, the class name of the token generator, or the Java Authentication and Authorization Service (JAAS) configuration name.

For application policy sets, policy set bindings exist at the cell-level and server-level using default binding configurations, or at the application level using application-specific binding configurations. You can also specify cell-level general bindings. For system policy sets, bindings exist at the cell level and server level, or you can create application-specific bindings.

Use the following procedure to delete application-specific bindings for trust policy sets and application level bindings for application policy sets:

1. Launch the wsadmin scripting tool using the Jython scripting language.
2. Retrieve the current binding configuration for the policy of interest.

   Use the getBinding command to display a properties object that contains all configuration attributes for a specific binding. Specify the location of the binding by passing a properties object using the bindingLocation parameter and the following reference table:

Type of Binding	Value for the -bindingLocation parameter
Application	`-bindingLocation "[[application application1][attachmentId 123]]"`
Trust service	`-bindingLocation "[[attachmentId 123]]"`
WS-Notification client	`-bindingLocation "[[bus myBus][WSNService myService][attachmentId 123]"`
General binding	`-bindingLocation []`

   In this example, the command displays the current binding configuration for the `WSAddressing` policy, with the `123` attachmentId, for the `application1` application:

```
AdminTask.getBinding('[-policyType WSAddressing -bindingLocation  "[[application
 application1][attachmentId 123]]"]')
```

   To display general policy set bindings, identify the bindings by specifying the -bindingName parameter, as the following example demonstrates:

```
AdminTask.getBinding('[-bindingLocation [] -attachmentType application
 -bindingName "General Provider Binding"]')
```

3. Remove the binding of interest from each attachment.

   You cannot remove a binding from your configuration if that binding is referenced by one or more attachments. Modify and use the following example command to remove a binding from an attachment:

```
AdminTask.setBinding('[-bindingLocation "[[application application1][attachmentId
 123]]"  -remove true]')
```

4. Delete the binding of interest.

   Use the setBinding command to delete a application-specific binding configuration. Specify the binding of interest with the -bindingName parameter, an asterisk (*) for the -attachmentId property, and set the -remove parameter to `true`. The following example setBinding command removes the `WSAddressing123binding` application policy set binding:

```
AdminTask.setBinding('[-attachmentType application -bindingName
 WSAddressing123binding  -bindingLocation "[[application application1][attachmentId *]]" -remove
 true]')
```

   The following example setBinding command removes the `customTrust` trust service binding:

```
AdminTask.setBinding('[-attachmentType "system/trust" -bindingName
 customTrust  -bindingLocation "[attachmentId *]" -remove true]')
```

   The following example setBinding command removes the `General Provider Binding` general binding:

```
AdminTask.setBinding('[-attachmentType application -bindingName "General Provider
 Binding" -bindingLocation [] -bindingScope domain -remove true]')
```

Note: You cannot delete general bindings if an attachment references the binding, or if the binding is set as the default for a server or domain.

5. Save your configuration changes.

Results

The application-specific binding of interest is removed from your configuration.

You can use the Jython or Jacl scripting languages to manage policy set configurations with the wsadmin tool. Use the commands and parameters in the PolicySetManagement group to create, delete, and manage policy set, policy, and policy set attachment configurations.

Importing and exporting policy sets to client or server environments using scripting

Use the wsadmin tool, which supports the Jython and Jacl scripting languages, to export and import application or system policy sets for Web services. The exportPolicySet command creates an archive file based on the policy set configuration, and the importPolicySet command imports a default policy set or policy set from an archive file.

Before you begin

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to import and export policy sets.
Configurator	The Configurator role cannot import and export policy sets.
Deployer	The Deployer role cannot import and export policy sets.
Operator	The Operator role cannot import and export policy sets.
Monitor	The Monitor role cannot import and export policy sets.

About this task

You can use the exportPolicySet and importPolicySet commands to exchange system or application policy sets between servers or between a client and a provider. To reuse a policy set on a new server or client, export the policy set to an archive file, then import the archive file on the destination server or client. This topic provides examples for exporting a policy set, importing a policy set from an archive file, and importing a default policy set.

- Export an application or system policy set to an archive file.

  Use the exportPolicySet command to create an archive file for the policy set of interest. For example, the following command creates the customSC.zip archive file in the C:\IBM\WebSphere\AppServer\PolicySets\ directory for the customSecureConversation policy set:

  ```
  AdminTask.exportPolicySet('[-policySet customSecureConversation
  -pathName C:\IBM\WebSphere\AppServer\PolicySets\customSC.zip]')
  ```

- Move the policy set archive file to the destination environment.

  If you are exporting the policy set to a client environment, then place the archive file on the classpath of the client.

- Import a policy set from an archive file or import a default policy set.

  Use the importPolicySet command to import the archive file containing the policy set configuration of interest to the destination environment. You cannot import a policy set onto a server or client environment if the policy set already exists in the destination environment.

  For example, the following command creates a customSecureConversation policy set from the customSC.zip archive file:

  ```
  AdminTask.importPolicySet('[-importFile C:\IBM\WebSphere\AppServer\bin\customSC.zip]')
  ```

  Additionally, you can also use the importPolicySet command to import a default policy set onto a server environment, as the following example demonstrates:

  ```
  AdminTask.importPolicySet('[-defaultPolicySet SecureConversation -policySet copyOfdefaultSC]')
  ```

- Save the configuration changes.

  Enter the following command to save your changes:

  ```
  AdminConfig.save()
  ```

Removing policy set bindings using the wsadmin tool

You can use the Jython or Jacl scripting language to remove binding configurations for policies and resources to match your installation environment or requirements.

Before you begin

Before you use the commands in this topic, verify that you are using the most recent version of the wsadmin tool. The policy set management commands that accept a properties object as the value for the **attributes** or **bindingLocation** parameters are not supported on previous versions of the wsadmin tool. For example, the commands do not run on a Version 6.1.0.x node.

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to delete bindings. If you have access to a specific resource only, you can delete bindings for the resource for which you have access.
Configurator	The Configurator role can unassign bindings, but cannot delete bindings.
Deployer	The Deployer role can unassign bindings, but cannot delete bindings.
Operator	The Operator role cannot modify bindings.
Monitor	The Monitor role cannot modify bindings.

About this task

Use the following steps to remove specific policies from your application-specific binding configuration, or to remove your entire binding configuration. For both of these removal options, you must use the -bindingLocation parameter to specify whether you are deleting an application-specific binding, server-specific default binding, or a binding for the trust service. Use the following table for examples using Jython syntax when specifying the type of binding to modify or remove:

Type of binding	Value for the -bindingLocation parameter
Server-level (for Version 6.1 bindings only)	`-bindingLocation "[[node node1][server server1]]"`
Application	`-bindingLocation "[[application application1][attachmentId 123]]"`
Trust service binding	`-bindingLocation "[[systemType trustService] [attachmentId 123]]"`
WS-Notification client	`-bindingLocation "[[bus myBus][WSNService myService][attachmentId 123]"`
General bindings	`-bindingLocation []`

- Remove a policy from your application-specific binding configuration.

  Use the following steps to remove a specific policy from your binding configuration. If you remove the last policy remaining in your binding configuration, the command removes binding information from all attachments and deletes it from your configuration.

  1. Launch the wsadmin scripting tool using the Jython scripting language.
  2. Review the binding configuration to edit.

     Use the getBinding command to view the attributes for the binding, as the following example demonstrates:

```
AdminTask.getBinding('-policyType WSAddressing -bindingLocation "[[application application1][attachmentId 1234]]"')
```

     If the binding of interest is not referenced by an attachment ID, specify an asterisk character (*) for the attachmentId parameter to view the attributes for the binding, as the following example demonstrates:

```
AdminTask.getBinding('-policyType WSAddressing -bindingLocation "[[application application1][attachmentId *]]"')
```

  3. Remove the policy from the binding configuration.

     Use the setBinding command with the -policyType and -remove parameters to remove the policy of interest from the binding configuration. For example, use the following command to remove the `WSAddressing` policy from the binding configuration for the `application1` application:

```
AdminTask.setBinding('-policyType WSAddressing -remove true -bindingLocation "[[application application1][attachmentId 1234]]"
```

     If the binding to delete is not referenced by an attachment ID, specify an asterisk character (*) for the attachmentId parameter to delete the binding, as the following example demonstrates:

```
AdminTask.setBinding('-policyType WSAddressing -remove true -bindingLocation "[[application application1][attachmentId *]]"')
```

4. Save your configuration changes.

- Remove binding configurations from an attachment.

  Use the following steps to remove a server-specific default binding or a custom binding. You cannot remove cell-level default bindings from your configuration. When a binding is removed from an attachment, the resource it was removed from will inherit the server-level default binding, if one is present, or the cell-level default binding if the server-level binding is not present. Use the following steps to remove a binding configuration:

  1. Launch the wsadmin scripting tool using the Jython scripting language.
  2. Verify the current binding configuration to delete.

     Before removing the binding from the attachment, use the getBinding command to view the attributes for the binding, as the following example demonstrates:

```
AdminTask.getBinding('-policyType WSAddressing -bindingLocation "[[application application1][attachmentId 123]]"')
```

  3. Remove the current binding configuration from the attachment.

     For this example, this command removes the bindings from the `123` attachment for the `application1` application:

```
AdminTask.setBinding('-bindingLocation "[[application application1][attachmentId 123]]" -remove true')
```

     If the binding to delete is not referenced by an attachment ID, specify an asterisk character (*) for the -attachmentId parameter to remove the binding, as the following example demonstrates:

```
AdminTask.setBinding('-bindingLocation "[[application application1][attachmentId *]]" -remove true')
```

     To remove a server-specific default binding, specify the node name and server name with the -bindingLocation parameter. Server specific default bindings are deprecated. For example, this command removes the server-level default binding for the WS-Addressing policy from the `server1` server on the `node1` node:

```
AdminTask.setBinding('-policyType WSAddressing -bindingLocation "[[node node1][server server1]]" -remove true')
```

  4. Save your configuration changes.

- Remove a policy from a general binding.

  Use the following steps to remove a

  1. Launch the wsadmin scripting tool using the Jython scripting language.
  2. Verify the current binding configuration to delete.

     Before removing the binding from the attachment, use the getBinding command to view the attributes for the binding, as the following example demonstrates:

```
AdminTask.getBinding('-policyType WSAddressing -bindingName "General Provider Binding" -bindingLocation []')
```

  3. Remove the general binding.

     For this example, this command removes the `General Provider Binding` general binding:

```
AdminTask.setBinding('-bindingLocation [] -bindingName "General Provider Binding" -remove true')
```

  4. Save your configuration changes.

“PolicySetManagement command group for the AdminTask object” on page 573
You can use the Jython or Jacl scripting languages to manage policy set configurations with the wsadmin tool. Use the commands and parameters in the PolicySetManagement group to create, delete, and manage policy set, policy, and policy set attachment configurations.

Removing policy set attachments using the wsadmin tool

You can use the Jython or Jacl scripting language to remove and transfer policy sets from application artifacts. You can also remove resources that apply to a policy set attachment without deleting the policy set attachment.

Before you begin

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to remove policy set attachments. If you have access to a specific resource only, you can remove policy set attachments for the resource for which you have access.
Configurator	The Configurator role must have cell-wide access to remove policy set attachments. If you have access to a specific resource only, you can remove policy set attachments for the resource for which you have access.
Deployer	The Deployer role with cell-wide or resource specific access can remove policy set attachments for application resources only.
Operator	The Operator role cannot remove policy set attachments.
Monitor	The Monitor role cannot remove policy set attachments.

Determine which applications and policy sets to remove, detach, or transfer. Use the listWebServices command to list all Web services and for the application to edit. Enter the command to list all Web services and attributes for a specific application.

```
AdminTask.listWebServices('[–application application_name]')
```

To view a list of all Web services and associated applications, do not provide the -application parameter. For each Web service, the command returns the associated application name, module name, service name, and service type. You can also use the listAttachmentsForPolicySet and getPolicySetAttachments administrative commands to view existing configuration data. For additional information about these commands, use the information center topic for the PolicySetManagement group of commands for the AdminTask object.

About this task

There are four ways to remove policy set attachments, including:

- Remove a policy set attachment from an application.
- Remove resources that apply to a policy set attachment.
- Remove all attachments for a specific policy set and application.
- Transfer attachments between policy sets for a specific application.

Choose the appropriate procedure to remove your policy set attachments.

- Remove a policy set attachment from the application.
  1. Enter the following command to remove the policy set attachment from the application:

     ```
     AdminTask.deletePolicySetAttachment('[-attachmentId attachment_name -applicationName application_name]')
     ```

     The command returns a success or failure message. If you receive a success message, the policy set attachment is successfully removed from your application. If you receive a failure message, verify that the chosen policy set attachment exists in your configuration.
  2. Save the configuration changes.

     Enter the following command to save your changes:

     ```
     AdminConfig.save()
     ```
- Remove resources that apply to a policy set attachment.
  1. You can customize the command to remove resources for the Web service, endpoint, or operation.

     For the commands in the PolicySetManagement group, the term *resource* refers to a Web service artifact. For application and service client policy sets, the artifacts use the application hierarchy: Web service, module name, endpoint, or operation. Enter the value for the -resource parameter as a string, with a backslash (/) character as a delimiter. Use the following format for application and client policy set attachments:

WebService:/
Refers to all artifacts in the application to the policy set.

WebService:/webapp1.war:{http://www.ibm.com}myService
Refers to all artifacts within the Web service *{http://www.ibm.com}myService* to the policy set. You must provide a fully qualified name (QName) for the service.

WebService:/webapp1.war:{http://www.ibm.com}myService/endpointA
Refers to all operations for the *endpointA* endpoint to the policy set.

WebService:/webapp1.war:{http://www.ibm.com}myService/endpointA/operation1
Refers to only the *operation1* operation to the policy set.

The format for the **resource** string differs for system policy set attachments for the trust service. Use the following format for system policy set attachments:

Trust.<opName>:/
The *<opName>* attribute can be issue, renew, cancel, or validate.

Trust.<opName>:/url
The *<opName>* attribute can be issue, renew, cancel, or validate. You can specify any valid URL for the *url* attribute.

In the following example, the command removes the `attachment_name` attachment from the `operation1` operation, which is associated with the application, `application1`.

```
AdminTask.removeFromPolicySetAttachment('[-attachmentId attachment_name -resources
"WebService:/webapp1.war:{http://www.ibm.com}myService/endpointA/operation1" -applicationName application1]')
```

The command returns a success or failure message. You can also use the **updatePolicySetAttachments** command to remove attached resources.

2. Save the configuration changes.

   Enter the following command to save your changes:

   ```
   AdminConfig.save()
   ```

- Remove all attachments for a specific policy set.
  1. Remove application attachments for the policy set. To remove an attachment from an application, use the following command:

     ```
     AdminTask.deleteAttachmentsForPolicySet('[-policySet PolicySet1 -applicationName application1]')
     ```

     To remove all attachments from the policy set, use the following command:

     ```
     AdminTask.deleteAttachmentsForPolicySet('[-policySet PolicySet1]')
     ```

     Both commands return a success or failure message.
  2. Save the configuration changes.

     Enter the following command to save your changes:

     ```
     AdminConfig.save()
     ```

- Transfer attachments from one policy set to another policy set. This command detaches all Web services from the source policy set and attaches the Web services to the destination policy set.
  1. Enter the transferAttachmentsForPolicySet command to transfer all attachments within an application. Use the following command to transfer the attachments from the *PolicySet1* policy set to the *PolicySet2* policy set within the *application1* application:

     ```
     AdminTask.transferAttachmentsForPolicySet('[-sourcePolicySet PolicySet1
     -destinationPolicySet PolicySet2 -applicationName application1]')
     ```

     The command returns a success or failure message.
  2. Save the configuration changes.

     Enter this command to save your changes:

     ```
     AdminConfig.save()
     ```

Related tasks

Configuring attachments for the trust service using the administrative console
You can attach the trust service operations for a service endpoint to a system policy set and binding. Each new endpoint that is specified initially has the following four operations: issue, renew, cancel, and validate. By default, all endpoints inherit the policy set and binding that are attached to the respective trust service operation under Trust Service Defaults. However, you can explicitly attach a different policy set.

"PolicySetManagement command group for the AdminTask object" on page 573
You can use the Jython or Jacl scripting languages to manage policy set configurations with the wsadmin tool. Use the commands and parameters in the PolicySetManagement group to create, delete, and manage policy set, policy, and policy set attachment configurations.

Deleting policy sets using the wsadmin tool

Use the Jython or Jacl scripting language to delete policy sets from your configuration with the wsadmin tool. You must remove all policy set attachments before removing the policy set.

Before you begin

To complete this task, you must use the Administrator role with cell-wide access when administrative security is enabled.

Before deleting a policy set, you must delete or transfer all attachments to applications. You cannot delete default policy sets.

About this task

Use the following steps to delete custom policy sets from your configuration with the wsadmin tool:

1. Launch a scripting command.
2. List all policy sets in your configuration.
   - Enter the following command to list all application policy sets:
     ```
     AdminTask.listPolicySets()
     ```
   - Enter the following command to list all policy sets for the trust service:
     ```
     AdminTask.listPolicySets('[-policySetType system/trust]')
     ```
   - Enter the following command to list all system policy sets:
     ```
     AdminTask.listPolicySets('[-policySetType system]')
     ```
3. Determine which policy set to delete. Enter the following command to view the description and default indicator for a specific policy set:
   ```
   AdminTask.getPolicySet('[-policySet policySet_name]')
   ```
4. Delete the policy set.

   Enter the following command to delete a specific policy set.
   ```
   AdminTask.deletePolicySet('[-policySet PolicySet1)')
   ```

   The command returns a success or failure response. If you receive an error message, make sure that you have deleted all policy set attachments before entering the deletePolicySet command.
5. Save the configuration changes.

   Enter the command to save your changes.
   ```
   AdminConfig.save()
   ```

What to do next

If you deleted a policy set that was previously attached to an application, restart the affected application to update the configuration changes.

You can use the Jython or Jacl scripting languages to manage policy set configurations with the wsadmin tool. Use the commands and parameters in the PolicySetManagement group to create, delete, and manage policy set, policy, and policy set attachment configurations.

Refreshing policy set configurations using scripting

Use the wsadmin tool to refresh the policy set configuration data. After refreshing the policy set configuration, the changes apply after restarting the application.

1. Launch the wsadmin scripting tool using the Jython scripting language.
2. Get the object name of each PolicySetManager object.

   Use the completeObjectName option for the AdminControl object to set the object name for each PolicySetManager type object to the `objNameString` variable, as the following example demonstrates:

```
objNameString = AdminControl.completeObjectName('type=PolicySetManager,*')
```

3. Connect to the Managed Bean (MBean).

   The MBean supplies a remote interface to the MBean server that runs in the application server. The following example shows how to look up the MBean:

```
import javax.management as mgmt
```

4. Set the PolicySetManager MBean object name.

   The following example sets the PolicySetManager MBean object name to the `mbeanObj` variable, parameters to the `param` variable, and signature settings to the `sig` variable:

```
mbeanObj = mgmt.ObjectName(objNameString)
param=[]
sig=[]
```

5. Refresh the PolicySetManager MBean.

   The following example refreshes the policy set configuration:

```
AdminControl.invoke_jmx(mbeanObj, 'refresh', param, sig)
```

Example

The following example provides the Jython script that refreshes the policy set configuration:

```
objNameString = AdminControl.completeObjectName('type=PolicySetManager,*')
import javax.management as mgmt
mbeanObj = mgmt.ObjectName(objNameString)
param=[]
sig=[]
AdminControl.invoke_jmx(mbeanObj, 'refresh', param, sig)
```

Policy configuration properties for all policies

You can use the **attributes** parameter with the setPolicyType and setBinding commands to specify various properties for each quality of service (QoS) within a policy set. You can use the properties in this topic with each QoS within application and system policy sets.

Use the following commands and parameters in the PolicySetManagement group of the AdminTask object to customize your policy set configuration.

- Use the **attributes** parameter for the getPolicyType and getBinding commands to view the properties for your policy and binding configuration. To get an attribute, pass the property name to the getPolicyType or getBinding command.
- Use the **attributes** parameter for the setPolicyType and setBinding commands to add, update, or remove properties from your policy and binding configurations. To add or update an attribute, specify the property name and value. The setPolicyType and setBinding commands update the value if the attribute exists, or adds the attribute and value if the attribute does not exist. To remove an attribute, specify the value as an empty string (""). The **attributes** parameter accepts a properties object.

Note: If a property name or value supplied with the **attributes** parameter is not valid, then the setPolicyType and setBinding commands fail with an exception. The property that is not valid is logged as an error or warning in the `SystemOut.log` file. However, the command exception might not contain the detailed information for the property that caused the exception. When the setPolicyType and setBinding commands fail, examine the `SystemOut.log` file for any error and warning messages that indicate that the input for the **attributes** parameter contains one or multiple properties that are not valid.

Before you use the commands in this topic, verify that you are using the most recent version of the wsadmin tool. The policy set management commands that accept a properties object as the value for the **attributes** or **bindingLocation** parameters are not supported on previous versions of the wsadmin tool. For example, the commands do not run on a Version 6.1.0.x node.

Attributes to configure for all QoS policies

Use the following list of attributes to configure attributes across all QoS policies using the Jython scripting language and the wsadmin tool:

enabled

Specifies whether the policy type is enabled or disabled. The following example provides the format to enter the attributes parameter:

```
-attributes "[[enabled true]]"
```

provides

Provides a description for your configuration. The following example provides the format to enter the attributes parameter:

```
-attributes "[[provides [Messaging Security]]]"
```

The following example uses the setPolicyType command to set the `enabled` and `provides` properties for the myCustomSecurityPS custom policy set, which contains a ReliableMessaging policy:

```
AdminTask.setPolicyType('[-policySet myCustomSecurityPS -policyType
WSReliableMessaging -attributes [[enabled true][provides
[Messaging security]]]]')
```

WSSecurity policy and binding properties

Use the **attributes** parameter for the setPolicyType and setBinding commands to specify additional configuration information for the WSSecurity policy and binding configurations. Application and system policy sets can use the WSSecurity policy and binding configuration.

Before you use the commands in this topic, verify that you are using the most recent version of the wsadmin tool. The policy set management commands that accept a properties object as the value for the **attributes** or **bindingLocation** parameters are not supported on previous versions of the wsadmin tool. For example, the commands do not run on a Version 6.1.0.x node.

Use the following commands and parameters in the PolicySetManagement group of the AdminTask object to customize your policy set configuration.

- Use the **attributes** parameter for the getPolicyType and getBinding commands to view the properties for your policy and binding configuration. To get an attribute, pass the property name to the getPolicyType or getBinding command.
- Use the **attributes** parameter for the setPolicyType and setBinding commands to add, update, or remove properties from your policy and binding configurations. To add or update an attribute, specify the property name and value. The setPolicyType and setBinding commands update the value if the attribute exists, or adds the attribute and value if the attribute does not exist. To remove an attribute, specify the value as an empty string (″″). The **attributes** parameter accepts a properties object.

Note: If a property name or value supplied with the **attributes** parameter is not valid, then the setPolicyType and setBinding commands fail with an exception. The property that is not valid is logged as an error or warning in the `SystemOut.log` file. However, the command exception might not contain the detailed information for the property that caused the exception. When the setPolicyType and setBinding commands fail, examine the `SystemOut.log` file for any error and warning messages that indicate that the input for the **attributes** parameter contains one or multiple properties that are not valid.

Note: In WebSphere Application Server Version 7.0, the security model is enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

To support a mixed-cell environment, WebSphere Application Server supports Version 7.0 and Version 6.1 bindings. General cell-level bindings are specific to Version 7.0 Application-specific bindings remain at the version that the application requires. When the user creates an application-specific binding, the application server determines the required binding version to use for application.

If the **attributes** parameter is not specified for the getPolicyType or getBinding command, the command returns all properties. If a partial property name is passed to the getPolicyType or getBinding command, the command returns all properties with names that start with the partial property name. For example, If SignatureProtection is passed to the getPolicyType command, the command returns all properties with names that start with ″SignatureProtection″, which might include:

```
SignatureProtection.response:
   int_body.SignedParts.Body,SignatureProtection.response:int_body.SignedParts.Header_0.Name
```

, and

```
SignatureProtection.response:int_body.SignedParts.Header_0.Namespace
```

.

There are an extensive number of combinations of settings that are available to secure your Web service applications. Because of the number of attributes and configuration options from the WS-Security Version 1.0 specification, all attributes are not defined in this topic. The following sections explain the hierarchy structure for the WSSecurity policy and binding attributes:

- WSSecurity policy properties
- WSSecurity binding properties
- “setPolicyType and setBinding command examples” on page 556

WSSecurity policy properties

Use the getPolicyType command to review a properties object with the properties that are configured in your current WSSecurity policy file. Security policy schemata define the security assertions. Because the elements in the schema have hierarchical relationship, the property names for security policy also have the similar hierarchy. The hierarchical relationship between property names in the security policy is represented by a period (.) between two levels, concatenating the parent and child attributes. Examples of the properties include, but are not limited to, IncludeToken, Name, Namespace, XPath, XPathVersion. The following list describes the top-level assertion policy property names for the WSSecurity policy file:

AsymmetricBinding
You can specify zero or one binding assertion.

SymmetricBinding
You can specify zero or one binding assertion. AsymmetricBinding and SymmetricBinding cannot co-exist in a security policy file.

Wss11
You can specify zero or one Wss11 assertion.

Wss10
You can specify zero or one Wss10 assertion.

Trust10
You can specify zero or one Trust10 assertion.

SignatureProtection
You can specify zero or any number of signature protection assertions.

EncryptionProtection
You can specify zero or any number of encryption protection assertions

SupportingTokens
You can specify zero or any number of supporting token assertions.

For example, the following policy file example displays an AsymmetricBinding assertion:

```
<sp:AsymmetricBinding>
  <wsp:Policy>
    <sp:InitiatorSignatureToken>
      <wsp:Policy>
        <sp:X509Token sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy
  /200512/IncludeToken/AlwaysToRecipient">
          <wsp:Policy>
            <sp:WssX509V3Token10 />
          </wsp:Policy>
        </sp:X509Token>
      </wsp:Policy>
    </sp:InitiatorSignatureToken>
    <sp:RecipientSignatureToken>
      <wsp:Policy>
        <sp:X509Token sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy
  /200512/IncludeToken/AlwaysToInitiator">
          <wsp:Policy>
            <sp:WssX509V3Token10 />
          </wsp:Policy>
        </sp:X509Token>
      </wsp:Policy>
    </sp:RecipientSignatureToken>
    <sp:AlgorithmSuite>
      <wsp:Policy>
        <sp:Basic256/>
      </wsp:Policy>
    </sp:AlgorithmSuite>
    <sp:Layout>
      <wsp:Policy>
        <sp:Strict/>
      </wsp:Policy>
```

```
      </sp:Layout>
    </wsp:Policy>
  </sp:AsymmetricBinding><sp:AsymmetricBinding>
    <wsp:Policy>
      <sp:InitiatorSignatureToken>
        <wsp:Policy>
          <sp:X509Token sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy
    /200512/IncludeToken/AlwaysToRecipient">
            <wsp:Policy>
              <sp:WssX509V3Token10 />
            </wsp:Policy>
          </sp:X509Token>
        </wsp:Policy>
      </sp:InitiatorSignatureToken>
      <sp:RecipientSignatureToken>
        <wsp:Policy>
          <sp:X509Token sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy
    /200512/IncludeToken/AlwaysToInitiator">
            <wsp:Policy>
              <sp:WssX509V3Token10 />
            </wsp:Policy>
          </sp:X509Token>
        </wsp:Policy>
      </sp:RecipientSignatureToken>
    </wsp:Policy>
    <sp:AlgorithmSuite>
      <wsp:Policy>
        <sp:Basic256/>
      </wsp:Policy>
    </sp:AlgorithmSuite>
    <sp:Layout>
      <wsp:Policy>
        <sp:Strict/>
      </wsp:Policy>
    </sp:Layout>
  </sp:AsymmetricBinding>
```

The AsymmetricBinding assertion returns the following property name and value pairs. The nested `wsp:Policy` layers are not displayed in the returned properties. Additionally, some properties return the `true` value which indicates that the WSSecurity configuration includes the related XML elements. To edit these properties, set the value as `true` to include the property, or set the value as an empty string,"", to remove the property.

```
AsymmetricBinding.Layout = Strict
AsymmetricBinding.AlgorithmSuite.Basic256 = true
AsymmetricBinding.RecipientSignatureToken.X509Token_0.IncludeToken = http://docs.oasis-open.org
/ws-sx/ws-securitypolicy/200512/IncludeToken/AlwaysToInitiator
AsymmetricBinding.InitiatorSignatureToken.X509Token_0.WssX509V3Token10 = true
AsymmetricBinding.InitiatorSignatureToken.X509Token_0.IncludeToken = http://docs.oasis-open.org
/ws-sx/ws-securitypolicy/200512/IncludeToken/AlwaysToRecipient
AsymmetricBinding.RecipientSignatureToken.X509Token_0.WssX509V3Token10 = true
```

Additionally, the following policy file example displays a SupportingTokens assertion:

```
<sp:SupportingTokens>
        <wsp:Policy wsu:Id="request:custom_auth">
            <spe:CustomToken sp:IncludeToken="http://docs.oasis-open.org/ws-sx/
       ws-securitypolicy/200512/IncludeToken/AlwaysToRecipient">
                <wsp:Policy>
                    <spe:WssCustomToken uri=http://bar.com/MyCustomToken localname="tokenv1">
                    </spe:WssCustomToken>
                </wsp:Policy>
            </spe:CustomToken>
        </wsp:Policy>
    </sp:SupportingTokens
```

The SupportingTokens assertion returns the following property name and value pairs. The nested `wsp:Policy` layers are not displayed in the returned property.

```
SupportingTokens.request:custom_auth.CustomToken_0.WssCustomToken.uri=http://bar.com
/MyCustomToken
SupportingTokens.request:custom_auth.CustomToken_0.IncludeToken=http://docs.oasis-open.org
/ws-sx/ws-securitypolicy/200512/IncludeToken/AlwaysToRecipient
SupportingTokens.request:custom_auth.CustomToken_0.WssCustomToken.localname=tokenv1
```

Note: The CustomToken property contains a subscript zero notation (_0) because the property might be displayed multiple times from the same type of token such as the RecipientSignatureToken or InitiatorSignatureToken tokens.

Although most property names follow the hierarchical relationship format described previously, the following exceptions exist:

- The wsu:Id element

  This element uses the actual value for the ID instead of using `Id` as the attribute name. The following policy file example property:

  ```
  <wsp:Policy wsu:Id="response:int_body">
    <sp:SignedParts>
      <sp:Body/>
    </sp:SignedParts>
  </wsp:Policy>
  ```

  The previous wsu:Id example returns the following properties:

  ```
  SignatureProtection.response:int_body.SignedParts.Body = true
  ```

- The Header element

  Because there can be multiple Header elements, the `Header_n` notation is used to represent this property. See the following policy file example:

  ```
  <wsp:Policy wsu:Id="request:conf_body">
     <sp:EncryptedParts>
       <sp:Body/>
       <sp:Header Name="MyElement" Namespace="http://foo.com/MyNamespace" />
     </sp:EncryptedParts>
   </wsp:Policy>
  ```

  The previous Header example returns the following properties:

  ```
  EncryptionProtection.request:conf_body.EncryptedParts.Header_0.Name=MyElement
  EncryptionProtection.request:conf_body.EncryptedParts.Header_0.Namespace=http://
  foo.com/MyNamespace
  ```

- The XPath element

  The `XPath_n` notation is used to represent this property because there can be multiple XPath elements. See the following policy file example:

  ```
  <wsp:Policy wsu:Id="request:int_body">
       <sp:SignedElements>
         <sp:XPath>SomeXPathExpression</sp:XPath>
         <sp:XPath>SomeOtherXPathExpression</sp:XPath>
       </sp:EncryptedElements>
     </wsp:Policy>
  ```

  The previous XPath example returns the following properties:

  ```
  SignatureProtection.request:int_body.SignedElements.XPath_0=SomeXPathExpression
  SignatureProtection.request:int_body.SignedElements.XPath_1=SomeOtherXPathExpression
  ```

- The X509Token element

  Use the X509Token_*n* notation to represent this property because multiple X509Token elements can exist. For an example, see the AsymmetricBinding assertion.

- The CustomToken element

  Use the CustomToken_*n* notation to represent this property because multiple CustomToken elements can exist. For an example, see the SupportingTokens assertion.

WSSecurity binding properties

Use the getBinding command to review a properties object with the properties that are configured in your current WSSecurity binding configuration. You can also use the administrative console to configure your WSSecurity bindings. Use the information center topics for configuring WSSecurity bindings with administrative console for more information.

The properties defined in this section reflect the hierarchy of the binding schema. Each part of the property name is a lowercase version of the schema type. For example, the application.securityinboundbindingconfig.tokenconsumer_0.jaasconfig.configname property follows the hierarchal format. The attributes begin with **application** or **bootstrap**. Attributes that begin with

application represent bindings that are associated with the main WS-Security policy. Attributes that begin with **bootstrap** represent bindings that are associated with the WS-Security bootstrap policy, where the WS-Security policy uses Secure Conversation.

Some property names might have an _n notation appended to them. This notation represents a list of items. For example, multiple **tokenconsumer** properties exist and are listed from tokenconsumer_*0* through tokenconsumer_*n*, where the set of **tokenconsumer** values are:

```
application.securityinboundbindingconfig.tokenconsumer_0.callbackhandler.
certpathsettings.certstoreref.reference
application.securityinboundbindingconfig.tokenconsumer_0.callbackhandler.
certpathsettings.trustanchorref.reference
application.securityinboundbindingconfig.tokenconsumer_0.callbackhandler.classname
application.securityinboundbindingconfig.tokenconsumer_0.classname
application.securityinboundbindingconfig.tokenconsumer_0.jaasconfig.configname
application.securityinboundbindingconfig.tokenconsumer_0.name
application.securityinboundbindingconfig.tokenconsumer_0.valuetype.localname
application.securityinboundbindingconfig.tokenconsumer_0.valuetype.uri
```

Additionally, some properties in the security binding file return a value of true when queried. To set these properties, set the value to true to include the property, or set the value to an empty string ("") to remove the property. For example, the time stamp, nonce, and trustAnyCertificate properties follow this pattern.

Use the setBinding command and the **attributes** parameter to add or remove properties to your WSSecurity binding configuration.

- To add a property, use the setBinding command to pass the property name with a non-zero length string value. To add a list item, use the _n notation to reflect a numeric value that is greater than any current numeric value for the property. For example, if the tokenconsumer_0 and tokenconsumer_1 properties exist in your configuration, specify the new tokenconsumer property as tokenconsumer_2. After adding a property, use the getBinding command to view the most recent list of configured properties.
- To remove a property, use the setBinding command to pass the property name with an empty string (""). For example, to remove all of the tokenconsumer_0 properties, specify the following property with the **attributes** parameter:

  ```
  application.securityinboundbindingconfig.tokenconsumer_0=""
  ```

  The previous example removes all properties that begin with the application.securityinboundbindingconfig.tokenconsumer_0 property name.

The following examples display several sets of properties to configure for your binding. This list does not include all properties to configure for the WSSecurity binding. Use this information as a reference to determine how to form specific property names.

signinginfo element

Use this property to configure signing information. For a custom binding, an unlimited number of **signinginfo** elements specified for the securityoutboundbindingconfig and securityinboundbindingconfig assertions can exist. In the default bindings, the system allows a maximum of two **signinginfo** elements for the securityoutboundbindingconfig and securityinboundbindingconfig assertions. The following example displays the format for two **signinginfo** elements:

```
application.securityinboundbindingconfig.signinginfo_0.signingkeyinfo_0
.reference=con_signkeyinfo
application.securityinboundbindingconfig.signinginfo_0.signingpartreference_0
.reference=request:int_body
application.securityoutboundbindingconfig.signinginfo_0.signingpartreference_0
.reference=response:int_body
application.securityoutboundbindingconfig.signinginfo_0.signingpartreference_0.timestamp=true
```

encryptioninfo element

Use this property to configure encryption information. For a custom binding, an unlimited number of **encryptioninfo** elements specified for the securityoutboundbindingconfig and securityinboundbindingconfig assertions can exist. In the default bindings, the system accepts a

maximum of two **encryptioninfo** elements for the `securityoutboundbindingconfig` and `securityinboundbindingconfig` assertions. The following example displays the format for two **encryptioninfo** properties:

```
application.securityinboundbindingconfig.encryptioninfo_0.encryptionpartreference
.nonce=true
application.securityinboundbindingconfig.encryptioninfo_0.encryptionpartreference
.reference=request:conf_body
application.securityoutboundbindingconfig.encryptioninfo_0.encryptionpartreference
.nonce=true
application.securityoutboundbindingconfig.encryptioninfo_0.encryptionpartreference
.timestamp=true
```

tokengenerator element

In the default bindings, the **tokengenerator** elements that the **signinginfo** or **encryptioninfo** elements do not reference are considered to be authentication token generators. Each authentication token generator must have a unique **valuetype** element. The following example displays an example of a generator for an X.509 protection token:

```
application.securityoutboundbindingconfig.tokengenerator_0.name=gen_signtgen
application.securityoutboundbindingconfig.tokengenerator_0.classname=com.ibm.ws.wssecurity.wssapi.token
.impl.CommonTokenGenerator
application.securityoutboundbindingconfig.tokengenerator_0.valuetype.uri=
application.securityoutboundbindingconfig.tokengenerator_0.valuetype.localname=http://docs.oasis-open.org
/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3
application.securityoutboundbindingconfig.tokengenerator_0.callbackhandler.classname=com.ibm.websphere.wssecurity
.callbackhandler.X509GenerateCallbackHandler
application.securityoutboundbindingconfig.tokengenerator_0.callbackhandler.key.alias=soaprequester
application.securityoutboundbindingconfig.tokengenerator_0.callbackhandler.key.keypass={xor}PDM2OjEr
application.securityoutboundbindingconfig.tokengenerator_0.callbackhandler.key.name=CN=SOAPRequester,
OU=TRL, O=IBM, ST=Kanagawa, C=JP
application.securityoutboundbindingconfig.tokengenerator_0.callbackhandler.keystore.path=${USER_INSTALL_ROOT}
/etc/ws-security/samples/dsig-sender.ks
application.securityoutboundbindingconfig.tokengenerator_0.callbackhandler.keystore.storepass={xor}PDM2OjEr
application.securityoutboundbindingconfig.tokengenerator_0.callbackhandler.keystore.type=JKS
application.securityoutboundbindingconfig.tokengenerator_0.jaasconfig.configname=system.wss.generate.x509
```

The following example displays a generator for a username authentication token:

```
application.securityoutboundbindingconfig.tokengenerator_1.name=gen_usernametoken
application.securityoutboundbindingconfig.tokengenerator_1.classname=com.ibm.ws.wssecurity
.wssapi.token.impl.CommonTokenGenerator
application.securityoutboundbindingconfig.tokengenerator_1.valuetype.uri=
application.securityoutboundbindingconfig.tokengenerator_1.valuetype.localname=http://docs
.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken
application.securityoutboundbindingconfig.tokengenerator_1.callbackhandler.classname=com.ibm
.websphere.wssecurity.callbackhandler.UNTGenerateCallbackHandler
application.securityoutboundbindingconfig.tokengenerator_1.callbackhandler.basicAuth.userid=user1
application.securityoutboundbindingconfig.tokengenerator_1.callbackhandler.basicAuth.password=myPassword
application.securityoutboundbindingconfig.tokengenerator_1.securityTokenReference.reference=request:uname_token
application.securityoutboundbindingconfig.tokengenerator_1.jaasconfig.configname=system.wss.generate.unt
```

tokenconsumer element

In the default bindings, the **tokenconsumer** elements that the **signinginfo** or **encryptioninfo** elements do not reference are authentication token consumers. Each authentication token consumer must have a unique **valuetype** element. The following example displays the format for a set of **tokenconsumer** elements:

```
application.securityinboundbindingconfig.tokenconsumer_0.name=con_unametoken
application.securityinboundbindingconfig.tokenconsumer_0.classname=com.ibm.ws.wssecurity.wssapi
.token.impl.CommonTokenConsumer
application.securityinboundbindingconfig.tokenconsumer_0.valuetype.localname=http://docs.oasis-open.org
/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken
application.securityinboundbindingconfig.tokenconsumer_0.valuetype.uri=
application.securityinboundbindingconfig.tokenconsumer_0.callbackhandler.classname=com.ibm.websphere
.wssecurity.callbackhandler.UNTConsumeCallbackHandler
application.securityinboundbindingconfig.tokenconsumer_0.jaasconfig.configname=system.wss.consume.unt
application.securityinboundbindingconfig.tokenconsumer_0.securitytokenreference.reference=request:uname_token
```

actor element

Defines the actor uniform resource identifier (URI) to be included in the WSSecurity headers of a generated message, as displayed by the following example:

```
application.securityinboundbindingconfig.actor=http://myActor.com
application.securityoutboundbindingconfig.actor=http://myActor.com
```

certstorelist element

Defines certificate store configurations and signing information, as displayed by the following example:

```
application.securityinboundbindingconfig.certstorelist.collectioncertstores_0
.name=DigSigCertStore
application.securityinboundbindingconfig.certstorelist.collectioncertstores_0
.provider=IBMCertPath
application.securityinboundbindingconfig.certstorelist.collectioncertstores_0
.x509certificates_0.path=${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer
```

keyinfo element

Defines key information for signing and encryption configurations, as displayed by the following example:

```
application.securityinboundbindingconfig.keyinfo_0.classname=com.ibm.ws.wssecurity.wssapi
.CommonContentConsumer
application.securityinboundbindingconfig.keyinfo_0.name=con_signkeyinfo
application.securityinboundbindingconfig.keyinfo_0.tokenreference.reference=con_tcon
application.securityinboundbindingconfig.keyinfo_0.type=STRREF
```

trustanchor property

Defines configuration information that is used to validate the trust of the signer certificate, as displayed by the following example:

```
application.securityinboundbindingconfig.trustanchor_0.keystore.path=${USER_INSTALL_ROOT}
/etc/ws-security/samples/dsig-receiver.ks
application.securityinboundbindingconfig.trustanchor_0.keystore.storepass={xor}LDotKTot
application.securityinboundbindingconfig.trustanchor_0.keystore.type=JKS
application.securityinboundbindingconfig.trustanchor_0.name=DigSigTrustAnchor
```

timestampexpires element

Defines an expiration date for the configuration, as displayed by the following example:

```
application.securityoutboundbindingconfig.timestampexpires.expires=5
```

application.securityinboundbindingconfig.caller_X.order

Specifies the order for a caller when using wsadmin scripts, where X is the unique string that identifies the instance of the caller:

```
-attributes [[application.securityinboundbindingconfig.caller_0.order 2]]
```

setPolicyType and setBinding command examples

Use the previous reference information with the setPolicyType and setBinding commands to modify your policy and binding configuration data.

Note: The administrative console command assistance provides incorrect Jython syntax for the setPolicyType command. The XPath expression for the response message part protection of the Username WSSecurity policy set contains single quotes (') within each XPath property value, which Jython does not support. To fix the command from the administrative console command assistance, add a backslash character (\) before each single quote to escape the single quote.

The following example uses the setBinding command to set the enabled and provides properties for the myCustomSecurityPS custom policy set, which contains a ReliableMessaging policy:

```
AdminTask.setBinding('[-bindingLocation "" -bindingName cellWideBinding2 -policyType WSSecurity
 -attributes [[application.securityinboundbindingconfig.caller_0.order 2][inResponsewithSSL:configAlias NodeDefaultSSLSettings]
[inResponsewithSSL:config properties_directory/ssl.client.props][outAsyncResponsewithSSL:configFile properties_directory/ssl.client.props]
[outAsyncResponsewithSSL:configAlias NodeDefaultSSLSetings][outRequestwithSSL:configFile properties_directory/ssl.client.props]
[outRequestwithSSL:configAlias NodeDefaultSSLSettings]]]')
```

The following setPolicyType command enables the WSSecurity policy and creates a signature protection assertion:

```
AdminTask.setPolicyType('-policySet myPolicySet -policyType WSSecurity -attributes "[[enabled true][provides
Some_amount_of_security][SignatureProtection.request:app_signparts.SignedElements.XPath_0 SignatureProtectionV2]]"')
```

The following setBinding command specifies key information for a server-specific binding:

```
AdminTask.setBinding('-policyType WSSecurity -bindingLocation "[[server server1][node node01]]"
-attributes "[[application.securityinboundbindingconfig.keyinfo_0.name dec_server_keyinfo]
[application.securityinboundbindingconfig.keyinfo_0.classname com.ibm.ws.wssecurity.wssapi.CommonContentGenerator]
[application.securityinboundbindingconfig.keyinfo_0.type STRREF]]"')
```

The following setBinding command specifies key information for an attachment-specific binding:

```
AdminTask.setBinding('-policyType WSSecurity -bindingLocation "[[application PolicySet][attachmentId 999]]"
-attributes "[[application.securityinboundbindingconfig.keyinfo_0.name dec_app_keyinfo]
[application.securityinboundbindingconfig.keyinfo_0.classname com.ibm.ws.wssecurity.wssapi.CommonContentGenerator]
[application.securityinboundbindingconfig.keyinfo_0.type STRREF]]" -attachmentType application
 -bindingName myBindingName')
```

The following setBinding command specifies trust anchor information for a cell-wide binding:

```
AdminTask.setBinding('-policyType WSSecurity -bindingLocation "" -attributes
"[application.securityinboundbindingconfig.trustanchor_0.name DigSigTrustAnchor2]"')
```

WSReliableMessaging policy and binding properties

Use the **attributes** parameter for the setPolicyType and setBinding commands to specify additional configuration information for the ReliableMessaging policy and policy set binding. The WSReliableMessaging quality of service (QoS) is only available for application policy sets.

WSReliableMessaging is an interoperability standard for the reliable transmission of messages between two endpoints. Use WSReliableMessaging to secure and verify transactions when using Web services between businesses.

Use the following commands and parameters in the PolicySetManagement group of the AdminTask object to customize your policy set configuration.

- Use the **attributes** parameter for the getPolicyType and getBinding commands to view the properties for your policy and binding configuration. To get an attribute, pass the property name to the getPolicyType or getBinding command.
- Use the **attributes** parameter for the setPolicyType and setBinding commands to add, update, or remove properties from your policy and binding configurations. To add or update an attribute, specify the property name and value. The setPolicyType and setBinding commands update the value if the attribute exists, or adds the attribute and value if the attribute does not exist. To remove an attribute, specify the value as an empty string (""). The **attributes** parameter accepts a properties object.

Note: If a property name or value supplied with the **attributes** parameter is not valid, then the setPolicyType and setBinding commands fail with an exception. The property that is not valid is logged as an error or warning in the `SystemOut.log` file. However, the command exception might not contain the detailed information for the property that caused the exception. When the setPolicyType and setBinding commands fail, examine the `SystemOut.log` file for any error and warning messages that indicate that the input for the **attributes** parameter contains one or multiple properties that are not valid.

Note: In WebSphere Application Server Version 7.0, the security model is enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

To support a mixed-cell environment, WebSphere Application Server supports Version 7.0 and Version 6.1 bindings. General cell-level bindings are specific to Version 7.0 Application-specific bindings remain at the version that the application requires. When the user creates an application-specific binding, the application server determines the required binding version to use for application.

WSReliableMessaging policy properties

Configure the WSReliableMessaging policy by specifying the following properties with the setPolicyType command:

specLevel

Choose the WS-ReliableMessaging standard to use for reliable transmission of your messages. The WS-ReliableMessaging specification Version 1.1 is the default value. Use the following information to choose a specification level:

- Specify `1.0` as the value for the specLevel attribute to use the WS-ReliableMessaging specification Version 1.0, February 2005 specification level.
- Specify `1.1` as the value for the specLevel attribute to use the OASIS WS-ReliableMessaging specification Version 1.1, August 2006 specification level.

The following example code sets the specLevel property to the OASIS WS-ReliableMessaging specification Version 1.1, August 2006:

```
AdminTask.setPolicyType('[-policySet "CustomWSReliableMessaging"  -policyType
 WSReliableMessaging -attributes "[[specLevel 1.1]]"]')
```

inOrderDelivery

Specifies whether to process messages in the order that they are received. If you use the inOrderDelivery property, then inbound messages might be queued while waiting for earlier messages.

The following example code enables the inOrderDelivery property:

```
AdminTask.setPolicyType('[-policySet "CustomWSReliableMessaging" -policyType WSReliableMessaging -attributes "[[inOrderDelivery true]]"]')
```

qualityOfService

Specifies the quality of the WSReliableMessaging service to use. Define one of the following three values for the qualityOfService attribute:

- unmanagedNonPersistent

  This setting tolerates network and remote system failures. The unmanagedNonPersistent quality of service is non-transactional. With this setting configured, messages are lost if a server fails. This quality of service is supported for all environments only if the environment is configured as a Web service requester.
- managedNonPersistent

  This setting tolerates system, network, and remote system failures. However, the message state is discarded when the messaging engine restarts. The managedNonPersistent quality of service is non-transactional. This setting prevents message loss if a server fails. However, messages are lost if the messaging engine fails. Managed and thin client applications cannot use this quality of service.
- managedPersistent

  This setting tolerates system, network, and remote system failures. With this setting, messages are processed within transactions, persisted at the Web service requester and provider. Messages can be recovered if a server fails. Messages that are not successfully transmitted at the time of failure continue when the messaging engine or application restarts. Managed and thin client applications cannot use this quality of service.

The following example sets the qualityOfService property as unmanaged nonpersistent:

```
AdminTask.setPolicyType('[-policySet "CustomWSReliableMessaging" -policyType
 WSReliableMessaging -attributes "[[qualityOfService unmanagedNonPersistent]]"]')
```

The following example uses the setPolicyType command to set a value for each policy property:

```
AdminTask.setPolicyType('[-policySet "CustomWSReliableMessaging" -policyType
 WSReliableMessaging -attributes "[[specLevel 1.1][inOrderDelivery true][qualityOfService
 unmanagedNonPersistent]]"]')
```

WSReliableMessaging binding configuration attributes

If you set the qualityOfService policy property to managedNonPersistent or managedPersistent, configure the WSReliableMessaging binding by specifying values for the following properties with the setBinding command:

busName

The name of the service integration bus that contains the messaging engine to use for the managedNonPersistent or managedPersistent Quality of Service options.

The following example sets the busName property as `myBus`:

```
AdminTask.setBinding('[-bindingLocation "" -bindingName cellWideBinding2 -policyType
 WSReliableMessaging -attributes "[[busName myBus]]"]')
```

messagingEngineName

The name of the messaging engine to use for the managedNonPersistent or managedPersistent quality of service options.

The following example sets the messagingEngineName property as `messagingEngine001`:

```
AdminTask.setBinding('[-bindingLocation "" -bindingName cellWideBinding2 -policyType
 WSReliableMessaging -attributes "[[messageEngineName messageEngine001]]"]')
```

The following code example demonstrates how to use the **setBinding** command to set values for each binding attribute:

```
AdminTask.setBinding('[-bindingLocation "" -bindingName cellWideBinding2 -policyType
 WSReliableMessaging -attributes "[[busName myBus][messageEngineName messageEngine001]]"]')
```

WSAddressing binding properties

Use the -attributes parameter for the setBinding command to enable or disable workload management for the WSAddressing binding. Application and system policy sets use the WSAddressing policy and binding.

WSAddressing is an interoperability standard that you can use to create endpoint references that you can distribute across firewalls and intermediary nodes. For more information, see the W3C Candidate Recommendation (CR) versions of the WS-Addressing core and SOAP specifications.

Use the following commands and parameters in the PolicySetManagement group of the AdminTask object to customize your policy set configuration.

- Use the **attributes** parameter for the getPolicyType and getBinding commands to view the properties for your policy and binding configuration. To get an attribute, pass the property name to the getPolicyType or getBinding command.
- Use the **attributes** parameter for the setPolicyType and setBinding commands to add, update, or remove properties from your policy and binding configurations. To add or update an attribute, specify the property name and value. The setPolicyType and setBinding commands update the value if the attribute exists, or adds the attribute and value if the attribute does not exist. To remove an attribute, specify the value as an empty string (""). The **attributes** parameter accepts a properties object.

Note: If a property name or value supplied with the **attributes** parameter is not valid, then the setPolicyType and setBinding commands fail with an exception. The property that is not valid is logged as an error or warning in the `SystemOut.log` file. However, the command exception might not contain the detailed information for the property that caused the exception. When the setPolicyType and setBinding commands fail, examine the `SystemOut.log` file for any error and warning messages that indicate that the input for the **attributes** parameter contains one or multiple properties that are not valid.

Note: In WebSphere Application Server Version 7.0, the security model is enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

To support a mixed-cell environment, WebSphere Application Server supports Version 7.0 and Version 6.1 bindings. General cell-level bindings are specific to Version 7.0 Application-specific bindings remain at the version that the application requires. When the user creates an application-specific binding, the application server determines the required binding version to use for application.

WSAddressing binding properties

Configure the WSAddressing policy by specifying the following property with the setBinding command:

preventWLM
Specifies whether to prevent workload management for references to endpoints that were created by the application programming interface (API) in a cluster environment. Messages that target Endpoint References (EPRs) within a cluster environment are workload managed by default.

Preventing workload management routes messages that target EPRs to the node or server on which the EPR was created. You might disable workload management if the endpoint maintains the in-memory state, which has not been replicated across other nodes or servers within the cluster.
For example, the following command prevents workload management for a cell-wide general binding, from the WSAddressing policy.

```
AdminTask.setBinding('[-bindingLocation "" -bindingName cellWideBinding2 -policyType WSAddressing -attributes "[preventWLM true]"]')
```

SSLTransport policy and binding properties

Use the -attributes parameter for the setPolicyType and setBinding commands to specify additional configuration information for the SSLTransport policy and policy set binding. Application and system policy sets can use the SSLTransport policy and binding.

Use the following commands and parameters in the PolicySetManagement group of the AdminTask object to customize your policy set configuration.

- Use the **attributes** parameter for the getPolicyType and getBinding commands to view the properties for your policy and binding configuration. To get an attribute, pass the property name to the getPolicyType or getBinding command.
- Use the **attributes** parameter for the setPolicyType and setBinding commands to add, update, or remove properties from your policy and binding configurations. To add or update an attribute, specify the property name and value. The setPolicyType and setBinding commands update the value if the attribute exists, or adds the attribute and value if the attribute does not exist. To remove an attribute, specify the value as an empty string (""). The **attributes** parameter accepts a properties object.

Note: If a property name or value supplied with the **attributes** parameter is not valid, then the setPolicyType and setBinding commands fail with an exception. The property that is not valid is logged as an error or warning in the SystemOut.log file. However, the command exception might not contain the detailed information for the property that caused the exception. When the setPolicyType and setBinding commands fail, examine the SystemOut.log file for any error and warning messages that indicate that the input for the **attributes** parameter contains one or multiple properties that are not valid.

Note: In WebSphere Application Server Version 7.0, the security model is enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

To support a mixed-cell environment, WebSphere Application Server supports Version 7.0 and Version 6.1 bindings. General cell-level bindings are specific to Version 7.0 Application-specific bindings remain at the version that the application requires. When the user creates an application-specific binding, the application server determines the required binding version to use for application.

SSLTransport policy properties

Use the SSLTransport policy to ensure message security.

Configure the SSLTransport policy by specifying the following properties with the setPolicyType command:

outRequestSSLenabled
Specifies whether to enable the SSL security transport for outbound service requests.

outAsyncResponseSSLenabled
Specifies whether to enable the SSL security transport for asynchronous service responses.

inResponseSSLenabled
Specifies whether to enable the SSL security transport for inbound service responses.

The following setPolicyType command example sets values for all SSLTransport policy properties:

```
AdminTask.setPolicyType('[-policySet "WSHTTPS default" -policyType SSLTransport
-attributes "[[inReponseSSLenabled yes][outAsyncResponseSSLenabled yes][outRequestSSLenabled
 yes]]"]')
```

SSLTransport binding properties

Use the SSLTransport policy type to ensure message security.

Configure the SSLTransport binding by specifying the following properties using the setBinding command:

outRequestwithSSL:configFile
outRequestwithSSL:configAlias
If you enable SSL outbound service requests, then these two attributes define the specific SSL security transport binding and location. The default value for the outRequestwithSSL:configFile attribute is the location of the ssl.client.props file. The default value for the outRequestwithSSL:configAlias attribute is `NodeDefaultSSLSettings`.

outAsyncResponsewithSSL:configFile
outAsyncResponsewithSSL:configAlias
If you enable SSL asynchronous service responses, then these two attributes define the specific SSL security transport binding and location. The default value for the outAsyncRequestwithSSL:configFile attribute is the location of the ssl.client.props file. The default value for the outAsyncRequestwithSSL:configAlias attribute is `NodeDefaultSSLSettings`.

inResponsewithSSL:configFile
inResponsewithSSL:configAlias
If you enable SSL inbound service responses, then these two attributes define the specific SSL security transport binding and location. The default value for the inResponsewithSSL:configFile attribute is the location of the ssl.client.props file. The default value for the inResponsewithSSL:configAlias property is `NodeDefaultSSLSettings`.

The following setBinding command example sets values for all SSLTransport binding attributes:

```
AdminTask.setBinding('[-bindingLocation "" -bindingName cellWideBinding2 -policyType
 SSLTransport -attributes "[[inResponsewithSSL:configAlias NodeDefaultSSLSettings] [inResponsewithSSL:config
 properties_directory/ssl.client.props][outAsyncResponsewithSSL:configFile properties_directory/ssl.client.props]
[outAsyncResponsewithSSL:configAlias NodeDefaultSSLSetings][outRequestwithSSL:configFile
 properties_directory/ssl.client.props][outRequestwithSSL:configAlias NodeDefaultSSLSettings]]"]')
```

HTTPTransport policy and binding properties

Use the -attributes parameter for the setPolicyType and setBinding commands to specify additional configuration information for the HTTPTransport policy and policy set binding. Application and system policy sets can use the HTTPTransport policy and binding.

Use the following commands and parameters in the PolicySetManagement group of the AdminTask object to customize your policy set configuration.

- Use the **attributes** parameter for the getPolicyType and getBinding commands to view the properties for your policy and binding configuration. To get an attribute, pass the property name to the getPolicyType or getBinding command.
- Use the **attributes** parameter for the setPolicyType and setBinding commands to add, update, or remove properties from your policy and binding configurations. To add or update an attribute, specify the property name and value. The setPolicyType and setBinding commands update the value if the attribute exists, or adds the attribute and value if the attribute does not exist. To remove an attribute, specify the value as an empty string (""). The **attributes** parameter accepts a properties object.

Note: If a property name or value supplied with the **attributes** parameter is not valid, then the setPolicyType and setBinding commands fail with an exception. The property that is not valid is logged as an error or warning in the `SystemOut.log` file. However, the command exception might not contain the detailed information for the property that caused the exception. When the setPolicyType and setBinding commands fail, examine the `SystemOut.log` file for any error and warning messages that indicate that the input for the **attributes** parameter contains one or multiple properties that are not valid.

Note: In WebSphere Application Server Version 7.0, the security model is enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

To support a mixed-cell environment, WebSphere Application Server supports Version 7.0 and Version 6.1 bindings. General cell-level bindings are specific to Version 7.0 Application-specific bindings remain at the version that the application requires. When the user creates an application-specific binding, the application server determines the required binding version to use for application.

The following sections explain the policy and binding properties to configure:

- HTTPTransport policy properties
- HTTPTransport binding properties

HTTPTransport policy properties

The HTTPTransport policy set can be used for HTTPS, basic authorization, compression, and binary encoding transport methods.

Configure the HTTPTransport policy by specifying the following attributes with the **setPolicyType** command:

protocolVersion
Specifies the version of HTTP to use. The valid version values are `HTTP/1.1` and `HTTP/1.0`.

maintainSession
Specifies whether the HTTP session is enabled when a message is sent. The valid values are `yes` or `no`.

chunkTransferEnc
Specifies whether to enable chunked transfer encoding. The valid values are `yes` or `no`.

sendExpectHeader
Specifies whether to send an expect 100-request header. The valid values are `yes` or `no`.

compressRequest:name
Specifies whether to compress the request. The valid values are `gzip`, `x-gzip`, `deflate`, or `none`.

compressResponse:name
Specifies whether to compress the response. The valid values are `gzip`, `x-gzip`, `deflate`, or `none`.

acceptRedirectionURL
Specifies whether to accept URL redirection automatically. The valid values are `yes` or `no`.

messageResendOnce
Specifies if a message can be sent more than once. The valid values are `yes` or `no`.

connectTimeout
Specifies the amount of time, in seconds, before a connection times out when sending a message. Specify an integer value that is greater than zero. If a value of zero or less is specified, the connectTimeout property is set to the default value of 180 seconds. No maximum value is set for this property.

writeTimeout
Specifies the amount of time, in seconds, before the write time out occurs. Specify an integer value. Specify an integer value that is greater than zero. If a value of zero or less is specified, the connectTimeout property is set to the default value of 300 seconds. No maximum value is set for this property.

readTimeout
Specifies the amount of time, in seconds, before the read time out occurs. Specify an integer value. Specify an integer value that is greater than zero. If a value of zero or less is specified, the connectTimeout property is set to the default value of 300 seconds. No maximum value is set for this property.

persistConnection
Specifies whether to use a persistent connection when sending messages. Valid values are `yes` or `no`.

The following setPolicyType example command sets values for each HTTPTransport binding property:

```
AdminTask.setPolicyType('[-policySet "WSHTTPS custom" -policyType HTTPTransport -attributes "[[protocolVersion HTTP/1.1]
[sessionEnable yes][chunkTransferEnc yes][sendExpectHeader yes][compressRequest:name gzip][compressResponse:name
 gzip][acceptRedirectionURL yes][messageResendOnce no][connectTimeout 300][writeTimeout 300]
[readTimeout 300][persistConnection yes]]"]')
```

HTTPTransport binding properties

Configure the HTTPTransport binding by specifying the following attributes with the **setBinding** command:

outAsyncResponseBasicAuth:userid
Specifies the user name for basic authentication of outbound asynchronous responses.

outAsyncResponseBasicAuth:password
Specifies the password for basic authentication of outbound asynchronous responses.

outAsyncResponseProxy:userid
Specifies the user name for the outbound asynchronous service responses proxy.

outAsyncResponseProxy:password
Specifies the password for the outbound asynchronous service responses proxy.

outAsyncResponseProxy:port
Specifies the port number for the outbound asynchronous service responses proxy.

outAsyncResponseProxy:host
Specifies the host name for the outbound asynchronous service responses proxy.

outRequestBasicAuth:userid
Specifies the user name or basic authentication of outbound service requests.

outRequestBasicAuth:password
Specifies the password for basic authentication of outbound service requests.

outRequestProxy:userid
Specifies the user name for the outbound service request proxy.

outRequestProxy:password
Specifies the password for the outbound service request proxy.

outRequestProxy:port
Specifies the port number for the outbound service request proxy.

outRequestProxy:host
Specifies the host name for the outbound service request proxy.

The following **setBinding** example command sets values for each HTTPTransport binding property:

```
AdminTask.setBinding('[-bindingLocation "" -bindingName generalCellWideBind1 -policyType HTTPTransport
-attributes "[[outAsyncResponseBasicAuth:userid myID][outAsyncResponseBasicAuth:password myPW][outAsyncResponseProxy:host hostname]
[outAsyncResponseProxy:port 9060][outAsyncResponseProxy:userid myID][outAsyncResponseProxy:password myPW]
[outRequestBasicAuth:userid myID][outRequestBasicAuth:password myPW][outRequestProxy:userid myID]
[outRequestProxy:password myPW][outRequestProxy:port 9061][outRequestProxy:host hostname]]"]')
```

JMSTransport policy and binding properties

Use the -attributes parameter for the setPolicyType and setBinding commands to specify additional configuration information for the JMSTransport policy and policy set binding. Application policy sets can use the JMSTransport policy and binding.

Use the following commands and parameters in the PolicySetManagement group of the AdminTask object to customize your policy set configuration.

- Use the **attributes** parameter for the getPolicyType and getBinding commands to view the properties for your policy and binding configuration. To get an attribute, pass the property name to the getPolicyType or getBinding command.
- Use the **attributes** parameter for the setPolicyType and setBinding commands to add, update, or remove properties from your policy and binding configurations. To add or update an attribute, specify the property name and value. The setPolicyType and setBinding commands update the value if the attribute exists, or adds the attribute and value if the attribute does not exist. To remove an attribute, specify the value as an empty string (""). The **attributes** parameter accepts a properties object.

Note: If a property name or value supplied with the **attributes** parameter is not valid, then the setPolicyType and setBinding commands fail with an exception. The property that is not valid is logged as an error or warning in the `SystemOut.log` file. However, the command exception might not contain the detailed information for the property that caused the exception. When the setPolicyType and setBinding commands fail, examine the `SystemOut.log` file for any error and warning messages that indicate that the input for the **attributes** parameter contains one or multiple properties that are not valid.

Note: In WebSphere Application Server Version 7.0, the security model is enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global

security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

To support a mixed-cell environment, WebSphere Application Server supports Version 7.0 and Version 6.1 bindings. General cell-level bindings are specific to Version 7.0 Application-specific bindings remain at the version that the application requires. When the user creates an application-specific binding, the application server determines the required binding version to use for application.

The following sections explain the policy and binding properties to configure:

- JMSTransport policy properties
- JMSTransport binding properties

JMSTransport policy properties

Use the JMSTransport policy set to configure JMS transport for applications that use the Java Messaging Service (JMS) to exchange request and response messages.

Configure the JMSTransport policy by specifying the following attributes with the **setPolicyType** command:

requestTimeout
Specifies the request timeout value. The request timeout value is the amount of time, in seconds, that the client waits for a response after sending the request to the server. The default value is `300` seconds. If you specify an integer value of zero or less, the system sets the requestTimeout property to the default value of `300` seconds. No maximum value exists for this property.

allowTransactionalAsyncMessaging
Specifies whether a client uses transactions in one-way or asynchronous two-way requests. The default value for this property is `false`. Set the value of this property to `true` to enable transactional messaging. When enabled, the client runtime exchanges SOAP request and response messages with the server over the JMS transport in a transactional manner if the client operates under a transaction.

The client transaction is used to send the SOAP request message to the destination queue or topic, and the server receives the request message only after the client commits the transaction. Similarly, the server receives the request message under the control of a container-managed transaction and sends the reply message, if applicable, back to the client using that same transaction. Then, the client receives the reply message after the server transaction is committed.

The following setPolicyType example command sets values for each JMSTransport binding property:

```
AdminTask.setPolicyType('[-policySet "JMS custom" -policyType JMSTransport
 -attributes "[[requestTimeout 300][allowTransactionalAsynMessaging false]]"]')
```

JMSTransport binding properties

Configure the JMSTransport binding by specifying the following attributes with the **setBinding** command:

outRequestBasicAuth:userid
Specifies the user name or basic authentication of outbound service requests.

outRequestBasicAuth:password
Specifies the password for basic authentication of outbound service requests.

The following **setBinding** example command sets values for each HTTPTransport binding property:

```
AdminTask.setBinding('[-bindingLocation "" -bindingName generalCellWideBind1
 -policyType JMSTransport -attributes "[[outRequestBasicAuth:userid myID] [outRequestBasicAuth:password myPW]]"]')
```

SecureConversation command group for the AdminTask object (Deprecated)

Use this topic as a reference for the commands for the SecureConversation group of the AdminTask object. Use these commands with your administrative scripts to query, update, and remove secure conversation client cache configuration data.

Note: The commands in the SecureConversation command group are deprecated in WebSphere Application Server Version 7.0. Use the commands in the WSSCacheManagement command group to manage WS-Security distributed cache configurations.

Use the following commands in the SecureConversation group to manage your custom and non-custom secure conversation client cache configurations:

- "querySCClientCacheConfiguration command"
- "querySCClientCacheCustomConfiguration command"
- "updateSCClientCacheConfiguration command" on page 567
- "updateSCClientCacheCustomConfiguration command" on page 568
- "deleteSCClientCacheConfigurationCustomProperties command" on page 568

querySCClientCacheConfiguration command

The querySCClientCacheConfiguration command lists all non-custom client cache configuration data for WS-SecureConversation.

Target object

None

Required parameters

None.

Optional parameters

None.

Return value

This command returns a list of all non-custom client cache configuration data.

Batch mode example usage

- Using Jython:

```
print AdminTask.querySCClientCacheConfiguration()
```

Interactive mode example usage

- Using Jython:

```
AdminTask.querySCClientCacheConfiguration('-interactive')
```

querySCClientCacheCustomConfiguration command

The querySCClientCacheCustomConfiguration command lists all custom client cache configuration data for WS-SecureConversation.

Target object

None.

Required parameters

None.

Optional parameters

None.

Return value

This command returns a list of all custom client cache configuration data.

Batch mode example usage

- Using Jython:

```
print AdminTask.querySCClientCacheCustomConfiguration()
```

Interactive mode example usage

- Using Jython:

```
AdminTask.querySCClientCacheCustomConfiguration('-interactive')
```

updateSCClientCacheConfiguration command

The updateSCClientCacheConfiguration command sets the cache cushion time in minutes and enables or disables distributed cache.

Target object

None.

Required parameters

None.

Optional parameters

-distributedCache
Specifies whether distributed cache is enabled or disabled. If you set the -distributedCache parameter to `true` when you run the updateSCClientCacheConfiguration command, the system enables distributed cache for the WS-Security runtime. (Boolean, optional)

-minutesInCacheAfterTimeout
Specifies the amount of time, in minutes, that the token remains in the cache after it expires. The token is renewable for this amount of time. (Integer, optional)

-renewIntervalBeforeTimeoutMinutes
Specifies the amount of time, in minutes, that a renew request is allowed before the token expires. (Integer, optional)

Return value

This command returns a success or failure message.

Batch mode example usage

- Using Jython string:
  ```
  AdminTask.updateSCClientCacheConfiguration('-minutesInCacheAfterTimeout 100 -distributedCache true')
  ```
- Using Jython list:
  ```
  AdminTask.updateSCClientCacheConfiguration(['-minutesInCacheAfterTimeout', '100', '-distributedCache', 'true'])
  ```

Interactive mode example usage
- Using Jython:
  ```
  AdminTask.updateSCClientCacheConfiguration('-interactive')
  ```

updateSCClientCacheCustomConfiguration command

The updateSCClientCacheCustomConfiguration command updates custom properties for the secure conversation client cache configuration.

Target object

None.

Required parameters

None.

Optional parameters

-customProperties
The custom properties for the secure conversation client cache configuration. (Properties, optional)

Return value

This command returns a success or failure message.

Batch mode example usage
- Using Jython string:
  ```
  AdminTask.updateSCClientCacheCustomConfiguration('[-customProperties "[ [property2 value2] [property1 value1] ]"]')
  ```
- Using Jython list:
  ```
  AdminTask.updateSCClientCacheCustomConfiguration(['-customProperties', '[ [property2 value2] [property1 value1] ]'])
  ```

Interactive mode example usage
- Using Jython:
  ```
  AdminTask.updateSCClientCacheCustomConfiguration('-interactive')
  ```

deleteSCClientCacheConfigurationCustomProperties command

The deleteSCClientCacheConfigurationCustomProperties command removes specific properties from a custom secure conversation client cache configuration.

Target object

None.

Required parameters

-propertyNames
The names of the properties to delete. (String, required).

Optional parameters

None.

Return value

This command returns a success or failure message.

Batch mode example usage

- Using Jython string:
  `AdminTask.deleteSCClientCacheConfigurationCustomProperties('[-propertyNames [property1,property2]]')`
- Using Jython list:
  `AdminTask.deleteSCClientCacheConfigurationCustomProperties(['-propertyNames', '[property1,property2]'])`

Interactive mode example usage

- Using Jython:
  `AdminTask.deleteSCClientCacheConfigurationCustomProperties('-interactive')`

WSSCacheManagement command group for the AdminTask object

Use this topic as a reference for the commands for the WSSCacheManagement group of the AdminTask object. Use these commands with your administrative scripts to query, update, and remove distributed cache configuration data.

Use the following commands in the WSSCacheManagement group to manage your custom and non-custom distributed cache configurations:

- "deleteWSSDistributedCacheConfigCustomProperties command"
- "queryWSSDistributedCacheConfig command" on page 570
- "queryWSSDistributedCacheCustomConfig command" on page 571
- "updateWSSDistributedCacheConfig command" on page 571
- "updateWSSDistributedCacheCustomConfig command" on page 572

deleteWSSDistributedCacheConfigCustomProperties command

The deleteWSSDistributedCacheConfigCustomProperties command removes WS-Security distributed cache custom properties.

Target object

None

Required parameters

-propertyNames
Specifies the names of the custom properties to delete from the distributed cache configuration. (String[])

Optional parameters

None.

Return value

This command returns a message that indicates the success or failure of the command.

Batch mode example usage

- Using Jython string:

```
AdminTask.deleteWSSDistributedCacheConfigCustomProperties('[-propertyNames [prop1,prop2,prop3]]')
```

- Using Jython list:

```
AdminTask.deleteWSSDistributedCacheConfigCustomProperties([',-'propertyNames', '[prop1,prop2,prop3]'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.deleteWSSDistributedCacheConfigCustomProperties('-interactive')
```

queryWSSDistributedCacheConfig command

The queryWSSDistributedCacheConfig command lists the WS-Security distributed cache configuration non-custom properties.

Target object

None.

Required parameters

None.

Optional parameters

None.

Return value

This command returns a properties object that contains the configuration properties and values for the distributed cache configuration. The following table displays the configuration properties that the command returns:

Property	Description
tokenRecovery	Specifies whether token recovery is enabled or disabled. If the tokenRecovery property is set to `true`, the Datasource property specifies the shared data source that is assigned to the distributed cache.
distributedCache	Specifies whether distributed caching is enabled or disabled.
Datasource	Specifies the name of the shared data source that is assigned to the distributed cache if token recovery is enabled.
renewIntervalBeforeTimeoutMinutes	Specifies the amount of time, in minutes, that the client waits before it attempts to renew the token.
synchronousClusterUpdate	Specifies whether the system performs a synchronous update of distributed caches on cluster members. By default, synchronous cluster updating is enabled.
minutesInCacheAfterTimeout	Specifies the amount of time that the token remains in the cache after the token times out.

Batch mode example usage

- Using Jython:

```
print AdminTask.queryWSSDistributedCacheConfig()
```

Interactive mode example usage

- Using Jython:

```
AdminTask.queryWSSDistributedCacheConfig('-interactive')
```

queryWSSDistributedCacheCustomConfig command

The queryWSSDistributedCacheCustomConfig command lists the WS-Security distributed cache configuration custom properties.

Target object

None.

Required parameters

None.

Optional parameters

None.

Return value

This command returns a properties object that contains the name and value pairs that correspond to each custom property.

Batch mode example usage

- Using Jython:

```
AdminTask.queryWSSDistributedCacheCustomConfig()
```

Interactive mode example usage

- Using Jython:

```
AdminTask.queryWSSDistributedCacheCustomConfig('-interactive')
```

updateWSSDistributedCacheConfig command

The updateWSSDistributedCacheConfig command updates the WS-Security distributed cache configuration non-custom properties.

Target object

None.

Required parameters

None.

Optional parameters

-renewIntervalBeforeTimeoutMinutes
Specifies the amount of time, in minutes, that a renew request is allowed before the token expires. (Integer)

-minutesInCacheAfterTimeout
Specifies the amount of time, in minutes, that the token remains in the cache after it expires. The token is renewable for this amount of time. (Integer)

-distributedCache
Specifies whether distributed cache is enabled or disabled. (Boolean)

-synchronousClusterUpdate
Specifies whether the system performs a synchronous update of distributed caches on cluster members. By default, synchronous cluster updating is enabled. Specify `false` to disable synchronous cluster updating. (Boolean)

-tokenRecovery
Specifies whether token recovery is enabled or disabled. If you set the tokenRecovery property to `true`, specify the shared data source to assign to the distributed cache with the -Datasource parameter. (Boolean)

-Datasource
Specifies the name of the shared data source that is assigned to the distributed cache if token recovery is enabled. (String)

Return value

This command returns a success or failure message.

Batch mode example usage

- Using Jython string:
  ```
  AdminTask.updateWSSDistributedCacheConfig('[-customProperties "[ [property2 value2] [property1 value1] ]"]')
  ```
- Using Jython list:
  ```
  AdminTask.updateWSSDistributedCacheConfig(['-customProperties', '[ [property2 value2] [property1 value1] ]'])
  ```

Interactive mode example usage

- Using Jython:
  ```
  AdminTask.updateWSSDistributedCacheConfig('-interactive')
  ```

updateWSSDistributedCacheCustomConfig command

The updateWSSDistributedCacheCustomConfig command updates the WS-Security distributed cache configuration custom properties.

Target object

None.

Required parameters

-customProperties
Specifies the name and value of each custom property to add or update in the WS-Security distributed cache configuration. (java.util.Properties)

Optional parameters

None.

Return value

This command returns a success or failure message.

Batch mode example usage

- Using Jython string:
  ```
  AdminTask.updateWSSDistributedCacheCustomConfig('[-customProperties [[property1 value1][property2 value2]]]')
  ```
- Using Jython list:

```
AdminTask.updateWSSDistributedCacheCustomConfig(['-customProperties', '[[property1 value1][property2 value2]]'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.updateWSSDistributedCacheCustomConfig('-interactive')
```

PolicySetManagement command group for the AdminTask object

You can use the Jython or Jacl scripting languages to manage policy set configurations with the wsadmin tool. Use the commands and parameters in the PolicySetManagement group to create, delete, and manage policy set, policy, and policy set attachment configurations.

Before you use the commands in this topic, verify that you are using the most recent version of the wsadmin tool. The policy set management commands that accept a properties object as the value for the **attributes** or **bindingLocation** parameters are not supported on previous versions of the wsadmin tool. For example, the commands do not run on a Version 6.1.0.x node.

Use the following command to manage policy set configurations:

Use the following command to manage policy settings:

Use the following commands to manage policy set attachments:

Use the following commands to manage policy set bindings:

listPolicySets

The listPolicySets command returns a list of all existing policy sets. If administrative security is enabled, each user role can use this command.

Target object

None.

Optional parameters

-policySetType
Specifies the type of policy set. Specify `application` to display application policy sets. Specify `system` to display system policy sets for trust service or WS-MetadataExchange attachments. Specify `system/trust` to display the policy sets for the trust service. Specify `default` to display the default policy sets. The default value for this parameter is `application`. (String, optional)

-fromDefaultRepository
Specifies whether to use the default repository. (Boolean, optional)

Return value

The command returns a list of all existing policy sets. Each entry in the list is the name of a policy set.

Batch mode example usage

- Using Jython string:

```
AdminTask.listPolicySets('[-policySetType system/trust]')
```

- Using Jython list:

```
AdminTask.listPolicySets(['-policySetType', 'system/trust'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.listPolicySets('-interactive')
```

getPolicySet

The getPolicySet command returns general attributes, such as description and default indicator, for the specified policy set. If administrative security is enabled, each user role can use this command.

Target object

None.

Required parameters

-policySet
Specifies the policy set name. For a list of all policy set names, use the listPolicySets command. (String, required)

Optional parameters

-isDefaultPolicySet
Specifies whether to display a default policy set. The default value is `false`. (Boolean, optional)

-fromDefaultRepository
Specifies whether to use the default repository. (Boolean, optional)

Return value

The command returns a list of attributes for the specified policy set name.

Batch mode example usage

- Using Jython string:

```
AdminTask.getPolicySet('[-policySet SecureConversation]')
```

- Using Jython list:

```
AdminTask.getPolicySet(['-policySet', 'SecureConversation'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.getPolicySet('-interactive')
```

createPolicySet

The createPolicySet command creates a new policy set. Policies are not created with the policy set. The default indicator is set to `false`.

If administrative security is enabled, you must use the Administrator role to create policy sets.

Target object

None.

Required parameters

-policySet
Specifies the name of the policy set. (String, required)

Optional parameters

-description
Adds a description for the policy set. (String, required)

-policySetType
Specifies the type of policy set. When the value is `application`, the command creates application policy sets. When the value is `system`, the command creates a policy set that you can use for trust service or WS-MetadataExchange attachments. When the value is `system/trust`, the command creates a policy set for the trust service. The default value for this parameter is `application`. (String, optional)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.createPolicySet('[-policySet myCustomPS -description  [my new custom policy
 set] -policySetType system/trust]')
```

- Using Jython list:

```
AdminTask.createPolicySet(['-policySet', 'myCustomPS', '-description',  '[my new custom
 policy set]', '-policySetType', 'system/trust'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.createPolicySet('-interactive')
```

copyPolicySet

The copyPolicySet command creates a copy of an existing policy set. By default, the policy set attachments are transferred to the new policy set.

If administrative security is enabled, you must use the Administrator role to copy policy sets.

Target object

None.

Required parameters

-sourcePolicySet
Specifies the name of the existing policy set to copy. (String, required)

-newPolicySet
Specifies the name of the new policy set you are creating. (String, required)

-newDescription
Specifies a description for the new policy set. (String, required)

Optional parameters

-transferAttachments
If this parameter is set to `true`, all attachments transfer from the source policy set to the new policy set. The default value is `false`. (Boolean, optional)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.copyPolicySet('[-sourcePolicySet SecureConversation -newPolicySet
 CustomSecureConversation -newDescription [my new copied policy set] -transferAttachments true]')
```

- Using Jython list:

```
AdminTask.copyPolicySet(['-sourcePolicySet', 'SecureConversation', '-newPolicySet',
 'CustomSecureConversation', '-newDescription', '[my new copied policy set]',  '-transferAttachments',
 'true'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.copyPolicySet('-interactive')
```

deletePolicySet

The deletePolicySet command deletes the specified policy set. If attachments exist for the policy set, the command returns a failure message.

If administrative security is enabled, you must use the Administrator role to delete policy sets.

Target object

None.

Required parameters

-policySet
Specifies the name of the policy set to delete. (String, required)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.deletePolicySet('[-policySet customSecureConversation]')
```

- Using Jython list:

```
AdminTask.deletePolicySet(['-policySet', 'customSecureConversation'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.deletePolicySet('-interactive')
```

updatePolicySet

The updatePolicySet command enables you to input an attribute list to update the policy set. You can use this command to update all attributes for the policy set, or a subset of attributes.

If administrative security is enabled, you must use the Administrator role to update policy set configurations.

Target object

None.

Required parameters

-policySet
Specifies the name of the policy set to update. (String, required)

-attributes
Specifies a properties object that contains the attributes to update for the specified policy set. (Properties, required)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.updatePolicySet('-policySet policySet1 -attributes [[type application]
 [description [my policy set description]]]')
```

- Using Jython list:

```
AdminTask.updatePolicySet(['-policySet', 'policySet1', '-attributes', '[[type
 application] [description [my policy set description]]]'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.updatePolicySet('-interactive')
```

addPolicyType

The addPolicyType command adds a policy with default values for the specified policy set. You must indicate whether to enable or disable the added policy.

If administrative security is enabled, you must use the Administrator role to add policies.

Target object

None.

Required parameters

-policySet
Specifies the name of the policy set to update. (String, required)

-policyType
Specifies the name of the policy to add to the policy set. (String, required)

-enabled
If this parameter is set to `true`, new policy is enabled in the policy set. If this parameter is set to `false`, the configuration is contained within the policy set but the configuration does not have an effect on the system. (Boolean, required)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.addPolicyType('[-policySet customPolicySet -policyType WSTransaction
 -enabled true]')
```

- Using Jython list:

```
AdminTask.addPolicyType(['-policySet', 'customPolicySet', '-policyType',
 'WSTransaction', '-enabled', 'true'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.addPolicyType('-interactive')
```

deletePolicyType

The deletePolicyType command deletes a policy from a policy set.

If administrative security is enabled, you must use the Administrator role to remove policies from your configuration.

Target object

None.

Required parameters

-policySet
Specifies the name of the policy set to update. (String, required)

-policyType
Specifies the name of the policy to remove from the policy set. (String, required)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.deletePolicyType('[-policySet customPolicySet -policyType WSTransaction]')
```

- Using Jython list:

```
AdminTask.deletePolicyType(['-policySet', 'customPolicySet', '-policyType',
 'WSTransaction'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.deletePolicyType('-interactive')
```

validatePolicySet

The validatePolicySet command validates the policy set configuration.

If administrative security is enabled, you must use the Administrator role to validate policy sets.

Target object

None.

Required parameters

-policySet
Specifies the policy set to update. (String, required)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.validatePolicySet('[-policySet customSecureConversation]')
```

- Using Jython list:

```
AdminTask.validatePolicySet(['-policySet', 'customSecureConversation'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.validatePolicySet('-interactive')
```

exportPolicySet

The exportPolicySet command exports a policy set as an archive that can be copied onto a client environment.

If administrative security is enabled, you must use the Administrator role to export policy sets.

Target object

None.

Required parameters

-policySet
Specifies the policy set to export. (String, required)

-pathName
Specifies the path name of the archive file to create. (String, required)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.exportPolicySet('[-policySet customSecureConversation -pathName
 C:/IBM/WebSphere/AppServer/PolicySets/customSC.zip]')
```

- Using Jython list:

```
AdminTask.exportPolicySet(['-policySet', 'customSecureConversation;, '-pathName', '
 C:/IBM/WebSphere/AppServer/PolicySets/customSC.zip'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.exportPolicySet('-interactive')
```

importPolicySet

The importPolicySet command imports a policy set from a compressed archive file or from a selection of default policy sets onto the server environment.

If administrative security is enabled, you must use the Administrator role to import policy sets.

Target object

None.

Optional parameters

-importFile
Specifies the path name of the archive file to import. (String, optional)

-defaultPolicySet
Specifies the name of the default policy set to import. (String, optional)

-policySet
Specifies the name to assign to the new policy set. If you do not specify this parameter, the system uses the original name of the policy set. (String, optional)

-verifyPolicySetType
Specifies that the policy set type to import matches a specific type. Specify `system` or `system/trust` to verify that the policy set to import is a type of system policy set, including trust service policy sets. Specify `application` to verify that the policy set is an application policy set. (String, optional)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.importPolicySet('[-importFile C:/IBM/WebSphere/AppServer/PolicySets/customSC.zip]')
```

- Using Jython list:

```
AdminTask.importPolicySet(['-importFile', 'C:/IBM/WebSphere/AppServer/PolicySets/customSC.zip'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.importPolicySet('-interactive')
```

listPolicyTypes

The listPolicyTypes command returns a list of the names of the policies configured on your system. The input parameters allow you to list each policy type configured in the system, the policy types configured in a policy set, or the policy types in a binding.

If administrative security is enabled, each administrative role can list policy types.

Target object

None.

Optional parameters

-policySet
Specifies the name of the policy set to query for policies. If the policy set is not specified, the command lists all policies defined in your configuration. (String, optional)

-bindingLocation
Specifies the location of the binding. This value is cell-wide default binding, server-specific default binding, or attachment-specific binding. Specify the bindingLocation parameter as a properties object following these guidelines:

- For cell-wide default binding, use a null or empty properties.
- For server-specific default binding, specify the node and server names in the properties. The property names are `node` and `server`. Server-specific default bindings are deprecated.
- For attachment-specific binding, specify the application name and attachment ID in the properties. The property names are `application` and `attachmentId`.
- For system bindings, set the `systemType` property as `trustService`.
- For WSNClient binding, specify the bus name, service name, and attachment ID in the properties. The property names are `bus`, `WSNService`, and `attachmentId`.

(Properties, optional)

-attachmentType
Specifies whether the attachment type is an application binding, client binding, trust service binding, or WS-Notification client binding. (String, optional)

Note: The `application` and `system/trust` values for the -attachmentType parameter are deprecated. Specify the `provider` value in place of the `application` value. For system policy set attachments, specify the `provider` value for the attachmentType parameter and the `"[systemType trustService]"` value for the -attachmentProperties parameter. For WSNClient attachments, specify the `client` value for the attachmentType parameter and the `bus` and `WSNService` properties with the -attachmentProperties parameter.

-bindingName
Specifies a specific general binding. If you specify this parameter, the system displays policy types in the specific binding. (String, optional)

-fromDefaultRepository
Specifies whether to use the default repository. (Boolean, optional)

Return value

The command returns a list of policy types.

Batch mode example usage

- Using Jython string:

```
AdminTask.listPolicyTypes('[-policySet customSecureConversation]')
```

- Using Jython list:

```
AdminTask.listPolicyTypes(['-policySet', 'customSecureConversation'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.listPolicyTypes('[-interactive]')
```

getPolicyType

The getPolicyType command returns the attributes for a specified policy.

If administrative security is enabled, each administrative role can query attributes for policies.

Target object

None.

Required parameters

-policySet
Specifies the name of the policy set to query. (String, required)

-policyType
Specifies the name of the policy of interest. (String, required)

Optional parameters

-attributes
Specifies the specific attributes to display. If this parameter is not used, the command returns all attributes for the specified policy. (String[], optional)

-fromDefaultRepository
Specifies whether to use the default repository. (Boolean, optional)

Return value

The command returns a properties object containing the policy attributes.

Batch mode example usage

- Using Jython string:

```
AdminTask.getPolicyType('[-policySet customSecureConversation -policyType
 SecureConversation]')
```

- Using Jython list:

```
AdminTask.getPolicyType(['-policySet', 'customSecureConversation', '-policyType', 'SecureConversation'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.getPolicyType (['-interactive'])
```

setPolicyType

The setPolicyType command updates the attributes of a specified policy.

Note: The administrative console command assistance provides incorrect Jython syntax for the setPolicyType command. The XPath expression for the response message part protection of the Username WSSecurity policy set contains single quotes (') within each XPath property value, which Jython does not support. To fix the command from the administrative console command assistance, add a backslash character (\) before each single quote to escape the single quote.

If administrative security is enabled, you must use the Administrator role to configure policies.

Target object

None.

Required parameters

-policySet
Specifies the name of the policy set of interest. (String, required)

-policyType
Specifies the name of the policy of interest. (String, required)

-attributes
Specifies the specific attributes to be updated. The properties could include all of the policy attributes or a subset of attributes. (Properties, required)

Optional parameters

-replace
Indicates whether the new attributes provided from the command replace the existing policy attributes. For policies with complex data, you can remove optional parts of the configuration when necessary. Use this parameter to get all attributes, perform edits, and replace the binding configuration with the edited data. The default value is `false`. (Boolean, optional)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.setPolicyType('[-policySet customSecureConversation -policyType
 SecureConversation -attributes [[type application] [description [my new description]]]]')
```

- Using Jython list:

```
AdminTask.setPolicyType(['-policySet', 'customSecureConversation', '-policyType', 'SecureConversation', '-attributes',
 '[[type application] [description [my new description]]]'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.setPolicyType('-interactive')
```

getPolicyTypeAttribute

The getPolicyTypeAttribute command returns the value for the specified policy attribute.

If administrative security is enabled, each administrative role can query policy type attribute values.

Target object

None.

Required parameters

-policySet
Specifies the name of the policy set of interest. (String, required)

-policyType
Specifies the name of the policy of interest. (String, required)

-attributeName
Specifies the name of the attribute of interest. (String, required)

-fromDefaultRepository
Specifies whether to use the default repository. (Boolean, optional)

Optional parameters

-fromDefaultRepository
Specifies whether to use the default repository. (Boolean, optional)

Return value

The command returns a string that contains the value of the specified attribute.

Batch mode example usage

- Using Jython string:

```
AdminTask.getPolicyTypeAttribute('[-policySet customSecureConversation  -policyType
 SecureConversation -attributeName type]')
```

- Using Jython list:

```
AdminTask.getPolicyTypeAttribute(['-policySet', 'customSecureConversation',  '-policyType',
 'SecureConversation', '-attributeName', 'type'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.getPolicyTypeAttribute('-interactive')
```

setPolicyTypeAttribute

The setPolicyTypeAttribute command sets the value for the specified policy attribute.

If administrative security is enabled, you must use the Administrator role to configure policy attributes.

Target object

None.

Required parameters

-policySet
Specifies the name of the policy set of interest. (String, required)

-policyType
Specifies the name of the policy of interest. (String, required)

-attributeName
Specifies the name of the attribute of interest. (String, required)

-attributeValue
Specifies the value of the attribute of interest. (String, required)

Return value

If the attribute is successfully added to the policy, the command returns the `true` string value.

Batch mode example usage

- Using Jython string:

```
AdminTask.setPolicyTypeAttribute('[-policySet customPolicySet  -policyType
 WSReliableMessaging -attributeName specLevel  -attributeValue 1.0]')
```

- Using Jython list:

```
AdminTask.setPolicyTypeAttribute(['-policySet', 'customPolicySet',  '-policyType',
 'WSReliableMessaging', '-attributeName', 'specLevel',  '-attributeValue', '1.0'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.setPolicyTypeAttribute('-interactive')
```

getPolicySetAttachments

The getPolicySetAttachments command lists the properties for all policy set attachments configured in a specified application.

If administrative security is enabled, each administrative role can query for policy set attachments.

Target object

None.

Optional parameters

-applicationName
Specifies the name of the application to query for policy set attachments. For application and client attachments, this parameter is required. This parameter is not required to query for trust service attachments. (String, optional)

-attachmentType
Specifies the type of policy set attachments. (String, optional)

Note: The `application` and `system/trust` values for the -attachmentType parameter are deprecated. Specify the `provider` value in place of the `application` value. For system policy set attachments, specify the `provider` value for the attachmentType parameter and the `"[systemType trustService]"` value for the -attachmentProperties parameter. For WSNClient attachments, specify the `client` value for the attachmentType parameter and the `bus` and `WSNService` properties with the -attachmentProperties parameter.

-expandResources
Provides expanded information that details the attachment properties for each resource. An asterisk (*

) character returns all Web services. This parameter is valid if the value for the -attachmentType parameter is set to `provider` or `client`. (String, optional)

-attachmentProperties
Specifies information that is required to identify the location of the attachment. For WSNClient attachments, specify the attachmentType parameter as `client`, and use the -attachmentProperties parameter to specify the `bus` and `WSNService` properties. For system policy set attachments, specify the attachmentType parameter as `provider`, and use the -attachmentProperties parameter to set the `systemType` property value to `trustService`. (Properties, optional)

Return value

The command returns a list of properties for each attachment in the application, including the policy set name, attachment ID, and resource list. If you specify the expandResources parameter, the command returns the resource, attachmentId, policySet, binding, and directAttachment properties. If a resource is not attached to a policy set, then the system only displays the resource property. The binding property only exists if the attachment contains a custom binding.

Batch mode example usage

- Using Jython string:

```
AdminTask.getPolicySetAttachments('[-attachmentType provider -attachmentProperties "[systemType trustService]"]')
```

- Using Jython list:

```
AdminTask.getPolicySetAttachments(['-attachmentType', 'provider', '-attachmentProperties',
 '[systemType trustService]'])
```

Interactive mode example usage

- Using Jython list:

```
AdminTask.getPolicySetAttachments('-interactive')
```

createPolicySetAttachment

The createPolicySetAttachment command creates a new policy set attachment for an application.

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to create policy set attachments. If you have access to a specific resource only, you can create policy set attachments for the resource for which you have access.
Configurator	The Configurator role must have cell-wide access to create policy set attachments. If you have access to a specific resource only, you can create policy set attachments for the resource for which you have access.
Deployer	The Deployer role with cell-wide or resource specific access can create policy set attachments for application resources only.
Operator	The Operator role cannot create policy set attachments.
Monitor	The Monitor role cannot create policy set attachments.

Target object

None.

Required parameters

-policySet
Specifies the name of the policy set to attach. (String, required)

-resources
Specifies the name of the application resources to attach to the policy set. (String[], required)

Optional parameters

-applicationName
Specifies the name of the application of interest for policy set attachments. For application and client attachments, this parameter is required. This parameter is not required for trust service attachments. (String, optional)

-attachmentType
Specifies the type of policy set attachments. (String, optional)

Note: The `application` and `system/trust` values for the -attachmentType parameter are deprecated. Specify the `provider` value in place of the `application` value. For system policy set attachments, specify the `provider` value for the attachmentType parameter and the `"[systemType trustService]"` value for the -attachmentProperties parameter. For WSNClient attachments, specify the `client` value for the attachmentType parameter and the `bus` and `WSNService` properties with the -attachmentProperties parameter.

-dynamicClient
Set this parameter to `true`, the system will not recognize the client resources. This option specifies that the client resources are not validated. (Boolean, optional)

-attachmentProperties
Specifies information that is required to identify the location of the attachment. For WSNClient attachments, specify the attachmentType parameter as `client`, and use the -attachmentProperties parameter to specify the `bus` and `WSNService` properties. For system policy set attachments, specify the attachmentType parameter as `provider`, and use the -attachmentProperties parameter to set the `systemType` property value to `trustService`. (Properties, optional)

Return value

The command returns a string with the ID of the new attachment.

Batch mode example usage

- Using Jython string:

```
AdminTask.createPolicySetAttachment('[-policySet policyset1 -resources "WebService:/" -applicationName WebService -attachmentType provider]')
```

- Using Jython list:

```
AdminTask.createPolicySetAttachment(['-policySet', 'policyset1', '-resources', '"WebService:/"', '-applicationName', 'WebService',
 '-attachmentType', 'provider'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.createPolicySetAttachment('-interactive')
```

updatePolicySetAttachment

The updatePolicySetAttachment command updates the resources that apply to a policy set attachment.

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to configure policy set attachments. If you have access to a specific resource only, you can configure policy set attachments for the resource for which you have access.
Configurator	The Configurator role must have cell-wide access to configure policy set attachments. If you have access to a specific resource only, you can configure policy set attachments for the resource for which you have access.
Deployer	The Deployer role with cell-wide or resource specific access can configure policy set attachments for application resources only.
Operator	The Operator role cannot configure policy set attachments.
Monitor	The Monitor role cannot configure policy set attachments.

Target object

None.

Required parameters

-attachmentId
Specifies the name of the attachment to update. (String, required)

-resources
Specifies the names of the application resources to attach to the policy set. (String, required)

Optional parameters

-applicationName
Specifies the name of the application of interest for policy set attachments. For application and client attachments, this parameter is required. This parameter is not required for trust service attachments. (String, optional)

-attachmentType
Specifies the type of policy set attachments. (String, optional)

Note: The `application` and `system/trust` values for the -attachmentType parameter are deprecated. Specify the `provider` value in place of the `application` value. For system policy set attachments, specify the `provider` value for the attachmentType parameter and the `"[systemType trustService]"` value for the -attachmentProperties parameter. For WSNClient attachments, specify the `client` value for the attachmentType parameter and the `bus` and `WSNService` properties with the -attachmentProperties parameter.

-dynamicClient
Set this parameter to `true`, the system will not recognize the client resources. This option specifies that the client resources are not validated. (Boolean, optional)

-attachmentProperties
Specifies information that is required to identify the location of the attachment. For WSNClient attachments, specify the attachmentType parameter as `client`, and use the -attachmentProperties parameter to specify the `bus` and `WSNService` properties. For system policy set attachments, specify the attachmentType parameter as `provider`, and use the -attachmentProperties parameter to set the `systemType` property value to `trustService`. (Properties, optional)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.updatePolicySetAttachment('[-attachmentId 123 -resources "WebService:/"]')
```

- Using Jython list:

```
AdminTask.updatePolicySetAttachment(['-attachmentId', '123', '-resources',
 '"WebService:/"'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.updatePolicySetAttachment ('-interactive')
```

addToPolicySetAttachment

The addToPolicySetAttachment command adds additional resources that apply to a policy set attachment.

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to add resources to policy set attachments. If you have access to a specific resource only, you can add resources to policy set attachments for the resource for which you have access.
Configurator	The Configurator role must have cell-wide access to add resources to policy set attachments. If you have access to a specific resource only, you can add resources to policy set attachments for the resource for which you have access.
Deployer	The Deployer role with cell-wide or resource specific access can add resources to policy set attachments for application resources only.
Operator	The Operator role cannot add resources to policy set attachments.
Monitor	The Monitor role cannot add resources to policy set attachments.

Target object

None.

Required parameters

-attachmentId
Specifies the name of the attachment to update. (String, required)

-resources
Specifies the names of the application resources to attach to the policy set. (String, required)

Optional parameters

-applicationName
Specifies the name of the application of interest for policy set attachments. For application and client attachments, this parameter is required. This parameter is not required for trust service attachments. (String, optional)

-attachmentType
Specifies the type of policy set attachments. (String, optional)

Note: The `application` and `system/trust` values for the -attachmentType parameter are deprecated. Specify the `provider` value in place of the `application` value. For system policy set

attachments, specify the provider value for the attachmentType parameter and the "[systemType trustService]" value for the -attachmentProperties parameter. For WSNClient attachments, specify the client value for the attachmentType parameter and the bus and WSNService properties with the -attachmentProperties parameter.

-dynamicClient
Set this parameter to true, the system will not recognize the client resources. This option specifies that the client resources are not validated. (Boolean, optional)

-attachmentProperties
Specifies information that is required to identify the location of the attachment. For WSNClient attachments, specify the attachmentType parameter as client, and use the -attachmentProperties parameter to specify the bus and WSNService properties. For system policy set attachments, specify the attachmentType parameter as provider, and use the -attachmentProperties parameter to set the systemType property value to trustService. (Properties, optional)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.addToPolicySetAttachment('[-attachmentId 123 -resources
 "WebService:/webapp1.war:{http://www.ibm.com}myService"]')
```

- Using Jython list:

```
AdminTask.addToPolicySetAttachment(['-attachmentId', '123', '-resources',
 '"WebService:/webapp1.war:{http://www.ibm.com}myService"'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.addToPolicySetAttachment('-interactive')
```

removeFromPolicySetAttachment

The removeFromPolicySetAttachment command removes resources that apply to a policy set attachment.

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to remove resources from policy set attachments. If you have access to a specific resource only, you can remove resources for which you have access.
Configurator	The Configurator role must have cell-wide access to remove resources from policy set attachments. If you have access to a specific resource only, you can remove the resource for which you have access.
Deployer	The Deployer role with cell-wide or resource specific access can remove resources from policy set attachments for application resources only.
Operator	The Operator role cannot remove resources from policy set attachments.
Monitor	The Monitor role cannot remove resources from policy set attachments.

Target object

None.

Required parameters

-attachmentId
Specifies the name of the attachment to remove. (String, required)

-resources
Specifies the names of the application resources to attach to the policy set. (String, required)

Optional parameters

-applicationName
Specifies the name of the application of interest for policy set attachments. For application and client attachments, this parameter is required. This parameter is not required for trust service attachments. (String, optional)

-attachmentType
Specifies the type of policy set attachments. (String, optional)

Note: The `application` and `system/trust` values for the -attachmentType parameter are deprecated. Specify the `provider` value in place of the `application` value. For system policy set attachments, specify the `provider` value for the attachmentType parameter and the `"[systemType trustService]"` value for the -attachmentProperties parameter. For WSNClient attachments, specify the `client` value for the attachmentType parameter and the `bus` and `WSNService` properties with the -attachmentProperties parameter.

-attachmentProperties
Specifies information that is required to identify the location of the attachment. For WSNClient attachments, specify the attachmentType parameter as `client`, and use the -attachmentProperties parameter to specify the `bus` and `WSNService` properties. For system policy set attachments, specify the attachmentType parameter as `provider`, and use the -attachmentProperties parameter to set the `systemType` property value to `trustService`. (Properties, optional)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.removeFromPolicySetAttachment('[-attachmentId 123 -resources
 "WebService:/webapp1.war:{http://www.ibm.com}myService"]')
```

- Using Jython list:

```
AdminTask.removeFromPolicySetAttachment(['-attachmentId', '123', '-resources',
 '"WebService:/webapp1.war:{http://www.ibm.com}myService"'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.removeFromPolicySetAttachment('-interactive')
```

deletePolicySetAttachment

The deletePolicySetAttachment command removes a policy set attachment from an application.

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to delete policy set attachments. If you have access to a specific resource only, you can delete policy set attachments for the resource for which you have access.
Configurator	The Configurator role must have cell-wide access to delete policy set attachments. If you have access to a specific resource only, you can delete policy set attachments for the resource for which you have access.
Deployer	The Deployer role with cell-wide or resource specific access can delete policy set attachments for application resources only.
Operator	The Operator role cannot delete policy set attachments.
Monitor	The Monitor role cannot delete policy set attachments.

Target object

None.

Required parameters

-attachmentId
Specifies the name of the attachment to delete. (String, required)

Optional parameters

-applicationName
Specifies the name of the application of interest for policy set attachments. For application and client attachments, this parameter is required. This parameter is not required for trust service attachments. (String, optional)

-attachmentType
Specifies the type of policy set attachments. (String, optional)

Note: The `application` and `system/trust` values for the -attachmentType parameter are deprecated. Specify the `provider` value in place of the `application` value. For system policy set attachments, specify the `provider` value for the attachmentType parameter and the `"[systemType trustService]"` value for the -attachmentProperties parameter. For WSNClient attachments, specify the `client` value for the attachmentType parameter and the `bus` and `WSNService` properties with the -attachmentProperties parameter.

-attachmentProperties
Specifies information that is required to identify the location of the attachment. For WSNClient attachments, specify the attachmentType parameter as `client`, and use the -attachmentProperties parameter to specify the `bus` and `WSNService` properties. For system policy set attachments, specify the attachmentType parameter as `provider`, and use the -attachmentProperties parameter to set the `systemType` property value to `trustService`. (Properties, optional)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.deletePolicySetAttachment('[-attachmentId 123]')
```

- Using Jython list:

```
AdminTask.deletePolicySetAttachment(['-attachmentId', '123'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.deletePolicySetAttachment('-interactive')
```

listAssetsAttachedToPolicySet

The listAssetsAttachedToPolicySet command lists the applications or WS-Notification service clients to which a specific policy set is attached.

If administrative security is enabled, each administrative role can list applications that are attached to policy sets.

Target object

None.

Required parameters

-policySet
Specifies the name of the policy set of interest. (String, required)

Optional parameters

-attachmentType
Specifies the type of policy set attachments. The value for this parameter must be `provider`, `client`, `WSNClient`, `WSMex`, or `all`. The default value is `all`. (String, optional)

Return value

The command returns a list of properties that describe each asset. Each properties object contains the `assetType` property, which specifies the type of asset.

Batch mode example usage

- Using Jython string:

```
AdminTask.listAssetsAttachedToPolicySet('[-policySet SecureConversation]')
```

- Using Jython list:

```
AdminTask.listAssetsAttachedToPolicySet(['-policySet', 'SecureConversation'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.listAssetsAttachedToPolicySet('-interactive')
```

listAttachmentsForPolicySet

The listAttachmentsForPolicySet command lists the applications to which a specific policy set is attached.

If administrative security is enabled, each administrative role can query for policy set attachments.

Target object

None.

Required parameters

-policySet
Specifies the name of the policy set of interest. (String, required)

Optional parameters

-attachmentType
Specifies the type of policy set attachments. The value for this parameter must be `application`, `client`, or `system/trust`. The default value is `application`. (String, optional)

Return value

The command returns a list of application names.

Batch mode example usage

- Using Jython string:

```
AdminTask.listAttachmentsForPolicySet('[-policySet SecureConversation]')
```

- Using Jython list:

```
AdminTask.listAttachmentsForPolicySet(['-policySet', 'SecureConversation'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.listAttachmentsForPolicySet('-interactive')
```

deleteAttachmentsForPolicySet

The deleteAttachmentsForPolicySet command removes all attachments for a specific policy set.

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to delete policy set attachments. If you have access to a specific resource only, you can delete policy set attachments for the resource for which you have access.
Configurator	The Configurator role must have cell-wide access to delete policy set attachments. If you have access to a specific resource only, you can delete policy set attachments for the resource for which you have access.
Deployer	The Deployer role with cell-wide or resource specific access can delete policy set attachments for application resources only.
Operator	The Operator role cannot delete policy set attachments.
Monitor	The Monitor role cannot delete policy set attachments.

Target object

None.

Required parameters

-policySet
Specifies the name of the policy set from which to remove the attachments. (String, required)

Optional parameters

-applicationName
Specifies the name of the application of interest. The command only deletes attachments for the application of interest if you specify this parameter. (String, optional)

-attachmentProperties
Specifies information that is required to identify the location of the attachment. You can specify values for the `bus` and `WSNService` properties. (Properties, optional)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.deleteAttachmentsForPolicySet('[-policySet customSecureConversation
 -applicationName newApp1]')
```

- Using Jython list:

```
AdminTask.deleteAttachmentsForPolicySet(['-policySet', 'customSecureConversation',
 '-applicationName', 'newApp1'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.deleteAttachmentsForPolicySet('-interactive')
```

transferAttachmentsForPolicySet

The transferAttachmentsForPolicySet command transfers all attachments from one policy set to another policy set.

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to transfer policy set attachments. If you have access to a specific resource only, you can transfer policy set attachments for the resource for which you have access.
Configurator	The Configurator role must have cell-wide access to transfer policy set attachments. If you have access to a specific resource only, you can transfer policy set attachments for the resource for which you have access.
Deployer	The Deployer role with cell-wide or resource specific access can transfer policy set attachments for application resources only.
Operator	The Operator role cannot transfer policy set attachments.
Monitor	The Monitor role cannot transfer policy set attachments.

Target object

None.

Required parameters

-sourcePolicySet
Specifies the source policy set from which to copy attachments. (String, required)

-destinationPolicySet
Specifies the name of the policy set to which the attachments are copied. (String, required)

Optional parameters

-applicationName
Specifies the name of the application of interest. The command only transfers attachments for the application of interest if you specify this parameter. (String, optional)

-attachmentProperties
Specifies information that is required to identify the location of the attachment. You can specify values for the `bus` and `WSNService` properties. (Properties, optional)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.transferAttachmentsForPolicySet('[-sourcePolicySet SecureConversation
 -destinationPolicySet customSecureConversation -applicationName newApp1]')
```

- Using Jython list:

```
AdminTask.transferAttachmentsForPolicySet(['-sourcePolicySet', 'SecureConversation',
 '-destinationPolicySet', 'customSecureConversation', '-applicationName', 'newApp1'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.transferAttachmentsForPolicySet('-interactive')
```

getBinding

The getBinding command returns the binding configuration for a specified policy and scope. You can use the getBinding command to return a list of available custom bindings, which includes bindings that are and are not referenced by attachments.

If administrative security is enabled, each administrative role can query for binding configuration information.

Note: In WebSphere Application Server Version 7.0, the security model is enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

To support a mixed-cell environment, WebSphere Application Server supports Version 7.0 and Version 6.1 bindings. General cell-level bindings are specific to Version 7.0 Application-specific bindings remain at the version that the application requires. When the user creates an application-specific binding, the application server determines the required binding version to use for application.

Target object

None.

Required parameters

-policyType
Specifies the policy of interest. (String, required)

-bindingLocation
Specifies the location of the binding. (Properties, required)

Specify the bindingLocation parameter as a properties object following these guidelines:

- For cell-wide general binding or WebSphere Application Server Version 6.1 cell default bindings, specify a null or empty properties.
- For WebSphere Application Server Version 6.1 server-specific default binding, specify the node and server names in the properties. The property names are `node` and `server`. Server-specific default bindings are deprecated.
- For WebSphere Application Server Version 7.0 server default bindings, specify a null or empty properties. Use the bindingName parameter to identify the binding location.
- For attachment-specific, specify the application name and attachment ID in the properties. The property names are `application` and `attachmentId`.
- For WSNClient bindings, specify the bus name, service name, and attachment ID in the properties. The property names are `bus`, `WSNService`, and `attachmentId`. If you specify an asterisk character (*) as the attachment ID, then the command returns the list of binding names that corresponds to the attachment type of interest.
- For system/trust bindings, set the `systemType` property as `trustService`.

Optional parameters

-attachmentType
Specifies the type of policy set attachment. Use this parameter to distinguish between types of attachment custom bindings. (String, optional)

Note: The `application` and `system/trust` values for the -attachmentType parameter are deprecated. Specify the `provider` value in place of the `application` value. For system policy set attachments, specify the `provider` value for the attachmentType parameter and the `"[systemType trustService]"` value for the -attachmentProperties parameter. For WSNClient attachments, specify the `client` value for the attachmentType parameter and the `bus` and `WSNService` properties with the -attachmentProperties parameter.

-attributes
Specifies the names of the attributes to return. If this parameter is not specified, the command returns all attributes. (String[], optional)

-bindingName
Specifies the binding name of interest. Specify this parameter to display a general cell-level binding or a custom attachment binding. (String, optional)

Return value

The command returns a properties object that contains the requested configuration attributes for the policy binding.

Batch mode example usage

- Using Jython string:

  The following example returns a list of application bindings:

```
AdminTask.getBinding('[-policyType WSAddressing -attachmentType provider
 -bindingLocation [[application application_name] [attachmentId *]]]')
```

  The following example returns a list of client bindings:

```
AdminTask.getBinding('[-policyType WSAddressing -attachmentType client
 -bindingLocation [[application application_name] [attachmentId *]]]')
```

  The following example returns a list of system bindings:

```
AdminTask.getBinding('[-policyType WSAddressing -attachmentType provider
 -bindingLocation [[systemType trustService] [application application_name] [attachmentId *]]]')
```

- Using Jython list:

```
AdminTask.getBinding(['-policyType', 'WSAddressing', '-bindingLocation', '""'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.getBinding('-interactive')
```

setBinding

The setBinding command updates the binding configuration for a specified policy. Use this command to add a server-specific binding, update an attachment to use a custom binding, edit binding attributes, or to remove a binding configuration.

When administrative security is enabled, verify that you use the correct administrative role, as the following table describes:

Administrative role	Authorization
Administrator	The Administrator role must have cell-wide access to configure bindings. If you have access to a specific resource only, you can configure custom bindings for the resource for which you have access. The Administrator role is the only role that can modify binding configurations.
Configurator	The Configurator role must have cell-wide access to assign and unassign bindings. If you have access to a specific resource only, you can assign and unassign bindings for the resource for which you have access.
Deployer	The Deployer role with cell-wide or resource specific access can assign or unassign bindings for application resources only.
Operator	The Operator role cannot configure bindings.
Monitor	The Monitor role cannot configure bindings.

Note: In WebSphere Application Server Version 7.0, the security model is enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

To support a mixed-cell environment, WebSphere Application Server supports Version 7.0 and Version 6.1 bindings. General cell-level bindings are specific to Version 7.0 Application-specific bindings remain at the version that the application requires. When the user creates an application-specific binding, the application server determines the required binding version to use for application.

Target object

None.

Required parameters

-bindingLocation

Specifies the location of the binding. (Properties, required)

Specify the bindingLocation parameter as a properties object following these guidelines:

- For cell-wide general binding or WebSphere Application Server Version 6.1 cell default bindings, specify a null or empty properties.
- For WebSphere Application Server Version 6.1 server-specific default binding, specify the node and server names in the properties. The property names are `node` and `server`. Server-specific default bindings are deprecated.
- For WebSphere Application Server Version 7.0 server default bindings, specify a null or empty properties. Use the bindingName parameter to identify the binding location.
- For attachment-specific, specify the application name and attachment ID in the properties. The property names are `application` and `attachmentId`.
- For WSNClient bindings, specify the bus name, service name, and attachment ID in the properties. The property names are `bus`, `WSNService`, and `attachmentId`. If you specify an asterisk character (*) as the attachment ID, then the command returns the list of binding names that corresponds to the attachment type of interest.
- For system/trust bindings, set the `systemType` property as `trustService`.

-policyType
Specifies the policy of interest. (String, required)

Optional parameters

-attachmentType
Specifies the type of policy set attachment. Use this parameter to distinguish between types of attachment custom bindings. (String, optional)

Note: The `application` and `system/trust` values for the -attachmentType parameter are deprecated. Specify the `provider` value in place of the `application` value. For system policy set attachments, specify the `provider` value for the attachmentType parameter and the `"[systemType trustService]"` value for the -attachmentProperties parameter. For WSNClient attachments, specify the `client` value for the attachmentType parameter and the `bus` and `WSNService` properties with the -attachmentProperties parameter.

-attributes
Specifies the attribute values to update. This parameter can include all binding attributes for the policy or a subset to update. If the **attributes** parameter is not specified, the command only updates the binding location used by the specified attachment. (Properties, optional)

-bindingName
Specifies the name for the binding. Specify this parameter to assign a new name to an attachment binding or cell-level binding. A name is generated if it is not specified. (String, optional)

-domainName
Specifies the domain name for the binding. This parameter is required when using the command to create and scope a binding to a specific domain other than the administrative security domain. The default value is `global`. (String, optional)

-replace
Specifies whether to replace all of the existing binding attributes with the attributes specified in the command. Use this parameter to remove optional parts of the configuration for policies with complex data. The default value is false. (Boolean, optional)

-remove
Specifies whether to remove a server-specific default binding or to remove a custom binding from an attachment. You cannot remove cell-level default binding. The default value is `false`. (Boolean, optional)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.setBinding('[-policyType WSAddressing -bindingLocation [[application myApplication] [attachmentId 123]] -attributes "[preventWLM false]"
 -attachmentType provider]')
```

- Using Jython list:

```
AdminTask.setBinding(['-policyType', 'WSAddressing', '-bindingLocation', '[[application myApplication] [attachmentId 123]]', '-attributes', '[preventWLM
 false]', '-attachmentType', 'provider'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.setBinding('-interactive')
```

getDefaultBindings

The getDefaultBindings command displays the provider and client default bindings if the bindings are set. If the command does not return output, then the system default binding is the current default.

If administrative security is enabled, each administrative role can query for default bindings.

Target object

None.

Optional parameters

-bindingLocation
Specifies the location of the binding. Specify the bindingLocation parameter as a properties object with values for the `node` and `server` properties. (Properties, optional)

-domainName
Specifies the domain name for the binding of interest. This parameter is required if the domain of interest is not in the global security domain and you specified the bindingLocation parameter. The bindingLocation and domainName parameters are mutually exclusive. The default value is `global`. (String, optional)

Return value

The command returns a properties object that contains the names of the provider and client default bindings, if the bindings are set.

Batch mode example usage

- Using Jython string:

```
AdminTask.getDefaultBinding('[-bindingLocation [[node myNode] [server myServer]]]')
```

- Using Jython list:

```
AdminTask.getDefaultBinding(['-bindingLocation', '[[node myNode] [server myServer]]'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.getDefaultBinding('-interactive')
```

getRequiredBindingVersion

The getRequiredBindingVersion command displays the version number of the binding for a specific application.

Target object

None.

Optional parameters

-assetProps
Specifies the name of the application of interest. (Properties, optional)

Return value

The command returns the binding version number as a number, such as `7.0.0.0` or `6.1.0.0`.

Batch mode example usage

- Using Jython string:

```
AdminTask.getRequiredBindingVersion('[-assetProps [[application myApplication]]]')
```

- Using Jython list:

```
AdminTask.getRequiredBindingVersion(['-assetProps', '[[application myApplication]]'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.getRequiredBindingVersion('-interactive')
```

setDefaultBindings

The setDefaultBindings command to set a binding as the default binding.

If administrative security is enabled, you must use the Administrator role with cell-wide access to configure bindings. If you use the Administrator role and do not have cell-wide access, you can only configure bindings on resources for which you have access.

Target object

None.

Required parameters

-defaultBinding
Specifies the names of the default bindings for the provider, client, or both. (Properties, required)

Optional parameters

-bindingLocation
Specifies the location of the binding. Specify the bindingLocation parameter as a properties object with values for the `node` and `server` properties. (Properties, optional)

-domainName
Specifies the domain name for the binding of interest. This parameter is required if the domain of interest is not in the global security domain and you specified the bindingLocation parameter. The bindingLocation and domainName parameters are mutually exclusive. The default value is `global`. (String, optional)

Return value

The command returns a value of `true` if the command successfully sets the default binding.

Batch mode example usage

- Using Jython string:

```
AdminTask.setDefaultBinding('[-bindingName myDefaultBinding -bindingLocation [[node myNode] [server myServer]]]')
```

- Using Jython list:

```
AdminTask.setDefaultBinding(['-bindingName', 'myDefaultBinding', '-bindingLocation', '[[node
 myNode] [server myServer]]'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.setDefaultBinding('-interactive')
```

exportBinding

The exportBinding command export a general, cell-level binding to an archive file. You can copy this file to a client environment or import the archive to a server environment.

If administrative security is enabled, you must use the Administrator role with cell-wide access to export bindings.

Target object

None.

Required parameters

-bindingName
Specifies the name of the binding to assign as the default binding. If you do not specify this parameter, the system specifies the system default as the default binding. (String, required)

-pathName
Specifies the file path for the archive file to create. (String, required)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.exportBinding('[-bindingName myDefaultBinding -pathName
 C:/IBM/WebSphere/AppServer/PolicySets/Bindings/]')
```

- Using Jython list:

```
AdminTask.exportBinding(['-bindingName', 'myDefaultBinding', '-pathName',
 'C:/IBM/WebSphere/AppServer/PolicySets/Bindings/'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.exportBinding('-interactive')
```

importBinding

The importBinding command imports a general, cell-level binding from a compressed archive file to a server environment.

If administrative security is enabled, you must use the Administrator role with cell-wide access to import bindings.

Target object

None.

Required parameters

-pathName
Specifies the file path for the archive file to import. (String, required)

Optional parameters

-bindingName
Specifies the name of the binding to assign as the imported binding. If you do not specify this parameter, the system specifies the binding name in the archive file. (String, optional)

-domainName
Specifies a new name of the domain of the binding to import. If you do not specify this parameter, the command uses the domain specified in the archive file. (String, optional)

-verifyBindingType
Verifies that the type of binding to import matches a specific binding type. Specify `provider` to verify that the binding to import is a provider binding, or specify `client` to verify that it is a client binding. (String, optional)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.importBinding('[-bindingName myDefaultBinding -pathName
 C:/IBM/WebSphere/AppServer/PolicySets/Bindings/myBinding.ear]')
```

- Using Jython list:

```
AdminTask.importBinding(['-bindingName', 'myDefaultBinding', '-pathName',
 'C:/IBM/WebSphere/AppServer/PolicySets/Bindings/myBinding.ear'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.importBinding('-interactive')
```

copyBinding

The copyBinding command creates a new general, cell-level binding from an existing binding.

If administrative security is enabled, you must use the Administrator role with cell-wide access to copy bindings.

Target object

None.

Required parameters

-sourceBinding
Specifies the name of the existing binding that the system uses to create the new binding. (String, required)

-newBinding
Specifies the name of the binding to create. (String, required)

Optional parameters

-newDescription
Specifies the description text for the new binding. (String, optional)

-domainName
Specifies the domain name for the binding. This parameter is only required if you scope the binding to a domain other than the domain of the source binding. (String, optional)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.copyBinding('[-sourceBinding mySourceBinding -newBinding mySourceCopyBinding]')
```

- Using Jython list:

```
AdminTask.copyBinding(['-sourceBinding', 'mySourceBinding', '-newBinding',
 'mySourceCopyBinding'])
```

Interactive mode example usage

- Using Jython list:

```
AdminTask.copyBinding('-interactive')
```

upgradeBindings

The upgradeBindings command upgrades application bindings for a specific asset to the latest version.

If administrative security is enabled, you must use the Administrator role with cell-wide access to import bindings.

Target object

None.

Required parameters

-assetProps
Specifies the name of the asset of interest. Specify the name of the application as the value for the **application** property. (Properties, required)

Optional parameters

None

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.upgradeBindings('[-assetProps [[application myApplication]]]')
```

- Using Jython list:

```
AdminTask.upgradeBindings(['-assetProps', '[[application myApplication]]'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.upgradeBindings('-interactive')
```

WS-Policy commands for the AdminTask object

You can use the Jython or Jacl scripting languages to manage WS-Policy settings for Web service resources with the wsadmin tool. You can view or manage how a service provider shares its policies, and how a service client obtains and applies the policies of a service provider.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

These commands are valid only when they are used with WebSphere Application Server Version 7 and later application servers. Do not use them with earlier versions.

The commands to manage WS-Policy settings for Web service resources are part of the PolicySetManagement command group for the AdminTask object.

For a list of the available policy set management administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('PolicySetManagement')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using these commands, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

The commands that are listed as subtopics are available to manage WS-Policy settings in the PolicySetManagement group of the AdminTask object.

The following commands are available to manage WS-Policy settings in the PolicySetManagement group of the AdminTask object:

- getProviderPolicySharingInfo command
- setProviderPolicySharingInfo command
- getClientDynamicPolicyControl command
- setClientDynamicPolicyControl command

getProviderPolicySharingInfo command

Use the getProviderPolicySharingInfo command to find out whether an application or service that is a Web service provider can share its policy configuration, and list the properties that apply to sharing that configuration.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available policy set management administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('PolicySetManagement')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the getProviderPolicySharingInfo command to find out how a Web services application, or a service in a Web services application, shares its policy configuration with clients, service registries, or services that support the WS-Policy specification. The policy configuration is shared in WS-PolicyAttachments format.

The command returns properties that show whether the policy configuration of the resource can be shared with clients through a WS-MetadataExchange request or through Web Service Description Language (WSDL) that is obtained by a ?WSDL HTTP Get request.

Target object

None.

Required parameters

-applicationName
The name of the application for which you want to find out how it shares its policy configuration. The application must be a service provider. (String)

Optional parameters

-resource
The name of the resource for which you want to find out how it shares its policy configuration. If you specify this parameter, only the properties for that resource are returned. To retrieve information for the application, specify `WebService:/`. Alternatively, you can specify a service, endpoint or operation. However, policy sets are attached only at the application or service level, so the properties returned for an endpoint or operation are the settings that are inherited from the service. (String)

Return value

Returns a list of properties that include the resource name and that show whether the policy configuration of the resource can be shared. The following properties can be returned:

wsMexPolicySetName
The name of the policy set that specifies message-level security when the resource shares its policy configuration through a WS-MetadataExchange request. This property is returned if the value of the sharePolicyMethods property is wsMex and a policy set to provide message-level security was specified.

wsMexPolicySetBinding
The name of the binding that is applied when the resource shares its policy configuration through a WS-MetadataExchange request. This property is returned if the value of the sharePolicyMethods property is wsMex and a binding to provide message-level security was specified.

resource
The resource that you specified.

directSetting
How the properties apply to the resource. Valid values for this property are:

true
The properties apply directly to the resource.

false
The properties are inherited from the parent application or service.

sharePolicyMethods
How the policy configuration of the resource can be shared. Valid values for this property are:

httpGet
The resource shares its policy configuration through an HTTP Get request.

wsMex
The resource shares its policy configuration through a WS-MetadataExchange request.

Example

The following command displays the policy sharing configuration properties for the EchoService service in the WSSampleServices application. The provider is configured to share its policy through an HTTP Get request, and a WS-MetadataExchange request with message-level security. Message-level security for the WS-MetadataExchange request is provided using the SystemWSSecurityDefault policy set and the "Provider sample" general binding.

```
AdminTask.getProviderPolicySharingInfo(['-applicationName', 'WSSampleServices',
'-resource', 'WebService:/SampleServicesSei.war:{http://example_path/}EchoService'])
.
.
[ [wsMexPolicySetName SystemWSSecurityDefault] [wsMexPolicySetBinding [Provider sample]]
[resource WebService:/SampleServicesSei.war:{http://example_path/}EchoService/]
[directSetting true] [sharePolicyMethods [httpGet wsMex]] ]
```

setProviderPolicySharingInfo command

Use the setProviderPolicySharingInfo command to set how an application or service that is a Web service provider can share its policy configuration with other clients, service registries, or services that support the WS-Policy specification. You can set or remove this information about how a provider policy is shared.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic "Configure Qshell to run WebSphere Application Server scripts".

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available policy set management administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('PolicySetManagement')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the setProviderPolicySharingInfo command to set how an application, or a service in an application, shares its policy configuration with clients, service registries, or services that support the WS-Policy specification. The policy configuration is shared in WS-PolicyAttachments format.

The policy configuration of the resource can be shared with clients through a WS-MetadataExchange request, through Web Service Description Language (WSDL) exported by a `?WSDL` HTTP Get request, or through both methods.

Target object

None.

Required parameters

-applicationName
The name of the application for which you want to set how the provider policy is shared. (String)

-resource
The name of the resource for which you want to set how the provider policy is shared. For all resources in an application, specify `WebService:/`. For a service in an application, specify `WebService:/`*`module`*`:{`*`namespace`*`}`*`service_name`*. Endpoints or operations inherit the settings of the parent application or service. (String)

Optional parameters

-sharePolicyMethods
Specifies how the policy configuration of the resource can be shared. (String array)

Enter either or both of the following values:

`httpGet`
The resource can share its policy configuration through WSDL that is obtained by a `?WSDL` HTTP Get request.

`wsMex` The resource can share its policy configuration through a WS-MetadataExchange request.

-wsMexProperties
Specifies that message-level security is required for WS-MetadataExchange requests and specifies the settings that provide the message-level security. (Properties)

Enter the following values, following each value with the setting that you require for that value:

`wsMexPolicySetName`
The name of the system policy set that specifies message-level security when the resource shares its policy configuration through a WS-MetadataExchange request. Specify a system policy set that contains only WS-Security policies, only WS-Addressing policies, or both. The default policy set is SystemWSSecurityDefault.

`wsMexPolicySetBinding`
The name of the general binding for the policy set attachment when the resource shares its policy configuration through a WS-MetadataExchange request. Specify a general binding that is scoped to the global domain, or scoped to the security domain of this service. If you do not specify this property, the default binding is used.

This parameter is valid only when you specify `wsMex` for the **sharePolicyMethods** parameter.

-remove
Specifies whether the information about how the provider policy is shared is removed from the resource. (Boolean)

This parameter takes the following values:

true The information about how the provider policy is shared is removed from the resource.

false This value is the default. The information about how the provider policy is shared is not removed from the resource.

Examples

The following example removes the information about how the provider policy is shared from the WSSampleServices application:

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WSSampleServices
-resource WebService:/ -remove true]')
```

The following example enables policy sharing, using WSDL exported by a `?WSDL` HTTP Get request, for the EchoService service in the WSSampleServices application:

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WSSampleServices
-resource WebService:/WSSampleServicesSei.war:{http://example_path/}EchoService
-sharePolicyMethods [httpGet ]]')
```

The following example enables policy sharing, using a WS-MetadataExchange request with message-level security, for the WSSampleServices application. Message level security is provided using the MexPS policy set and the “Client sample” general binding.

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WSSampleServices
-resource WebService:/ -sharePolicyMethods [wsMex ]
-wsMexProperties [ [wsMexPolicySetName [SystemWSSecurityDefault]]
[wsMexPolicySetBinding [Provider sample]] ]]')
```

getClientDynamicPolicyControl command

Use the getClientDynamicPolicyControl command to find out whether an application that is a Web service client obtains the policy configuration of a Web service provider, and to list the properties that apply to obtaining that configuration.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available policy set management administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('PolicySetManagement')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the getClientDynamicPolicyControl command to find out how an application, or a service in an application, obtains the policy configuration of a service provider. The client can obtain the policy configuration of the provider through a Web Services Metadata Exchange (WS-MetadataExchange) request or through an HTTP Get request.

Target object

None.

Required parameters

-applicationName
The name of the application for which you want to find out how it obtains the policy configuration of a service provider. The application must be a service client. (String)

Optional parameters

-resource
The name of the resource for which you want to find out how it obtains the policy configuration of a service provider. If you specify this parameter, only the properties for that resource are returned. To retrieve information for the application, specify `WebService:/`. Alternatively, you can specify a service, endpoint, or operation. However, policy sets are attached only at the application or service level, so the properties returned for an endpoint or operation are the settings that are inherited from the service. (String)

Return value

Returns a list of properties that include the resource name and that show how it obtains the policy configuration of a service provider. The following properties can be returned:

`httpGetTargetURI`
The target URL of the HTTP Get request. This property is returned if the value of the acquireProviderPolicyMethod property is httpGet.

`wsMexPolicySetName`
The name of the policy set that specifies message-level security when the resource shares its policy configuration through a WS-MetadataExchange request. This property is returned if the value of the acquireProviderPolicyMethod property is wsMex and a policy set to provide message-level security was specified.

`wsMexPolicySetBinding`
The name of the binding that is used when the resource shares its policy configuration through a WS-MetadataExchange request. This property is returned if the value of the acquireProviderPolicyMethod property is wsMex and a binding to provide message-level security was specified.

`acquireProviderPolicyMethod`
How the policy configuration of the provider can be obtained. Valid values for this property are:

`wsMex`
The resource can obtain the policy configuration of a service provider through a WS-MetadataExchange request.

`httpGet`
The resource can obtain the policy configuration of a service provider through an HTTP Get request.

resource
The resource that you specified.

directSetting
How the properties apply to the resource. Valid values for this property are:

true
The properties apply directly to the resource.

false
The properties are inherited from the parent application or service.

Examples

The following example displays the properties that control how the EchoService service of the WSPolicyClient application obtains the policy configuration of a service provider. The client is configured to retrieve the provider policy through a WS-MetadataExchange request with message-level security, using the SystemWSSecurityDefault policy set and the “Client sample” general binding.

```
AdminTask.getClientDynamicPolicyControl(['-applicationName', 'WSPolicyClient',
'-resource', 'WebService:/WSPClient.war:{http://example_path/}EchoService'])
.
.
[ [wsMexPolicySetName SystemWSSecurityDefault] [wsMexPolicySetBinding [Client sample]]
[acquireProviderPolicyMethod [wsMex]]
[resource WebService:/WSPClient.war:{http://example_path/}EchoService/]
[directSetting true] ]
```

The following example displays the properties that control how the EchoService service of the WSPolicyClient application obtains the policy configuration of a service provider when the client is configured to retrieve the provider policy through an HTTP Get request.

```
AdminTask.getClientDynamicPolicyControl(['-applicationName', 'WSPolicyClient',
'-resource', 'WebService:/WSPClient.war:{http://example_path/}EchoService'])
.
.
[ [httpGetTargetURI http://example_path/EchoService?wsdl]
[acquireProviderPolicyMethod [httpGet]]
[resource WebService:/WSPClient.war:{http://example_path/}EchoService/]
[directSetting true] ]
```

setClientDynamicPolicyControl command

Use the setClientDynamicPolicyControl command to set how an application that is a Web services client obtains the policy configuration of a Web services provider. You can set, refresh, or remove this information about how a provider policy is obtained.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available policy set management administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('PolicySetManagement')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the setClientDynamicPolicyControl command to set how a client obtains the policy configuration of a service provider.

The client can obtain the policy configuration of the provider through a Web Services Metadata Exchange (WS-MetadataExchange) request or through an HTTP Get request. The service provider must publish its policy in WS-PolicyAttachment format in its Web Service Description Language (WSDL) and the client must be able to support those provider policies.

At run time, the client uses the information to establish a policy configuration that is acceptable to both the client and the service provider.

Target object

An application or service that is a Web services client.

Required parameters

-applicationName
The name of the application for which you want to obtain the policy configuration of the provider. (String)

-resource
The name of the resource for which you want to obtain the policy configuration of the provider. For all resources in an application, specify `WebService:/`. For a service in an application, specify `WebService:/`*`module`*`:{`*`namespace`*`}`*`service_name`*. Endpoints or operations inherit the settings of the parent application or service. (String)

Optional parameters

-acquireProviderPolicyMethod
Specifies how the policy configuration of the provider can be obtained. (String)

Enter one of the following values:

`httpGet`
Obtain the policy configuration of the provider using an HTTP Get request. By default, the HTTP Get request is targeted at the URL for each service endpoint followed by `?WSDL`. If you specify this value for a service, you can use the **httpGetProperties** parameter to change the target of the request.

`wsMex` Obtain the policy configuration of the provider using a WS-MetadataExchange request.

-wsMexProperties
Specifies that message-level security is required for WS-MetadataExchange requests and specifies the settings that provide the message-level security. (Properties)

Enter the following values, following each value with the setting that you require for that value:

`wsMexPolicySetName`
The name of the system policy set that specifies message-level security when the policy configuration of the provider is obtained through a WS-MetadataExchange request. Specify a system policy set that contains only WS-Security policies, only WS-Addressing policies, or both. The default policy set is SystemWSSecurityDefault.

wsMexPolicySetBinding
The name of the general binding for the policy set attachment when the resource shares its policy configuration through a WS-MetadataExchange request. Specify a general binding that is scoped to the global domain, or scoped to the security domain of this service. If you do not specify this property, the default binding is used.

This parameter is valid only when you specify `wsMex` for the **acquireProviderPolicyMethod** parameter.

-httpGetProperties
Specifies the target for an HTTP Get request for a service if you do not want to use the default. (Properties)

Enter the following value, followed by the setting that you require for that value:

httpGetTargetURI
The URL for the service endpoint followed by `?WSDL`.

This parameter is valid only when you specify `httpGet` for the **acquireProviderPolicyMethod** parameter and the resource is a service. Do not use this parameter if the resource is an application.

-remove
Specifies whether to remove the information about how the client obtains the policy configuration of the provider. (Boolean)

This parameter takes the following values:

true Information about how the client obtains the policy configuration of the provider is removed.

false This value is the default. Information about how the client obtains the policy configuration of the provider is not removed.

Examples

The following example removes the information about how the client obtains the policy configuration of the provider from the EchoService service of the WSPolicyClient client application.

```
AdminTask.setClientDynamicPolicyControl('[-applicationName WSPolicyClient
-resource WebService:/WSPolicyClient.war:{http://example_path/}EchoService
-remove true]')
```

The following example configures the EchoService service of the WSPolicyClient client application to obtain the policy configuration of the provider using an HTTP Get request.

```
AdminTask.setClientDynamicPolicyControl('[-applicationName WSPolicyClient
-resource WebService:/WSPolicyClient.war:{http://example_path/}EchoService
-acquireProviderPolicyMethod [httpGet ]
-httpGetProperties [httpGetTargetURI http://example_path?WSDL]]')
```

The following example configures the EchoService service of the WSPolicyClient client application to obtain the the policy configuration of the provider through a WS-MetadataExchange request with message-level security, using the SystemWSSecurityDefault policy set and the “Client sample” general binding.

```
AdminTask.setClientDynamicPolicyControl('[-applicationName WSPolicyClient
-resource WebService:/WSPolicyClient.war:{http://example_path/}EchoService
-acquireProviderPolicyMethod [wsMex ]
-wsMexProperties [ [wsMexPolicySetName [SystemWSSecurityDefault]]
[wsMexPolicySetBinding [Client sample]] ]]')
```

Configuring secure sessions between clients and services using the wsadmin tool

Use the wsadmin tool, which supports the Jython and Jacl scripting language, to edit trust service configurations. Use the STSManagement command group for the AdminTask object to specify details related to secure sessions between clients and target services.

About this task

The trust service uses the secure messaging mechanisms of the Web Services Trust (WS-Trust) specification to define additional extensions for issuing, exchanging, and validating security tokens. Use the STSManagement command group for the AdminTask object to configure the trust service using the wsadmin tool. Complete any of the following tasks using the STSManagement commands:

- Manage token provider configurations.

  Use the wsadmin tool to manage token providers. Customize token providers by defining properties such as token type schema URI, handler factory, cache cushion time, class name, and token timeout. You can also allow or restrict the use of post-dated tokens, distributed cache, and renewable tokens after timeout.
- Query existing token provider configurations.

  Use the wsadmin tool to query the existing trust service token provider configuration.
- Manage endpoint token assignments.

  Use the wsadmin tool to assign, unassign, and modify endpoint token assignments.
- Refresh your configuration changes.

  Use the wsadmin tool to force the trust service to reload the token provider configuration during run time. Complete this action to use new configuration changes before you restart the application server.

What to do next

Use the information center topics for managing token providers using the STSManagement group of commands and the AdminTask object.

Querying the trust service using scripting

Use the wsadmin tool, which supports the Jython and Jacl scripting languages, to query the trust service for existing configuration settings. Use the commands in this topic to view current trust service configurations before adding, removing, or editing token provider and endpoint configurations.

About this task

Query your current token provider configurations or endpoint configurations using the STSManagement group of commands. Use the following Jython syntax command examples when writing automation scripts to retrieve configuration attributes and set the output to a variable. Pass the newly set variable to administrative commands in the STSManagement group to automate the editing of token provider and endpoint configurations.

- Use the following command examples to query the trust service for token provider configurations.
  - Determine the local name of the default token provider and set it to the myDefaultTokenType variable.

    The following command sets the *myDefaultTokenType* variable to the local name string for the default token provider:

    ```
    myDefaultTokenType = AdminTask.querySTSDefaultTokenType()
    print myDefaultTokenType
    ```
  - List the local names of each configured token provider.

    The following command sets the *myTokenTypes* variable to an array containing the local names of the configured token providers:

    ```
    myTokenTypes = AdminTask.listSTSConfiguredTokenTypes()
    print myTokenTypes
    ```
  - Display the non-custom properties for the default token provider.

    The following command returns a java.util.Properties instance that contains the values for each non-custom property for the default token provider stored in the *myDefaultTokenType* variable.

    ```
    AdminTask.querySTSTokenTypeConfigurationDefaultProperties(myDefaultTokenType)
    ```

To use this command to query a specific token provider, use the following Jython syntax:

```
AdminTask.querySTSTokenTypeConfigurationDefaultProperties('"Security Context Token"')
```

– Display a properties object containing all custom properties for a token provider configuration.

The following command returns a java.util.Properties instance that contains the values for each of the custom properties for the token provider stored in the *myDefaultTokenType* variable.

```
AdminTask.querySTSTokenTypeConfigurationCustomProperties(myDefaultTokenType)
```

To use this command to query a specific token provider, use the following Jython syntax:

```
AdminTask.querySTSTokenTypeConfigurationCustomProperties('"Security Context Token"')
```

- Use the following command examples to query endpoint target configurations and security constraints for endpoint targets.
  – Display each uniform resource identifier (URI) for each assigned endpoint.

The following command sets the *allMyURIs* variable to an array containing the URIs for each assigned endpoint:

```
allMyURIs = AdminTask.listSTSAssignedEndpoints()
print allMyURIs
```

– Display the token provider that is assigned to a specific endpoint URI.

The following command sets the *myTokenType* variable to the name of the token provider that is assigned to the `http://myserver.mysom.com:9080/Example` endpoint URI:

```
myTokenType = AdminTask.querySTSEndpointTokenType('http://myserver.mysom.com:9080/Example')
print myTokenType
```

What to do next

Use the wsadmin tool to manage and edit token provider and endpoint configurations.

“STSManagement command group for the AdminTask object” on page 622
You can use the Jython or Jacl scripting languages to configure security with the wsadmin tool. The commands and parameters in the STSManagement group can be used to manage and query trust service token provider configurations and endpoint configurations.

Related information

Trust service targets collection
Use this page to view a list of targets, which are application server service endpoints. You can manage tokens by specifying which token is to be issued when access to a specific endpoint is requested.

Trust service token providers collection
Use this page to view information about or manage token providers for the trust service.

Managing existing token providers with scripting

You can use the wsadmin tool, which supports the Jython and Jacl scripting languages, to manage the trust service. Use this topic to modify token provider configuration data, and to add custom properties.

Before you begin

You must have an existing token provider configured in the trust service.

About this task

Use the commands in the STSManagement group of the AdminTask object to modify existing configuration data. This topics includes examples for modifying existing non-custom configuration data.

Modify existing configuration data.
Use the **updateSTSTokenTypeConfiguration** command to update existing properties for a specific token provider configuration. If you specify the -distributedCache parameter, the security context token provider generates a warning and modifies the WS-Security distributed cache configuration. Do not specify a value for the -distributedCache parameter for custom tokens.

1. Determine the token provider configuration to edit.

   Enter the following command to view the list of names of the configured token providers:

   ```
   AdminTask.listSTSConfiguredTokenTypes()
   ```

2. Review the current configuration data for the token provider configuration to edit.

   Enter the following command to view a Properties object containing all non-custom configuration data for the Security Context Token token provider:

```
AdminTask.querySTSTokenTypeConfigurationDefaultProperties('Security Context Token')
```

3. Update the token provider configuration with new configuration data.

   Determine which parameters to update in your configuration, using the following table as a reference:

Parameter	Data type
LocalName Specifies the unique token provider name as the target object of the command.	String, required
-HandlerFactory Specifies the configuration class name, including package information.	String, required
-URI Specifies the unique token type schema URI.	String, required
-lifetimeMinutes Specifies the amount of time, in minutes, that the token is valid.	Integer, optional Default: 120 (minutes) Minimum: 10 (minutes)
-renewalWindowMinutes Specifies the amount of time after the token expires during which the token can be renewed.	Integer, optional Default: 120 (minutes) Minimum: 10 (minutes)
-postdatable Set to `true` to specify that tokens of the token provider are valid at a later time. Tokens can be created with or without a future start time.	Boolean, optional Default: false
-distributedCache (deprecated) Set to `true` to enable distributed cache. If you specify the -distributedCache parameter, the security context token provider generates a warning and modifies the WS-Security distributed cache configuration. Do not specify a value for the -distributedCache parameter for custom tokens.	Boolean, optional Default: false
-renewableAfterExpiration Set to `true` to specify that tokens of the token provider are renewable after expiration.	Boolean, optional Default: false

Parameter	Data type
-tokenCacheFactory (deprecated) Specifies the fully qualified class name for the token provider. The secure conversation token handler class does not recognize this parameter.	String, optional Default: `com.ibm.ws.wssecurity.platform.websphere.trust .server.sts.ext.cache.STSTokenCacheFactoryImpl`

Use the **updateSTSTokenTypeConfiguration** command to update the configuration data for the `Security Context Token` token provider. The following example changes the time that the token is valid from 60 minutes to 100 minutes, disables token renewal after expiration, and enables distributed caching:

```
AdminTask.updateSTSTokenTypeConfiguration('Security Context Token', '[-lifetimeMinutes 100 -renewableAfterExpiration false -distributedCache true]')
```

The command returns a message indicating the success or failure of the operation.

4. Save your configuration changes.

   Use the following command to save your changes:

   ```
   AdminConfig.save()
   ```

5. Reload the modified configuration changes.

   Use the following command to force the trust service to reload your modified configuration without restarting the application server:

   ```
   AdminTask.refreshSTS()
   ```

You can use the Jython or Jacl scripting languages to configure security with the wsadmin tool. The commands and parameters in the STSManagement group can be used to manage and query trust service token provider configurations and endpoint configurations.

Adding and removing token provider custom properties using scripting

Use the wsadmin tool, which supports the Jython and Jacl scripting languages, to administer the trust service. Use this topic to set internal system configuration properties for your token provider configuration by adding or removing custom properties.

Before you begin

You must have an existing token provider configured for the trust service.

About this task

Use custom properties to set internal system configuration properties and specify these properties using the customProperties parameter. Custom properties are arbitrary name and value pairs of data, where the name can be a property key or a class implementation, and where the value might be a string or Boolean value. Use this topic and the commands in the STSManagement group for the AdminTask object to add or remove custom properties from your configuration with the Jython scripting language.

- Add new custom properties to a specific token provider configuration.

  Use the **updateSTSTokenTypeConfiguration** command to add or update custom properties to your token provider configuration. Do not use the **updateSTSTokenTypeConfiguration** command to remove custom properties. If you specify the -distributedCache parameter, the security context token provider generates a warning and modifies the WS-Security distributed cache configuration. Do not specify a value for the -distributedCache parameter for custom tokens.

  1. Launch the wsadmin scripting tool using the Jython scripting language.
  2. Determine the token provider configuration to edit.

     Enter the following command to view a list of the names for each configured token provider:

     ```
     AdminTask.listSTSConfiguredTokenTypes()
     ```
  3. Review the configured custom properties for the token provider of interest.

     Enter the following command to view a properties object containing custom configuration data for the *Security Context Token* token provider:

     ```
     AdminTask.querySTSTokenTypeConfigurationCustomProperties('Security Context Token')
     ```
  4. Add custom properties to the token provider configuration.

     Use the **updateSTSTokenTypeConfiguration** command to add the configuration data for the `Security Context Token` token provider. Use the following example to add the `com.ibm.ws.security.webChallengeIfCustomSubjectNotFound` custom property with a value of `false` and the `com.ibm.ws.security.defaultLoginConfig` custom property with a value of `system.DEFAULT` to the configuration:

     ```
     AdminTask.updateSTSTokenTypeConfiguration('Security Context Token', '[-customProperties
     [[com.ibm.ws.security.webChallengeIfCustomSubjectNotFound false]
     [com.ibm.ws.security.defaultLoginConfig system.DEFAULT]] ]')
     ```

     The command returns a message indicating the success or failure of the operation.
  5. Save your configuration changes.

     Use the following command to save your changes:

     ```
     AdminConfig.save()
     ```
  6. Reload the modified configuration changes.

     Use the following command to force the trust service to reload your modified configuration without restarting the application server.

     ```
     AdminTask.refreshSTS()
     ```
- Edit custom properties for a specific token provider configuration.
  1. View configured custom properties for the token provider of interest.

     Enter the following command to view a properties object containing custom configuration data for the *Security Context Token* token provider:

     ```
     AdminTask.querySTSTokenTypeConfigurationCustomProperties('Security Context Token')
     ```
  2. Modify the configuration data for the token provider of interest.

     Use the **updateSTSTokenTypeConfiguration** command to modify the existing configuration data for the *Security Context Token* token provider. This example specifies that the *Security Context*

Token token provider configuration includes the com.ibm.ws.security.webChallengeIfCustomSubjectNotFound custom property with a value of false and the com.ibm.ws.security.defaultLoginConfig custom property with a value of system.DEFAULT. Use the following command to change the value of the com.ibm.ws.security.defaultLoginConfig custom property from system.DEFAULT to system.CUSTOM, and does not change any other configured custom properties:

```
AdminTask.updateSTSTokenTypeConfiguration('Security Context Token', '[-customProperties
[[com.ibm.ws.security.defaultLoginConfig system.CUSTOM]]]')
```

The command returns a message indicating the success or failure of the operation.

3. Save your configuration changes.

   Use the following command to save your changes:

   ```
   AdminConfig.save()
   ```

4. Reload the modified configuration changes.

   Use the following command to force the trust service to reload your modified configuration without restarting the application server:

   ```
   AdminTask.refreshSTS()
   ```

- Remove custom properties from token provider configurations.

1. View configured custom properties for the token provider of interest.

   Enter the following command to view a properties object containing custom configuration data for the *Security Context Token* token provider:

   ```
   AdminTask.querySTSTokenTypeConfigurationCustomProperties('Security Context Token')
   ```

2. Delete the custom property from the token provider configuration.

   Use the **deleteSTSTokenTypeConfigurationCustomProperties** command to delete custom properties from your configuration. Specify the names of the custom properties to remove using the propertyNames parameter. If the specified name does not exist in the configuration, no configuration changes are made. The following command removes the com.ibm.ws.security.webChallengeIfCustomSubjectNotFound and com.ibm.ws.security.defaultLoginConfig custom properties from the *Security Context Token* token provider configuration:

   ```
   AdminTask.deleteSTSTokenTypeConfigurationCustomProperties('Security Context Token',
   '[-propertyNames com.ibm.ws.security.webChallengeIfCustomSubjectNotFound
   com.ibm.ws.security.defaultLoginConfig]')
   ```

   The command returns a message indicating the success or failure of the operation.

3. Save your configuration changes.

   Use the following command to save your changes:

   ```
   AdminConfig.save()
   ```

4. Reload the modified configuration changes.

   Use the following command to force the trust service to reload your modified configuration without restarting the service:

   ```
   AdminTask.refreshSTS()
   ```

You can use the Jython or Jacl scripting languages to configure security with the wsadmin tool. The commands and parameters in the STSManagement group can be used to manage and query trust service token provider configurations and endpoint configurations.

Associating token providers with endpoint services (targets) using scripting

You can use the wsadmin tool, which supports the Jython and Jacl scripting languages, to manage the association of endpoints and tokens. Use this topic to query, assign, and unassign the association of a token provider with an endpoint Uniform Resource Identifier (URI).

Before you begin

Before you can assign and manage endpoint configurations, at least one token provider configuration and a Web service must exist.

About this task

Use the STSManagement group of commands to specify a custom service endpoint Uniform Resource Identifier (URI) and to assign and unassign the association of trust service token providers with endpoint configurations. Complete the steps in this topic to query the trust service for the existing endpoint configuration, associate the default token with an endpoint, and unassociate a token from an endpoint. You can perform these steps in any order.

- Associate a token with a specific endpoint.
  1. View a list of all endpoint URIs that are currently associated with a token provider.

     Before invoking changes on your endpoint configurations, use the following listSTSAssignedEndpoints command to examine your current settings:

     ```
     AdminTask.listSTSAssignedEndpoints()
     ```

If the endpoint of interest is currently associated with a token, do not use the assignSTSEndpointTokenType command. To update the token that is associated with the endpoint, use the updateSTSEndpointTokenType command in the next step.

2. Associate a token with an endpoint.

   Use the assignSTSEndpointTokenType command to specify the token to issue for access to a specific endpoint. You do not need to specify the name of the token provider to assign if the token provider is set as the default configuration. For example, the following command assigns the `Security Context Token` default token to the `http://www.mycompany.com:8080/Ecommerce/Catalog` endpoint URI:

   ```
   AdminTask.assignSTSEndpointTokenType('http://www.mycompany.com:8080/Ecommerce/Catalog')
   ```

   If `Security Context Token` is not the default token provider, use the following command:

   ```
   AdminTask.assignSTSEndpointTokenType('http://www.mycompany.com:8080/Ecommerce/Catalog',
   '-LocalName Security Context Token')
   ```

   The command returns a message indicating the success of the operation.

3. Save your configuration changes.

   Use the following command to save your changes:

   ```
   AdminConfig.save()
   ```

4. Reload the modified configuration changes.

   Use the following command to force the trust service to reload your modified configuration without restarting the application server:

   ```
   AdminTask.refreshSTS()
   ```

- Disassociate a token from an endpoint.

1. Examine the current endpoint configuration.

   Use the listSTSAssignedEndpoints to view a list of each endpoint URI with assigned token providers, as the following example describes:

   ```
   AdminTask.listSTSAssignedEndpoints()
   ```

   The following sample output is displayed:

   ```
   'http://www.mycompany.com:8080/Ecommerce/Catalog'
   ```

2. Choose the endpoint to edit.

   Use the querySTSEndpointTokenType to return the token provider associated with the endpoint of interest. Enter the following command to view the token provider associated with the `http://www.mycompany.com:8080/Ecommerce/Catalog` endpoint URI:

   ```
   AdminTask.querySTSEndpointTokenType('http://www.mycompany.com:8080/Ecommerce/Catalog')
   ```

   The following sample output is displayed:

   ```
   'Security Context Token'
   ```

3. Disassociate the token type from the endpoint.

   Use the **unassignSTSEndpointTokenType** command to disassociate the token provider and endpoint configuration. The following command removes the `Security Context Token` token provider that is associated with the `http://www.mycompany.com:8080/Ecommerce/Catalog` endpoint URI:

   ```
   AdminTask.unassignSTSEndpointTokenType('http://www.mycompany.com:8080/Ecommerce/Catalog',
   '-LocalName Security Context Token')
   ```

   The command returns a message indicating the success of the operation.

4. Save your configuration changes.

   Use the following command to save your changes:

   ```
   AdminConfig.save()
   ```

5. Reload the modified configuration changes.

Use the following command to force the trust service to reload your modified configuration without restarting the service:

```
AdminTask.refreshSTS()
```

STSManagement command group for the AdminTask object

You can use the Jython or Jacl scripting languages to configure security with the wsadmin tool. The commands and parameters in the STSManagement group can be used to manage and query trust service token provider configurations and endpoint configurations.

The STSManagement command group contains commands that allow you to configure existing token providers, assign token providers to endpoints, and modify general trust service configuration data. The commands in this group that perform configuration changes require that you execute the save command to commit the changes. No configuration changes are made if an exception is created when executing a command.

Use the following commands to modify and query token provider configurations:

- "createSTSTokenTypeConfiguration "
- "deleteSTSTokenTypeConfigurationCustomProperties " on page 623
- "listSTSConfiguredTokenTypes " on page 624
- "querySTSDefaultTokenType " on page 624
- "querySTSTokenTypeConfigurationDefaultProperties " on page 625
- "querySTSTokenTypeConfigurationCustomProperties " on page 626
- "setSTSDefaultTokenType " on page 626
- "updateSTSTokenTypeConfiguration " on page 627
- "removeSTSTokenTypeConfiguration" on page 628

Use the following commands to assign, unassign, and query endpoint configurations:

- "assignSTSEndpointTokenType " on page 628
- "listSTSAssignedEndpoints " on page 629
- "listSTSEndpointTokenTypes " on page 630
- "unassignSTSEndpointTokenType " on page 630
- "updateSTSEndpointTokenType " on page 631

Use the following commands to add, edit, delete, and list properties of the trust service:

- "addSTSProperty" on page 631
- "deleteSTSProperty" on page 632
- "editSTSProperty" on page 632
- "listSTSProperties" on page 633

Use the following command to force the trust service to reload your modified configuration without restarting the application server:

- "refreshSTS " on page 634

createSTSTokenTypeConfiguration

The createSTSTokenTypeConfiguration command is used to create a token provider configuration.

Target object

Specify the LocalName object, which is used as an identifier for the various configurations. The value for the LocalName object must be unique.

Required parameters

-URI
The URI of the token provider. This value must be unique across all configuration token type URIs. (String, required)

-HandlerFactory
Provide the fully qualified class name of an implementation of the `org.eclipse.higgins.sts.IObjectFactory` interface. (String, required)

Optional parameters

-lifetimeMinutes
Specifies the maximum lifetime to assign to an issued token provider. The default value is 120 minutes. (Integer, optional)

-distributedCache
Specifies whether to enable or disable distributed cache. Specify `true` to enable distributed cache capability. The default value is `false`. If you specify this option, the security context token provider generates a warning and modifies the WS-Security distributed cache configuration. Do not specify a value for this parameter for custom tokens. (Boolean, optional)

-tokenCacheFactory
Specifies the fully qualified class name for the token provider. The secure conversation token handler class does not recognize this parameter. (String, optional).

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.createSTSTokenTypeConfiguration('myTokenType', '[-HandlerFactory
 test.ibm.samples.myTokenType -URI http://ibm.com/tokens/schema/myTokenType]')
```

- Using Jython list:

```
AdminTask.createSTSTokenTypeConfiguration('myTokenType', ['-HandlerFactory',
 'test.ibm.samples.myTokenType', '-URI', 'http://ibm.com/tokens/schema/myTokenType'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.createSTSTokenTypeConfiguration('-interactive')
```

deleteSTSTokenTypeConfigurationCustomProperties

The deleteSTSTokenTypeConfigurationCustomProperties command is used to remove custom properties from a token provider configuration.

Target object

Specify the LocalName object of the token provider of interest.

Required parameters

None

Optional parameters

-propertyNames
Specify the names of the custom properties to delete from the configuration. If any of the specified properties do not exist in your configuration, you will receive an error message. (String[], optional)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.deleteSTSTokenTypeConfigurationCustomProperties('myTokenType', '[-propertyNames
 com.ibm.ws.security.webChallengeIfCustomSubjectNotFound com.ibm.ws.security.defaultLoginConfig]')
```

- Using Jython list:

```
AdminTask.deleteSTSTokenTypeConfigurationCustomProperties('myTokenType', ['-propertyNames',
 'com.ibm.ws.security.webChallengeIfCustomSubjectNotFound com.ibm.ws.security.defaultLoginConfig'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.deleteSTSTokenTypeConfigurationCustomProperties('-interactive')
```

listSTSConfiguredTokenTypes

The listSTSConfiguredTokenTypes command is used to list the local names of all configured token providers.

Target object

None

Required parameters

None

Optional parameters

None

Return value

The command returns the local names of all configured token providers.

Batch mode example usage

- Using Jython:

```
AdminTask.listSTSConfiguredTokenTypes()
```

Interactive mode example usage

- Using Jython:

```
AdminTasklistSTSConfiguredTokenTypes('-interactive')
```

querySTSDefaultTokenType

The querySTSDefaultTokenType command is used to determine the local name of the default token provider.

Target object

None

Required parameters

None

Optional parameters

None

Return value

The command returns the local name of the default token provider.

Batch mode example usage

- Using Jython:

```
AdminTask.querySTSDefaultTokenType()
```

Interactive mode example usage

- Using Jython:

```
AdminTask.querySTSDefaultTokenType('-interactive')
```

querySTSTokenTypeConfigurationDefaultProperties

The querySTSTokenTypeConfigurationDefaultProperties command is used to query the trust service for the non-custom properties of a token provider.

Target object

Specify the LocalName object of the token provider to query.

Required parameters

None

Optional parameters

None

Return value

The command returns a `java.util.Properties` instance which contains the values of the non-custom properties. Non-custom properties include URI, HandlerFactory, lifetimeMinutes, distributedCache, postdatable, renewableAfterExpiration, and renewalWindowMinutes.

Batch mode example usage

- Using Jython:

```
AdminTask.querySTSTokenTypeConfigurationDefaultProperties('TokenType2')
```

Interactive mode example usage

- Using Jython:

```
AdminTask.querySTSTokenTypeConfigurationDefaultProperties('-interactive')
```

querySTSTokenTypeConfigurationCustomProperties

The querySTSTokenTypeConfigurationCustomProperties command is used to query the trust service.

Target object

Specify the LocalName object of the token provider of interest.

Required parameters

None

Optional parameters

None

Return value

The command returns a `java.util.Properties` instance containing the values of the custom properties.

Batch mode example usage

- Using Jython:

```
AdminTask.querySTSTokenTypeConfigurationCustomProperties('TokenType2')
```

Interactive mode example usage

- Using Jython:

```
AdminTask.querySTSTokenTypeConfigurationCustomProperties('-interactive')
```

setSTSDefaultTokenType

The setSTSDefaultTokenType command is used to set the default token provider for the trust service.

Target object

Specify the LocalName object of the token provider as default.

Required parameters

None

Optional parameters

None

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython:

```
AdminTask.setSTSDefaultTokenType('TokenType2')
```

Interactive mode example usage

- Using Jython:

```
AdminTask.setSTSDefaultTokenType('-interactive')
```

updateSTSTokenTypeConfiguration

The updateSTSTokenTypeConfiguration command is used to update configuration data for a token provider. All parameters are optional. The parameters that are specified are updated in the configuration if the property already exists. If the property does not exist, it is added to the configuration. To remove custom properties, use the **deleteSTSTokenTypeConfigurationCustomProperties** command.

Target object

Specify the LocalName object of the token provider of interest.

Required parameters

None

Optional parameters

-URI
The URI of the token provider. This value must be unique across all configuration token type URIs. (String, optional)

-HandlerFactory
Provide the fully qualified class name of an implementation of the `org.eclipse.higgins.sts.utilities.IObjectFactory` interface. (String, optional)

-lifetimeMinutes
The maximum lifetime to assign to an issued token provider. The default value is 120 minutes. (Integer, optional)

-distributedCache
Specifies whether to enable or disable distributed cache. Specify `true` to enable distributed cache capability. The default value is `false`. If you specify this option, the security context token provider generates a warning and modifies the WS-Security distributed cache configuration. Do not specify a value for this parameter for custom tokens. (Boolean, optional)

-postdatable
Set the value of this parameter to `true` to allow tokens of this token provider to be valid starting at a future time. The default value is false. (Boolean, optional)

-renewableAfterExpiration
Set the value of this parameter to `true` to allow tokens of this token provider to be renewable after expiration. The default value is false. (Boolean, optional)

-renewableWindowMinutes
Provide the number of minutes after a token has expired that a token of this token provider can be renewed. If this specified time has elapsed after expiration, then the token will no longer be available for renewal. The default value is 120 minutes. (Integer, optional)

-tokenCacheFactory
Specifies the fully qualified class name for the token provider. The secure conversation token handler class does not recognize this parameter. (String, optional).

-customProperties
Provide any additional custom properties. (java.util.Properties, optional).

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.updateSTSTokenTypeConfiguration('myTokenType', '[-lifetimeMinutes 100
 -renewableAfterExpiration false -distributedCache true]')
```

- Using Jython list:

```
AdminTask.updateSTSTokenTypeConfiguration('myTokenType', ['-lifetimeMinutes', '100', '
 -renewableAfterExpiration', 'false', '-distributedCache', 'true'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.updateSTSTokenTypeConfiguration('-interactive')
```

removeSTSTokenTypeConfiguration

The removeSTSTokenTypeConfiguration command removes a token provider configuration.

Target object

Specify the LocalName object of the token provider of interest.

Required parameters

None

Optional parameters

None

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython:

```
AdminTask.removeSTSTokenTypeConfiguration('myTokenType')
```

Interactive mode example usage

- Using Jython:

```
AdminTask.removeSTSTokenTypeConfiguration ('-interactive')
```

assignSTSEndpointTokenType

The assignSTSEndpointTokenType command is used to give a token provider when a specific endpoint is accessed.

Target object

Specify the endpointURI object of the endpoint to assign a given token provider. If the specified endpoint has already been assigned a token provider, you will receive an error message.

Required parameters

None

Optional parameters

-LocalName
Specify the local name of the token provider to assign to the specified endpoint. If the token provider configuration does not exist, you will receive an error message. If this parameter is not specified, the default token provider is used. (String, optional)

-issuer
Specify the URI of the issuer that specifies the token provider to issue. This value can be null. (String, optional)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.assignSTSEndpointTokenType('www.ibm.tokenservice/Ecommerce/', '[-LocalName
 tokenType1]')
```

- Using Jython list:

```
AdminTask.assignSTSEndpointTokenType('www.ibm.tokenservice/Ecommerce/', ['-LocalName',
 'tokenType1'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.assignSTSEndpointTokenType ('-interactive')
```

listSTSAssignedEndpoints

The listSTSAssignedEndpoints command is used to list the URIs of assigned endpoints.

Target object

None

Required parameters

None

Optional parameters

None

Return value

The command returns the URIs of all assigned endpoints.

Batch mode example usage

- Using Jython:

```
AdminTask.listSTSAssignedEndpoints()
```

Interactive mode example usage

- Using Jython:

```
AdminTask.listSTSAssignedEndpoints ('-interactive')
```

listSTSEndpointTokenTypes

The listSTSEndpointTokenTypes command is used to query the Trust Service for the token provider assigned to a specific endpoint.

Target object

Specify the endpointURI object of the endpoint to query. An exception is raised if the specified endpoint has not been assigned a token provider.

Required parameters

None

Optional parameters

None

Return value

The command returns the local name of the token provider assigned to the specified endpoint.

Batch mode example usage

- Using Jython:

```
AdminTask.listSTSEndpointTokenTypes()
```

Interactive mode example usage

- Using Jython:

```
AdminTask.listSTSEndpointTokenTypes ('-interactive')
```

unassignSTSEndpointTokenType

The unassignSTSEndpointTokenType command is used to unassign an endpoint from its token provider.

Target object

Specify the endpointURI object of the endpoint to unassign from a given token provider. An exception is raised if the specified endpoint has not been assigned a token provider.

Required parameters

-LocalName
Specify the local name of the token provider configuration to unassign from the specified endpoint. (String, required)

Optional parameters

-issuer
Specify the URI of the issuer in the token provider assignment to remove. (String, optional)

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.unassignSTSEndpointTokenType('www.ibm.tokenservice/Ecommerce/','[-LocalName
 tokenType2]')
```

- Using Jython list:

```
AdminTask.unassignSTSEndpointTokenType('www.ibm.tokenservice/Ecommerce/', ['-LocalName',
 'tokenType2'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.unassignSTSEndpointTokenType ('-interactive')
```

updateSTSEndpointTokenType

The updateSTSEndpointTokenType command is used to assign a different token provider to a specified endpoint.

Target object

Specify the endpointURI object of the endpoint to update. An exception is raised if the specified endpoint has not been assigned a token provider.

Required parameters

-LocalName
Specify the local name of the token provider to assign to the specified endpoint. If the token provider configuration does not exist, you will receive an error message. If this parameter is not specified, the default token provider is used. (String, optional)

Optional parameters

None

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.updateSTSEndpointTokenType('www.ibm.tokenservice/Ecommerce/', '[-LocalName
 tokenType2]')
```

- Using Jython list:

```
AdminTask.updateSTSEndpointTokenType('www.ibm.tokenservice/Ecommerce/', ['-LocalName',
 'tokenType2'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.updateSTSEndpointTokenType('-interactive')
```

addSTSProperty

The addSTSProperty command adds a new property for the trust service.

Target object

Specify a unique name for the new property (string, required).

Required parameters

-propertyValue
Specifies the value of the property to add. (String, required)

Optional parameters

None

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.addSTSProperty('pluginSCTVersion', '[-propertyValue 2.0]')
```

- Using Jython list:

```
AdminTask.addSTSProperty('pluginSCTVersion', ['-propertyValue', '2.0'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.addSTSProperty('-interactive')
```

deleteSTSProperty

The deleteSTSProperty command deletes an existing property from the trust service.

Target object

Specify the name of the property to delete.

Required parameters

None

Optional parameters

None

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython:

```
AdminTask.deleteSTSProperty('pluginSCTVersion')
```

Interactive mode example usage

- Using Jython:

```
AdminTask.deleteSTSProperty('-interactive')
```

editSTSProperty

The editSTSProperty command modifies an existing property for the trust service.

Target object

Specify the name of the property to edit. (String, required)

Required parameters

-propertyValue
Specifies the new value for the property of interest. (String, required)

Optional parameters

None

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython string:

```
AdminTask.editSTSProperty('pluginSCTVersion', '[-propertyValue 2.1]')
```

- Using Jython list:

```
AdminTask.editSTSProperty('pluginSCTVersion', ['-propertyValue', '2.1'])
```

Interactive mode example usage

- Using Jython:

```
AdminTask.editSTSProperty('-interactive')
```

listSTSProperties

The listSTSProperties command lists all existing properties and their corresponding values for the trust service.

Target object

None

Required parameters

None

Optional parameters

None

Return value

The command returns a java.util.Properties instance that contains the names and values of the properties.

Batch mode example usage

- Using Jython:

```
AdminTask.listSTSProperties()
```

Interactive mode example usage

- Using Jython:

```
AdminTask.listSTSProperties('-interactive')
```

refreshSTS

The refreshSTS command refreshes your trust service configuration changes without restarting the application server.

Target object

None

Required parameters

None

Optional parameters

None

Return value

The command returns a success or failure message.

Batch mode example usage

- Using Jython:

```
AdminTask.refreshSTS()
```

Adding assured delivery to Web services through WS-ReliableMessaging

WS-ReliableMessaging is an interoperability standard for the reliable transmission of messages between two endpoints. With WS-ReliableMessaging, you can make your SOAP over HTTP-based Web services reliable without having to write custom code. You can get different qualities of service with WS-ReliableMessaging. These range from protecting against loss of messages across a network, through to protecting against a server becoming unavailable.

About this task

With WebSphere Application Server, you can use WS-ReliableMessaging with Java API for XML-Based Web Services (JAX-WS) 2.1 Web services applications that use a SOAP over HTTP binding. To configure a Web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent.

Note:

Support for the WS-ReliableMessaging standard was first introduced as part of the IBM WebSphere Application Server Version 6.1 Feature Pack for Web Services. At that time, the Reliable Asynchronous Messaging Profile (RAMP) Version 1.0 specification used WS-ReliableMessaging to ensure the reliable delivery of messages, and the Feature Pack for Web Services in WebSphere Application Server Version 6.1 included default policy sets that support this specification. You can migrate WebSphere Application Server Version 6.1 WS-ReliableMessaging configurations that use RAMP-based policy sets to the current version of the product.

Following on from the RAMP Version 1.0 specification, the Web Services Interoperability organization (WS-I) Reliable Secure Profile working group has developed Version 1.0 of an interoperability profile dealing with secure, reliable messaging capabilities for Web services. This

profile is similar to RAMP Version 1.0, except that it is updated to use WS-ReliableMessaging Version 1.1 with the OASIS WS-SecureConversation Version 1.3 specification. The WS-I RSP default policy sets provided in this version of WebSphere Application Server are an implementation of the Reliable Secure Profile Version 1.0 specification.

If you create JAX-WS based WS-Notification services, you can apply WS-ReliableMessaging policies to them to make your WS-Notification services reliable. For more information, see Configuring WS-Notification for reliable notification.

The WS-Policy implementation in WebSphere Application Server supports Web Services Reliable Messaging Policy Assertion Version 1.0 and Web Services Reliable Messaging Policy Assertion Version 1.1. For more information, see “WS-Policy” on page 645.

To enable WS-ReliableMessaging for an application, you take the following broad actions:

1. Develop a Java API for XML-Based Web Services (JAX-WS) Web service provider or requester application.
2. Install the application into WebSphere Application Server.
3. Attach a reliable messaging policy set (either a default policy set or one that you have created) to an aspect of your application (that is, application level or Web service level). Policy sets define the reliability level (quality of service) and other configuration options that you want to apply to your reliable messaging application.
4. Define the bindings for each attachment to a policy set that specifies a managed quality of service. That is, choose the service integration bus and messaging engine to use to maintain the state for the managed persistent and managed non-persistent qualities of service.

At any stage - that is, before or after you have built your reliable Web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

For more information about using WS-ReliableMessaging, see the following topics:

- Learn about WS-ReliableMessaging.
- Configure endpoints to only support clients that use WS-ReliableMessaging.
- Build a reliable Web service application.
- Configure a WS-ReliableMessaging policy set.
- Attach and bind a WS-ReliableMessaging policy set to a Web service application.
- Detect and fix problems with WS-ReliableMessaging.

Learning about WS-ReliableMessaging

WS-ReliableMessaging is an interoperability standard for the reliable transmission of messages between two endpoints. Use these topics to learn more about WS-ReliableMessaging.

About this task

Without WS-ReliableMessaging, your Web services that require assured delivery of SOAP messages can either use a vendor-specific binding such as SOAP over JMS (which provides limited interoperability) or they can use SOAP over HTTP and rely upon you to write the associated durable message stores, custom retry logic at the sender, and duplicate detection at the receiver. With WS-ReliableMessaging, you can make your SOAP over HTTP-based Web services reliable without having to write custom code.

To enable WS-ReliableMessaging for an application, you take the following broad actions:

1. Develop a Java API for XML-Based Web Services (JAX-WS) Web service provider or requester application.

2. Install the application into WebSphere Application Server.
3. Attach a reliable messaging policy set (either a default policy set or one that you have created) to an aspect of your application (that is, application level or Web service level). Policy sets define the reliability level (quality of service) and other configuration options that you want to apply to your reliable messaging application.
4. Define the bindings for each attachment to a policy set that specifies a managed quality of service. That is, choose the service integration bus and messaging engine to use to maintain the state for the managed persistent and managed non-persistent qualities of service.

At any stage - that is, before or after you have built your reliable Web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

To learn about the WS-ReliableMessaging implementation in WebSphere Application Server, see the following topics:

WS-ReliableMessaging - How it works

WebSphere Application Server uses WS-ReliableMessaging as part of the transport layer for SOAP over HTTP messages. The message exchange patterns supported at the API layer are one-way "fire and forget", or two-way request and reply.

The reliability is provided by reliable messaging middleware that sits between the Web service requester and the Web service provider. This middleware layer is shown beneath the dotted line in the following diagram, and includes the reliable messaging source and the reliable messaging destination.

Note: When using WS-ReliableMessaging with a two-way programming API, if the requesting application fails and is restarted it will not receive its reply message. In this model, WS-ReliableMessaging is being used to protect from network failures only. Moreover:

- Client-side retransmissions only start after the client starts sending new messages to the service (this is true for both one-way and two-way operations).
- Two-way operations that resume cannot drive the response message right back to the client application; the message only gets back as far as the inbound sequence on the client.

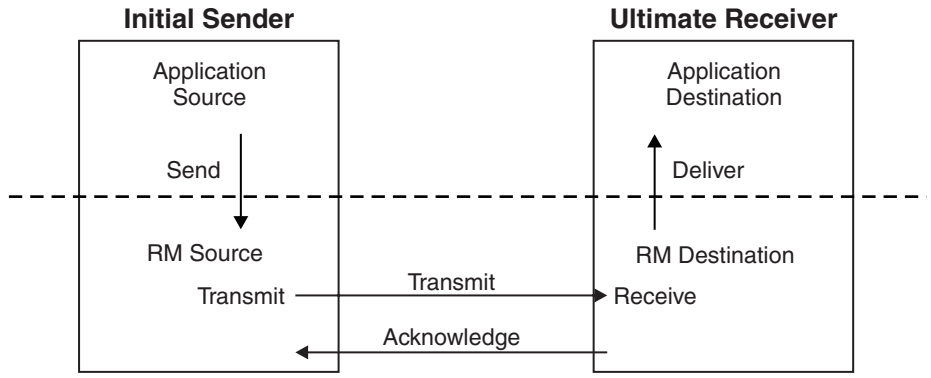

Figure 6. The interactions used to exchange Web services messages reliably.

In the previous diagram, the application source invokes a Web service. The sequence of interactions is as follows:

- The invocation is passed to the reliable messaging source.
- The reliable messaging source stores the message and then returns control to the application.
- The reliable messaging source sends the message to the reliable messaging destination.
- After the reliable messaging destination receives the message, it stores it locally and sends an acknowledgement message back to the reliable messaging source.
- The reliable messaging source can now delete its copy of the message.
- The reliable messaging destination can deliver the message to the application destination at any time after it receives it from the reliable messaging source.

To configure a Web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent.

The managed qualities of service, managed persistent and managed non-persistent, are supported by the service integration bus. For each attachment between an application and a policy set, you can select the bus and messaging engine to use for the reliable messaging protocol state.

Benefits of using WS-ReliableMessaging

With WS-ReliableMessaging, along with the other components of the Reliable Secure Profile, you can support your business-to-business Web services scenarios without having to write your own custom retry logic, duplicate detection code and persistence code.

WS-ReliableMessaging composes with other Web services standards as described in "WS-ReliableMessaging: supported specifications and standards" on page 643.

Qualities of service for WS-ReliableMessaging

You can get different qualities of service with WS-ReliableMessaging, depending on the level of durability and transaction support provided by the store used to manage the reliable messaging state. These qualities of service range from protecting against loss of messages across a network, through to protecting against server failure.

WebSphere Application Server provides the following three qualities of service for WS-ReliableMessaging using a SOAP over HTTP binding. All three qualities of service are supported when applications are deployed to the application server. Thin client and client container applications use the first option only.

Unmanaged non-persistent

You can configure Web service applications to use WS-ReliableMessaging with a default

in-memory store. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages.

Managed non-persistent
This in-memory quality of service option uses a messaging engine to manage the sequence state, and messages are written to disk if memory is low. This quality of service allows for the re-sending of messages that are lost in the network, and can also recover from server failure. However, state is discarded after a messaging engine restart so in this case you will lose messages.

Managed persistent
This quality of service for asynchronous Web service invocations is recoverable. This option also uses a messaging engine and message store to manage the sequence state. Messages are persisted at the Web service requester server and at the Web service provider server, and are recoverable if the server becomes unavailable. Messages that have not been successfully transmitted when a server becomes unavailable can continue to be transmitted after the server restarts.

Note:

- The quality of service you get when using WS-ReliableMessaging is a direct result of the durability of the store managing the messages.
- When you use in-order delivery and either of the managed qualities of service, if the service causes an error then the message is re-dispatched to the service.
- You must ensure that when interacting with other vendors implementations of WS-ReliableMessaging, the other implementations provide the quality of service you require.

How the different qualities of service are implemented

When the Web service application invokes the Web service, the SOAP message is added into the WS-ReliableMessaging store. For the Managed qualities of service, the sending application's transaction is used to put the message into the message store. After the transaction commits, the message is eligible for delivery. The other quality of service option is not transactional, so it considers the message eligible for delivery immediately.

The WS-ReliableMessaging protocol is used to reliably deliver the message to the target server where it is stored and acknowledged.

The message is read from the store and dispatched to the receiving application. For the Managed Persistent quality of service, a transaction is used to read the message and then dispatch the application.

For more information about using WS-ReliableMessaging transactions, see "Providing transactional recoverable messaging through WS-ReliableMessaging" on page 653.

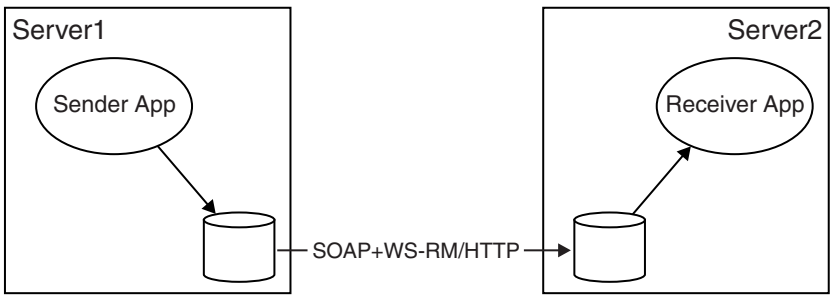

Figure 7. Using stores to exchange Web services messages reliably.

The managed qualities of service, managed persistent and managed non-persistent, are supported by the service integration bus. For each attachment between an application and a policy set, you can select the bus and messaging engine to use for the reliable messaging protocol state.

Use patterns for WS-ReliableMessaging

Links to descriptions of the use patterns that motivate WS-ReliableMessaging. Each use pattern description includes an overview of the business problem, of the technical solution without WS-ReliableMessaging, of the shortcomings of this solution, and of how you can use WS-ReliableMessaging to overcome these shortcomings.

Historically, most business-to-business integration has been implemented on a point-to-point basis. However this situation is rapidly changing and hub-and-spoke is becoming more important, particularly for supply chain use patterns. The point-to-point use pattern is also important because, although your eventual goal might be to implement a business-to-business hub, you might nonetheless begin with point-to-point prototypes and proofs of concept.

For a description of each use pattern, see the following topics:

- "Assured delivery for B2B Web services: point-to-point use pattern."
- "Assured delivery for B2B Web services: hub-and-spoke use pattern" on page 640.
- "Interoperation with other WS-ReliableMessaging providers: use pattern" on page 641.

Assured delivery for B2B Web services: point-to-point use pattern:

In this use pattern, a manufacturer sells its products through a network of affiliated dealerships. This manufacturer has initiated a pilot project to improve the IT integration between its own retail organization and half a dozen of the largest, most important dealerships.

The existing technical solution

Historically, business-to-business ″e-commerce″ has been conducted using Electronic Data Interchange (EDI). EDI is a set of standards for the content and formatting of business-to-business messages. For examples of these standards and messages, see the United Nations Directories for Electronic Data Interchange.

If the identities of communication partners are known and unchanging, the use of industry standard message definitions is not strictly necessary. Although other XML-based standards are available for conducting business-to-business e-commerce (such as the OASIS Electronic Business using eXtensible Markup Language (ebXML) specifications) the manufacturer has decided to investigate the use of Web services technologies, and is using WSDL documents from a variety of sources to define the service interfaces.

The interactions between the manufacturer and its dealers for the initial pilot project fall into two categories:

- Requests for information. The interaction is two-way, in that a request message is sent requesting some information, and a reply message is sent in the reverse direction containing the requested information. An example of a request for information going from a dealer to the manufacturer might be ″getOrderStatus″.
- Requests for update. These interactions are one-way, in that the sender of a request for update is not dependent on receiving a response in order to proceed with other work. An example of a request for update going from dealer to manufacturer might be ″placeOrder″. An example of a request for update going from manufacturer to dealer might be ″deliveryConfirmed″.

The manufacturer uses WebSphere Application Server to implement requests for information using SOAP over HTTP and SOAP over JMS. Dealers are free to choose their own implementation technology; they do not have to use WebSphere Application Server.

The manufacturer implements requests for update in two different ways:

- Using SOAP over HTTP. In this case the service is represented as a request and reply interaction that is considered to have succeeded when the requestor successfully receives a reply. The services have to be implemented to detect and successfully respond to duplicate requests (this is termed an idempotent operation), and the client has to be implemented to retry if the communication is interrupted after the request has been sent but before the reply has been received.
- To avoid the above limitations, the manufacturer also uses SOAP over JMS support from WebSphere Application Server and WebSphere MQ. In this case the request is represented as a one-way service, and the messages are delivered reliably. The manufacturer uses WebSphere MQ as the JMS Provider, and makes this solution available to all dealers that also use WebSphere Application Server and WebSphere MQ. It is not required that the dealer and manufacturer be connected in order for the message to be sent.

The messages are transmitted over Virtual Private Networks, to ensure the integrity and confidentiality of messages transmitted between the two businesses, and as a part of establishing the identity of the sender.

The business problem

Although both the manufacturer and its dealers are happy with the implementation of the request for information services, there are a number of issues in the request for update case:

- Using SOAP over HTTP:
  - For the manufacturer, implementing idempotent services is complicated and therefore more expensive in developer time. It increases the likelihood of coding errors, reducing the robustness of the solution and introducing the possibility of expensive dropped or duplicated orders.
  - For dealers, implementing the retry logic is similarly complex, expensive, and error-prone.
  - For both the manufacturer and the dealers, the requirement for both to be available in order to invoke the service is an issue. In particular, many dealers do not maintain seven-day availability of their systems, whereas for the manufacturer weekends are the ideal time to deliver price updates to the dealers. Similarly, being unable to place orders when connectivity between dealer and manufacturer is unavailable is a real business issue.
- Using SOAP over JMS:
  - Although requiring the use of WebSphere Application Server and WebSphere MQ is acceptable to the current collection of dealers, as the project expands there might be other partners who are unwilling or unable to use a common software platform.

The solution using WS-ReliableMessaging

With WS-ReliableMessaging support in WebSphere Application Server, the manufacturer can replace their existing custom-retry solutions for reliable one-way messaging with standard SOAP over HTTP one-way messaging. The removal of the retry logic from the application simplifies the application code, enabling simpler and quicker application development.

With WS-ReliableMessaging, the dealer and manufacturer do not need to be connected in order for the message to be sent.

The WS-ReliableMessaging standard adds reliability to SOAP over HTTP messaging, reducing the need to use SOAP over JMS.

Because WS-ReliableMessaging with SOAP over HTTP is an interoperable standard, the network of dealers need not use a common software platform.

Assured delivery for B2B Web services: hub-and-spoke use pattern:

In this use pattern, a manufacturer is looking for more than the ability to conduct transactions electronically with a fixed set of partners; the manufacturer needs a service that provides visibility to their inventory levels, so that the suppliers can manage their own product and inventory levels accordingly.

The manufacturer has many suppliers - around 2000 major suppliers and 250,000 other suppliers - and the set of supplier companies with which they do business is constantly changing.

The existing technical solution

The manufacturer currently has a custom-built supplier purchasing system. The system provides a trading hub into which suppliers can integrate, and a supplier portal that enables suppliers to continue with their (largely manual) existing processes. The interactions fall into three tiers:

- Tier one: XML message exchanges.
- Tier two: FTP and similar tools.
- Tier three: Fax.

Tiers one and two are conducted over a combination of leased lines and Virtual Private Networks (VPNs).

The business problem

The custom purchasing system has had disappointing take-up by the suppliers, and as a result the manufacturer continues to face large costs associated with the manual processes that it still uses with the vast majority of its suppliers. A major barrier to adoption of the new system by suppliers has been the cost of integrating supplier systems with the trading hub.

The current solution also has costs for the manufacturers. In particular, the use of leased lines is expensive, and the use of VPNs is difficult to manage when scaled to a large number of suppliers.

The solution using WS-ReliableMessaging

Describing the services using WSDL, and using Web services standards to implement them, reduces the costs incurred by the manufacturer and suppliers:

- The prevalence of support for Web services amongst diverse software vendors makes it easier and cheaper for suppliers to exploit this technology.
- The familiarity of the developer community with Web services technologies (and WSDL in particular), and the rich tool support, means that the use of WSDL-described messages make the message schemas easier to use in the context of Web services.
- WS-ReliableMessaging is used to ensure that messages are reliably delivered, and duplicate messages are eliminated.
- Web services security technologies enable secure interactions across the Internet, without requiring leased lines and VPNs.

Interoperation with other WS-ReliableMessaging providers: use pattern:

Web services enable interoperability between heterogeneous platforms. This requirement arises whenever an organization finds itself with applications on one platform (for example WebSphere Application Server) that need to work with applications on another platform, whether as a result of merger and acquisition activity, of a deliberate multi-vendor strategy, or as a result of independent software purchasing decisions taken in different parts of the business.

The existing technical solution

A variety of technical solutions exist for application-to-application integration between WebSphere Application Server and other environments. Most of these involve the use of additional third-party or IBM software to facilitate the integration.

More recently, the introduction of Web services support has made interoperability possible without the use of additional components.

The business problem

Basic Web services support (using SOAP over HTTP) does enable interoperability, but has the following limitations:

- Reliability: The absence of a WS-ReliableMessaging implementation means that the application logic needs to be extended to handle lost or duplicated messages.
- Flexibility: The absence of asynchronous support for Web services means that support is limited to synchronous interactions.

Note: Although both request and reply and one-way messaging are supported in earlier version of WebSphere Application Server, they were implemented in a synchronous fashion. This meant that when a Web services client invoked a service it did not receive control back from the middleware until after the service application endpoint had been invoked.

The absence of asynchronous, reliable support for Web services often leads you to use one of the other approaches, involving additional components. The additional components often use proprietary communication channels or APIs.

The solution using WS-ReliableMessaging

The addition of WS-ReliableMessaging support to WebSphere Application Server and to other environments enables you to develop reliable asynchronous Web services on both platforms. These services should interoperate without additional IBM or third-party components or proprietary bindings.

WS-ReliableMessaging sequences

The WS-ReliableMessaging protocol relies on a “sequence” to manage the transmission of messages from reliable messaging source to reliable messaging destination. Each application message is given an identifier that identifies both the sequence and the message number (the position) within the sequence. Protocol flows are used to create sequences, to acknowledge messages and to terminate sequences.

You can think of a sequence as being a structured conversation between the reliable source and the reliable destination, through which each message in the sequence is passed reliably. A sequence also passes on the set of messages in the sequence in the order in which it receives them, so if it is important that messages are processed in a particular order - for example, if money must be credited to a bank account before a debit instruction is received to pay for a purchase - then those messages should be included in the same sequence.

The developer of a reliable Web services application does not need to be aware of sequences, but the system administrator needs to monitor and manage sequences, as described in “Detecting and fixing problems with WS-ReliableMessaging” on page 661.

WS-ReliableMessaging - terminology

Foreign destination
A foreign destination is a software agent, outside of the system, that receives messages reliably using WS-ReliableMessaging.

Foreign source
A Foreign source is a software agent, outside of the system, that sends messages reliably using WS-ReliableMessaging.

Implementation WSDL
A WSDL document that describes not only the interface to a service (that is the messages, port

types and bindings) but also the service implementation (that is, it has service and port elements). The service interface should preferably be defined by importing a separate *interface WSDL* document.

Interface WSDL
A WSDL document that describes only the interface to a service. That is, it defines messages, port types and bindings, but not services and ports.

Policy set instance document
A document containing configuration details for a selection of Web services standards. For more information, see Securing Web services applications with policy sets using the administrative console

Provider application
A provider application is an application that implements a service.

Reliable Web service provider
See also the general definition of a *provider application*. The Reliable Web service provider is a provider application that has been deployed into the system being modeled, and is configured to use WS-ReliableMessaging. This is the WebSphere Application Server-hosted equivalent of a *foreign destination*. It is outside of the boundary of the system and interacts with the system.

Reliable Web service requester
See also the general definition of a *requester application*. The Reliable Web service requester is a requester application that has been deployed into the system being modeled, and is configured to use WS-ReliableMessaging. This is the WebSphere Application Server-hosted equivalent of a *foreign source*. It is outside of the boundary of the system and interacts with the system.

Requester application
A requester application is an application that makes Web service requests.

Terminate (a sequence)
When the reliable messaging source has completed its use of a sequence, it sends a TerminateSequence message to the reliable messaging destination to indicate that the sequence is complete and that it will not be sending any further messages related to the sequence. The reliable messaging destination can then safely reclaim any resources associated with the sequence.

WS-ReliableMessaging: supported specifications and standards

WebSphere Application Server provides support for two levels of the WS-ReliableMessaging specification. This enables backward compatibility with vendors that provide WS-ReliableMessaging support at the February 2005 level, as well as meeting the requirements of the current OASIS specification. This implementation of WS-ReliableMessaging also composes with many other Web services standards.

Details of the supported WS-ReliableMessaging specifications are available at the following Web addresses:

- The WS-ReliableMessaging specification Version 1.0, February 2005.
- The OASIS WS-ReliableMessaging specification Version 1.1, February 2007.

Support for the WS-ReliableMessaging standard was first introduced as part of the IBM WebSphere Application Server Version 6.1 Feature Pack for Web Services. At that time, the Reliable Asynchronous Messaging Profile (RAMP) Version 1.0 specification used WS-ReliableMessaging to ensure the reliable delivery of messages, and the Feature Pack for Web Services in WebSphere Application Server Version 6.1 included default policy sets that support this specification. You can migrate WebSphere Application Server Version 6.1 WS-ReliableMessaging configurations that use RAMP-based policy sets to the current version of the product.

Following on from the RAMP Version 1.0 specification, the Web Services Interoperability organization (WS-I) Reliable Secure Profile working group has developed Version 1.0 of an interoperability profile

dealing with secure, reliable messaging capabilities for Web services. This profile is similar to RAMP Version 1.0, except that it is updated to use WS-ReliableMessaging Version 1.1 with the OASIS WS-SecureConversation Version 1.3 specification. The WS-I RSP default policy sets provided in this version of WebSphere Application Server are an implementation of the Reliable Secure Profile Version 1.0 specification.

The extent to which WS-ReliableMessaging composes with other Web services standards is described in the following sections:

- "WS-Addressing"
- "WS-AtomicTransactions"
- "WS-MakeConnection"
- "WS-Notification" on page 645
- "WS-Policy" on page 645
- "WS-SecureConversation" on page 645
- "WS-Security" on page 645

WS-Addressing

The WS-ReliableMessaging specification uses WS-Addressing, and the implementation fully supports the asynchronous request and reply model given in the WS-Addressing specification.

Note: WS-ReliableMessaging Version 1.1 messaging requires WS-Addressing to be mandatory. If you use a policy set that includes WS-ReliableMessaging and WS-Addressing policies, and the WS-Addressing policy is configured as optional, then WebSphere Application Server overrides the WS-Addressing setting and automatically enables WS-Addressing.

WS-AtomicTransactions

WS-ReliableMessaging transactions do not use the WS-AtomicTransactions protocol. The relationship between these two protocols is as follows:

- WS-AtomicTransactions and WS-ReliableMessaging are mutually exclusive when WS-ReliableMessaging is being used, with a managed store, to provide transactional recoverable messaging.
- If WS-ReliableMessaging is configured to use an in-memory store, then there are cases where a WS-AtomicTransaction can be flowed between the reliable messaging source and the reliable messaging destination for two-way invocations. In this situation, WS-ReliableMessaging only protects against network failures, not against server failure.

For more information about WS-AtomicTransactions, see Transaction support in WebSphere Application Server. For more information about using WS-ReliableMessaging transactions, see "Providing transactional recoverable messaging through WS-ReliableMessaging" on page 653.

WS-MakeConnection

WS-ReliableMessaging Version 1.1 uses the WS-MakeConnection protocol to enable synchronous message exchange. For more information about this protocol, see the WS-MakeConnection specification Version 1.1, February 28 2008.

WS-MakeConnection uses information contained in WS-Addressing message headers, so for any application that uses reliable synchronous message exchange you must include both WS-ReliableMessaging and WS-Addressing policy in the policy set.

WS-Notification

If you create JAX-WS based WS-Notification services, you can apply WS-ReliableMessaging policies to them to make your WS-Notification services reliable. For more information, see Configuring WS-Notification for reliable notification.

Note: In this release, there are two types of WS-Notification service:

- **Version 7.0**: You configure a Version 7.0 WS-Notification service and service points if you want to compose a JAX-WS WS-Notification service with WS-ReliableMessaging, or if you want to apply JAX-WS handlers to your WS-Notification service. This is the recommended type of service for new deployments.
- **Version 6.1**: You configure a Version 6.1 WS-Notification service and service points if you want to expose a JAX-RPC WS-Notification service using the same technology provided in WebSphere Application Server Version 6.1, including the ability to apply JAX-RPC handlers to the service.

WS-Policy

The WS-Policy implementation in WebSphere Application Server supports Web Services Reliable Messaging Policy Assertion Version 1.0 and Web Services Reliable Messaging Policy Assertion Version 1.1.

You can use the WS-Policy protocol to exchange policies in standard format. You can communicate the policy configuration to any other client, service registry or service that supports the WS-Policy specification, including non-WebSphere Application Server products in a heterogeneous environment. For a service provider, the policy configuration can be shared in published WSDL. For a client, the client can obtain the policy of the service provider in the standard WS-PolicyAttachments format and use this information to establish a configuration that is acceptable to both the client and the service provider. In other words, the client can be configured dynamically, based on the policies supported by its service provider.

At any stage - that is, before or after you have built your reliable Web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

WS-SecureConversation

WS-ReliableMessaging is designed to work with WS-SecureConversation. A secure conversation context is established and this is used to secure the application messages and the WS-ReliableMessaging protocol messages.

To use WS-SecureConversation, create or apply a policy set that includes both WS-ReliableMessaging and WS-SecureConversation. For example, either of the WS-I RSP default policy sets.

WS-Security

WS-ReliableMessaging composes with WS-Security. The WS-ReliableMessaging headers appended to application messages are signed if required. The WS-ReliableMessaging protocol messages are signed and encrypted if required.

Security processing is done close to the transport: after WS-ReliableMessaging processing at the Web service requester and before WS-ReliableMessaging processing at the Web service provider. This means the messages held in the WS-ReliableMessaging store are not signed and encrypted, so the emphasis is on the administrator to secure the store, if the store being used is the messaging engine in a service integration bus.

Note: If possible, use WS-SecureConversation rather than WS-Security because the WS-SecureConversation protocol is less susceptible to security attacks.

Configuring endpoints to only support clients that use WS-ReliableMessaging

By default, when a WS-ReliableMessaging enabled policy set is attached to an endpoint, the server supports clients that use reliable messaging and clients that do not use reliable messaging. In this version of the product, you can configure endpoints to only support clients that use reliable messaging.

About this task

You configure endpoints to only support clients that use reliable messaging by setting a property in either of the following ways:

- Set a property when packaging the application.
- Set a property as a JVM argument for the server.

This setting is reflected by WS-Policy if engaged. For information about how to engage WS-Policy, see "Using WS-Policy to exchange policies in a standard format" on page 714.

- When packaging the application, configure endpoints to only support clients that use reliable messaging by setting the **strictlyEnforceWSRM** property in the META-INF/MANIFEST.MF of a WAR file or EJB module.
- Using a JVM argument for the server, configure endpoints to only support clients that use reliable messaging by defining the Java virtual machine custom property **com.ibm.ws.websvcs.rm.strictlyEnforceWSRM** on the server. For more information, see Configuring the JVM.

Building a reliable Web service application

Develop a Java API for XML-Based Web Services (JAX-WS) provider or requester application, and configure a policy set to enable WS-ReliableMessaging. Install your application then attach the policy set. If you want to use either of the managed qualities of service, bind the application or policy set to a service integration bus and messaging engine.

Before you begin

At any stage - that is, before or after you have built your reliable Web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

About this task

To configure a Web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent. The managed qualities of service, managed persistent and managed non-persistent, are supported by the service integration bus.For each attachment between an application and a policy set, you can select the bus and messaging engine to use for the reliable messaging protocol state.

To enable WS-ReliableMessaging for an application, you take the following broad actions:

1. Develop a Java API for XML-Based Web Services (JAX-WS) Web service provider or requester application.
2. Install the application into WebSphere Application Server.

3. Attach a reliable messaging policy set (either a default policy set or one that you have created) to an aspect of your application (that is, application level or Web service level). Policy sets define the reliability level (quality of service) and other configuration options that you want to apply to your reliable messaging application.
4. Define the bindings for each attachment to a policy set that specifies a managed quality of service. That is, choose the service integration bus and messaging engine to use to maintain the state for the managed persistent and managed non-persistent qualities of service.

1. Develop your JAX-WS Web service application.

   For a Web service requester application that sends messages reliably:

   a. Get an implementation WSDL document, and select the SOAP over HTTP binding. The WSDL should be WS-I Basic Profile compliant.
   b. Build the JAX-WS application from the WSDL implementation document.
   c. (Optional) Enable transaction support for outbound (requester) one-way message sends. For more information, see “Providing transactional recoverable messaging through WS-ReliableMessaging” on page 653.
   d. (Optional) Use the **waitUntilSequenceCompleted** method on the sequenceManager to ensure that reliable messaging state is released after the client finishes messaging, as described in “Example: Code for waiting for a sequence to complete” on page 652.
   e. (Optional) If you want to use in-order delivery (that is, you want WS-ReliableMessaging to make messages available to your requester application in the order that they were sent), then you must also configure your requester application to poll for the messages in the order in which it wants to receive them. For more information, see “Configuring the WS-ReliableMessaging policy” on page 907.

   For a Web service provider application that requires reliable messaging:

   a. Write or get an interface WSDL document that describes the service interface. The document should be compliant with the WS-I Basic Profile.
   b. Write or get an implementation WSDL document, and select the SOAP over HTTP binding. The WSDL should remain WS-I Basic Profile compliant.
   c. Build the JAX-WS application from the WSDL implementation document.

   Your client application can also take programmatic control of WS-ReliableMessaging sequences. This helps manage resources on the server, for example by removing sequences after a client application has finished messaging. You can add code to create sequences, send acknowledgement requests, close sequences, terminate sequences and wait until sequences are complete. For more information, including example code, see “Controlling WS-ReliableMessaging sequences programmatically.”
2. Configure a policy set instance to enable WS-ReliableMessaging.
3. Install your reliable JAX-WS Web service application.
4. Attach and bind a WS-ReliableMessaging policy set to your application.
5. Save your changes to the master configuration.
6. Stop then restart the server.

Results

A reliable JAX-WS application is deployed into a suitably configured environment and started.

Controlling WS-ReliableMessaging sequences programmatically

Your client application can use the WSRMSequenceManager, part of the WebSphere Application Server SPI for reliable messaging, to gain programmatic control over reliable messaging sequences. This helps manage resources on the server, for example by removing sequences after a client application has finished messaging. You can add code to create sequences, send acknowledgement requests, close sequences, terminate sequences and wait until sequences are complete.

Before you begin

The WebSphere Application Server SPI for reliable messaging always uses the static policy set configuration that is applied to the client from which the SPI is called. It does not use any alternative policy set that is subsequently configured by WS-Policy to meet the requirements of a WS-Policy intersection.

About this task

By closing sequences programmatically, you limit the number of open sequences a single client has to support in a single JVM at one time.

For your client application to gain programmatic control over reliable messaging sequences, it needs access to a WSRMSequenceManager instance. Use the following code fragment to achieve this:

```
import com.ibm.wsspi.wsrm.WSRMSequenceManager;
import com.ibm.wsspi.wsrm.WSRMSequenceManagerFactory;

.........

     // Get the factory
     WSRMSequenceManagerFactory factory = WSRMSequenceManagerFactory
         .getInstance();

     // Get the sequence manager instance
     WSRMSequenceManager sequenceManager = factory.createWSRMSequenceManager();
```

All **WSRMSequenceManager** methods take the following parameters:

- The client instance object. This is either a **Dispatch client** instance, or the **Dynamic proxy client**. For details of the client types, see JAX-WS client programming model.
- 2) The **Port QName** instance for the target endpoint.

To control WS-ReliableMessaging sequences programmatically, add code to your client application as described in the following steps:

- Add code to create a sequence.
- Add code to send an acknowledgement request.
- Add code to close a sequence.
- Add code to terminate a sequence.
- Add code to wait for a sequence to complete.

Example: Code for creating a sequence:

Your client application can use the WSRMSequenceManager, part of the WebSphere Application Server SPI for reliable messaging, to gain programmatic control over reliable messaging sequences. Use these code fragments as guidance for coding your reliable messaging client application to create a sequence.

Before you begin

The WebSphere Application Server SPI for reliable messaging always uses the static policy set configuration that is applied to the client from which the SPI is called. It does not use any alternative policy set that is subsequently configured by WS-Policy to meet the requirements of a WS-Policy intersection.

For your client application to gain programmatic control over reliable messaging sequences, it needs access to a WSRMSequenceManager instance. The first of the following code examples includes code to create a WSRMSequenceManager object. If you need more information about working with this object, see “Controlling WS-ReliableMessaging sequences programmatically” on page 647.

Example code

To create a new reliable messaging sequence, first create a **WSRMSequenceProperties** object:

```
import com.ibm.wsspi.wsrm.WSRMSequenceProperties

.........

WSRMSequenceManager sequenceManager = WSRMSequenceManagerFactory
         .getInstance().createWSRMSequenceManager();

WSRMSequenceProperties sequenceProperties = sequenceManager
         .createNewWSRMSequenceProperties();
```

To set the available properties use the following methods:

```
  /**
   * Sets the target provider endpoint.
   * A null value will cause a NullPointerException when the WSRMSequenceProperties object is used.
   *
   * @param providerEndPoint The target service endpoint URI
   */
  public void setTargetEndpointUri(String providerEndPoint);

  /**
   * This is used to indicate that a response flow is required between the provider and requester and the response
   * flow will be established at create sequence time
   *
   * By calling this method it will indicate that a response flow is required.
   */
  public void setUseOfferedSequenceId();

  /**
   * Set the Soap version for RM protocol messages.
   * The default value for this property is WSRMSequenceProperties.SOAP_11
   *
   * @param soapVersion
   */
  public void setSoapVersion(int soapVersion);

  /**
   * If the Sequence Acknowledgement messages are to be sent back asynchronously call this method.
   *
   */
  public void useAsyncTransport();
```

To create the reliable messaging sequence use the **createNewWSRMSequence** method on the **WSRMSequenceManager**:

```
  /**
   * Initiates a new sequence handshake between this client and the target EPR specified in the
   * WSRMSequenceProperties instance.
   *
   * This sequence will only be valid for the client issuing the createNewWSRMSequence call.
   *
   * When returning from this call, there is no guarantee that the sequence has been established.
   *
   * @throws NullPointerException if the sequenceProperties object is null, or the target EPR is null
   *
   * @param clientObject The JAX-WS Dispatch instance, or the Dynamic Proxy client instance.
   * @param sequencePropeties The properties for creating the reliable messaging sequence
   * @throws WSRMNotEnabledException
   * @throws WSRMSequenceAlreadyExistsException
   */
```

```
public void createNewWSRMSequence(Object clientObject, QName portQName, WSRMSequenceProperties sequencePropeties)

throws WSRMNotEnabledException,
       WSRMSequenceAlreadyExistsException;
```

Example: Code for sending an acknowledgement request:

Your client application can use the WSRMSequenceManager, part of the WebSphere Application Server SPI for reliable messaging, to gain programmatic control over reliable messaging sequences. Use these code fragments as guidance for coding your reliable messaging client application to send an acknowledgement request.

Before you begin

The WebSphere Application Server SPI for reliable messaging always uses the static policy set configuration that is applied to the client from which the SPI is called. It does not use any alternative policy set that is subsequently configured by WS-Policy to meet the requirements of a WS-Policy intersection.

For your client application to gain programmatic control over reliable messaging sequences, it needs access to a WSRMSequenceManager instance. For information and example code explaining how to achieve this, see “Controlling WS-ReliableMessaging sequences programmatically” on page 647.

For a more complete specification of sending an acknowledgement request, see the “WS-ReliableMessaging: supported specifications and standards” on page 643.

Example code

To send an acknowledgement request for a WS-ReliableMessaging sequence, use the following method on the **WSRMSequenceManager**:

```
/**
 * Sending an acknowledgement request sends the ACK requested message to the specified target endPointUri.
 * The target will respond with a range of messages that can be acknowledged for the current reliable messaging
 * sequence.
 *
 * @param clientObject The JAX-WS Dispatch instance, or the Dynamic Proxy client instance.
 * @param portQName
 * @param endPointUri The target endpoint uri
 * @throws WSRMNotEnabledException
 * @throws WSRMSequenceUnknownException
 * @throws WSRMSequenceTerminatedException
 * @throws WSRMSequenceClosedException
 */
public void sendAcknowledgementRequest(Object clientObject, QName portQName, String endPointUri)

throws WSRMNotEnabledException,
       WSRMSequenceUnknownException,
       WSRMSequenceTerminatedException,
       WSRMSequenceClosedException;
```

Example: Code for closing a sequence:

Your client application can use the WSRMSequenceManager, part of the WebSphere Application Server SPI for reliable messaging, to gain programmatic control over reliable messaging sequences. Use these code fragments as guidance for coding your reliable messaging client application to close a sequence.

Before you begin

The WebSphere Application Server SPI for reliable messaging always uses the static policy set configuration that is applied to the client from which the SPI is called. It does not use any alternative policy set that is subsequently configured by WS-Policy to meet the requirements of a WS-Policy intersection.

For your client application to gain programmatic control over reliable messaging sequences, it needs access to a WSRMSequenceManager instance. For information and example code explaining how to achieve this, see “Controlling WS-ReliableMessaging sequences programmatically” on page 647.

For a more complete specification of closing a sequence, see the “WS-ReliableMessaging: supported specifications and standards” on page 643.

By closing sequences programmatically, you limit the number of open sequences a single client has to support in a single JVM at one time.

Example code

To close a WS-ReliableMessaging sequence use the following method on the **WSRMSequenceManager**:

```
/**
 * Closes the Web services reliable messaging session from this application to
 * the endpoint url specified.
 *
 * Throws a WSRMSequenceTerminatedException if the session between this application
 * and the target endpoint url is already closed
 *
 * Throws a WSRMSequenceTerminatedException when the session between this application
 * and the target endpoint has already been terminated.
 *
 * Throws WSRMSequenceUnknownException exception when either reliable messaging is not engaged to
 * the specified endpoint url or the sequence has previously been terminated and removed.
 *
 * @param clientObject The JAX-WS Dispatch instance, or the Dynamic Proxy client instance.
 * @param endPointUri The target endpoint url
 *
 * @throws WSRMNotEnabledException
 * @throws WSRMSequenceUnknownException
 * @throws WSRMSequenceClosedException
 * @throws WSRMSequenceTerminatedException
 */
public void closeSequence(Object clientObject, QName portQName, String endPointUri)

throws WSRMNotEnabledException,
       WSRMSequenceUnknownException,
       WSRMSequenceClosedException,
       WSRMSequenceTerminatedException;
```

Example: Code for terminating a sequence:

Your client application can use the WSRMSequenceManager, part of the WebSphere Application Server SPI for reliable messaging, to gain programmatic control over reliable messaging sequences. Use these code fragments as guidance for coding your reliable messaging client application to terminate a sequence.

Before you begin

The WebSphere Application Server SPI for reliable messaging always uses the static policy set configuration that is applied to the client from which the SPI is called. It does not use any alternative policy set that is subsequently configured by WS-Policy to meet the requirements of a WS-Policy intersection.

For your client application to gain programmatic control over reliable messaging sequences, it needs access to a WSRMSequenceManager instance. For information and example code explaining how to achieve this, see “Controlling WS-ReliableMessaging sequences programmatically” on page 647.

For a more complete specification of terminating a sequence, see the “WS-ReliableMessaging: supported specifications and standards” on page 643.

By closing sequences programmatically, you limit the number of open sequences a single client has to support in a single JVM at one time.

Example code

To terminate a WS-ReliableMessaging sequence use the following method on the **WSRMSequenceManager**:

```
/**
 * Terminates Web services reliable messaging session from this application to
 * the endpoint url specified.
 *
 * Throws a WSRMSequenceTerminatedException when the session between this application
 * and the target endpoint has already been terminated.
 *
 * Throws WSRMSequenceUnknownException exception when either reliable messaging is not engaged to
 * the specified endpoint url or the sequence has previously been terminated and removed.
 *
 * @param clientObject The JAX-WS Dispatch instance, or the Dynamic Proxy client instance.
 * @param endPointUri The target endpoint url
 * @throws WSRMNotEnabledException
 *
 * @throws WSRMSequenceTerminatedException
 * @throws WSRMSequenceUnknownException
 */
public void terminateSequence(Object clientObject, QName portQName, String endPointUri) throws WSRMNotEnabledException;
```

Example: Code for waiting for a sequence to complete:

Your client application can use the WSRMSequenceManager, part of the WebSphere Application Server SPI for reliable messaging, to gain programmatic control over reliable messaging sequences. Use the **waitUntilSequenceCompleted** method on the sequenceManager to ensure that reliable messaging state is released after the client finishes messaging.

Before you begin

The WebSphere Application Server SPI for reliable messaging always uses the static policy set configuration that is applied to the client from which the SPI is called. It does not use any alternative policy set that is subsequently configured by WS-Policy to meet the requirements of a WS-Policy intersection.

For your client application to gain programmatic control over reliable messaging sequences, it needs access to a WSRMSequenceManager instance. For information and example code explaining how to achieve this, see “Controlling WS-ReliableMessaging sequences programmatically” on page 647.

Example code

To wait for a reliable messaging sequence to complete, you use a method call that ensures that all messages have been sent and acknowledged by the target service. After the sequence is completed, it is terminated and cleaned up. By closing sequences programmatically, you limit the number of open sequences a single client has to support in a single JVM at one time.

There are two ways of using the **waitUntilSequenceCompleted** method:

- `public boolean waitUntilSequenceCompleted(Object clientObject, QName portQName, String endPointUri, long waitTime)`

  This method call waits for the specified **waitTime** for the reliable messaging sequence to complete. If the sequence does not complete in the specified time, the method returns false. If the sequence does complete in time, the method returns true.
- `public boolean waitUntilSequenceCompleted(Object clientObject, QName portQName, String endPointUri)`

  This method call does not return until the reliable messaging sequence is completed.

Providing transactional recoverable messaging through WS-ReliableMessaging

If your WS-ReliableMessaging application is running inside the Web container and using a managed quality of service, you can use WS-ReliableMessaging to provide transactional recoverable messaging.

About this task

The WS-ReliableMessaging transactional model is as follows:

- On the Web service requester side, the transaction is between the application and the local managed store.
- The WS-ReliableMessaging protocol delivers the message to the Web service provider side, where a different transaction is used between the second managed store and the application being dispatched.

For the outbound (requestor) case on a one-way message send, if the **enableTransactionalOneWay** property is set to true, then the send is performed under any transactional context currently held by the application's thread. (Note that transactions are not supported under an outbound two-way message exchange).

For the inbound (provider) case, if the **inOrderDelivery** property is set to true, then an inbound message is dispatched to the application under a transaction. In the case of an inbound two way message exchange, the response is also generated under that transaction and is not sent until that transaction has committed.

Note:

WS-ReliableMessaging transactions do not use the WS-AtomicTransactions protocol. The relationship between these two protocols is as follows:

- WS-AtomicTransactions and WS-ReliableMessaging are mutually exclusive when WS-ReliableMessaging is being used, with a managed store, to provide transactional recoverable messaging.
- If WS-ReliableMessaging is configured to use an in-memory store, then there are cases where a WS-AtomicTransaction can be flowed between the reliable messaging source and the reliable messaging destination for two-way invocations. In this situation, WS-ReliableMessaging only protects against network failures, not against server failure.

For more information, see "WS-AtomicTransactions" on page 644.

To provide transactional recoverable messaging through WS-ReliableMessaging, work through the steps described in "Building a reliable Web service application" on page 646 and also complete the following additional steps:

- To enable transactional messaging for outbound (requester) one-way message sends, when you develop your JAX-WS Web service application set the **enableTransactionalOneWay** property to Boolean.TRUE (or the string "true") in the jaxWS request context map.
- To enable transactional messaging for inbound (provider) one-way and two-way message exchanges, when you configure your WS-ReliableMessaging policy either use the administrative console to select the option **Deliver messages in the order that they were sent** or use the wsadmin tool to set the **inOrderDelivery** property to "true".

Configuring a WS-ReliableMessaging policy set using the administrative console

To configure a Web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent. Use the administrative console to configure a policy set for reliable messaging.

Before you begin

You can configure a reliable messaging policy set using the administrative console as described in this task, or you can configure a reliable messaging policy set using the wsadmin tool.

The following default policy sets work with WS-ReliableMessaging applications:

- WS-I RSP
- WS-I RSP ND
- LTPA WS-I RSP
- Username WS-I RSP
- WSReliableMessaging 1_0
- WSReliableMessaging default
- WSReliableMessaging persistent

For more information, see “WS-ReliableMessaging default policy sets” on page 811.

If you can use any of these default policy sets without needing to modify their configuration, you need not complete this task. You are ready to attach and bind the default policy set to your application.

At any stage - that is, before or after you have built your reliable Web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

About this task

To configure a reliable messaging policy set using the administrative console, complete the following steps:

1. Create a policy set. You can create a new policy set, or copy and rename an existing policy set - either one that you have previously created, or one of the WS-ReliableMessaging default policy sets.
2. Check that your policy set includes the policy types **WS-ReliableMessaging** and **WS-Addressing**. Add these policy types if necessary. These policy types contain the configuration options that support WS-ReliableMessaging. WS-Addressing provides the asynchronous request and reply capabilities for WS-ReliableMessaging, and is also required for WS-ReliableMessaging Version 1.1 synchronous messaging.

   Note:

   - If you want to use secure conversation and reliable messaging policies in the same policy set, the secure conversation bindings must be configured to require that the reliable messaging headers are signed. The reliable secure profile default policy sets (WS-I RSP and WS-I RSP ND) are specifically designed and configured to use secure conversation and reliable messaging in the same policy set. If you use a copy of one of the reliable secure profile default policy sets (WS-I RSP and WS-I RSP ND), no further configuration of the secure conversation bindings is required. Otherwise, see “Configuring WS-SecureConversation to work with WS-ReliableMessaging” on page 656.
   - WS-ReliableMessaging Version 1.1 messaging requires WS-Addressing to be mandatory. If you use a policy set that includes WS-ReliableMessaging and WS-Addressing policies, and the WS-Addressing policy is configured as optional, then WebSphere Application Server overrides the WS-Addressing setting and automatically enables WS-Addressing.
3. Configure the **WS-ReliableMessaging** policy type attributes. For the WS-ReliableMessaging policy you can configure the version of the WS-ReliableMessaging standard that you want to use, the order in which messages are delivered, and the required quality of service (the reliability level) for message delivery.

Note: In WebSphere Application Server Version 6.1, you could also configure whether or not to use the WS-MakeConnection protocol. This configuration option has now been removed from the administrative console panel, because the product now automatically determines whether WS-MakeConnection is used, based on the following criteria:

- Whether you are using WS-ReliableMessaging Version 1.0 or Version 1.1.
- Whether the requester supports WS-MakeConnection.
- Whether the message exchange protocol is synchronous or asynchronous.

4. Save your changes to the master configuration.

What to do next

You are now ready to attach your application to the policy set and define the bindings that you want to use.

Configuring a WS-ReliableMessaging policy set using the wsadmin tool

To configure a Web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent. Use command scripts to configure a policy set for reliable messaging.

Before you begin

You can configure a reliable messaging policy set using the wsadmin tool as described in this task, or you can configure a reliable messaging policy set using the administrative console.

The following default policy sets work with WS-ReliableMessaging applications:

- WS-I RSP
- WS-I RSP ND
- LTPA WS-I RSP
- Username WS-I RSP
- WSReliableMessaging 1_0
- WSReliableMessaging default
- WSReliableMessaging persistent

For more information, see “WS-ReliableMessaging default policy sets” on page 811.

If you can use any of these default policy sets without needing to modify their configuration, you need not complete this task. You are ready to attach your application to the default policy set and define the bindings that you want to use.

At any stage - that is, before or after you have built your reliable Web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

About this task

To configure a reliable messaging policy set using the wsadmin tool, complete the following steps:

1. Create a policy set. Use the createPolicySet command to create a new policy set, or the **copyPolicySet** command to copy and rename an existing policy set - either one that you have previously created, or one of the two “WS-ReliableMessaging default policy sets” on page 811. For more information, see Creating and copying policy sets using the wsadmin tool.

2. If the policy set does not include both the policy types **WSReliableMessaging** and **WSAddressing**, add these policy types using the addPolicyType command as described in Creating and copying policy sets using the wsadmin tool. For example:

```
AdminTask.addPolicyType('[-policySet PolicySet1 -policyType WSReliableMessaging]')
AdminTask.addPolicyType('[-policySet PolicySet1 -policyType WSAddressing]')
```

   These policy types contain the configuration options that support WS-ReliableMessaging. WS-Addressing provides the asynchronous request and reply capabilities for WS-ReliableMessaging, and is also required for WS-ReliableMessaging Version 1.1 synchronous messaging.

   Note:

   - If you want to use secure conversation and reliable messaging policies in the same policy set, the secure conversation bindings must be configured to require that the reliable messaging headers are signed. The reliable secure profile default policy sets (WS-I RSP and WS-I RSP ND) are specifically designed and configured to use secure conversation and reliable messaging in the same policy set. If you use a copy of one of the reliable secure profile default policy sets (WS-I RSP and WS-I RSP ND), no further configuration of the secure conversation bindings is required. Otherwise, see "Configuring WS-SecureConversation to work with WS-ReliableMessaging."
   - WS-ReliableMessaging Version 1.1 messaging requires WS-Addressing to be mandatory. If you use a policy set that includes WS-ReliableMessaging and WS-Addressing policies, and the WS-Addressing policy is configured as optional, then WebSphere Application Server overrides the WS-Addressing setting and automatically enables WS-Addressing.

3. Configure the **WS-ReliableMessaging** policy type attributes.

   For the WS-ReliableMessaging policy you can configure the version of the WS-ReliableMessaging standard that you want to use, the order in which messages are delivered, and the required quality of service (the reliability level) for message delivery. For detailed information about these configurable attributes, see "WS-ReliableMessaging settings" on page 908.

   Use the setPolicyType command to configure these attributes. For example:

```
AdminTask.setPolicyType('-policySet PolicySet1 -policyType WSReliableMessaging -attributes "[[inOrderDelivery false][specLevel 1.0]
[enabled true][qualityOfService managedPersistent][type WSReliableMessaging]]" -replace'
```

4. Save your changes to the master configuration.

   To save your configuration changes, enter the following command:

   ```
   AdminConfig.save()
   ```

What to do next

You are now ready to attach your application to the default policy set and define the bindings that you want to use.

Configuring WS-SecureConversation to work with WS-ReliableMessaging

Configure secure conversation to expect the reliable messaging headers to be signed, and to ensure that the scoping security context token does not expire before reliable messaging recovers and resends persistent messages.

- "Configure secure conversation to expect the reliable messaging headers to be signed"
- "Configure secure conversation to increase the timeout setting for the scoping security context token" on page 657

Configure secure conversation to expect the reliable messaging headers to be signed:

About this task

Although secure conversation allows message headers to remain unsigned, the reliable messaging policy requires the reliable messaging headers to be signed. If you want to use secure conversation and reliable messaging policies in the same policy set, the secure conversation bindings must be configured to require

that the reliable messaging headers are signed. To achieve this, complete one of the following steps:

- Create your policy set from a copy of one of the reliable secure profile default policy sets (WS-I RSP and WS-I RSP ND). This policy set contains instances of the secure conversation and reliable messaging policies that are configured to work together.
- Create your policy set from a copy of the secure conversation policy set:
  1. Add the reliable messaging policy to your copy of the secure conversation policy set.
  2. Specify in the secure conversation bindings that the reliable messaging headers must be signed. For more information about how to do this, see “Defining and managing policy set bindings” on page 824.
  3. Save your changes to the master configuration.

  Note: The reliable secure profile default policy sets (WS-I RSP and WS-I RSP ND) are specifically designed and configured to use secure conversation and reliable messaging in the same policy set. Only create your policy set from a copy of the secure conversation policy set if you have a clear business need to do so. Otherwise, always use a copy of one of the reliable secure profile default policy sets (WS-I RSP and WS-I RSP ND).

Configure secure conversation to increase the timeout setting for the scoping security context token:

About this task

When you use a persistent WS-I RSP policy set, which includes WS-SecureConversation, if the scoping security context token is expired when the server is restarted then WS-ReliableMessaging cannot resend its messages and system messages are written to the log file stating that the reliable messaging sequence was not secured using the correct security token.

To ensure that the scoping security context token does not expire before WS-ReliableMessaging can recover and resend its messages, use the administrative console to complete the following steps:

1. In the navigation pane, click **Services** → **Security cache**. The Security cache detail form is displayed.
2. Set the **Time token is in cache after timeout** property to a value of at least 120 minutes. This value specifies the length of time to keep tokens after they expire. By default, this is 10 minutes. These expired tokens can be used for reliable messaging recovery.
3. In the navigation pane, click **Services** → **Trust service** → **Token providers**. In the content pane, select a security context token. The Security Context Token detail form is displayed.
4. Set the following values for the security context token:
   a. Check that the **Time in cache after expiration** property is set to a value of at least 120 minutes.
   b. Check that the **Token timeout** property is set to a value of at least 120 minutes.
   c. Select the **Allow renewal after timeout** check box.
5. Save your changes to the master configuration.

Attaching and binding a WS-ReliableMessaging policy set to a Web service application using the administrative console

To configure a Web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent. Use the administrative console to attach the policy set to your application, and (for managed qualities of service) define bindings to a service integration bus and messaging engine.

Before you begin

You can attach a WS-ReliableMessaging policy set and define bindings using the administrative console as described in this task, or you can attach and bind a WS-ReliableMessaging policy set using the wsadmin tool.

This task assumes that you have already developed and installed the Web service application to which you want to attach a policy set.

The following default policy sets work with WS-ReliableMessaging applications:

- WS-I RSP
- WS-I RSP ND
- LTPA WS-I RSP
- Username WS-I RSP
- WSReliableMessaging 1_0
- WSReliableMessaging default
- WSReliableMessaging persistent

For more information, see “WS-ReliableMessaging default policy sets” on page 811.

If you can use any of these default policy sets, or you have configured your own reliable messaging policy set, then you are ready to complete this task.

About this task

Use this task to complete the following broad actions:

1. Attach a reliable messaging policy set (either a default policy set or one that you have created) to an aspect of your application (that is, application level or Web service level). Policy sets define the reliability level (quality of service) and other configuration options that you want to apply to your reliable messaging application.
2. Define the bindings for each attachment to a policy set that specifies a managed quality of service. That is, choose the service integration bus and messaging engine to use to maintain the state for the managed persistent and managed non-persistent qualities of service.

To attach a WS-ReliableMessaging policy set and define bindings using the administrative console, complete the following steps:

1. Attach a policy set to your reliable messaging application at either application level or service level..

   Note:

   - You can attach one policy set at each level.
   - You can only apply a WS-ReliableMessaging policy at application level or service level.
   - If you apply reliable messaging at service level, then all services must use the same WS-ReliableMessaging policy and bindings values.
   - You can attach any policy set at operation level. For a policy set that includes the WS-ReliableMessaging policy, attachment at the operation level configures the other components of the policy set (for example WS-Security and WS-Addressing) but any WS-ReliableMessaging configuration at operation level is ignored.
2. If your chosen policy set specifies a managed quality of service, define bindings to a service integration bus and messaging engine.

   If the policy set instance specifies managed non-persistent or managed persistent quality of service, choose the service integration bus and messaging engine that is to manage the

WS-ReliableMessaging state. Use the “WS-ReliableMessaging policy binding” on page 910 panel to select or create the service integration bus and messaging engine that you want to use.

Note: When many applications use the same messaging engine, it can impact performance. Factors to consider include the number of applications that are already binding to the messaging engine, the CPU utilization, and the message throughput. To improve performance for a single server configuration, create a new messaging engine to bind to your application.

To define the default WS-ReliableMessaging policy binding for provider and client policy set attachments within WebSphere Application Server Version 6.1 applications, and for attachments to service applications that are deployed to a Version 6.1 server, navigate to **Services** → **Policy sets** → **Default policy set bindings** → **Version 6.1 default policy set bindings** → **WS-ReliableMessaging**.

To define the bindings for a WebSphere Application Server Version 7.0 provider or client policy set, navigate to **Services** → **Policy sets** → **General provider policy set bindings** → ***provider_policy_set_binding_name*** → **WS-ReliableMessaging** or **Services** → **Policy sets** → **General client policy set bindings** → ***client_policy_set_binding_name*** → **WS-ReliableMessaging**

To define the bindings for an application that you have attached to a service provider policy set, navigate to **Applications** → **Application Types** → **WebSphere enterprise applications** → ***application_name*** → **[Web Service Properties] Service provider policy sets and bindings** and follow the instructions given in “Managing policy sets and bindings for service providers at the application level using the administrative console” on page 743.

To define the bindings for an application that you have attached to a service client policy set, navigate to **Applications** → **Application Types** → **WebSphere enterprise applications** → ***application_name*** → **[Web Service Properties] Service client policy sets and bindings** and follow the instructions given in “Managing policy sets and bindings for service clients at the application level using the administrative console” on page 760.

Note: If the application that you have attached to a service client policy set is a Version 7.0 WS-Notification service client, you can instead use the context-specific version of the “Service client policy sets and bindings” panel that can be reached through either of the following paths:

- **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional properties] Outbound request policy sets and bindings**
- **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional properties] Outbound request policy sets and bindings**

If you want to configure policy set and binding details for a single Version 7.0 WS-Notification service client, rather than for all clients for the service, you can instead use the following panel:

- **Services** → **Service clients** → ***ws-notification_service_client_name***

This panel also gives you links to the associated service integration bus and WS-Notification service.

3. Save your changes to the master configuration.

Attaching and binding a WS-ReliableMessaging policy set to a Web service application using the wsadmin tool

To configure a Web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent. Use the wsadmin tool to attach the policy set to your application, and (for managed qualities of service) to define bindings to a service integration bus and messaging engine.

Before you begin

You can attach a WS-ReliableMessaging policy set and define bindings using the wsadmin tool as described in this task, or you can attach and bind a WS-ReliableMessaging policy set using the administrative console.

This task assumes that you have already developed and installed the Web service application to which you want to attach a policy set.

The following default policy sets work with WS-ReliableMessaging applications:

- WS-I RSP
- WS-I RSP ND
- LTPA WS-I RSP
- Username WS-I RSP
- WSReliableMessaging 1_0
- WSReliableMessaging default
- WSReliableMessaging persistent

For more information, see “WS-ReliableMessaging default policy sets” on page 811.

If you can use any of these default policy sets, or you have configured your own reliable messaging policy set, then you are ready to complete this task.

About this task

Use this task to complete the following broad actions:

1. Attach a reliable messaging policy set (either a default policy set or one that you have created) to an aspect of your application (that is, application level or Web service level). Policy sets define the reliability level (quality of service) and other configuration options that you want to apply to your reliable messaging application.
2. Define the bindings for each attachment to a policy set that specifies a managed quality of service. That is, choose the service integration bus and messaging engine to use to maintain the state for the managed persistent and managed non-persistent qualities of service.

To attach a WS-ReliableMessaging policy set and define bindings using the wsadmin tool, complete the following steps:

1. Attach a policy set to your reliable messaging application at either application level or service level.

   Use the createPolicySetAttachment command as described in Creating policy set attachments using the wsadmin tool. Set the **-policySet** parameter to the name of the reliable messaging policy set that you want to use. For example: “WS-I RSP ND”

   Note:

   - You can attach one policy set at each level.
   - You can only apply a WS-ReliableMessaging policy at application level or service level.
   - If you apply reliable messaging at service level, then all services must use the same WS-ReliableMessaging policy and bindings values.
   - You can attach any policy set at operation level. For a policy set that includes the WS-ReliableMessaging policy, attachment at the operation level configures the other components of the policy set (for example WS-Security and WS-Addressing) but any WS-ReliableMessaging configuration at operation level is ignored.

   This command returns an attachment ID number. If your chosen policy set specifies a managed quality of service, make a note of this number. In the next step you use it to define the binding.
2. If your chosen policy set specifies a managed quality of service, define bindings to a service integration bus and messaging engine.

   If the policy set instance specifies managed non-persistent or managed persistent quality of service, choose the service integration bus and messaging engine that is to manage the WS-ReliableMessaging state. Use the setBinding command as described in Creating policy set

attachments using the wsadmin tool. Set the **-policyType** parameter to WSReliableMessaging. Set the bus name and the messaging engine name by using the following syntax for the **-attributes** parameter:

```
-attributes "[[busName ReliableMessagingBus] [messagingEngineName nodeName.serverName-busName]]"
```

Note: When many applications use the same messaging engine, it can impact performance. Factors to consider include the number of applications that are already binding to the messaging engine, the CPU utilization, and the message throughput. To improve performance for a single server configuration, create a new messaging engine to bind to your application.

3. Save your changes to the master configuration.

   To save your configuration changes, enter the following command:

   ```
   AdminConfig.save()
   ```

Detecting and fixing problems with WS-ReliableMessaging

The nature of WS-ReliableMessaging is that network and server failures are assumed, and therefore the target Web service or message store might not be available. In these cases, message sequences cannot be completed and collections of Web service messages are held awaiting transmission. You can use the `SystemOut.log` file, system events, and the runtime administrative panels to monitor the system and detect and fix problems with WS-ReliableMessaging.

About this task

If a sequence fails, a message is written to the application server `SystemOut.log` file and a system event is generated. Therefore you can detect failed sequences by looking at the `SystemOut.log` file, or by writing an event listener (or using third party software) to monitor system events.

Note: After a sequence has been established, WS-ReliableMessaging provides retransmission of messages to a service. However if the sequence is not established (that is, if the initial **CreateSequence** request is refused) then the messages are not transmitted to the service. For more information, see the troubleshooting tip “A sequence is not established, and therefore WS-ReliableMessaging cannot ensure messages are transmitted” on page 667.

For more detailed status information at run time, and facilities to help you fix problems, use the WS-ReliableMessaging administrative console runtime panels. These panels are available at many different scopes (for example cell; application server; messaging engine). For a full list of the WS-ReliableMessaging runtime panels, and details of the scopes at which they are available, see “WS-ReliableMessaging - administrative console panels” on page 671.

At all scopes, the parent panel is “Reliable messaging state settings” on page 672. From this panel you can investigate each of the three key runtime aspects of reliable messaging:

- Message stores
- Inbound sequences
- Outbound sequences

The following icons are displayed here and on several other reliable messaging runtime panels:

	**OK**	Everything here, and (if there is a link) in all runtime panels below this link, is running normally.

	**Warning**	Something here, or (if there is a link) in one of the runtime panels below this link, is in an unusual state and you might need to take some action to resolve it. For example, the system might be awaiting a response from an endpoint. In this case, either the response will be received (in which case you need take no action and the runtime information will be updated to ″OK″) or the reliable messaging destination has stopped acknowledging messages (in which case you need to take some action to resolve the failed sequence).
	**Error**	There is a definite error that you need to take some action to resolve, either here or (if there is a link) in one of the runtime panels below this link.

Note that for troubleshooting purposes you only need to follow links to the sub-panels if states other than ″OK″ are displayed.

To use the reliable messaging runtime panels to detect and fix problems with WS-ReliableMessaging, complete one or more of the following steps:

- Investigate problems with message stores.

  In the navigation pane, click one of the paths to this panel. For example **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Additional Properties] Reliable messaging state** → **Runtime** → **Message store**. The list of reliable messaging storage managers for the current scope is displayed in the “Message store collection” on page 673 form.

  For the managed qualities of service, the messages are written to a messaging engine. For the unmanaged non-persistent quality of service, the messages are stored in memory. For in-memory stores the only possible value is ″Running″. For messages stored by a messaging engine, the possible values are ″Running″ or ″Messaging engine not contactable″, probably because the messaging engine is not running. The ″OK″ icon indicates that the message store is running. If the messaging engine is not contactable, the ″Error″ icon is displayed.

  For each message store in the list, the name of the associated reliable messaging application is given in the *description* column. If a messaging engine is not contactable, restart the message store for that application.

- Investigate problems with inbound sequences.

  In the navigation pane, click one of the paths to this panel. For example **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Additional Properties] Reliable messaging state** → **Runtime** → **Inbound sequences**. The runtime state of each of the inbound sequences for the current scope is displayed in the “Inbound sequence collection” on page 679 form.

  You can use a filter to look at sequences that are in a particular state (for example “Failed due to missing message”) or that have a large number of messages awaiting dispatch to applications. If the sequence status is *Error*, there is a problem with the sequence and the source server hosting the other end of the sequence has terminated it. If the sequence is active and there are a large number of messages awaiting dispatch to the application, then there could be a problem with the application or, if in-order delivery is specified, delivery could be held up because the sequence has gaps in it.

  You can select one or more sequences, then use the buttons provided to dispatch the messages to their associated applications, to export the messages to ZIP files, to close or terminate the selected sequences, or to delete the selected sequences and all their messages.

  To see more detailed information about a particular sequence, click the Sequence identifier field. The “Inbound sequences settings” on page 681 form is displayed. This detailed information includes addressing information to help you identify the source of the sequence, and the value (true or false) for ″in-order delivery″ for the sequence. From this panel you can also display the following forms:

  – The “Acknowledgement state collection” on page 683 form. (The ranges of message sequence numbers received from the WS-ReliableMessaging source. If more than one range is displayed, this indicates a gap in the messages received. If ″In-order delivery″ is selected for the sequence manager, messages with a sequence number greater than the lowest gap cannot be delivered to the application until the gap is closed.)

  - The “Inbound message collection” on page 683 form. (The messages on the inbound sequence. You can use this form to delete individual messages.)
    - The “Message settings” on page 678 form. (The contents of an individual message in the sequence.)

  For more guidance on diagnosing problems with inbound sequences, see “Diagnosing the problem when a reliable messaging source cannot deliver its messages”

- Investigate problems with outbound sequences.

  In the navigation pane, click one of the paths to this panel. For example **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Additional Properties] Reliable messaging state** → **Runtime** → **Outbound sequences**. The runtime state of each of the outbound sequences for the current scope is displayed in the “Outbound sequence collection” on page 674 form.

  You can use a filter to look at sequences that are in a particular state. For example, the state “Cannot contact the remote endpoint” indicates that the sequence has been established but the reliable messaging destination has stopped acknowledging messages (which, coupled with a high number of messages awaiting transmission, could indicate a potential problem). If the sequence status is *Error*, there is a problem with the sequence and the server hosting the other end of the sequence has terminated it.

  You can select one or more sequences, and use one of the buttons provided to reallocate messages to new sequences, to export the messages to ZIP files, to close or terminate the selected sequences, or to delete the selected sequences and all their messages.

  Note: Before you delete a sequence, you can reassign its messages to new sequences or export them to a ZIP file. For more information, see “Deleting a failed WS-ReliableMessaging outbound sequence” on page 664

  To see more detailed information about a particular sequence, click the Sequence identifier field. The “Outbound sequences settings” on page 676 form is displayed. This detailed information includes addressing information to help you identify the server at which the sequence is targeted. From this panel you can also display the following forms:
  - The “Outbound message collection” on page 678 form. (The messages on the outbound sequence. You can use this form to delete individual messages.)
    - The “Message settings” on page 678 form. (The contents of an individual message in the sequence.)

  For more guidance on diagnosing problems with outbound sequences, see “Diagnosing and recovering a WS-ReliableMessaging outbound sequence that is in retransmitting state” on page 664.

Diagnosing the problem when a reliable messaging source cannot deliver its messages

If you know the sequence identifier, and the target URI for the messages, you can use the runtime administrative console panels to examine the sequence and determine why a reliable messaging source is not delivering its messages into the application server.

About this task

To diagnose this problem, complete the following steps:

1. Identify the target server from the target URI.
2. Use the administrative console to view the inbound sequences runtime information for the target server.

   In the navigation pane, click either **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Additional Properties] Reliable messaging state** → **Runtime** → **Inbound sequences** or **Servers** → **Clusters** → **WebSphere application server clusters** → ***cluster_name*** → **[Additional Properties] Reliable messaging state** → **Runtime** → **Inbound sequences**. The runtime state of each of the inbound sequences for the current scope is displayed in the “Inbound sequence collection” on page 679 form.

3. Specify a filter on the runtime view of the sequences, filtering on the Sequence identifier provided by the reliable messaging source owner.
4. Click on the Sequence identifier of the displayed sequence to get a more detailed view of it.
5. If the sequence has failed, examine the runtime status of the failed sequence and provide the reliable messaging source owner with details of which messages have been acknowledged, so that the owner can decide whether to delete, or to process out of order, any undelivered messages.
6. If the sequence has not failed, see whether there is a communications problem between the reliable messaging source and the application server.

Diagnosing and recovering a WS-ReliableMessaging outbound sequence that is in retransmitting state

You need to resolve a sequence in retransmitting state, because messages are backing up awaiting delivery to the target service. The retransmission could be due to a network failure, or a failure of the target server. The problem should resolve automatically, but you might want to investigate the cause to speed up recovery.

About this task

To resolve a sequence in retransmitting state, complete the following steps:

1. Check for network failures.
2. If no network failures are found, look up the target endpoint address (URI) for the sequence to determine the owner of the target service, then contact the owner to check if the target server is available.

   The target endpoint address is shown in the “Outbound sequences settings” on page 676 form. Use the administrative console to navigate to this form, as described in “Detecting and fixing problems with WS-ReliableMessaging” on page 661.
3. After the communication link between the two servers is re-established, use the runtime panels to confirm that messages in the sequence are now being delivered.

Deleting a failed WS-ReliableMessaging outbound sequence

You need to resolve an outbound sequence in failed state, so that messages can again be transmitted to the target service. A sequence in failed state shows an unrecoverable error. The sequence can no longer be used. If messages are being delivered in order, then the failed sequence must be resolved before a new sequence can be established.

About this task

Deleting an outbound sequence allows the runtime environment to automatically create a new sequence the next time that an application attempts to invoke a Web service at the destination address that the failed sequence was targeting. To work with outbound sequences you use the administrative console runtime panels as described in “Detecting and fixing problems with WS-ReliableMessaging” on page 661.

To diagnose and delete a failed outbound sequence, use the administrative console to complete the following steps:

1. In the navigation pane of the administrative console, click one of the paths to the outbound sequences collection form. For example **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Additional Properties] Reliable messaging state** → **Runtime** → **Outbound sequences**. The runtime state of each of the outbound sequences for the current scope is displayed in the “Outbound sequence collection” on page 674 form.
2. Examine the failure reason by clicking on the Sequence identifier field of the failed sequence. The “Outbound sequences settings” on page 676 form is displayed. The failure reason is based on the fault message received by the sequence manager from the target server.
3. If there are messages associated with the failed sequence, decide what to do with these messages. The messages might have been transmitted and received at the target server, or they might not. You

might choose to delete messages from the sequence, re-allocate them to a new sequence or export them to a ZIP file. If you choose to delete the messages, you can either delete individual messages or you can delete all the messages.

a. Optional: To delete one or more messages from a failed sequence, complete the following steps:
   1) In the main pane of the "Outbound sequences settings" on page 676 form, under the Additional Properties section, click **Messages**. The messages for the failed outbound sequence are listed in the "Outbound message collection" on page 678 form.
   2) Select the check boxes next to the names of the messages that you want to delete.
   3) Click **Delete**.

b. Optional: To re-allocate or export all the remaining messages in a failed sequence, complete the following steps:
   1) In the main pane of the "Outbound sequence collection" on page 674 form, select the check box next to the name of the failed sequence.
   2) Click **Re-allocate messages** or **Export unsent messages**. All remaining messages in the sequence are re-allocated to a new sequence or exported to a ZIP file.

4. Close or terminate the failed sequence.

   Note: In the WS-ReliableMessaging Version 1.1 specification, a sequence can be closed rather than terminated. This allows the final ACK state to be sent from the reliable messaging destination to the reliable messaging source. In the WS-ReliableMessaging Version 1.0 specification this does not happen, so the final ACK state might not be known at the reliable messaging source. For more information about the distinction between close and terminate, see "Outbound sequence collection" on page 674.

   a. In the main pane of the "Outbound sequence collection" on page 674 form, select the check box next to the name of the failed sequence.
   b. Click **Close sequence** or **Terminate sequence**.

5. Delete the failed sequence.
   a. In the main pane of the "Outbound sequence collection" on page 674 form, select the check box next to the name of the failed sequence.
   b. Click **Delete sequence**.

WS-ReliableMessaging troubleshooting tips

Tips for troubleshooting your WS-ReliableMessaging configuration.

To help you identify and resolve problems with WS-ReliableMessaging, you can use the TCP/IP monitor to view the messages that are flowing between your client applications and reliable messaging enabled Web services. You can also use the WebSphere Application Server trace and logging facilities as described in Tracing and logging configuration.

To enable trace for WS-ReliableMessaging, set the application server trace string as follows:

- For either of the managed qualities of service:

```
org.apache.sandesha2*=all=enabled:com.ibm.ws.websvcs.rm*=all=enabled:org.apache.axis2*=all=enabled:com.ibm.ws.sib.wsrm*=all=enabled
```

- For the Unmanaged Non-Persistent quality of service:

```
org.apache.sandesha2*=all=enabled:com.ibm.ws.websvcs.rm*=all=enabled:org.apache.axis2*=all=enabled
```

If you encounter a problem that you think might be related to WS-ReliableMessaging, you can check for error messages in the WebSphere Application Server administrative console, and in the application server `SystemOut.log` file. You can also enable the application server debug trace to provide a detailed exception dump.

A list of the main known restrictions that apply when using WS-ReliableMessaging is provided in "WS-ReliableMessaging known restrictions" on page 669.

WebSphere Application Server system messages are logged from a variety of sources, including application server components and applications. Messages logged by application server components and associated IBM products start with a unique message identifier that indicates the component or application that issued the message. The prefix for the WS-ReliableMessaging component is CWSKA.

The Troubleshooter reference: Messages topic contains information about all WebSphere Application Server messages, indexed by message prefix. For each message there is an explanation of the problem, and details of any action that you can take to resolve the problem.

Here is a set of tips to help you troubleshoot commonly-experienced problems:
- "If reliable messaging is running on a cluster, when you examine the runtime state of inbound or outbound sequences you see multiple entries for each sequence"
- "You get runtime errors when you migrate persisted WS-ReliableMessaging messages from Version 6.1.0.9 or 6.1.0.11 of the Feature Pack for Web Services to a later version of the product"
- "When an application server starts, a messaging engine used for reliable messaging is reported as unavailable" on page 667
- "A client application is unable to invoke a reliable messaging enabled Web service" on page 667
- "A sequence is not established, and therefore WS-ReliableMessaging cannot ensure messages are transmitted" on page 667
- "A sequence is established but cannot be used, and therefore WS-ReliableMessaging cannot ensure messages are transmitted" on page 668
- "The reliable messaging managed store is not initialized because the policy set binding is not complete or not valid" on page 668
- "A message is not recovered after a server becomes unavailable, even with the managed persistent quality of service" on page 668
- "When using reliable messaging with a persistent WS-I RSP profile and WS-SecureConversation, an exception message states that the security context token is not valid" on page 669

If reliable messaging is running on a cluster, when you examine the runtime state of inbound or outbound sequences you see multiple entries for each sequence

This is because, although reliable messaging only binds to one messaging engine in a cluster, the runtime panel is calculating and displaying the sequence information once for every cluster member. Ignore the duplicate entries. Note that the slight differences in the statistics being displayed for each duplicate entry is due to the entries being created sequentially, while polling for messages continues.

You get runtime errors when you migrate persisted WS-ReliableMessaging messages from Version 6.1.0.9 or 6.1.0.11 of the Feature Pack for Web Services to a later version of the product

If you are migrating from WebSphere Application Server Version 6.1, and you are using Version 6.1.0.9 or 6.1.0.11 of the Feature Pack for Web Services, and your configuration includes WS-ReliableMessaging configured for the managed persistent quality of service, you need to remove all persisted messages before you migrate.

Each message is persisted as part of a sequence that is currently being processed. To remove all persisted messages, use the administrative console to complete the following steps:

1. Navigate to the "Inbound sequence collection" on page 679 runtime panel for your reliable messaging application.
2. Select all the inbound sequences, then click the **delete sequence and messages** button to delete the sequences.
3. Navigate to the "Outbound sequence collection" on page 674 runtime panel, then repeat the previous steps for the outbound sequences.

When an application server starts, a messaging engine used for reliable messaging is reported as unavailable

When you use reliable messaging with a managed quality of service, you might see the following exception message when your application server starts:

```
CWSIT0019E: No suitable messaging engine is available on bus yourBus that matched the specified connection properties
```

If you suspect there is an underlying problem, for example the bindings are incorrect or the server that hosts the messaging engine is not going to start, complete the following checks:

- Check that the specified messaging engine and service integration bus exist.
- Check the system out log to ensure that the server that hosts the messaging engine has started.

A client application is unable to invoke a reliable messaging enabled Web service

If your client application is unable to invoke a reliable messaging enabled Web service, you can use the TCP-IP monitor to view the messages that are flowing between the client and the service. You should also check the following:

- The endpoint is available.
- The service is running.
- The service has been invoked.
- WS-ReliableMessaging is running.
- WS-ReliableMessaging is correctly configured. In particular, for either of the managed qualities of service, check that you have configured a valid binding to a service integration bus and messaging engine, and that the messaging engine is running. For more information, see “Attaching and binding a WS-ReliableMessaging policy set to a Web service application using the administrative console” on page 657 or “Attaching and binding a WS-ReliableMessaging policy set to a Web service application using the wsadmin tool” on page 659.
- There are not too many applications sharing a single messaging engine.

  Note: When many applications use the same messaging engine, it can impact performance. Factors to consider include the number of applications that are already binding to the messaging engine, the CPU utilization, and the message throughput. To improve performance for a single server configuration, create a new messaging engine to bind to your application.

A sequence is not established, and therefore WS-ReliableMessaging cannot ensure messages are transmitted

After a sequence has been established, WS-ReliableMessaging provides retransmission of messages to a service. However if the sequence is not established then the messages are not transmitted to the service and a message similar to the following example is displayed:

```
org.apache.axis2.AxisFault: The Create Sequence request has been refused by the RM Destination
```

The initial **createSequence** message has been refused. This is propagated back, and causes the client to fail. For information about **CreateSequence** and **CreateSequenceRefused**, see the “WS-ReliableMessaging: supported specifications and standards” on page 643.

You might also see a subsequent message to help explain why the request has been refused. For example:

```
Caused by: javax.xml.ws.soap.SOAPFaultException: com.ibm.ws.sib.wsrm.exceptions.WSRMRuntimeException:
CWSJZ0202I: A messaging engine connection is unavailable for bus myBus.
```

There is a problem with your reliable messaging configuration. Complete the following checks:

- Check that the policy sets are correctly applied. Specifically, check that the destination has reliable messaging correctly enabled.
- Check the logs for server-side problems.
- For the managed persistent quality of service, check that the associated messaging engine is available.

For further checks that might help you resolve the problem, see also the following troubleshooting tips:
- "A sequence is established but cannot be used, and therefore WS-ReliableMessaging cannot ensure messages are transmitted."
- "A client application is unable to invoke a reliable messaging enabled Web service" on page 667.

A sequence is established but cannot be used, and therefore WS-ReliableMessaging cannot ensure messages are transmitted

If you get an exception like the following exception, then the sequence is established but cannot be used:

```
javax.xml.ws.WebServiceException: org.apache.axis2.AxisFault: The value of wsrm:Identifier is not a known Sequence identifier.
```

For checks that might help you resolve the problem, see the following troubleshooting tips:
- "A sequence is not established, and therefore WS-ReliableMessaging cannot ensure messages are transmitted" on page 667.
- "A client application is unable to invoke a reliable messaging enabled Web service" on page 667.

The reliable messaging managed store is not initialized because the policy set binding is not complete or not valid

If your policy set specifies a managed quality of service, but you have not specified a binding to a messaging engine to support that quality of service, you get the following exception message:

```
CWSKA0102E: The managed Web services reliable messaging storage manager could not be initialized because the policy set binding
 was incomplete or invalid.
```

Perhaps you have attached a managed policy set to your application, and used the default bindings (which do not support the managed qualities of service). You need to create a new binding for your application that specifies a service integration bus and messaging engine to support the managed qualities of service. To do this, see "Attaching and binding a WS-ReliableMessaging policy set to a Web service application using the administrative console" on page 657.

A message is not recovered after a server becomes unavailable, even with the managed persistent quality of service

When the reliable messaging layer receives a request message, it sends an acknowledgement then delivers the message to the target service. There is a marginal possibility that the server hosting the reliable messaging layer could become unavailable after the request message has been acknowledged and before it has been delivered. In this case, the message is only recovered if you are using in-order delivery as well as managed persistent quality of service. To specify in-order delivery, select the WS-ReliableMessaging policy option to "Deliver messages in the order that they were sent" as described in "Configuring the WS-ReliableMessaging policy" on page 907.

Note: There is a performance overhead in using in-order delivery, because messages are held in a queue until they can be delivered in order. However, where the highest level of reliability is paramount it is recommended that you always specify in-order delivery in conjunction with the managed persistent quality of service.

When using reliable messaging with a persistent WS-I RSP profile and WS-SecureConversation, an exception message states that the security context token is not valid

When you use a persistent WS-I RSP policy set, which includes WS-SecureConversation, if the scoping security context token is expired when the server is restarted then WS-ReliableMessaging cannot resend its messages and system messages are written to the log file stating that the reliable messaging sequence was not secured using the correct security token. For example:

```
CWWSS7215E: Cannot get valid security context token from the cache.
```

To ensure that the scoping security context token does not expire before WS-ReliableMessaging can recover and resend its messages, complete the following task: “Configuring WS-SecureConversation to work with WS-ReliableMessaging” on page 656.

WS-ReliableMessaging known restrictions:

The main known restrictions that apply to the implementation of WS-ReliableMessaging in WebSphere Application Server.

- “IBM HTTP Server is not supported as a proxy server with WS-ReliableMessaging”
- “A WS-ReliableMessaging policy can only be applied at application or service level.”
- “WS-SecureConversation must expect the WS-ReliableMessaging headers to be signed”

IBM HTTP Server is not supported as a proxy server with WS-ReliableMessaging

When WS-ReliableMessaging is enabled, you cannot use IBM HTTP Server as a proxy server to route responses back to an individual server in a clustered environment. If you use IBM HTTP Server in this scenario, replies to protocol messages, such as WS-ReliableMessaging CreateSequenceResponse messages, are not routed back to the originating server. This is because WS-ReliableMessaging protocol messages use WS-Addressing affinity headers to ensure that the protocol responses are routed back to the originating server. These affinity headers are supported in IBM WebSphere Application Server proxy server, but are not supported in IBM HTTP Server.

Use the IBM WebSphere Application Server proxy server to route messages from and back to the cluster, instead of IBM HTTP Server.

A WS-ReliableMessaging policy can only be applied at application or service level.

You can only apply a WS-ReliableMessaging policy at application level or service level.

If you apply reliable messaging at service level, then all services must use the same WS-ReliableMessaging policy and bindings values.

You can attach any policy set at operation level. For a policy set that includes the WS-ReliableMessaging policy, attachment at the operation level configures the other components of the policy set (for example WS-Security and WS-Addressing) but any WS-ReliableMessaging configuration at operation level is ignored.

WS-SecureConversation must expect the WS-ReliableMessaging headers to be signed

Although secure conversation allows message headers to remain unsigned, the reliable messaging policy requires the reliable messaging headers to be signed. If you want to use secure conversation and reliable messaging policies in the same policy set, the secure conversation bindings must be configured to require that the reliable messaging headers are signed.

The reliable secure profile default policy sets (WS-I RSP and WS-I RSP ND) are specifically designed and configured to use secure conversation and reliable messaging in the same policy set. If you use a copy of

one of the reliable secure profile default policy sets (WS-I RSP and WS-I RSP ND), no further configuration of the secure conversation bindings is required. Otherwise, see “Configuring WS-SecureConversation to work with WS-ReliableMessaging” on page 656.

WS-ReliableMessaging roles and goals

Computing roles that members of your organization might perform, and how you can use WS-ReliableMessaging to help meet the goals of each role.

For a general description of each of the following roles, see “WebSphere Application Server roles and goals” on page 397.

Application developer

The application developer is responsible for creating the WS-ReliableMessaging requester applications and provider applications. The application developer is responsible for writing the application code and packaging the application into a deployable unit.

Developing

- Goal: Develop a JAX-WS Web service application.

System administrator

The system administrator is responsible for providing the infrastructure, such as configured application servers, through which the applications can be deployed and executed. The system administrator is also responsible for deploying applications into the configured environment, and for maintaining the environment and applications in good working order. This maintenance role includes operational management of state, such as messages and transaction state, and problem diagnosis to determine message or transaction outcomes.

Deploying

- Goal: Configure a policy set instance to enable WS-ReliableMessaging.
- Goal: Install your reliable JAX-WS Web service application.
- Goal: Attach and bind a WS-ReliableMessaging policy set to your application.

Operating

- Goal: Detect and fix problems with WS-ReliableMessaging.

WS-ReliableMessaging - requirements for interaction with other implementations

The information and configuration that is needed for another vendor’s reliable messaging source to send messages to a WebSphere Application Server reliable messaging destination, or for a WebSphere Application Server reliable messaging source to send messages to another vendor’s reliable messaging destination.

Using another vendor’s reliable messaging source to send messages to a WebSphere Application Server reliable messaging destination

For another vendor’s WS-ReliableMessaging implementation to interact with a WebSphere Application Server WS-ReliableMessaging endpoint, the other vendor’s reliable messaging source needs to know the target endpoint address and port for the WebSphere Application Server application that is enabled for reliable messaging. The WS-ReliableMessaging protocol messages are sent to the same endpoint address as the application messages. You can get this address from the WSDL published by the WebSphere Application Server endpoint.

The reliable messaging source controls the endpoint reference used for acknowledgement messages, so the other vendor's product might need to use the WS-Addressing anonymous URI. For more information, see WS-ReliableMessaging - How it works. Whether or not the reliable messaging source uses the WS-Addressing anonymous URI, the WebSphere Application Server reliable messaging destination can work with the reliable messaging source without further configuration.

A WebSphere Application Server reliable messaging destination cannot tell whether or not the reliable messaging source is durable and transactional. If you want durable transactional Web services, check that the other vendor's reliable messaging source supports that mode of operation, as well as configuring the WebSphere Application Server end of the link.

Using a WebSphere Application Server reliable messaging source to send messages to another vendor's reliable messaging destination

For an application in WebSphere Application Server to invoke a Web service using WS-ReliableMessaging, the information required is the target endpoint address and port for the Web service being invoked. The WS-ReliableMessaging protocol messages are sent to the same endpoint address as the application messages. You can usually get this address from the WSDL published by the target Web service.

The WebSphere Application Server Source is provided with additional WS-ReliableMessaging configuration, modeled as part of the policy set associated with the Web service client. The policy set might configure the reliable messaging source to use the WS-Addressing anonymous URI as the address within the endpoint reference used for acknowledgement messages. For more information, see "WS-ReliableMessaging - How it works" on page 636

WebSphere Application Server cannot tell whether the reliable messaging destination is durable and transactional. If you want durable transactional Web services, check that the other vendor's reliable messaging destination supports that mode of operation, as well as configuring the WebSphere Application Server end of the link.

WS-ReliableMessaging - administrative console panels

Links to topics that describe the contents of the administrative console panels that you can use to configure and operate WS-ReliableMessaging. Each topic gives details of the purpose and use of a panel, the administrative console navigation path to the panel, and the values that you can set in each field of the panel.

Configuration panels

- "WS-ReliableMessaging settings" on page 908
- "WS-ReliableMessaging policy binding" on page 910

Runtime panels

This set of panels is available at any of the following scopes within the administrative console:

Cell: **Services** → **Reliable messaging state**

Application server:
Servers → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Additional Properties] Reliable messaging state**

Enterprise application:
Applications → **Enterprise Applications** → ***application_name*** → **[Web Services Properties] Reliable messaging state**

Bus: **Service integration** → **Buses** → ***bus_name*** → **[Services] Reliable messaging state**

Messaging engine:
Service integration → Buses → *bus_name* → [Topology] Messaging engines → *messaging_engine_name* → [Additional Properties] Reliable messaging state

At each of the previous scopes, the panels navigation structure is as follows:

- "Reliable messaging state settings"
  - "Message store collection" on page 673
  - "Inbound sequence collection" on page 679
    - "Inbound sequences settings" on page 681
      - "Acknowledgement state collection" on page 683
      - "Inbound message collection" on page 683
        - "Message settings" on page 678
    - "Export messages settings" on page 684
  - "Outbound sequence collection" on page 674
    - "Outbound sequences settings" on page 676
      - "Outbound message collection" on page 678
        - "Message settings" on page 678
    - "Export messages settings" on page 684

Reliable messaging state settings

This page provides an overview of the WS-ReliableMessaging runtime state. Use this page to manage reliable messaging at run time.

To view this pane in the console, click one of the paths to this panel. For example **Servers → Server Types → WebSphere application servers → *server_name* → [Additional Properties] Reliable messaging state**.

The WS-ReliableMessaging runtime panels are available at many different scopes within the administrative console. For more information, see "WS-ReliableMessaging - administrative console panels" on page 671.

Related tasks

"Detecting and fixing problems with WS-ReliableMessaging" on page 661
The nature of WS-ReliableMessaging is that network and server failures are assumed, and therefore the target Web service or message store might not be available. In these cases, message sequences cannot be completed and collections of Web service messages are held awaiting transmission. You can use the `SystemOut.log` file, system events, and the runtime administrative panels to monitor the system and detect and fix problems with WS-ReliableMessaging.

Runtime tab: Runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

Reliable messaging state

Select the aspect of WS-ReliableMessaging for which you want to view runtime information.

The following icons are displayed here and on several other reliable messaging runtime panels:

	**OK**	Everything here, and (if there is a link) in all runtime panels below this link, is running normally.

	**Warning**	Something here, or (if there is a link) in one of the runtime panels below this link, is in an unusual state and you might need to take some action to resolve it. For example, the system might be awaiting a response from an endpoint. In this case, either the response will be received (in which case you need take no action and the runtime information will be updated to ″OK″) or the reliable messaging destination has stopped acknowledging messages (in which case you need to take some action to resolve the failed sequence).
	**Error**	There is a definite error that you need to take some action to resolve, either here or (if there is a link) in one of the runtime panels below this link.

Note that for troubleshooting purposes you only need to follow links to the sub-panels if states other than ″OK″ are displayed.

Message stores
This page displays the collection of reliable messaging storage managers for the current scope.

Inbound sequences
This page displays the collection of inbound sequences for the current scope. Each inbound sequence is used to receive messages that have been transmitted reliably.

Outbound sequences
This page displays the collection of outbound sequences for the current scope. Outbound sequences are used to transmit messages reliably from the local application to the remote endpoint. Each sequence has a unique identifier.

Message store collection

This page displays the collection of reliable messaging storage managers for the current scope.

To view this pane in the console, click one of the paths to this panel. For example **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Additional Properties] Reliable messaging state** → **Runtime** → **Message store**.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

The WS-ReliableMessaging runtime panels are available at many different scopes within the administrative console. For more information, see “WS-ReliableMessaging - administrative console panels” on page 671.

The following icons are displayed here and on several other reliable messaging runtime panels:

	**OK**	Everything here, and (if there is a link) in all runtime panels below this link, is running normally.
	**Warning**	Something here, or (if there is a link) in one of the runtime panels below this link, is in an unusual state and you might need to take some action to resolve it. For example, the system might be awaiting a response from an endpoint. In this case, either the response will be received (in which case you need take no action and the runtime information will be updated to ″OK″) or the reliable messaging destination has stopped acknowledging messages (in which case you need to take some action to resolve the failed sequence).
	**Error**	There is a definite error that you need to take some action to resolve, either here or (if there is a link) in one of the runtime panels below this link.

Note that for troubleshooting purposes you only need to follow links to the sub-panels if states other than ″OK″ are displayed.

Message store type
For the managed qualities of service, the messages are written to a messaging engine. For the unmanaged non-persistent quality of service, the messages are stored in memory.

Description
The quality of service being used and the application name.

Details
For in-memory stores the only possible value is ″Running″. For messages stored by a messaging engine, the possible values are ″Running″ or ″Messaging engine not contactable″, probably because the messaging engine is not running.

Status
The ″OK″ icon indicates that the message store is running. If the messaging engine is not contactable, the ″Error″ icon is displayed.

Related tasks

“Detecting and fixing problems with WS-ReliableMessaging” on page 661
The nature of WS-ReliableMessaging is that network and server failures are assumed, and therefore the target Web service or message store might not be available. In these cases, message sequences cannot be completed and collections of Web service messages are held awaiting transmission. You can use the `SystemOut.log` file, system events, and the runtime administrative panels to monitor the system and detect and fix problems with WS-ReliableMessaging.

Outbound sequence collection

This page displays the collection of outbound sequences for the current scope. Outbound sequences are used to transmit messages reliably from the local application to the remote endpoint. Each sequence has a unique identifier.

To view this pane in the console, click one of the paths to this panel. For example **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Additional Properties] Reliable messaging state** → **Runtime** → **Outbound sequences**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

The WS-ReliableMessaging runtime panels are available at many different scopes within the administrative console. For more information, see “WS-ReliableMessaging - administrative console panels” on page 671.

The following icons are displayed here and on several other reliable messaging runtime panels:

	**OK**	Everything here, and (if there is a link) in all runtime panels below this link, is running normally.
	**Warning**	Something here, or (if there is a link) in one of the runtime panels below this link, is in an unusual state and you might need to take some action to resolve it. For example, the system might be awaiting a response from an endpoint. In this case, either the response will be received (in which case you need take no action and the runtime information will be updated to ″OK″) or the reliable messaging destination has stopped acknowledging messages (in which case you need to take some action to resolve the failed sequence).
	**Error**	There is a definite error that you need to take some action to resolve, either here or (if there is a link) in one of the runtime panels below this link.

Note that for troubleshooting purposes you only need to follow links to the sub-panels if states other than ″OK″ are displayed.

Note:

If reliable messaging is running on a cluster, when you examine the runtime state of inbound or outbound sequences you see multiple entries for each sequence. This is because, although reliable messaging only binds to one messaging engine in a cluster, the runtime panel is calculating and displaying the sequence information once for every cluster member.

Ignore the duplicate entries. Note that the slight differences in the statistics being displayed for each duplicate entry is due to the entries being created sequentially, while polling for messages continues.

Sequence identifier
This URI is the unique identifier for the sequence.

Associated application
The application that created the sequence.

Target endpoint URI
The destination to which messages are transmitted.

Message depth
The count of messages, held by the reliable messaging layer, that have not yet been transferred.

Messages sent
The total count of messages sent by the application for this sequence.

Details
The current state of the sequence. ″Establishing″ indicates that the sequence is awaiting a CreateSequenceResponse message from the reliable messaging destination; ″Active″ indicates that the sequence has been established; ″Cannot contact the remote endpoint″ indicates that the sequence has been established but the reliable messaging destination has stopped acknowledging messages; ″Sequence closing″ indicates that the sequence is closing and will accept no new messages; ″Sequence closed″ indicates that the sequence has been closed and will accept no new messages; ″Sequence terminating″ indicates that the sequence is terminating and will accept no new messages; ″The inbound side has lost state in a terminate″ indicates that the sequence has terminated with unacknowledged messages outstanding; ″The sequence has timed out″ indicates that the sequence has timed out.

Status
The icon indicates ″OK″, ″Warning″ or ″Error″ as previously described on this page. A more precise indication of the sequence state is given in the ″Details″ column.

Buttons

Re-allocate messages	Click this button to re-allocate the messages on the selected sequences to new sequences.
Export unsent messages	Click this button to export the messages from the selected sequences to ZIP files. If you select any sequences that have no messages to export, a warning or error message is displayed.

Close sequence	Click this button to close the selected sequences and send a CloseSequence message to indicate that the sequence is complete and will not be sending any further messages. The *close* protocol does not delete the resources for the sequence, so you can still access any undispatched or unsent messages. If you are using Version 1.0 of the WS-ReliableMessaging specification (which does not support this option) an error message is displayed. For more information on the reliable messaging *close* protocol, see “WS-ReliableMessaging: supported specifications and standards” on page 643.
Terminate sequence	Click this button to close the selected sequences and send a TerminateSequence message to indicate that the sequence is complete and will not be sending any further messages. The *terminate* protocol deletes all resources for the sequence. For more information on the reliable messaging *terminate* protocol, see “WS-ReliableMessaging: supported specifications and standards” on page 643.
Delete sequence	Click this button to delete the selected sequences without sending a TerminateSequence message.

See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General properties

Sequence identifier
This URI is the unique identifier for the sequence.

Required	No
Data type	Text

Runtime identifier
The identifier that is used within the application server runtime environment.

Required	No
Data type	Text

Associated application
The application that created the sequence.

Required	No
Data type	Text

WS-Addressing namespace
The WS-Addressing namespace that is associated with the sequence.

Required	No
Data type	Text

WS-ReliableMessaging namespace
The namespace that is defined by the version of the WS-ReliableMessaging specification used by the sequence.

Required	No
Data type	Text

Target endpoint URI
The destination to which messages are transmitted.

Required	No
Data type	Text

Reply to address
The WS-Addressing replyTo address that is used for WS-ReliableMessaging protocol messages.

Required	No
Data type	Text

Acknowledgement address
The address used for WS-ReliableMessaging acknowledgements.

Required	No
Data type	Text

Message depth
The count of messages, held by the reliable messaging layer, that have not yet been transferred.

Required	No
Data type	Text

Messages sent
The total count of messages sent by the application for this sequence.

Required	No
Data type	Text

Outbound message collection
The messages on the outbound sequence.

To view this pane in the console, click one of the paths to this panel. For example **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Additional Properties] Reliable messaging state** → **Runtime** → **Outbound sequences** → ***outbound_sequence_name*** → **[Additional properties] Messages**.

Inbound sequence collection

This page displays the collection of inbound sequences for the current scope. Each inbound sequence is used to receive messages that have been transmitted reliably.

To view this pane in the console, click one of the paths to this panel. For example **Servers → Server Types → WebSphere application servers → *server_name* → [Additional Properties] Reliable messaging state → Runtime → Inbound sequences**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

The WS-ReliableMessaging runtime panels are available at many different scopes within the administrative console. For more information, see "WS-ReliableMessaging - administrative console panels" on page 671.

The following icons are displayed here and on several other reliable messaging runtime panels:

	**OK**	Everything here, and (if there is a link) in all runtime panels below this link, is running normally.

	**Warning**	Something here, or (if there is a link) in one of the runtime panels below this link, is in an unusual state and you might need to take some action to resolve it. For example, the system might be awaiting a response from an endpoint. In this case, either the response will be received (in which case you need take no action and the runtime information will be updated to ″OK″) or the reliable messaging destination has stopped acknowledging messages (in which case you need to take some action to resolve the failed sequence).
	**Error**	There is a definite error that you need to take some action to resolve, either here or (if there is a link) in one of the runtime panels below this link.

Note that for troubleshooting purposes you only need to follow links to the sub-panels if states other than ″OK″ are displayed.

Note:

If reliable messaging is running on a cluster, when you examine the runtime state of inbound or outbound sequences you see multiple entries for each sequence. This is because, although reliable messaging only binds to one messaging engine in a cluster, the runtime panel is calculating and displaying the sequence information once for every cluster member.

Ignore the duplicate entries. Note that the slight differences in the statistics being displayed for each duplicate entry is due to the entries being created sequentially, while polling for messages continues.

Sequence identifier
This URI is the unique identifier for the sequence.

Associated application
The application that is receiving messages from the sequence.

Message depth
The count of messages, held by the reliable messaging layer, that have not yet been transferred.

Messages received
The total count of application messages received for the sequence since its creation.

Details
The current state of the sequence. ″Connected″ indicates that the sequence has been established; ″Awaiting redelivery of a missing msg.″ indicates that there is a gap in the sequence; ″Closed″ indicates that the sequence has been closed; ″Failed due to missing message″ indicates that the sequence terminated with a gap in the sequence.

Status
The icon indicates ″OK″, ″Warning″ or ″Error″ as previously described on this page. A more precise indication of the sequence state is given in the ″Details″ column.

Buttons

Dispatch messages to application	Click this button to dispatch the messages on the selected sequences to the associated applications.
Export undispatched messages	Click this button to export the messages from the selected sequences to ZIP files. If you select any sequences that have no messages to export, a warning or error message is displayed.

Close sequence	Click this button to close the selected sequences and send a CloseSequence message to indicate that the sequence is complete and will not be sending any further messages. The *close* protocol does not delete the resources for the sequence, so you can still access any undispatched or unsent messages. If you are using Version 1.0 of the WS-ReliableMessaging specification (which does not support this option) an error message is displayed. For more information on the reliable messaging *close* protocol, see "WS-ReliableMessaging: supported specifications and standards" on page 643.
Terminate sequence	Click this button to close the selected sequences and send a TerminateSequence message to indicate that the sequence is complete and will not be sending any further messages. The *terminate* protocol deletes all resources for the sequence. For more information on the reliable messaging *terminate* protocol, see "WS-ReliableMessaging: supported specifications and standards" on page 643.
Delete sequence and messages	Click this button to delete the selected sequences and all their messages. Use this in cases where the remote endpoint is unable to respond to any reliable messaging protocol messages, and therefore the sequence cannot be closed or terminated.

WS-Notification Service client settings

Use this page to manage policy sets and bindings or to access additional information for this WS-Notification service client.

To view this pane in the console, click the following path:

Services → **Service clients** → ***ws-notification_service_client_name***

This panel shows the policy set and binding configuration information for a single Version 7.0 WS-Notification service client, and also gives you links to the associated service integration bus and WS-Notification service.

Note: The same policy set and binding configuration information can also be viewed and modified through the "Service client policy sets and bindings" panel, which gives an upper-level view of all service clients associated with a particular WS-Notification service. Through the "Service client policy sets and bindings" panel, you can assign a policy set or binding to a specific service client, or to all clients for the service. To view the "Service client policy sets and bindings" panel for a given WS-Notification service, click one of the following paths:

- **Service integration** → **WS-Notification** → **Services** → ***service_name*** → **[Additional properties] Outbound request policy sets and bindings**
- **Service integration** → **Buses** → ***bus_name*** → **[Services] WS-Notification services** → ***service_name*** → **[Additional properties] Outbound request policy sets and bindings**

Related concepts

WS-Notification and policy set configuration

"WS-ReliableMessaging default policy sets" on page 811
The WS-ReliableMessaging default policy sets are pre-configured to provide reliable message exchange between Web services. Two of these policy sets (WS-I RSP and WS-I RSP ND) are immediately available, and the rest are readily available for import from a default repository.

Related tasks

"Managing policy sets using the administrative console" on page 803
You can use policy sets, or assertions that define services, to simplify your Web services configuration because policy sets group security and other Web services settings into reusable units. You can use the administrative console to create, modify, and delete custom policy sets.

"Defining and managing policy set bindings" on page 824
Policy set bindings contain platform specific information, like keystore, authentication information or persistent information, required by a policy set attachment. Use this task to create and manage bindings.

"Adding assured delivery to Web services through WS-ReliableMessaging" on page 634
WS-ReliableMessaging is an interoperability standard for the reliable transmission of messages between two endpoints. With WS-ReliableMessaging, you can make your SOAP over HTTP-based Web services reliable without having to write custom code. You can get different qualities of service with WS-ReliableMessaging. These range from protecting against loss of messages across a network, through to protecting against a server becoming unavailable.

Using WS-Notification for publish and subscribe messaging for Web services

Administrative console preference settings
Use the preference settings to specify how you want information to display on an administrative console panel. The preference settings vary from one administrative console panel to another.

Configuration tab: Configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Service client
Specifies the name of the service client that is displayed.

Additional Properties

Service integration bus
The system integration bus hosting this WS-Notification service Web service client.

WS-Notification service
The WS-Notification service hosting this client.

Policy Set Attachments

This section allows you to attach a policy set to the WS-Notification service client. You can complete the attachment by providing system-specific configuration when you assign the appropriate binding.

For more information about the policy set attachment options, see “Service client settings” on page 756.

Note: For WS-Notification service clients, policy set attachments are not supported at the endpoint (port) or operation level. Therefore, endpoints or operations are not selectable, and they are shown as inheriting any policy set or binding that is attached to the service client.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

About policy set bindings

In WebSphere Application Server Version 7.0, there are two types of bindings, application-specific bindings and general bindings.

Application specific binding

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can only create application-specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. See service providers policy sets and bindings collection. Similarly, for service clients, you can only create application-specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

General bindings

General bindings are new for WebSphere Application Server Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust

service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general provider policy set bindings by accessing **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. See “Defining and managing service client or provider bindings” on page 831. General provider policy set bindings might also be used for trust service attachments.

Buttons

Attach Client Policy Set	Click this button to view a list of policy sets available for attachment to the selected WS-Notification service client. Select a policy set from the list to attach the policy set to the selected service client. To close the drop-down list, click **Attach Client Policy Set**.
Detach Client Policy Set	Click this button to detach a policy set from a selected WS-Notification service client. After the policy set is detached, if there is no policy set attached at the upper level (that is, at the level of the WS-Notification service), the **Attached Client Policy Set** column displays `None` and the **Binding** column displays `Not Applicable`. If there is a policy set attached at the level of the WS-Notification service, the **Attached Client Policy Set** column displays *`policy_set_name`*`(inherited)` and the binding used for the upper level attachment is applied. The binding name is displayed with `(inherited)` after it.
Assign Binding	Click this button to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options: • Default • New Application Specific Binding For more information about these options, see “Service client settings” on page 756. To close the drop-down list, click Assign Binding.

Using WS-Transaction policy to coordinate transactions or business activities for Web services

You can use WS-Transaction policy to configure how a Java API for XML Web Services (JAX-WS) service or client handles Web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) context.

About this task

The Web Services Atomic Transaction (WS-AT) support in the application server provides transactional quality of service to the Web services environment. Distributed Web services applications, and the resources they use, can take part in distributed global transactions. With Web Services Business Activity (WS-BA) support in the application server, Web services on different systems can coordinate activities that are more loosely coupled than atomic transactions. Such activities can be difficult or impossible to roll

back atomically, and therefore require a compensation process if an error occurs.

- Learn about WS-Transaction policy.
- Configure a JAX-WS client for WS-Transaction context.
- Configure a JAX-WS Web service for WS-Transaction context.
- Configure the WS-Transaction policy.
- Configure a WS-Transaction policy set using the wsadmin tool.
- Configure transaction properties for an application server.
- Configure the WS-Transaction specification level using the wsadmin tool.
- Configure WS-Transaction support in a secure environment.
- Configure an intermediary node for Web services transactions.
- Enable WebSphere Application Server to use an intermediary node for Web services transactions.
- Configure a server to use business activity support.
- Create an application that uses the Web Services Business Activity support.

Learning about WS-Transaction

WS-Transaction is an interoperability standard that includes the WS-AtomicTransaction, WS-BusinessActivity, and WS-Coordination specifications. Use these topics to learn more about WS-Transaction.

About this task

Note: In this release, when you work with policy sets, you can configure the WS-Transaction policy type for the WS-AtomicTransaction (WS-AT) and the WS-BusinessActivity (WS-BA) protocols. You can configure the way in which a Java API for XML Web Services (JAX-WS) client handles WS-AT or WS-BA context. You can specify that the client must send context, can send context if it is available, or must not send context.

The Web Services Atomic Transaction (WS-AT) support in the application server provides transactional quality of service to the Web services environment. Distributed Web services applications, and the resources they use, can take part in distributed global transactions. With Web Services Business Activity (WS-BA) support in the application server, Web services on different systems can coordinate activities that are more loosely coupled than atomic transactions. Such activities can be difficult or impossible to roll back atomically, and therefore require a compensation process if an error occurs. Web Services Coordination (WS-COOR) specifies a CoordinationContext and a Registration service with which participant Web services can enlist to take part in the protocols that are offered by specific coordination types.

To learn about WS-Transaction in WebSphere Application Server, see the following topics:

- “Web Services Atomic Transaction support in the application server”
- “Web Services Business Activity support in the application server” on page 693
- “Web Services transactions, firewalls and intermediary nodes” on page 695
- “Transaction compensation and business activity support” on page 696
- “WS-Transaction and mixed-version cells” on page 701

Web Services Atomic Transaction support in the application server

The Web Services Atomic Transaction (WS-AT) support in the application server provides transactional quality of service to the Web services environment. Distributed Web services applications, and the resources they use, can take part in distributed global transactions.

Web Services protocols provide standard ways of defining Web services applications, allowing the applications to operate independently of the product, platform, or programming language that is used. The

WS-AT support is an implementation of the following specifications on the application server. These specifications define a set of Web services that enable Web services applications to participate in global transactions that are distributed across the heterogeneous Web services environment.

- WS-AT is a specific coordination type that defines protocols for atomic transactions. The specifications are:
  - Web Services Atomic Transaction Version 1.0
  - Web Services Atomic Transaction Version 1.1
- Web Services Coordination (WS-COOR) specifies a CoordinationContext and a Registration service with which participant Web services can enlist to take part in the protocols that are offered by specific coordination types. The specifications are:
  - Web Services Coordination Version 1.0
  - Web Services Coordination Version 1.1

The WS-AT support is an interoperability protocol that introduces no new programming interfaces for transactional support. Global transaction demarcation is provided by standard enterprise application use of the Java Transaction API (JTA) UserTransaction interface. If an application component that is running under a global transaction makes a Web services request, a WS-AT CoordinationContext is implicitly propagated to the target Web service, but only if the appropriate application deployment descriptors have been set, as described in Configuring transactional deployment attributes.

If the application server is the system hosting the target endpoint for a Web services request that contains a WS-AT CoordinationContext, the application server automatically establishes a subordinate JTA transaction in the target runtime environment that becomes the transactional context under which the target Web services application runs.

The following figure, shows a transaction context shared between two application servers for a Web services request that contains a WS-AT CoordinationContext.

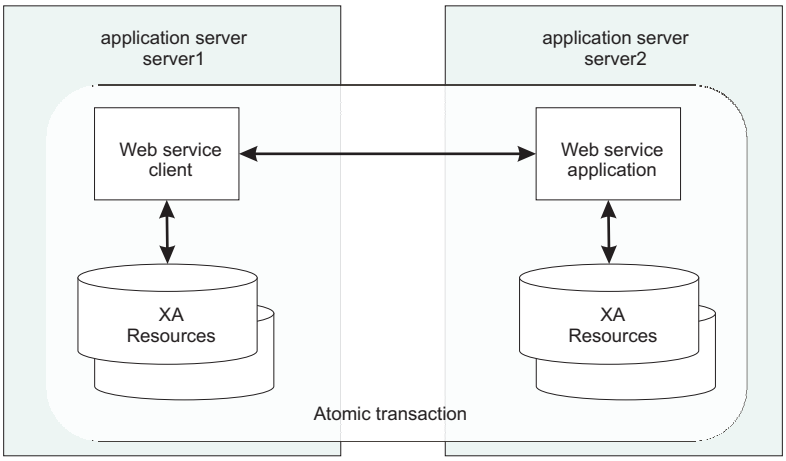

Figure 8. Transaction context shared between two application servers

You can configure the policies for the WS-AtomicTransaction protocol. You can configure whether a client propagates, and a server receives, a WS-AT context. To ensure that a client always sends WS-AtomicTransaction context when it makes an outbound service request, you must associate a policy set with the client, where the policy set must include the WS-Transaction policy type, and this policy type must have a WS-AtomicTransaction setting of Mandatory. Alternatively, if you know that the client always invokes remote endpoints that include the WS-AtomicTransaction ATAssertion policy type attribute, you can configure the client to apply the WS-Policy configuration of the provider so that the client adopts the mandatory policy of the provider automatically.

To ensure that any requests that a Web services provider receives include a WS-AtomicTransaction context, you must associate a policy set with the provider, where the policy set must include the WS-Transaction policy type, and this policy type must have a WS-AtomicTransaction setting of Mandatory.

To ensure that a client or provider never use WS-AtomicTransaction context, you must associate a policy set with the client or provider, where the policy set includes the WS-Transaction policy type, and this policy type must have a WS-AtomicTransaction setting of Never. You might use this configuration for environments where you do not want Web services requests to create a tight coupling between a client and a provider, for example when there are requests between enterprises.

If there is no policy set associated with a client or provider, or the WS-Transaction policy type is not included in the policy set, the default WS-Transaction behavior is used.

WS-AT support restrictions

In this version of the application server, WS-AT contexts cannot be started from a non-recoverable client process.

Application design considerations

WS-AT is a two-phase commit transaction protocol and is suitable for short duration transactions only.

An atomic transaction coordinates resource managers that isolate transactional updates by holding transactional locks on resources. Therefore, it is generally not recommended that WS-AT transactions are distributed across enterprise domains. Inter-enterprise transactions typically require a looser semantic than two-phase commit, and in such scenarios, it can be more appropriate to use a compensating business transaction, for example, a Web Services Business Activity, or be part of a Business Process Execution Language (BPEL) process.

WS-AT is most appropriate for distributing transaction context across Web services that are deployed in a single enterprise. Only request-response message exchange patterns carry transaction context because the originator (application or container) of a transaction must be sure that all business tasks that are run under that transaction have finished before requesting the completion of a transaction. Web services invoked by a one-way request never run under the transaction of the requesting client.

The effect of service faults on WS-AT transactions is similar to the effect of Enterprise JavaBeans (EJB) application exceptions on transactions, as described in the EJB specification. If a service that is running under a requester's WS-AT transaction returns a fault, the application server does not automatically mark the transaction rollback-only. The exception handler of the requester decides whether the transaction can progress and chooses whether to mark the transaction rollback-only. If the requester is running in the application server, the standard JTA or EJB APIs can be used to mark the transaction rollback-only. The service component that generates the fault might, itself, mark the transaction rollback-only before returning the fault. If the implementation of the service component encounters a system exception, it typically allows its container to handle the exception. Application server containers automatically mark any received transaction context rollback-only when handling a system exception that is generated by a service implementation.

Application development considerations

There are no specific development tasks required for Web services applications to take advantage of WS-AT.

For Java API for XML-based RPC (JAX-RPC) applications, there are some application deployment descriptors that you must set appropriately, as described in Configuring transactional deployment attributes. The JAX-RPC run time supports WS-AT 1.0.

Note: WebSphere Application Server supports both the WS-Transaction 1.1 and the WS-Transaction 1.0 specifications. You can configure the default WS-Transaction specification level to use for outbound requests if the specification level that the server requires cannot be determined from the provider policy. This applies to outbound requests that include a Web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) coordination context.

For Java API for XML-Based Web Services (JAX-WS) applications, enable WS-AT support by creating a policy set, adding the WS-Transaction policy type to the policy set, optionally configuring the policy type, and attaching the policy set to the application or client that will be involved in the WS-AT communication. The JAX-WS run time supports WS-AT 1.0, WS-AT 1.1 and the WS-Policy assertion for WS-AT.

When the JAX-WS runtime receives an inbound request, both WS-Transaction 1.0 and WS-Transaction 1.1 specification levels are supported. When an outbound JAX-WS request is sent, only one specification level can be used. If WS-Transaction WS-Policy assertions are available, either from the Web Services Description Language (WSDL) of the target Web service, or from the WS-Transaction policy type of the client, the specification level that is applicable to the client and the target Web service is used. For example, if the hosting environment of the target Web service supports only WS-Transaction 1.0, WS-AT 1.0 is used. If both specification levels are applicable, or if no WS-Transaction WS-Policy assertions are available, the default WS-Transaction specification level that is set in the Transaction service settings is used.

To move a JAX-WS application that was using WS-AT 1.0 to use WS-AT 1.1, alter the policy set that is attached to the application; you do not need to change the application.

The default behavior when there is no effective policy set, or when the WS-Transaction policy type is not included in the effective policy set, is as follows:

- For a client, if the client does not consider the policy of the provider, the client does not send any WS-AT or Web Services Business Activity (WS-BA) context. This behavior is equivalent to a WS-Transaction policy setting of Never.
- For a client, if the client considers the policy of the provider, the client sends WS-AT or WS-BA context if the policy of the provider includes WS-AT or WS-BA assertions. This behavior is equivalent to a WS-Transaction policy setting of Supports.
- For a server, the server does not receive any WS-AT or WS-BA context. This behavior is equivalent to a WS-Transaction policy configuration setting of Never.

Application developers do not need to explicitly register WS-AT participants. The application server run time takes responsibility for the registration of WS-AT participants, in the same way as the registration of XAResources in the JTA transaction to which the WS-AT transaction is federated. At transaction completion time, all XAResources and WS-AT participants are coordinated atomically by the application server transaction service.

If a JTA transaction is active on the thread when a Web services application request is made, the transaction is propagated across on the Web services request and established in the target environment. This process is similar to the distribution of transaction context over IIOP, as described in the EJB specification. Any transactional work performed in the target environment becomes part of the same global transaction.

WS-Transaction policy assertions

If you configure the policies for the WS-Transaction protocol for a provider, this configuration affects the assertions that are included in any WSDL that is generated for the Web service with which the policy type is associated. The WS-Policy assertion that is used to describe the transactional requirements of a client or provider that uses WS-AtomicTransaction is ATAssertion. If the WS-Transaction policy type has a WS-AtomicTransaction setting of Mandatory or Supports, a policy assertion is included in the WSDL.

The application server can also parse, understand, and apply such assertions that are in WSDL that it parses.

The following example shows WSDL where the WS-AtomicTransaction ATAssertion indicates that an endpoint must be invoked with WS-AT context included in the request message, and that the context can be in WS-Transaction 1.0 or 1.1 format. There are two namespaces and there are two assertions; one for each WS-Transaction specification level, using the WS-Policy ExactlyOne operator to show that the client must choose which specification level to use.

```
<wsdl:definitions targetNamespace="bank.example.com"
     xmlns:tns="bank.example.com"
     xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
     xmlns:wsp="http://schemas.xmlsoap.org/ws/2004/09/policy"
     xmlns:wsat11="http://docs.oasis-open.org/ws-tx/wsat/2006/06"
     xmlns:wsat10="http://schemas.xmlsoap.org/ws/2004/10/wsat"
     xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/
     oasis-200401-wss-wssecurity-utility-1.0.xsd">
     <wsp:Policy wsu:Id="ATPolicy">
         <wsp:ExactlyOne>
             <wsat11:ATAssertion />
             <wsat10:ATAssertion />
             <!-- omitted assertions -->
         </wsp:ExactlyOne />

     <wsdl:binding name="BankBinding" type="tns:BankPortType">
          <!-- omitted elements -->
          <wsdl:operation name="TransferFunds">
               <wsp:PolicyReference URI="#ATPolicy" wsdl:required="true"/>
               <!-- omitted elements -->
          </wsdl:operation>
     </wsdl:binding>
</wsdl:definitions>
```

Web Services Business Activity support in the application server

With Web Services Business Activity (WS-BA) support in the application server, Web services on different systems can coordinate activities that are more loosely coupled than atomic transactions. Such activities can be difficult or impossible to roll back atomically, and therefore require a compensation process if an error occurs.

Web Services protocols are defined by the Organization for the Advancement of Structured Information Standards (OASIS) group and provide standard ways of defining Web services applications, allowing the applications to operate independently of the product, platform or programming language that is used. The Web Services Business Activity (WS-BA) support is an implementation of the following specifications in the application server. These specifications define a set of protocols that enable Web services applications to participate in loosely coupled business processes that are distributed across the heterogeneous Web services environment, with the ability to compensate actions if an error occurs. For example, an application that sends an e-mail cannot retrieve that e-mail following a failure in the business task. However, the application can provide a business-level compensation handler that sends another e-mail advising of the new circumstances. A *business activity* is a group of general tasks that you want to link together so that the tasks have an agreed outcome.

- WS-BA is a specific coordination type that defines protocols for business activities. The specifications are:
  - Web Services Business Activity Version 1.0
  - Web Services Business Activity Version 1.1
- Web Services Coordination (WS-COOR) specifies a CoordinationContext and a Registration service with which participant Web services can enlist to take part in the protocols that are offered by specific coordination types. The specifications are:
  - Web Services Coordination Version 1.0
  - Web Services Coordination Version 1.1

In addition to supporting the WS-BA interoperability protocol, the application server provides a programming interface for creating business activities and compensation handlers. With this programming interface, you can specify compensation data and check or alter the status of a business activity.

You can also use this compensation facility with applications that are not Web services, as long as these applications involve communication between WebSphere Application Servers only. See the related topics for more information.

You can configure the policies for the WS-BusinessActivity protocol. You can configure whether a client propagates, and a server receives, a WS-BA context. To ensure that a client always sends WS-BusinessActivity context when it makes an outbound service request, you must associate a policy set with the client, where the policy set must include the WS-Transaction policy type, and this policy type must have a WS-BusinessActivity setting of Mandatory. Alternatively, if you know that the client always invokes remote endpoints that include the WS-BusinessActivity BAAtomicOutcomeAssertion policy type attribute, you can configure the client to apply the WS-Policy configuration of the provider so that the client adopts the mandatory policy of the provider automatically.

To ensure that any requests that a Web services provider receives includes a WS-BusinessActivity context, you must associate a policy set with the provider, where the policy set must include the WS-Transaction policy type, and this policy type must have a WS-BusinessActivity setting of Mandatory.

To ensure that a client or provider never use WS-BusinessActivity context, you must associate a policy set with the client or provider, where the policy set includes the WS-Transaction policy type, and this policy type must have a WS-BusinessActivity setting of Never. You might use this configuration for environments where you do not want Web services requests to create a tight coupling between a client and a provider, for example when there are requests between enterprises.

If no policy set is associated with a client or provider, or the WS-Transaction policy type is not included in the policy set, the default WS-Transaction behavior is used.

Application development considerations

No specific development tasks are required for Web services applications to take advantage of WS-BA.

For Java API for XML-based RPC (JAX-RPC) applications, any Enterprise JavaBeans (EJB) component that is configured to run under a BusinessActivity scope automatically propagates that scope when it makes an outbound JAX-RPC Web services request. The JAX-RPC run time supports WS-BA 1.0.

For Java API for XML-Based Web Services (JAX-WS) applications, enable WS-BA support by creating a policy set, adding the WS-Transaction policy type to the policy set, optionally configuring the policy type, and attaching the policy set to the application or client that will be involved in the WS-BA communication. The JAX-WS run time supports WS-BA 1.0, WS-BA 1.1, and the WS-Policy assertion for WS-BA.

When the JAX-WS run time receives an inbound request, both WS-Transaction 1.0 and WS-Transaction 1.1 specification levels are supported. When an outbound JAX-WS request is sent, only one specification level can be used. If WS-Transaction WS-Policy assertions are available, either from the Web Services Description Language (WSDL) of the target Web service, or from the WS-Transaction policy type of the client, the specification level that is applicable to the client and the target Web service is used. For example, if the hosting environment of the target Web service supports only WS-Transaction 1.0, WS-BA 1.0 is used. If both specification levels are applicable, or if no WS-Transaction WS-Policy assertions are available, the default WS-Transaction specification level that is set in the Transaction service settings is used.

The default behavior when there is no effective policy set, or when the WS-Transaction policy type is not included in the effective policy set, is as follows:

- If a client does not consider the policy of the provider, the client does not send any Web Service Atomic Transaction (WS-AT) or WS-BA context. This behavior is equivalent to a WS-Transaction policy configuration setting of Never.
- If a client does consider the policy of the provider, the client sends WS-AT or WS-BA context if the policy of the provider includes WS-AT or WS-BA assertions. This behavior is equivalent to a WS-Transaction policy configuration setting of Supports.
- A server does not receive any WS-AT or WS-BA context. This behavior is equivalent to a WS-Transaction policy configuration setting of Never.

WS-Transaction policy assertions

If you configure the policies for the WS-BusinessActivity protocol for a provider, this affects the assertions that are includes in any WSDL that is generated for the Web service with which the policy type is associated. The WS-Policy assertion that is used to describe the compensation requirements of a client or provider that uses WS-BusinessActivity is BAAtomicOutcomeAssertion. If the WS-Transaction policy type has a WS-BusinessActivity setting of Mandatory or Supports, a policy assertion is included in the WSDL.

The application server can also parse, understand, and apply such assertions that are in WSDL that it parses.

The following example shows WSDL where the WS-BusinessActivity BAAtomicOutcomeAssertion indicates that an endpoint must be invoked with WS-BA context included in the request message, and that the context can be in WS-Transaction 1.0 or 1.1 format. There are two namespaces and two assertions; one for each WS-Transaction specification level, using the WS-Policy ExactlyOne operator to show that the client must choose which specification level to use.

```
<wsdl:definitions targetNamespace="bank.example.com"
     xmlns:tns="bank.example.com"
     xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
     xmlns:wsp="http://schemas.xmlsoap.org/ws/2004/09/policy"
     xmlns:wsat11="http://docs.oasis-open.org/ws-tx/wsba/2006/06"
     xmlns:wsat10="http://schemas.xmlsoap.org/ws/2004/10/wsba"

          </wsdl:operation>
     </wsdl:binding>
</wsdl:definitions>
```

Web Services transactions, firewalls and intermediary nodes

You can configure your system to enable propagation of Web Services Atomic Transactions (WS-AT) message contexts and Web Service Business Activities (WS-BA) message contexts across firewalls or outside the WebSphere Application Server domain. With these configurations, you can distribute Web service applications that use WS-AT or WS-BA across disparate systems.

The topologies that are available to you are as follows:

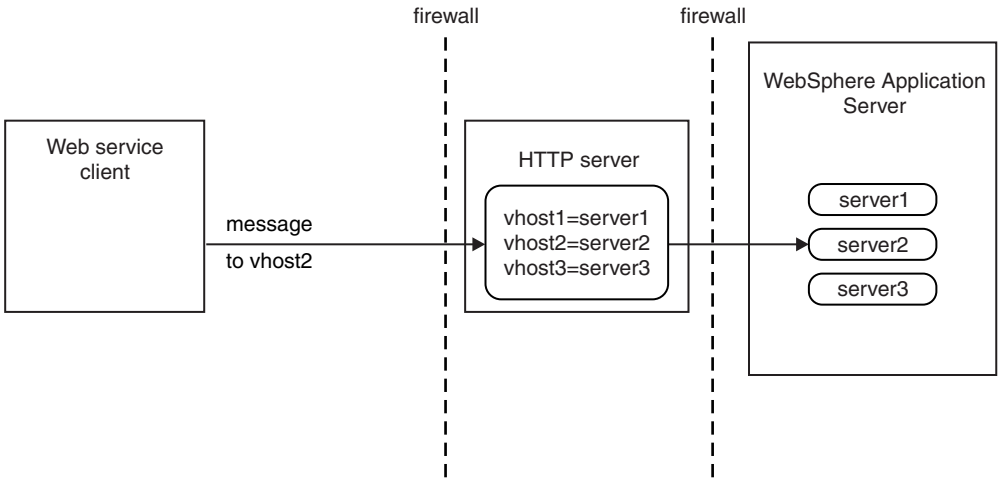
Direct connection

No intermediary node exists in this topology. The client communicates directly with the specific WebSphere Application Server on which the target service resides.

HTTP server, such as IBM HTTP Server

In this topology, the client communicates with an HTTP server, which always routes the client requests and Web services transaction protocol messages to a specific WebSphere Application Server. Also, you must configure the HTTP server for Web services transactions, that is, configure it to deliver Web services transaction protocol messages to the appropriate WebSphere Application Server.

Transactional integrity is assured, because recovery processing occurs after the failed server restarts.



Transaction compensation and business activity support

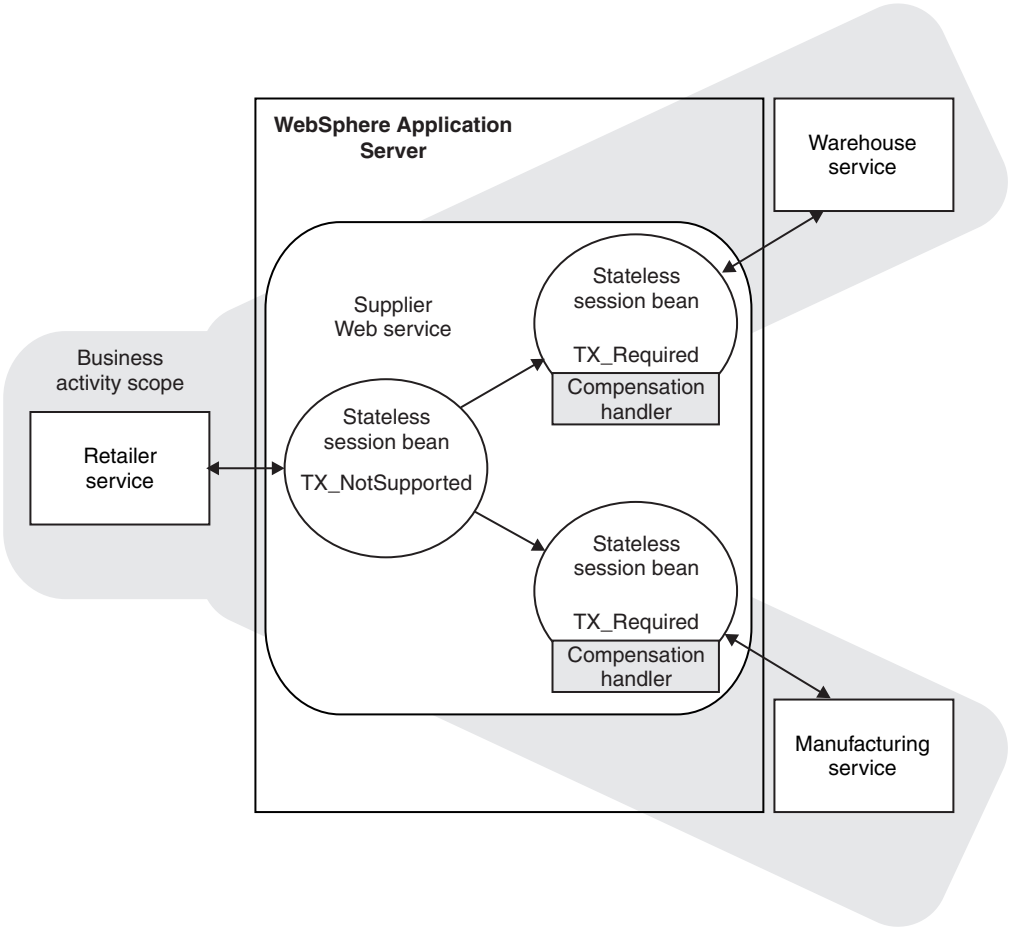
A *business activity* is a collection of tasks that are linked together so that they have an agreed outcome. Unlike atomic transactions, activities such as sending an e-mail can be difficult or impossible to roll back atomically, and therefore require a compensation process in the event of an error. The WebSphere Application Server business activity support provides this compensation ability through *business activity scopes*.

When to use business activity support

Use the business activity support when you have an application that requires compensation. An application requires compensation if its operations cannot be atomically rolled back. Typically, this scenario is because of one of the following reasons:

- The application uses multiple non-extended-architecture (XA) resources.
- The application uses more than one atomic transaction, for example, enterprise beans that have **Requires new** as the setting for the **Transaction** field in the container transaction deployment descriptor.
- The application does not run under a global transaction.

The following diagram shows a simple Web service application that uses the business activity support. The Retailer, Warehouse and Manufacturing services are running in non-WebSphere Application Server environments. The Retailer service calls the Supplier service, running on WebSphere Application Server, which delegates tasks to the Warehouse and Manufacturing services. The implementation of the Supplier service contains a stateless session bean, which calls other stateless session beans that are associated with the Warehouse and Manufacturing services, and that perform work that can be compensated. These other session beans each have a *compensation handler*, a piece of logic that is associated with an application component at run time, and performs compensation activity such as resending an e-mail.



Application design considerations

Business activity contexts are propagated with application messages, and can therefore be distributed between application components that are not co-located in the same server. Unlike atomic transaction contexts, business activity contexts are propagated on both synchronous (blocking) call-response messages and asynchronous one-way messages. An application component that runs under a business activity scope is responsible for ensuring that any asynchronous work it initiates is complete before the component's own processing is complete. An application that initiates asynchronous work using a fire-and-forget message pattern must not use business activity scopes, because such applications have no means of detecting whether this asynchronous processing has completed.

Only enterprise beans that have container-managed transactions can use the business activity functionality. Enterprise beans that exploit business activity scopes can offer Web service interfaces, but can also offer standard enterprise bean local or remote Java interfaces. Business activity context is propagated in Web service messages using a standard, interoperable Web Services Business Activity (WS-BA) `CoordinationContext` element. WebSphere Application Server can also propagate business activity context on RMI calls to enterprise beans when Web services are not being used, but this form of the context is not interoperable with non-WebSphere Application Server environments. You might want to use this homogeneous scenario if you require compensation for an application that is internal to your business. If you want to use business activity compensation in a heterogeneous environment, expose your application components as Web services.

Business activity contexts can be propagated across firewalls and outside the WebSphere Application Server domain. The topology that you use to achieve this propagation can affect the high availability and affinity behavior of the business activity transaction.

Application development and deployment considerations

WebSphere Application Server provides a programming model for creating business activity scopes, and for associating compensation handlers with those business activity scopes. WebSphere Application Server also provides an application programming interface to specify compensation data, and check or alter the status of a business activity. To use the business activity support you must set certain application deployment descriptors appropriately, provide a compensation handler class if required, and enable business activity support on any servers that run the application.

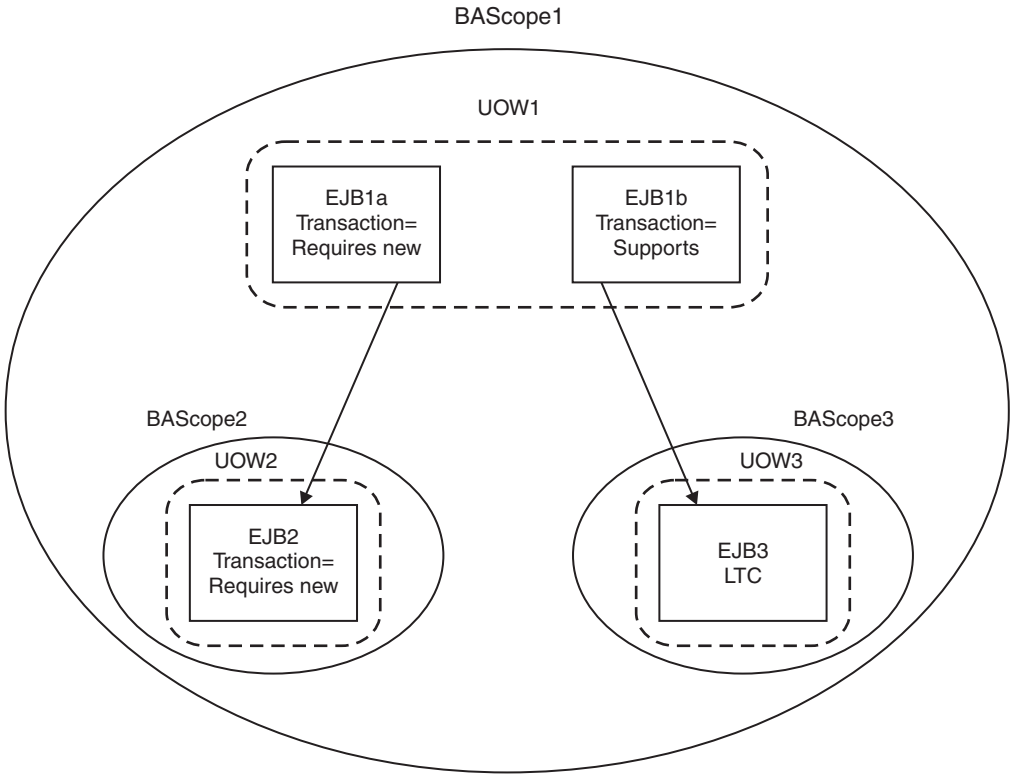
Business activity scopes

The scope of a business activity is that of a core WebSphere Application Server unit of work: a global transaction, an activity session, or local transaction containment (LTC). A business activity scope is not a new unit of work (UOW); it is an attribute of an existing core UOW. Therefore, a one-to-one relationship exists between a business activity scope and a UOW.

In a WS-BA deployment, the UOW must be container-managed:

- The UOW can be a container-managed transaction (CMT) enterprise bean that creates a global transaction.
- The UOW can be a local transaction containment (LTC) where the container is responsible for initiating and ending resource manager local transactions (RMLTs). That is, in the transactional deployment descriptor attributes, the Local Transaction attribute Resolver must be set to ContainerAtBoundary. To use WS-BA, you must not set the Resolver attribute to Application.

Any core UOW can have a business activity scope associated with it. If a component running under a UOW that is associated with a business activity scope calls another component, that request propagates the business activity scope; any work done by the new component is associated with the same business activity scope as the calling component. The called component can create a new UOW, for example if an enterprise bean has a **Transaction** setting of **Requires new**, or runs under the same UOW as the calling component. If a new UOW is started then a new business activity scope is created and associated with the new UOW. The newly created business activity scope is a child of the business activity scope associated with the calling UOW. In the following diagram, EJB1a running under UOW1 calls two components: EJB1b that also runs under UOW1, and EJB2 that creates a new UOW, UOW2. The enterprise bean EJB1b, calls another enterprise bean, EJB3, which creates another new UOW, UOW3. Because each new UOW is created by a calling component whose UOW already has an association with business activity scope BAScope1, the newly created UOWs are associated with new inner business activity scopes, BAScope2 and BAScope3.



Inner business activity scopes must complete before the outer business activity scope completes. Inner business activity scopes, for example BAScope2, have an association with the outer business activity scope, in this case BAScope1. Each business activity scope is directed to close if its associated UOW completes successfully, or to compensate if its associated UOW fails. If BAScope2 completes successfully, any active compensation handlers that are owned by BAScope2 are moved to BAScope1, and are directed in the same way as the completion direction of BAScope1: either compensate or close. If BAScope2 fails, the active compensation handlers are compensated automatically, and nothing is moved to the outer BAScope1. When an inner business activity scope fails, as a result of its associated UOW failing, an application server exception is thrown to the to calling application component, running in the outer UOW.

For example, if the inner UOW fails it might throw a TransactionRolledBackException exception. If the calling application can handle the exception, for example by retrying the called component or by calling another component, then the calling UOW, and its associated business activity scope, can complete successfully even though the inner business activity scope failed. If the application design requires the calling UOW to fail, and for its associated business activity scope to be compensated, then the calling application component must cause its UOW to fail, for example by allowing any system exception from the UOW that failed to be handled by its container.

When the outer business activity scope completes, its success or failure determines the completion direction (close or compensate) of any active compensation handlers that are owned by the outer business activity scope, including those promoted by the successful completion of inner business activity scopes. If the outer business activity scope completes successfully, it drives all active compensation handlers to close. If the outer business activity scope fails, it drives all active compensation handlers to compensate.

This compensation behavior is summarized in the following table.

Table 5. Compensation behavior for a single business activity scope

Inner business activity scope	Outer business activity scope	Compensation behavior
Succeeds	Succeeds	Any compensation handlers that are owned by the inner business activity scope wait for the outer UOW to complete. When the outer UOW succeeds, the outer business activity scope drives all compensation handlers to close.
Fails	Succeeds	Any active compensation handlers that are owned by the inner business activity scope are compensated. An exception is thrown to the outer UOW; if this exception is caught, when the outer UOW succeeds, the outer business activity scope drives all remaining active compensation handlers to close.
Fails	Fails	Any active compensation handlers that are owned by the inner business activity scope are compensated. An exception is thrown to the outer UOW; if this exception is not caught, the outer business activity scope fails. When the outer business activity scope fails, either because of the unhandled exception or for some other reason, all remaining active compensation handlers are compensated.
Succeeds	Fails	Any compensation handlers that are owned by the inner business activity scope wait for the outer UOW to complete. When the outer UOW fails, the outer business activity scope drives all compensation handlers to compensate.

When a UOW with an associated business activity scope completes, the business activity scope always completes in the same direction as the UOW that it is associated with. The only way that you can influence the direction of the business activity scope is to influence the UOW that it is associated with, which you can do by using the setCompensateOnly method of the business activity API.

A compensation handler that is registered within a transactional UOW might initially be inactive, depending on the method invoked from the business activity API. Inactive handlers in this situation become active when the UOW in which that handler is declared completes successfully. A compensation handler that is registered outside a transactional UOW always becomes active immediately. For more information, see “Business activity API” on page 702.

Each business activity scope in the diagram represents a business activity. For example, the outer business activity running under BAScope1 can be a holiday booking scenario, with BAScope2 being a flight booking activity and BAScope3 a hotel booking. If either the flight or hotel bookings fail, the overall holiday booking by default also fails. Alternatively if, for example, the flight booking fails, you might want your application to try booking a flight using another component that represents a different airline. If the overall holiday booking fails, the application can use compensation handlers to cancel any flights or hotels that are already successfully booked.

Use of business activity scopes by application components

Application components do not use business activity scopes by default. You use the WebSphere Application Server assembly tools to specify the use of a business activity scope and to identify any compensation handler class for the component:

Default configuration
: If a business activity context is present on a request received by a component with no business activity scope configuration, the context is stored by the container but never used during the method scope of the target component. A new business activity scope is not created. If the target component invokes another component, the stored business activity context is propagated and can be used by other compensating components.

Run enterprise bean methods under a business activity scope
: Any business activity context present on the incoming request is received by the container and made available to the target component. If a new UOW is created for the target method, for example because the enterprise bean method has a **Transaction** setting of **Requires new**, the received business activity scope becomes an outer business activity scope to a newly created business activity. If the UOW is propagated from the calling component and used by the method,

then the received business activity scope is used by the method. If a business activity scope does not exist on the invocation, a new business activity scope is created and used by the method.

To create a business activity scope when an enterprise bean is invoked, you must configure the enterprise bean to run enterprise bean methods under a business activity scope. You must also configure the deployment descriptors for the method being invoked, to specify the creation of a new UOW upon invocation. For instructions on how to perform these actions, see “Creating an application that uses the Web Services Business Activity support” on page 711.

WS-Transaction and mixed-version cells

Considerations exist for WS-Transaction policy type enablement and behavior, and the WS-Transaction specification level to use, when a cell contains servers at different versions; for example, WebSphere Application Server Version 7.0 and WebSphere Application Server Version 6.1 Feature Pack for Web Services.

WS-Transaction policy type enablement

For a Version 6.1 Feature Pack for Web Services server, you can enable the WS-Transaction policy type by including it in a policy set, but you cannot configure it. For a Version 7.0 server, you can both enable and configure the WS-Transaction policy type. Configuration information is written to the WS-Transaction policy type file.

In a cell with both Version 6.1 Feature Pack for Web Services and Version 7.0 servers, the following behavior occurs:

- If a Version 6.1 Feature Pack for Web Services server reads a WS-Transaction policy type file that is generated by a Version 7.0 server, the server enables the WS-Transaction policy type, but ignores any configuration information in the file.
- If a Version 7.0 server reads a WS-Transaction policy type that is generated by a Version 6.1 Feature Pack for Web Services server, the server enables the WS-Transaction policy type using a value of Supports for the WS-AtomicTransaction and WS-BusinessActivity protocols. This value is equivalent to the existing behavior of a Version 6.1 Feature Pack for Web Services server.

WS-Transaction specification level

A WebSphere Application Server Version 6.x server supports WS-Transaction 1.0. A Version 7.0 server supports WS-Transaction 1.0 and 1.1.

No special considerations exist for a cell with both Version 6.x and Version 7.0 servers.

Related concepts

“Using WS-Transaction policy to coordinate transactions or business activities for Web services” on page 688
You can use WS-Transaction policy to configure how a Java API for XML Web Services (JAX-WS) service or client handles Web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) context.

Highly available messaging engine configuration

Related reference

“WS-Transaction policy settings” on page 932
Use this page to specify the policies for the WS-AtomicTransaction (WS-AT) and WS-BusinessActivity (WS-BA) protocols. WS-AT supports coordination of activities so that either all the activities occur, or none of them occur. WS-BA supports coordination of activities that are more loosely coupled than atomic transactions, and that therefore, require a compensation process if an error occurs.

“Transaction service settings” on page 2145
Use this page to specify settings for the transaction service. The transaction service is a server runtime component that can coordinate updates to multiple resource managers to ensure atomic updates of data. Transactions are started and ended by applications or the container in which the applications are deployed.

Business activity API

Use the business activity application programming interface (API) to create business activities and compensation handlers for an application component, and to log data that is required to compensate an activity if there is a failure in the overall business activity.

Overview

The business activity support provides a UserBusinessActivity API and two interfaces: a serializable.CompensationHandler interface and a CompensationHandler interface. Each interface has two exceptions: RetryCompensationHandlerException and CompensationHandlerFailedException. You can look up the UserBusinessActivity interface from the application server Java Naming and Directory Interface (JNDI) at `java:comp/websphere/UserBusinessActivity`. For example:

```
InitialContext ctx = new InitialContext();
UserBusinessActivity uba = (UserBusinessActivity) ctx.lookup("java:comp/websphere/UserBusinessActivity");
```

You can use the getId method to access the unique identifier for the business activity that is currently associated with the calling thread. The identifier is the same as the one that is generated for the business activity scope at run time and that is used for information, warning, and error messages. For example, the application can use the identifier in audit or diagnostic messages, and it is possible to correlate between application-generated and runtime-generated messages.

```
InitialContext initialContext = new InitialContext();
UserBusinessActivity uba = initialContext.lookup("java:comp/websphere/UserBusinessActivity");
...
String activityId = uba.getId();
if (activityId == null)
// No activity on the thread
else
// Output audit message including activity id
```

If an application component runs work that might require compensating upon failure in the business activity, you must provide a compensation handler class that is assembled as part of the deployed application. This Java class must implement one of the following interfaces:

- com.ibm.websphere.wsba.serializable.CompensationHandler, which takes a takes a parameter of a serializable object
- com.ibm.websphere.wsba.CompensationHandler, which takes a parameter of a Service Data Object (SDO)

Typically, applications that already have their data available in DataObject format will use the CompensationHandler interface, and applications that do not will use the serializable.CompensationHandler interface. Both interfaces support the close and compensate methods.

An application must register a compensation handler implementation that works with the type of compensation data (serializable object or SDO) that the application uses. If there is a mismatch between the type of data that the application component uses and the compensation handler implementation, there is an error.

During normal application processing, the application can make one or more invocations to the `setCompensationDataImmediate` or `setCompensationDataAtCommit` methods, passing in either a serializable object or an SDO that represents the current state of the work performed.

When the underlying unit of work (UOW) that the root business activity is associated with completes, all registered compensators are coordinated to complete. During completion, either the compensate or the close method is called on the compensation handler, passing in the most recent compensation data logged by the application component as a parameter. Your compensation handler implementation must be able to understand the data that is stored in either the serializable object or the SDO DataObject; using this data, the compensation handler must be able to determine the nature of the work performed by the enterprise bean and compensate or close in an appropriate way, for example by undoing changes made to database rows if there is a failure in the business activity. You associate the compensation handler with an application component by using the assembly tooling, such as Rational Application Developer.

Active and inactive compensation handlers

You implement the serializable.CompensationHandler or CompensationHandler interface for any application component that executes code that might need to be compensated within a business activity scope. Compensation handler objects are registered implicitly with the business activity scope under which the application runs, whenever the application calls the UserBusinessActivity API to specify compensation data. Compensation handlers can be in one of two states, active or inactive, depending on any transactional UOW under which they are registered. A compensation handler that is registered within a transactional UOW might initially be inactive until the transaction commits, at which point the compensation handler becomes active (see the following section). A compensation handler that is registered outside a transactional UOW always becomes active immediately.

When a business activity completes, it drives only active compensation handlers. Any inactive compensation handlers that are associated with the business activity are discarded and never driven.

Logging compensation data

The business activity API specifies two methods that allow the application to log compensation data. This data is made available to the compensation handlers during their processing when the business activity completes. The application calls one of these methods, depending on whether it expects transactions to be part of the business activity.

`setCompensationDataAtCommit()`

Call the setCompensationDataAtCommit method when the application expects a global transaction on the thread.

- If a global transaction is present on the thread, the CompensationHandler object is initially inactive. If the global transaction fails, it rolls back any transactional work done within its transaction context in an atomic manner, and drives the business activity to compensate other completed UOWs. The compensation handler does not need to be involved. If the global transaction commits successfully, the compensation handler becomes active because if the overall business activity fails, the compensation handler is required to compensate the durable work that is completed by the global transaction. The setCompensationDataAtCommit method configures the CompensationHandler instance to perform this compensation function.

- If a global transaction is not present when the setCompensationDataAtCommit method is called, the compensation handler becomes active immediately.

For example, for an SDO, using the same business activity instance as in the previous example:

```
DataObject compensationData = doWorkWhichWouldNeedCompensating();
uba.setCompensationDataAtCommit(compensationData);
```

setCompensationDataImmediate()

Call the setCompensationDataImmediate method when the application does not expect a global transaction on the thread.

The setCompensationDataImmediate method makes a CompensationHandler instance active immediately, regardless of the current UOW context at the time that the method is invoked. The compensation handler is always able to participate during completion of the business activity.

The role of the setCompensationDataImmediate method is to compensate any non-transactional work, in other words, work that can be performed either inside or outside a global transaction, but that is not governed by the transaction. An example of this type of work is sending an e-mail. The compensation handler must be active immediately so that if a failure occurs in a business activity, this non-transactional work is always compensated.

For example, for a serializable object, using the same business activity instance as in the previous example:

```
Serializable compensationData = new MyCompensationData();
uba.setCompensationDataImmediate(compensationData);
```

Although these two compensation data logging methods, if called in the same enterprise bean, use the same compensation handler class, they create two separate instances of the compensation handler class at run time. Therefore, the actions of the methods are mutually exclusive; calling one of the methods does not overwrite any work carried out by the other method.

If a compensation handler instance is already added to the Business Activity using one of these methods, and then the same method is called, passing in `null` as a parameter, that compensation handler instance is removed from the business activity, and is not driven to close or compensate during completion of the business activity.

As described previously, the business activity support adds a compensation handler instance to the business activity when a compensation data logging method is called for the first time by the enterprise bean that uses that business activity. At the same time, a snapshot of the enterprise application context is taken and logged with the compensation data. When the business activity competes, all the compensation handlers that were added to the business activity are driven to compensate or close. The code that you create in the CompensationHandler or serializable.CompensationHandler class is guaranteed to run in the same enterprise application context that was captured in the earlier snapshot.

For details about the methods available in the business activity API, see Additional Application Programming Interfaces (APIs).

Configuring a JAX-WS client for WS-Transaction context

You can configure the way that a Java API for XML Web Services (JAX-WS) client handles Web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) context by configuring the Web Services Transaction (WS-Transaction) policy type. You can specify that the client must send context, can send context if it is available, or must not send context.

Before you begin

A JAX-WS client must be installed.

About this task

You can configure a WS-Transaction policy set using the administrative console, as described in this task, or you can configure a WS-Transaction policy set using the wsadmin tool.

To configure a JAX-WS client for WS-Transaction context using the administrative console, complete the following steps.

1. Create a new policy set, or copy and rename an existing policy set. You can copy an existing user-defined policy set, or one of the WS-Transaction default policy sets (WSTransaction or SSL WSTransaction). See “Creating policy sets using the administrative console” on page 806.
2. Check that your policy set includes the WS-Transaction policy type. If necessary, add the WS-Transaction policy type. See “Adding policies to policy sets using the administrative console” on page 903.
3. Configure the WS-Transaction policy.
4. Associate the policy set with the JAX-WS client. See Managing policy sets and bindings for service clients.
5. Choose a WS-Policy application rule that includes the configured policy of the client, that is, client only or client and provider. See “Configuring the client policy using a service provider policy” on page 724.
6. Save your changes to the master configuration.

What to do next

The JAX-WS client is configured to use WS-Transaction context in the way that you specified.

Configuring a JAX-WS Web service for WS-Transaction context

You can configure the way that a Java API for XML Web Services (JAX-WS) service handles Web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) context by configuring the Web Services Transaction (WS-Transaction) policy type. You can specify that the Web service must receive context, can receive context if it is available, or must not receive context.

Before you begin

A JAX-WS client must be installed.

About this task

You can configure a WS-Transaction policy set using the administrative console as described in this task, or you can configure a WS-Transaction policy set using the wsadmin tool.

To configure a JAX-WS service for WS-Transaction context using the administrative console, complete the following steps.

1. Create a new policy set, or copy and rename an existing policy set. You can copy an existing user-defined policy set, or one of the WS-Transaction default policy sets (WSTransaction or SSL WSTransaction). See “Creating policy sets using the administrative console” on page 806.
2. Check that your policy set includes the WS-Transaction policy type. If necessary, add the WS-Transaction policy type. See “Adding policies to policy sets using the administrative console” on page 903.
3. Configure the WS-Transaction policy.
4. Associate the policy set with the JAX-WS Web service, endpoint, or operation for which the specified behavior is required. See Managing policy sets and bindings for service providers.
5. Save your changes to the master configuration.

What to do next

The JAX-WS Web service, endpoint, or operation is configured to use WS-Transaction context in the way that you specified.

Configuring a WS-Transaction policy set using the wsadmin tool

You can configure the way that a Java API for XML Web Services (JAX-WS) client or Web service handles Web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) context by configuring the Web Services Transaction (WS-Transaction) policy type. You can specify that the client or service must use context, can use context if it is available, or must not use context. Use command scripts to configure a policy set for Web services transactions.

About this task

You can configure a WS-Transaction policy set using the wsadmin tool as described in this task, or you can configure a WS-Transaction policy set using the administrative console.

1. Start the wsadmin tool if it is not already running.
2. Use the createPolicySet command to create a new policy set, or the copyPolicySet command to copy and rename an existing policy set. You can copy an existing user-defined policy set, or one of the WS-Transaction default policy sets (WSTransaction or SSL WSTransaction).
3. Check that your policy set includes the WS-Transaction policy type. If necessary, add the WS-Transaction policy type. For example:

```
AdminTask.importPolicySet('[-defaultPolicySet WSTransaction]')
AdminTask.addPolicyType('[-policySet PolicySet1
-policyType WSTransaction -enabled true]')
```

4. Use the setPolicyType command to configure the WS-Transaction policy type attributes. For example:

```
AdminTask.setPolicyType('[-policySet PolicySet1
-policyType WSTransaction
-attributes "[ [BAAtomicOutcomeAssertion mandatory] [ATAssertion supports] ]"]
-replace')
```

   For detailed information about these configurable attributes, see “WS-Transaction policy settings” on page 932.

5. Save your changes to the master configuration. For example, enter the following command:

```
AdminConfig.save()
```

What to do next

You are now ready to associate the policy set with the JAX-WS client, or with the JAX-WS Web service, endpoint, or operation.

Configuring Web Services Transaction support in a secure environment

If you use Web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) support when administrative security is enabled, you might need to change the default transaction service configuration. You can disable the transaction coordination authorization setting, create a new Web container transport chain, or do both.

About this task

You might disable transaction coordination authorization if you want to interoperate with other servers and you do not want to set up security for the transaction manager to support the Common Criteria EAL4 evaluated configuration. When transaction coordination authorization is disabled, WebSphere Application Server does not automatically reject secure WS-Transactions protocol messages.

You might configure a new Web container transport chain for use by WS-Transactions in the following situations:

- You want to use an alternative port number for WS-AT or WS-BA protocol messages.
- You want to interoperate with a non-WebSphere Application Server product that requires client certificate authentication on the Secure Sockets Layer (SSL) connection that is used for protocol messages.

The transaction service, by default, selects a suitable Web container transport chain from the list of those configured and uses it for protocol messages. You can configure a new transport chain and specify your own settings. For example, you can specify an alternative SSL configuration that requires client certificate authentication, which is then used specifically for WS-Transactions protocol messages.

1. Optionally, use the following steps to disable transaction coordination authorization.
   a. In the administrative console, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Container Settings] Container Services** → **Transaction Service**.
   b. Clear the **Enable transaction coordination authorization** check box.
   c. Click **Apply** or **OK**.
   d. Save your changes to the master configuration.
2. Optionally, use the following steps to create a new Web container transport chain.
   a. In the administrative console, click **Servers** → **Application servers** → ***server_name*** → **[Container Settings] Web Container Settings** → **Web container transport chains**.
   b. Click **New** to create a new transport chain.
   c. Type a name for the transport chain.
   d. From the Transport chain template list, select an appropriate template.
   e. Click **Next** to select a new port for the chain.
   f. Type a name, host, and port number for the port. For a secure chain, the host must match the common name in the certificate that is used.
   g. Click **Next**, confirm the settings, then click **Finish**.
   h. Save your changes to the master configuration.
   i. If necessary, create a new SSL configuration and associate it with the SSL channel associated with your new chain. For more information, see Creating a Secure Sockets Layer configuration. You are now ready to configure the transaction service to use the new transport chain.
   j. Click **Servers** → **Application servers** → ***server_name*** → **[Container Settings] Container Services** → **Transaction Service**.
   k. In the External WS-Transaction HTTP(S) URL prefix section, click **Select prefix**, then select the Web container transport chain that you have just created from the list.

      If you are using an intermediary, such an HTTP proxy, in front of the application server, click **Specify custom prefix**, then type the external endpoint URL information for the intermediary node in the field. For more information, see “Enabling WebSphere Application Server to use an intermediary node for Web services transactions” on page 709.
   l. Click **Apply** or **OK**, then save your changes to the master configuration.
3. After you save all the configuration changes, restart the server for the changes to take effect.

Results

You configured your system to use WS-AT or WS-BA in a secure environment.

Configuring an intermediary node for Web services transactions

Intermediary nodes allow the exchange of Web Services Atomic Transaction (WS-AT) and Web Services Business Activity (WS-BA) protocol messages across firewalls and outside the WebSphere Application Server domain. You configure an intermediary node to specify which WebSphere Application servers the node routes requests to.

1. Configure the HTTP server so that it routes WS-AT and WS-BA requests that are targeted at WebSphere Application Server to WebSphere Application Server, rather than processing them itself.
2.
3.

Results

You configured the intermediary node ready for use by WebSphere Application Server.

Example

What to do next

Configure WebSphere Application Server to use the intermediary node by specifying, for each server, the appropriate virtual host of the intermediary node.

Example: Configuring IBM HTTP server as an intermediary node for Web services transactions

You can use an HTTP server intermediary nodes to enable the exchange of Web Services Atomic Transaction and Web Services Business Activity protocol messages across firewalls and outside the WebSphere Application Server domain. For IBM HTTP server, you achieve this behavior by modifying the plugin-cfg.xml file of the IBM HTTP server node.

Routing requests to WebSphere Application Server

You can use the IBM HTTP server as a single intermediary node, or you can combine it with a Proxy Server for IBM WebSphere Application Server. In both cases, update the plugin-cfg.xml file to indicate that the HTTP server should route requests that are targeted at WebSphere Application Server, those of the form http://*host:port*/_IBMSYSAPP/*, to WebSphere Application Server, rather than processing them itself.

To update the plugin-cfg.xml file, add a URI element with a name of _IBMSYSAPP, as shown in the following example. Add this URI to all UriGroup elements in the plugin-cfg.xml file.

```
<UriGroup Name="default_host_server1_99T73NKNode01_Cluster_URIs">
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/snoop/*" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/hello" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/hitcount" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="*.jsp" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="*.jsv" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="*.jsw" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/j_security_check" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/ibm_security_logout" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/servlet/*" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/SamplesGallery/*" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/WSsamples/*" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/PlantsByWebSphere/*" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/PlantsByWebSphere/docs/*" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/_IBMSYSAPP/*" />
</UriGroup>
```

Configuring virtual host mapping

If you are using IBM HTTP as the only intermediary node, in other words you are not also using Proxy Server for IBM WebSphere Application Server, configure virtual hosts to represent each WebSphere Application Server that the HTTP node routes requests to. Update the plugin-cfg.xml file by adding VirtualHostGroup, VirtualHost and Route elements.

The following example shows part of the plugin-cfg.xml file for a configuration in which the IBM HTTP server routes requests to one of two servers, server1 and server2, in WebSphere Application Server.

The plugin-cfg.xml file contains two virtual host aliases, with names name1.acme.com and name2.acme.com, that are defined using VirtualHost and VirtualHostGroup elements. The Route elements define the association between the virtual hosts and the ServerCluster elements. When a request is made, IBM HTTP server finds the best matching route to dispatch the request to. A request made to virtual host name1.acme.com, with a URI that matches a pattern in the default_URIs URI group, is sent to the server1_Cluster server cluster. This server cluster contains only one server, server1, so requests targeted at virtual host name1.acme.com are sent to server1, and similarly, requests targeted at virtual host name2.acme.com are sent to server2.

```
<UriGroup Name="default_URIs">
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/snoop/*" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/hello" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/hitcount" />
...
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/PlantsByWebSphere/*" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/PlantsByWebSphere/docs/*" />
  <Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/_IBMSYSAPP/*" />
</UriGroup>

<ServerCluster CloneSeparatorChange="false" LoadBalance="Round Robin" Name="server1_Cluster" PostBufferSize="64"
PostSizeLimit="-1" RemoveSpecialHeaders="true" RetryInterval="60">
      <Server ConnectTimeout="0" ExtendedHandshake="false" MaxConnections="-1" Name="server1" ServerIOTimeout="0" WaitForContinue="false">
         ...
      </Server>
      <PrimaryServers> <Server Name="server1"/> </PrimaryServers>
   </ServerCluster>
<ServerCluster CloneSeparatorChange="false" LoadBalance="Round Robin" Name="server2_Cluster" PostBufferSize="64" PostSizeLimit="-1" RemoveSpecialHeaders="true" R
      <Server ConnectTimeout="0" ExtendedHandshake="false" MaxConnections="-1" Name="server2" ServerIOTimeout="0" WaitForContinue="false">
         ...
     </Server>
      <PrimaryServers> <Server Name="server2"/>  </PrimaryServers>
</ServerCluster>
<VirtualHostGroup Name="vhost_server1"> <VirtualHost Name="name1.acme.com:9081"/> </VirtualHostGroup>
<VirtualHostGroup Name="vhost_server2"> <VirtualHost Name="name2.acme.com:9081"/> </VirtualHostGroup>
<Route ServerCluster="server1_Cluster" UriGroup="default_URIs" VirtualHostGroup=" vhost_server1 "/>
<Route ServerCluster="server2_Cluster" UriGroup="default_URIs" VirtualHostGroup=" vhost_server2"/>
```

Related concepts

“Web Services transactions, firewalls and intermediary nodes” on page 695
You can configure your system to enable propagation of Web Services Atomic Transactions (WS-AT) message contexts and Web Service Business Activities (WS-BA) message contexts across firewalls or outside the WebSphere Application Server domain. With these configurations, you can distribute Web service applications that use WS-AT or WS-BA across disparate systems.

Enabling WebSphere Application Server to use an intermediary node for Web services transactions

You can use intermediary nodes with Web Services Atomic Transactions (WS-AT) or Web Services Business Activities (WS-BA) to support the exchange of associated requests across firewalls and outside the WebSphere Application Server domain. You configure WebSphere Application Server to use an intermediary node by specifying the external endpoint URL information for the intermediary node in each server that is accessed through the intermediary.

Before you begin

Configure the intermediary node that you want to use, and ensure that you know the address or addresses of the intermediary node that you want to map to servers in your WebSphere Application Server configuration.

Configure the intermediary to listen on a specific port for protocol messages and to route these messages to the specific WebSphere Application Server instance that you want to enable. See the related information for an example configuration where an IBM HTTP server is the intermediary.

1. In the administrative console, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **[Container Services] Transaction Service**.

2. In the External WS-Transaction HTTP(S) URL prefix section, click **Specify custom prefix**, then type the external endpoint URL information for the intermediary node in the field. Use one of the following formats for the prefix, where *host_name* and *port* represent the intermediary node that is an HTTP or HTTPS proxy for the server, and *port* is optional.
   - `http://host_name:port`
   - `https://host_name:port`
3. Click **Apply** or **OK**.
4. Save your changes to the master configuration.
5. Repeat the previous steps for each server that is accessed through the intermediary node.
6. Restart the servers.

Results

You configured your system to use an intermediary node. Test your configuration to ensure that messages are routed as you expect.

Configuring a server to use business activity support

Business activity support provides compensation for activities such as sending an e-mail, which can be difficult or impossible to roll back atomically. With this compensation, applications on disparate systems can coordinate activities that are more loosely coupled than atomic transactions. To use the business activity support, you must first enable it on each server that you plan to use.

About this task

If an application component uses business activity support, you must enable the support on each server that runs the application.
