# Contents

**How to send your comments** . . . . . xvii

**Changes to serve you more quickly** . . . . . xix

**Chapter 1. Developing ActivitySessions** . . . . . 1
Developing an enterprise application to use ActivitySessions . . . . . 1
Developing an enterprise bean or enterprise application client to manage ActivitySessions . . . . . 2
ActivitySession service application programming interfaces . . . . . 3
Assembling applications that use ActivitySessions . . . . . 4
Setting EJB module ActivitySession deployment attributes . . . . . 4
Setting Web module ActivitySession deployment attributes . . . . . 7

**Chapter 2. Developing Application profiling** . . . . . 9
Using the TaskNameManager interface . . . . . 9
TaskNameManager interface . . . . . 11
Assembling applications for application profiling . . . . . 12

**Chapter 3. Developing Asynchronous beans** . . . . . 15
Developing work objects, event listeners, and asynchronous scopes . . . . . 15
Developing work objects to run code in parallel . . . . . 15
Developing event listeners . . . . . 19
Developing asynchronous scopes . . . . . 22
Assembling timer and work managers . . . . . 26
Assembling applications that use work managers and timer managers . . . . . 26

**Chapter 4. Developing batch applications** . . . . . 29
Developing batch applications . . . . . 29
Transactional batch and compute-intensive batch programming models . . . . . 29
Developing a simple compute-intensive application . . . . . 29
Developing a simple transactional batch application . . . . . 32
Using the batch data stream (BDS) framework . . . . . 43
Deploying batch applications . . . . . 65
Packaging EJB 3.0 modules in a batch application using Rational Application Developer . . . . . 65
Installing the batch application . . . . . 65
Submitting batch jobs . . . . . 66
xJCL elements . . . . . 66
Submitting batch jobs using the job scheduler EJB interface . . . . . 72
Submitting batch jobs using the job scheduler web services interface . . . . . 94

**Chapter 5. Developing applications that use the Bean Validation API** . . . . . 159
Bean Validation . . . . . 159
Bean validation built-in constraints . . . . . 162
Using bean validation in the product . . . . . 163
Bean validation in RAR modules . . . . . 165
Bean validation in JPA . . . . . 167

**Chapter 6. Developing Client applications** . . . . . 177
Developing client applications . . . . . 177
Choosing a type of client . . . . . 178
Installing, updating, rolling back, and uninstalling the Application Client for IBM WebSphere Application Server . . . . . 179
Developing stand-alone thin client applications . . . . . 210
Developing a Java EE client application . . . . . 211

© Copyright IBM Corp. 2011

Developing a Java thin client application . . . 215
Developing ActiveX client application code . . . 215
Developing applet client code . . . 231
Running the Pluggable Application Client code . . . 233
Example: Enabling logging and tracing for application clients . . . 252

**Chapter 7. Deploying client applications** . . . 255
Deploying applet client code . . . 255
Running an ActiveX client application . . . 256
Starting an ActiveX application and configuring service programs . . . 256
Starting an ActiveX application and configuring non-service programs . . . 257
setupCmdLineXJB.bat, launchClientXJB.bat and other ActiveX batch files . . . 258
Deploying and running a Java EE client application . . . 259
Deploying a Java EE client application . . . 259
Running a Java EE client application with launchClient . . . 343
Downloading and running a Java EE client application using Java Web Start . . . 349
Running the IBM Thin Client for Enterprise JavaBeans (EJB) . . . 363
Running Java thin client applications . . . 366
Running a Java thin client application on a client machine . . . 368
Running a Java thin client application on a server machine . . . 368

**Chapter 8. Developing Communications Enabled Applications** . . . 371
Developing communications enabled applications . . . 371
Developing SIP communications applications . . . 371

**Chapter 9. Developing Data access resources** . . . 373
Developing data access applications . . . 373
Developing data access applications . . . 373
Example: Setting client information with the setClientInformation(Properties) API . . . 456
Changing the error detection model to use the Exception Checking Model . . . 457
Exceptions pertaining to data access . . . 457
Assembling data access applications . . . 495
Creating or changing a resource reference . . . 496
Assembling resource adapter (connector) modules . . . 498
Deploying data access applications . . . 499
Available resources . . . 501
Map data sources for all 1.x CMP beans . . . 501
Map default data sources for modules containing 1.x entity beans . . . 502
Map data sources for all 2.x CMP beans settings . . . 503
Map data sources for all 2.x CMP beans . . . 505
Installing a resource adapter archive . . . 507
Installing resource adapters embedded within applications . . . 509
Install RAR . . . 510
Deploying SQLJ applications . . . 510
Deploying SQLJ applications that use container-managed persistence (CMP) . . . 511
Deploying SQLJ applications that use bean-managed persistence, servlets, or sessions beans 514
Customizing and binding profiles for Structured Query Language in Java (SQLJ) applications 515
Using embedded SQLJ with the DB2 for z/OS Legacy driver . . . 524
Directory conventions . . . 527

**Chapter 10. Developing Dynamic caching** . . . 531
Configuring cacheable objects with the cachespec.xml file . . . 531
Verifying the cacheable page . . . 532
cachespec.xml file . . . 533
Example: Configuring the dynamic cache service . . . 543
cacheinstances.properties file . . . 545

**Chapter 11. Developing Dynamic and EJB query** . . . 551
Developing applications that use EJB query . . . 551
EJB query language . . . 551
Using the dynamic query service . . . 574

**Chapter 12. Developing EJB applications** . . . 585
Developing EJB 2.x enterprise beans. . . . 585
Partial column update feature for container managed persistence . . . 585
Setting partial update for container-managed persistent beans . . . 587
Developing EJB 3.x enterprise beans. . . . 587
Enterprise JavaBeans (EJB) 3.1 specification. . . . 587
Enterprise JavaBeans (EJB) 3.0 specification. . . . 588
Application exceptions . . . 588
EJB 3.x module considerations . . . 592
EJB metadata annotations. . . . 594
EJB 3.x interceptors . . . 595
Create stubs command . . . 600
Developing entity beans . . . 603
Defining data sources for entity beans . . . 603
Lightweight local operational mode for entity beans . . . 604
Applying lightweight local mode to an entity bean . . . 605
Developing read-only entity beans . . . 605
Creating timers using the EJB timer service for enterprise beans . . . 606
Clustered environment considerations for timer service . . . 616
Developing enterprise beans . . . 625
Developing message-driven beans. . . . 628
Enterprise bean development best practices . . . 631
WebSphere extensions to the Enterprise JavaBeans specification . . . 632
Setting the run time for batched commands with JVM arguments . . . 633
Setting the run time for deferred create with JVM arguments . . . 633
Setting persistence manager cache invalidation . . . 633
Setting the system property to enable remote EJB clients to receive nested or root-cause exceptions. . . . 634
Unknown primary-key class . . . 634
Developing applications using the embeddable EJB container. . . . 634
Embeddable EJB container . . . 639
Running an embeddable container. . . . 640
Embeddable EJB container functions. . . . 641
Embeddable EJB container configuration properties . . . 642
Configuring EJB 3.1 session bean methods to be asynchronous. . . . 646
Configuring remote asynchronous EJB method results . . . 651
Configuring EJB asynchronous methods using scripting . . . 652
EJB 3.1 asynchronous methods. . . . 654
Developing client code that calls EJB asynchronous methods. . . . 655
Bean implementation programming model for EJB asynchronous methods . . . 659
EJB container work manager for asynchronous methods . . . 660
EJB asynchronous methods settings . . . 660
Developing session beans. . . . 662
Configuring EJB 3.1 session bean methods to be asynchronous. . . . 662
Developing a session bean to have a No-Interface Local View . . . 678
Developing singleton session beans . . . 679
Programming to use message-driven beans . . . 688
Developing message-driven beans. . . . 689
Designing an enterprise application to use message-driven beans . . . 691
Developing an enterprise application to use message-driven beans . . . 693

Deploying an enterprise application to use message-driven beans with JCA 1.5-compliant resources . . . 697
Deploying an enterprise application to use message-driven beans with listener ports . . . 699
Assembling EJB 2.1 enterprise beans . . . 702
Assembling EJB 2.x modules . . . 702
Sequence grouping for container-managed persistence in assembled EJB modules . . . 703
Setting the run time for CMP sequence groups . . . 704
Assembling EJB 3.x enterprise beans . . . 704
EJB 3.0 and EJB 3.1 application bindings overview . . . 704
EJB 3.x module packaging overview . . . 730
Assembling EJB 3.x modules . . . 735
Assembling EJB modules . . . 735
EJB modules . . . 736
EJB content in WAR modules . . . 737
EJB 3.x module packaging overview . . . 741
Defining container transactions for EJB modules . . . 745
References in application deployment descriptor files . . . 746
EJB references . . . 746
EJB JNDI names for beans . . . 747
Bind EJB business settings . . . 748
Deploying EJB 3.x enterprise beans . . . 749
EJB module settings . . . 749
Directory conventions . . . 749
Deploying EJB modules . . . 752
EJB 3.0 and EJB 3.1 deployment overview . . . 753
EJBDEPLOY relationships – troubleshooting tips . . . 755
Directory conventions . . . 755
Developing EJB 2.x entity beans that use access intents . . . 757
Using the AccessIntent API . . . 757
Assembling access intents to EJB 2.x entity beans . . . 760
Applying access intent policies to beans . . . 760
Configuring read-read consistency checking with an assembly tool . . . 761
Access intent service . . . 762
Applying access intent policies to methods . . . 764
Developing applications that use the Java Persistence API . . . 765
Developing JPA 2.x applications for a Java EE environment . . . 765
Developing JPA 2.x applications for a Java SE environment . . . 767
Bean validation in JPA . . . 770
wsjpa properties . . . 778
Criteria API . . . 778
wsappid command . . . 779
wsenhancer command . . . 780
wsmapping command . . . 782
wsreversemapping command . . . 785
wsschema command . . . 787
wsdbgen command . . . 790
ANT task WsJpaDBGenTask . . . 792
SQL statement batching for JPA applications . . . 793
Database generated version ID with JPA . . . 794
Mapping persistent properties to XML columns for JPA . . . 795
Directory conventions . . . 797
Assembling applications that use the Java Persistence API . . . 799
Assembling a JPA application in a Java EE environment . . . 799
Assembling JPA applications for a Java SE environment . . . 800
Using JPA access intent . . . 801
Associating persistence providers and data sources . . . 806

**Chapter 13. Developing Internationalization service** . . . . . 809
Task overview: Globalizing applications . . . . . 809
Globalization . . . . . 809
Working with locales and character encodings . . . . . 811
Language versions offered by this product . . . . . 812
Globalization: Resources for learning . . . . . 813
Task overview: Internationalizing interface strings (localizable-text API) . . . . . 814
Identifying localizable text . . . . . 814
Creating message catalogs . . . . . 815
Composing language-specific strings . . . . . 815
Preparing the localizable-text package for deployment . . . . . 823
Task overview: Internationalizing application components (internationalization service) . . . . . 825
Internationalization service . . . . . 826
Assembling internationalized applications . . . . . 826
Using the internationalization context API . . . . . 831
Administering the internationalization service . . . . . 850

**Chapter 14. Developing Mail, URLs, and other Java EE resources** . . . . . 857
Developing applications that use the JavaMail API . . . . . 857
Debugging mail sessions . . . . . 857

**Chapter 15. Developing Messaging resources** . . . . . 861
Programming to use asynchronous messaging . . . . . 861
Programming to use JMS and messaging directly . . . . . 862

**Chapter 16. Deploying an enterprise application to use JMS** . . . . . 883

**Chapter 17. Programming for interoperation with WebSphere MQ** . . . . . 885
Designing an application for interoperation with WebSphere MQ . . . . . 885
Mapping the message body to and from WebSphere MQ format . . . . . 886
Mapping the message header fields and properties to and from WebSphere MQ format . . . . . 888
Mapping the JMS delivery option and message reliability to and from the WebSphere MQ persistence value . . . . . 892
Mapping destinations to and from WebSphere MQ queues, topics, and destinations . . . . . 894
Mapping MQMD Report fields to JMS provider-specific properties . . . . . 897
Mapping additional MQRFH2 header fields in service integration . . . . . 900
How to process WebSphere MQ message headers . . . . . 901
WebSphere MQ functions not supported by service integration . . . . . 903

**Chapter 18. Programming to use message-driven beans** . . . . . 905
Developing message-driven beans . . . . . 905
Designing an enterprise application to use message-driven beans . . . . . 908
Developing an enterprise application to use message-driven beans . . . . . 909
Deploying an enterprise application to use message-driven beans with JCA 1.5-compliant resources 913
Configuring deployment attributes for a message-driven bean against JCA 1.5-compliant resources 914
Deploying an enterprise application to use message-driven beans with listener ports . . . . . 916
Configuring deployment attributes for a message-driven bean against a listener port . . . . . 916

**Chapter 19. Developing Naming and directory** . . . . . 919
Developing applications that use JNDI . . . . . 919
Example: Getting the default initial context . . . . . 923
Example: Getting an initial context by setting the provider URL property . . . . . 926
Example: Setting the provider URL property to select a different root context as the initial context 928
Example: Looking up an EJB home or business interface with JNDI . . . . . 929
JNDI interoperability considerations . . . . . 932
JNDI caching . . . . . 933

JNDI cache settings . . . 934
JNDI to CORBA name mapping considerations . . . 935
Developing applications that use CosNaming (CORBA Naming interface) . . . 935
Example: Getting an initial context with CosNaming . . . 936
Example: Looking up an EJB home with CosNaming . . . 938

**Chapter 20. Developing Object pools** . . . 941
Using object pools. . . . 941
Object pool managers . . . 942
Object pool managers collection . . . 944
Object pool service settings . . . 946
Object pools: Resources for learning . . . 947
MBeans for object pool managers and object pools . . . 947

**Chapter 21. Developing Object Request Broker (ORB)** . . . 949
Developing Object Request Brokers . . . 949
Client-side programming tips for the Object Request Broker service . . . 949
Directory conventions . . . 951

**Chapter 22. Developing OSGi applications** . . . 955
Developing and deploying an OSGi application . . . 955
Creating a service bundle . . . 956
Creating a client bundle. . . . 958
Creating an OSGi application . . . 961
Deploying an OSGi application as a business-level application . . . 964
Debugging bundles at run time using the command-line console. . . . 982
Developing a composite bundle . . . 989
Converting existing applications to OSGi applications . . . 990
Converting an enterprise application to an OSGi application . . . 990
Converting a Spring application to an OSGi application . . . 991
Sample OSGi applications . . . 997
OSGi blog sample application . . . 998
OSGi blabber sample application . . . 1003

**Chapter 23. Developing Portlet applications** . . . 1009
Portlet aggregation and preferences. . . . 1009
Supported optional features of the JSR-286 Portlet Specification . . . 1009
Portlet aggregation using JavaServer Pages . . . 1013
Portlet preferences . . . 1019
Portlet coordination . . . 1020
Converting portlet fragments to an HTML document . . . 1021
Assembling portlets . . . 1022
Portlet Uniform Resource Locator (URL) addressability . . . 1022
Example: Configuring the extended portlet deployment descriptor to disable PortletServingServlet 1024

**Chapter 24. Developing SCA composites** . . . 1025
Selecting the implementation type for an SCA composite . . . 1025
Developing Service Component Architecture (SCA) services . . . 1026
Developing SCA services from existing WSDL files . . . 1027
Developing SCA services with existing Java code. . . . 1032
Developing SCA service clients . . . 1036
Using business exceptions with SCA interfaces . . . 1041
Considerations for developing SCA applications using EJB bindings . . . 1046
Specifying bindings in an SCA environment . . . 1048
Configuring the SCA default binding. . . . 1050
Using the SCA default binding to find and locate SCA services . . . 1054

Configuring the SCA web services binding . . . 1055
Configuring EJB bindings in SCA applications . . . 1067
Configuring the SCA JMS binding . . . 1072
Using Atom bindings in SCA applications . . . 1101
Using HTTP bindings in SCA applications. . . . 1106
Using Widget implementation in JavaScript with Atom or HTTP bindings . . . 1111
Resolving SCA references . . . 1114
Routing HTTP requests to an SCA service when using an external web server . . . 1116
Interoperability between Open SCA client services and WebSphere Process Server SCA modules 1118
Creating wire format handlers . . . 1120
Wire format handler errors . . . 1122
Using existing Java EE modules and components as SCA implementations . . . 1124
Using non-SCA enhanced Java EE applications as SCA component implementations . . . 1126
Using SCA enhanced Java EE applications as SCA component implementations . . . 1128
SCA annotations . . . 1135
Rewiring EJB references to SCA references . . . 1136
Using OSGi applications as SCA component implementations . . . 1137
SCA programming model support in OSGi applications . . . 1140
Deploying OSGi applications that use SCA . . . 1143
Using Spring 2.5.5 containers in SCA applications . . . 1146
Additional Spring component implementation features . . . 1149
Directory conventions . . . 1150

**Chapter 25. Developing Scheduler service** . . . 1153
Developing and scheduling tasks . . . 1153
Accessing schedulers . . . 1154
Developing a task that calls a session bean . . . 1155
Developing a task that sends a Java Message Service message . . . 1157
Scheduling long-running tasks . . . 1158
Receiving scheduler notifications . . . 1159
Submitting a task to a scheduler . . . 1160
Task management methods using a scheduler . . . 1161
Identifying tasks that are currently running . . . 1163
Stopping tasks that are failing . . . 1163
Scheduler tasks and Java EE context . . . 1164
Securing scheduler tasks . . . 1167
Scheduler configuration or topology . . . 1168
Scheduler interface . . . 1169

**Chapter 26. Developing security** . . . 1173
Developing extensions to the WebSphere security infrastructure . . . 1173
Developing stand-alone custom registries . . . 1173
Implementing custom password encryption . . . 1180
Developing applications that use programmatic security . . . 1181
Customizing web application login . . . 1214
Secure transports with JSSE and JCE programming interfaces . . . 1221
Configuring Federal Information Processing Standard Java Secure Socket Extension files . . . 1225
Implementing tokens for security attribute propagation . . . 1228
Enabling a plugpoint for custom password encryption . . . 1259
Implementing a custom authentication provider using JASPI . . . 1262

**Chapter 27. Developing Startup beans** . . . 1275
Using startup beans . . . 1275
Enabling startup beans in the administrative console . . . 1276
Startup beans service settings . . . 1276

**Chapter 28. Developing Service integration** . . . . . 1279
Programming mediations . . . . . 1279
Serializing the content of SIMessage . . . . . 1280
Writing a mediation handler . . . . . 1280
Adding mediation function to handler code . . . . . 1281
Writing a routing mediation . . . . . 1312
Writing a mediation that maps between attachment encoding styles . . . . . 1313
Using durable subscriptions . . . . . 1314
Sending web service messages directly over the bus from a JAX-RPC client . . . . . 1316
sib: URL syntax . . . . . 1317

**Chapter 29. Developing Session Initiation Protocol (SIP) applications** . . . . . 1321
Developing SIP applications. . . . . 1321
Developing SIP applications that support PRACK . . . . . 1321
Setting up SIP application composition . . . . . 1322
SIP servlets . . . . . 1324
Developing applications that use the Asynchronous Invocation API . . . . . 1333
Deploying SIP applications . . . . . 1335
Deploying SIP applications through the console . . . . . 1335
Deploying SIP applications through scripting . . . . . 1336

**Chapter 30. Developing Spring applications** . . . . . 1339
Configuring access to a Spring application data source . . . . . 1339

**Chapter 31. Developing Transactions** . . . . . 1341
Developing components to use transactions . . . . . 1341
Configuring transactional deployment attributes . . . . . 1341
Using component-managed transactions . . . . . 1345
Using one-phase and two-phase commit resources in the same transaction . . . . . 1346

**Chapter 32. Developing web applications** . . . . . 1351
Developing web applications . . . . . 1351
Developing servlets . . . . . 1352
Developing JSP files . . . . . 1364
Developing JSF files . . . . . 1390
Defining an extension for the registry filter . . . . . 1399
Contexts and Dependency Injection (CDI) . . . . . 1404
Developing servlet applications using asyncrhonous request dispatcher . . . . . 1407
Assembling web applications . . . . . 1408
Assembling web applications . . . . . 1408
Configuring JavaServer Faces implementation . . . . . 1412
Deploying JavaServer Pages and JavaServer Faces files . . . . . 1413
JSP class loading settings . . . . . 1413
JavaServer Pages (JSP) runtime reloading settings . . . . . 1414
JSP and JSF option settings . . . . . 1419
JSP run time compilation settings . . . . . 1420
Provide options to compile JavaServer Pages settings . . . . . 1421
Developing session management in servlets . . . . . 1423
Assembling so that session data can be shared . . . . . 1424

**Chapter 33. Developing web services** . . . . . 1427
Using JAXB for XML data binding . . . . . 1427
Using JAXB schemagen tooling to generate an XML schema file from a Java class . . . . . 1428
Using JAXB xjc tooling to generate JAXB classes from an XML schema file . . . . . 1432
Using the JAXB runtime to marshal and unmarshal XML documents . . . . . 1434
xjc command for JAXB applications . . . . . 1435

schemagen command for JAXB applications . . . 1437
Developing JAX-WS web services (bottom up) . . . 1439
Setting up a development environment for web services . . . 1439
Developing JAX-WS web services with annotations . . . 1440
Generating Java artifacts for JAX-WS applications . . . 1463
Enabling MTOM for JAX-WS web services . . . 1471
Enforcing adherence to WSDL bindings in JAX-WS web services . . . 1478
Developing a webservices.xml deployment descriptor for JAX-WS applications . . . 1479
Completing the JavaBeans implementation for JAX-WS applications . . . 1483
Completing the EJB implementation for JAX-WS applications . . . 1483
Developing JAX-WS web services with WSDL files (top down) . . . 1484
Setting up a development environment for web services . . . 1484
Generating Java artifacts for JAX-WS applications from a WSDL file . . . 1485
Enabling MTOM for JAX-WS web services . . . 1490
Enforcing adherence to WSDL bindings in JAX-WS web services . . . 1497
Developing a webservices.xml deployment descriptor for JAX-WS applications . . . 1498
Completing the JavaBeans implementation for JAX-WS applications . . . 1502
Completing the EJB implementation for JAX-WS applications . . . 1502
Developing JAX-WS clients . . . 1503
Developing a JAX-WS client from a WSDL file . . . 1503
Developing deployment descriptors for a JAX-WS client . . . 1506
Developing a dynamic client using JAX-WS APIs . . . 1508
Invoking JAX-WS web services asynchronously . . . 1510
Implementing extensions to JAX-WS web services clients . . . 1514
Developing JAX-RPC web services . . . 1524
Setting up a development environment for web services . . . 1524
Developing a service endpoint interface from JavaBeans for JAX-RPC applications . . . 1525
Developing a service endpoint interface from enterprise beans for JAX-RPC applications . . . 1526
Developing a WSDL file for JAX-RPC applications . . . 1527
Completing the JavaBeans implementation for JAX-RPC applications . . . 1546
Completing the EJB implementation for JAX-RPC applications . . . 1547
Configuring the webservices.xml deployment descriptor for JAX-RPC web services . . . 1548
Configuring the webservices.xml deployment descriptor for handler classes . . . 1549
Configuring the ibm-webservices-bnd.xmi deployment descriptor for JAX-RPC web services 1550
Developing JAX-RPC web services with WSDL files (top down) . . . 1552
Setting up a development environment for web services . . . 1552
Developing Java artifacts for JAX-RPC applications from a WSDL file . . . 1552
Developing EJB implementation templates and bindings from a WSDL file for JAX-RPC web services . . . 1554
Completing the JavaBeans implementation for JAX-RPC applications . . . 1555
Completing the EJB implementation for JAX-RPC applications . . . 1556

# How to send your comments

Your feedback is important in helping to provide the most accurate and highest quality information.

- To send comments on articles in the WebSphere Application Server Information Center
  1. Display the article in your Web browser and scroll to the end of the article.
  2. Click on the **Feedback** link at the bottom of the article, and a separate window containing an e-mail form appears.
  3. Fill out the e-mail form as instructed, and click on **Submit feedback** .
- To send comments on PDF books, you can e-mail your comments to: **wasdoc@us.ibm.com** or fax them to 919-254-5250.

  Be sure to include the document name and number, the WebSphere Application Server version you are using, and, if applicable, the specific page, table, or figure number on which you are commenting.

When you send information to IBM, you grant IBM a nonexclusive right to use or distribute the information in any way it believes appropriate without incurring any obligation to you.

© Copyright IBM Corp. 2011

# Changes to serve you more quickly

**Print sections directly from the information center navigation**

PDF books are provided as a convenience format for easy printing, reading, and offline use. The information center is the official delivery format for IBM WebSphere Application Server documentation. If you use the PDF books primarily for convenient printing, it is now easier to print various parts of the information center as needed, quickly and directly from the information center navigation tree.

To print a section of the information center navigation:

1. Hover your cursor over an entry in the information center navigation until the **Open Quick Menu** icon is displayed beside the entry.
2. Right-click the icon to display a menu for printing or searching your selected section of the navigation tree.
3. If you select **Print this topic and subtopics** from the menu, the selected section is launched in a separate browser window as one HTML file. The HTML file includes each of the topics in the section, with a table of contents at the top.
4. Print the HTML file.

For performance reasons, the number of topics you can print at one time is limited. You are notified if your selection contains too many topics. If the current limit is too restrictive, use the feedback link to suggest a preferable limit. The feedback link is available at the end of most information center pages.

**Under construction!**

The Information Development Team for IBM WebSphere Application Server is changing its PDF book delivery strategy to respond better to user needs. The intention is to deliver the content to you in PDF format more frequently. During a temporary transition phase, you might experience broken links. During the transition phase, expect the following link behavior:

- Links to Web addresses beginning with http:// work
- Links that refer to specific page numbers within the same PDF book work
- The remaining links will *not* work. You receive an error message when you click them

Thanks for your patience, in the short term, to facilitate the transition to more frequent PDF book updates.

# Chapter 1. Developing ActivitySessions

This page provides a starting point for finding information about ActivitySessions, a WebSphere extension for reducing the complexity of commitment rules and limitations that are associated with one-phase commit resources.

Use ActivitySessions to extend the scope and group multiple local transactions. With this capability, you can commit these transactions based on either deployment criteria or through explicit program logic. More introduction...

## Developing an enterprise application to use ActivitySessions

This topic provides an overview of the high-level tasks for using ActivitySessions in enterprise applications.

### About this task

Before you use ActivitySessions in enterprise applications, consider the following points:

- An application that is accessed under an ActivitySession context can receive a javax.transaction.InvalidTransactionException RemoteException, thrown by the Enterprise JavaBeans (EJB) container when servicing any application method. This exception occurs when an instance of an enterprise bean that has an ActivitySession-based activation policy becomes involved with concurrent global and local transactions.
- To enable an enterprise bean to participate in an ActivitySession context and support ActivitySession-based operations, it must be configured with an ActivationPolicy of ACTIVITY_SESSION. A bean configured with ActivationPolicy of either TRANSACTION or ONCE cannot participate in an ActivitySession context.
- A session bean can either use container-managed ActivitySessions or implement bean-managed ActivitySessions; entity beans can use only container-managed ActivitySessions. A bean is deployed to be bean-managed or container-managed with respect to ActivitySession management by setting its transaction type deployment attribute to be bean-managed or container-managed when you deploy the enterprise bean. A bean that uses bean-managed transactions can use bean-managed ActivitySessions; a bean that uses container-managed transactions can use container-managed ActivitySessions.
- If you want a session bean or an enterprise application client to manage its own ActivitySessions, you must write the code that explicitly demarcates the boundaries of an ActivitySession, as described in Developing an enterprise bean or J2EE client to manage ActivitySessions.

The following high level tasks illustrate how to use an ActivitySession in an enterprise application:

### Procedure

- Develop an enterprise application that uses one or more enterprise beans that are persisted to non-transactional data stores. Use this approach for an application that needs to coordinate multiple one-phase resource managers, for example, for two or more entity enterprise beans whose persistence is delegated to LocalTransaction resource adapters.

  In this scenario, the enterprise beans that the application uses have an Activation policy of ActivitySession and a local transaction containment policy with a boundary of ActivitySession and resolution-control of ContainerAtBoundary. The container synchronizes the EJB state data with the one-phase resource managers at ActivitySession completion, and no application code needs to be aware of ActivitySession support.
- Develop an enterprise application in which an enterprise bean accesses a resource manager multiple times in different business methods. Use this approach for an application that needs to extend a resource manager local transaction (RMLT) over several business methods of an enterprise bean instance.

  In this scenario, the enterprise beans that the application uses have an Activation policy of ActivitySession and a local transaction containment policy with a boundary of ActivitySession and

© IBM Corporation 2009

resolution-control of Application. The application logic starts and ends the RMLTs, for example, using the javax.resource.cci.LocalTransaction interface offered by a LocalTransaction Connector, but is not constrained to start and commit the LocalTransaction in the same method.

- Develop an enterprise client application to use an ActivitySession to scope EJB activation and load-balancing. Use this approach for an application client that needs to access an entity bean instance several times in the same client session, either without needing to run under a transaction context, or with the need to run under a number of distinct and serially-executed transactions.

  In this scenario, the enterprise beans that the application uses have an Activation policy of ActivitySession and a local transaction containment policy appropriate to the function of the enterprise bean. The enterprise client application can represent a period of user activity, for example a signon period, during which a number of interactions occur with one or more enterprise beans. If the enterprise client application begins an ActivitySession and invokes the enterprise beans within the scope of the unit of work (UOW) that the ActivitySession represents, the container on the ActivitySession boundary activates the enterprise bean instances. The instances remain in the active state until the container passivates them at the end of the ActivitySession. Workload affinity management based on the ActivitySession is a platform quality of service. Global transactions can begin and end within the ActivitySession, if they are wholly encapsulated by the ActivitySession and run serially. EJB instances that are activated at the ActivitySession boundary remain active across the serial global transactions.
- Develop a Web application client to participate in an ActivitySession context. A Web application that runs in the WebSphere® Web container can participate in an ActivitySession context. Web applications can use the UserActivitySession interface to begin and end an ActivitySession context. Also, the ActivitySession can be associated with an HttpSession, thereby extending access to the ActivitySession over multiple HTTP invocations and supporting EJB activation periods that can be determined by the lifecycle of the Web HTTP client.

  The Web container manages ActivitySessions based on deployment descriptor attributes associated with the Web application module.

### Example

For examples of using ActivitySessions in enterprise applications, see the topic about ActivitySessions samples.

## Developing an enterprise bean or enterprise application client to manage ActivitySessions

Use this task to write the code needed by a session EJB or enterprise application client to manage an ActivitySession, based on the example code extract provided.

### About this task

In most situations, an enterprise bean can depend on the EJB container to manage ActivitySessions within the bean. In these situations, all you need to do is set the appropriate ActivitySession attributes in the EJB module deployment descriptor, as described in the topic about configuring EJB module ActivitySession deployment attributes.. Further, in general, it is practical to design your enterprise beans so that all ActivitySession management is handled at the enterprise bean level.

However, in some cases you may need to have a session bean or enterprise application client participate directly in ActivitySessions. You then need to write the code needed by the session bean or enterprise application client to manage its own ActivitySessions.

**Note:** Session beans that use BMT and have an **Activate at** setting of `Activity session` can manage ActivitySessions. Entity beans cannot manage ActivitySessions; the EJB container always manages ActivitySessions within entity beans.

When preparing to write code needed by a session bean or enterprise application client to manage ActivitySessions, consider the points described in the topic about ActivitySession and transaction contexts.

To write the code needed by a session EJB or enterprise application client to manage an ActivitySession, complete the following steps, based on the following example code extract.

### Procedure

1. Get an initial context for the ActivitySession.
2. Get an implementation of the UserActivitySession interface, by a JNDI lookup of the URL java:comp/websphere/UserActivitySession. The UserActivitySession interface is used to begin and end ActivitySessions and to query various attributes of the active ActivitySession associated with the thread.
3. Set the timeout, in seconds, after which any subsequently started ActivitySessions are automatically completed by the ActivitySession service. If the session bean or enterprise application client does not specifically set this value, the default timeout (300 seconds) is used.

   The default timeout can also be overridden for each application server, on the ***server*-> Activity Session Service** panel of the administrative console.
4. Start the ActivitySession, by calling the beginSession() method of the UserActivitySession.
5. Within the ActivitySession, call business methods to do the work needed. You can also call other methods of UserActivitySession to manage the ActivitySession; for example, to get the status of the ActivitySession or to checkpoint all the ActivitySession resources involved in the ActivitySession.
6. End the ActivitySession, by calling the endSession() method of the UserActivitySession.

### Example

The following code extract provides a basic example of using the UserActivitySession interface:

```
// Get initial context
  InitialContext ic = new InitialContext();
// Lookup UserActivitySession
  UserActivitySession uas =
 (UserActivitySession)ic.lookup("java:comp/websphere/UserActivitySession");

// Set the ActivitySession timeout to 60 seconds
  uas.setSessionTimeout(60);
// Start a new ActivitySession context
  uas.beginSession();
// Do some work under this context
  MyBeanA beanA.doSomething();
  ...
  MyBeanB beanB.doSomethingElse();
// End the context
  uas.endSession(EndModeCheckpoint);
```

## ActivitySession service application programming interfaces

The ActivitySession service provides an application programming interface that is available to Web applications, session Enterprise JavaBeans (EJBs), and Java platform for enterprise applications client applications for application-managed demarcation of ActivitySession context.

Applications use the UserActivitySession interface, which provides demarcation scope methods.

### ActivitySession API

The ActivitySession service provides the UserActivitySession interface for use by EJB Session beans using bean-managed context demarcation, Web application components that are configured with the **ActivitySession control** attribute set to `Web Application`, and Java platform for enterprise applications client applications. This UserActivitySession interface defines the set of ActivitySession operations that are available to an application component. To obtain an implementation of this interface, use a Java Naming and Directory Interface (JNDI) lookup of the URL `java:comp/websphere/UserActivitySession`. The

UserActivitySession interface is used to begin and end ActivitySessions and to query various attributes of the active ActivitySession that is associated with the thread.

For more information about the ActivitySession API, see the application programming interface (API) reference information.

The ActivitySession API and the implementation of its interfaces is contained in the com.ibm.websphere.ActivitySession package.

### Programming Examples

The following code extract provides a basic example of using the UserActivitySession interface:

```
// Get initial context
  InitialContext ic = new InitialContext();
// Lookup UserActivitySession
  UserActivitySession uas =
  (UserActivitySession)ic.lookup("java:comp/websphere/UserActivitySession");

// Set the ActivitySession timeout to 60 seconds
  uas.setSessionTimeout(60);
// Start a new ActivitySession context
  uas.beginSession();
// Do some work under this context
  MyBeanA beanA.doSomething();
  ...
  MyBeanB beanB.doSomethingElse();
// End the context
  uas.endSession(EndModeCheckpoint);
```

## Assembling applications that use ActivitySessions

You can set the ActivitySession deployment attributes for an enterprise bean or a Web application.

### About this task

For an enterprise bean, you can set the ActivitySession deployment attributes so that the bean can participate in an ActivitySession context and support ActivitySession-based operations.

For a Web application, you can set the ActivitySession deployment attributes so that the application can start UserActivitySessions and perform work scoped within ActivitySessions.

### Procedure

- Set EJB module ActivitySession deployment attributes.
- Set Web module ActivitySession deployment attributes.

## Setting EJB module ActivitySession deployment attributes

Use this task to set the ActivitySession deployment attributes for an enterprise bean to enable the bean to participate in an ActivitySession context and support ActivitySession-based operations.

### Before you begin

This task description assumes that you have an Enterprise Archive (EAR) file, which contains an application enterprise bean that can be deployed in WebSphere Application Server. For more details, see the topic about assembling applications.

### About this task

You configure the deployment attributes of an application by using an assembly tool. This topic describes the use of Rational® Application Developer to configure the ActivitySession deployment attributes. These

attributes are in addition to other deployment attributes, for example, “Load at”, which specifies when the bean loads its state from the database. For details about the fields in the assembly tool, and for associated task help, refer to the Rational Application Developer information.

To set the ActivitySession deployment attributes for an enterprise bean, complete the following steps:

## Procedure

1. Start the assembly tool. For more information, refer to the Rational Application Developer information.
2. Create or edit the application EAR file.

   **Note:** Ensure that you set the target server as WebSphere Application Server Version 7.0.

   For example, to change attributes of an existing application, use the Import wizard to import the EAR file into the assembly tool. To start the Import wizard:

   a. Click **File** > **Import** > **EAR file**.
   b. Click **Next**, then select the EAR file.
   c. In the Target server field, select `WebSphere Application Server v7.0`.
   d. Click **Finish**.
3. In the Project Explorer view of the Java EE perspective, right-click the EJB module for the enterprise bean instance, then click **Open With** > **Deployment Descriptor Editor**. A property dialog notebook for the enterprise bean instance is displayed in the property pane.
4. In the property pane, select the Beans tab.
5. Select the bean that you want to change.
6. In the WebSphere Extensions section, under **Bean Cache**, set the **Activate at** attribute to **ActivitySession**:

   An enterprise bean with this activation policy is activated and passivated as follows:
   - On an ActivitySession boundary, if an ActivitySession context is present on activation.
   - On a transaction boundary, if a transaction context, but no ActivitySession context, is present on activation.
   - Otherwise, on an invocation boundary.
7. In the Local Transactions group box, set the **Boundary** attribute to **ActivitySession**: When this setting is used, the local transaction must be resolved within the scope of any ActivitySession in which it was started or, if no ActivitySession context is present, within the same bean method in which it was started.

   A setting of ActivitySession does not apply to any EJB home methods, for example, create or finder methods. EJB home methods cannot participate in an ActivitySession because this situation might cause deadlocks.
8. For entity beans, or session beans, set the ActivitySession properties for each EJB method.
   a. In the property pane, select the ActivitySession tab.
   b. In the **Configure ActivitySession policies** field, click **Add** or **Edit** to set the **ActivitySession kind** attribute for methods of the enterprise bean. This specifies how the container must manage the ActivitySession boundaries when delegating a method invocation to an enterprise bean's business method:

      **Never** The container invokes bean methods without an ActivitySession context.
      - If the client invokes a bean method from within an ActivitySession context, the container throws an InvalidActivityException exception, which is a javax.rmi.RemoteException.
      - If the client invokes a bean method from outside an ActivitySession context, the container behaves in the same way as if the **Not Supported** value was set. The client must call the method without an ActivitySession context.

      **Mandatory**
      The container always invokes the bean method within the ActivitySession context associated with the client. If the client attempts to invoke the bean method without an

ActivitySession context, the container throws an ActivityRequiredException exception to the client. The ActivitySession context is passed to any EJB object or resource accessed by an enterprise bean method.

The ActivityRequiredException exception is javax.rmi.RemoteException.

**Requires new**
The container always invokes the bean method within a new ActivitySession context, regardless of whether the client invokes the method within or outside an ActivitySession context. The new ActivitySession context is passed to any enterprise bean objects or resources that are used by this bean method.

Any received ActivitySession context is suspended for the duration of the method and resumed after the method ends. The container starts a new ActivitySession before method dispatch and completes it after the method ends.

**Required**
The container invokes the bean method within an ActivitySession context. If a client invokes a bean method from within an ActivitySession context, the container invokes the bean method within the client ActivitySession context. If a client invokes a bean method outside an ActivitySession context, the container creates a new ActivitySession context and invokes the bean method from within that context. The ActivitySession context is passed to any enterprise bean objects or resources that are used by this bean method.

**Not supported**
The container invokes bean methods without an ActivitySession context. If a client invokes a bean method from within an ActivitySession context, the container suspends the association between the ActivitySession and the current thread before invoking the method on the enterprise bean instance. The container then resumes the suspended association when the method invocation returns. The suspended ActivitySession context is not passed to any enterprise bean objects or resources that are used by this bean method.

**Supports**
If the client invokes the bean method within an ActivitySession, the container invokes the bean method within an ActivitySession context. If the client invokes the bean method without a ActivitySession context, the container invokes the bean method without an ActivitySession context. The ActivitySession context is passed to any enterprise bean objects or resources that are used by this bean method.

c. Click **Next**.

d. Select the methods to which the ActivitySession kind policy is to be applied.

e. Click **Finish**.

How the container manages the ActivitySession boundaries when delegating a method invocation depends on both the **ActivitySession kind** set here, and the **Container transaction type**, as described in the topic about configuring transactional deployment attributes. For more detail about the relationship between these two properties, see the topic about ActivitySession and transaction container policies in combination.

9. Save your changes to the deployment descriptor.
   a. Close the Deployment Descriptor Editor.
   b. When prompted, click **Yes** to save changes to the deployment descriptor.
10. Verify the archive files. For more information about verifying files using Rational Application Developer, refer to the Rational Application Developer information.
11. From the popup menu of the project, click **Deploy** to generate EJB deployment code.
12. Optional: Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard.

**Important:** Use **Run On Server** for unit testing only. The assembly tool controls the WebSphere Application Server installation and, when an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use the **Run On Server** option on production servers.

### What to do next

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that is to run the application. For example, to use the administrative console, see the topic about deploying and administering enterprise applications.

## Setting Web module ActivitySession deployment attributes

Use this task to set the ActivitySession deployment attributes for a Web application to start UserActivitySessions and perform work scoped within ActivitySessions.

### Before you begin

This task assumes that you have an Enterprise Archive (EAR) file that contains an application enterprise bean that can be deployed in WebSphere Application Server. For more details, see the topic about assembling applications.

### About this task

You can configure the deployment attributes of an application by using an assembly tool. This topic describes the use of Rational Application Developer to configure the deployment attributes.

To set the ActivitySession deployment attributes for a Web application, complete the following steps:

### Procedure

1. Start the assembly tool. For more information, refer to the Rational Application Developer information.
2. Create or edit the Web module. For example, to change attributes of an existing module, click **File** > **Open**, then select the archive file for the module. For example, to change attributes of an existing module, use the Import wizard to import the EAR or WAR file into the assembly tool. To start the Import wizard:
   a. Click **File** > **Import**.
   b. Expand the Web folder, click **WAR file**, then click **Next**.
   c. Select the WAR file, then click **Finish**.
3. In the Project Explorer view of the Java EE perspective, right-click the component instance, right-click **Deployment Descriptor Editor**, then click **Open With** . A property dialog notebook for the Web module is displayed in the property pane.
4. In the property pane, select the Extended services tab.
5. Select the servlet that you want to change.
6. In the ActivitySession section, set the **ActivitySession control kind** attribute to Application, Container, or None.
   **Application**
   The Web application is responsible for starting and ending ActivitySessions, as follows:
   - If an HttpSession is active when an application begins an ActivitySession, the container associates the ActivitySession with the HttpSession.
   - If an ActivitySession is started in the absence of an HttpSession, the application must ensure it is completed before the dispatched method completes; otherwise, an exception results.
   - If an HttpSession is associated with a request dispatched to an application with this ActivitySession control value, and if that HttpSession has an ActivitySession associated

with it, the container dispatches the request in the context of that ActivitySession. For example, the container resumes the ActivitySession context onto the thread before the dispatch.

- A Web application can use both transactions and ActivitySessions. Any transactions started within the scope of an ActivitySession must be ended by the Web component that started them and within the same request dispatch.

**Container**
A servlet has no access to UserActivitySessions. Any HttpSession started by the servlet has an ActivitySession automatically associated with it by the container, and this ActivitySession is put onto the thread of execution. If such a servlet is dispatched by a request that has an HttpSession containing no ActivitySession, then the container starts an ActivitySession and associates it with the HttpSession and the thread.

A Web application can use both transactions and ActivitySessions. Any transactions started within the scope of an ActivitySession must be ended by the Web component that started them and within the same request dispatch.

**None** A servlet has no access to UserActivitySession. An HttpSession started by the servlet does not have an ActivitySession automatically associated with it by the container. If such a servlet is dispatched by a request that has an HttpSession containing an ActivitySession, then the container dispatches the request in the context of that ActivitySession. For example, the container resumes the ActivitySession context onto the thread before the dispatch.

7. To apply the changes and close the assembly tool, click **OK**. Otherwise, to apply the values but keep the property dialog open for additional edits, click **Apply**.
8. Save your changes to the deployment descriptor.
   a. Close the deployment descriptor editor.
   b. When prompted, click **Yes** to save changes to the deployment descriptor.
9. Verify the archive files. For more information about verifying files using Rational Application Developer, refer to the Rational Application Developer information.
10. From the popup menu of the project, click **Deploy** to generate EJB deployment code.
11. Optional: Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard.

**Important:** Use **Run On Server** for unit testing only. The assembly tool controls the WebSphere Application Server installation and, when an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use the **Run On Server** option on production servers.

## What to do next

After assembling your application, use a systems management tool to deploy the WAR file. For example, to use the administrative console, see the topic about deploying and administering enterprise applications.

# Chapter 2. Developing Application profiling

This page provides a starting point for finding information about application profiling, a WebSphere extension for defining strategies to dynamically control concurrency, prefetch, and read-ahead.

Application profiling and access intent provide a flexible method to fine-tune application performance for enterprise beans without impacting source code. Different enterprise beans, and even different methods in one enterprise bean, can have their own intent to access resources. Profiling the components based on their access intent increases performance in the application server run time.

## Using the TaskNameManager interface

Using the TaskNameManager interface, you can programmatically set the current task name. It enables both overriding of the current task associated with the thread of execution and resetting of the current task with the original task.

### About this task

Except for J2EE 1.3 applications that are running on a server where the 5.x Compatibility Mode attribute is selected, this interface cannot be used within Enterprise JavaBeans that are configured for container-managed transactions or container-managed ActivitySessions because units of work can only be associated with a task at the exact time that the unit of work is initiated. The call to set the task name must therefore be invoked before the unit of work is begun. Units of work cannot be named after they are begun. Calls on this interface during the execution of a container-managed unit of work are simply ignored.

Application profiling does not support queries of the task that is in operation at run time. Instead, applications interact with logical task names that are declaratively configured as application managed tasks. Logical references enable the actual task name to be changed without having to recompile applications.

Wherever possible, avoid setting tasks programmatically. The declarative method results in more portable function that can be easily adjusted without requiring redevelopment and recompilation.

**Note:** If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

For a Version 6.0 client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the launchClient command.

### Procedure

1. Configure application-managed tasks. Application profiling requires that a task name reference be declared for any task that is to be set programmatically. Task name references introduce a level of indirection so that the actual task set at run time can be adjusted by reassembly without requiring recoding or recompilation. Any attempt to set a task name that is undeclared as a task reference results in the raising of an exception. If a unit of work has already begun when a task name is set, then that existing unit of work is not associated with the task name. Only units of work that are begun after the task name is set are associated with the task.

© IBM Corporation 2009

Configure application-managed tasks as described in the following topics. To complete these tasks see the assembly tool information center:

- Configure application managed tasks for web components.
- Configure application managed tasks for application clients.
- Configure application managed tasks for Enterprise JavaBeans.

2. Perform a Java Naming and Directory Interface (JNDI) lookup on the TaskNameManager interface:

```
InitialContext ic = new InitialContext();
TaskNameManager tnManager = ic.lookup
("java:comp/websphere/AppProfile/TaskNameManager");
```

The *TaskNameManager* interface is not bound into the namespace if the application profiling service is disabled.

3. Set the task name:

```
try {
tnManager.setTaskName("updateAccount");
}
catch (IllegalTaskNameException e) {
// task name reference not configured. Handle error.
}
// . . .
//
```

The name passed to the setTaskName() method ("updateAccount" in this example) is actually a task name reference that you configured in step one.

4. Begin a UserTransaction

**Note:** If you are using a J2EE 1.3 application with the 5.x Compatibility mode set, the task name set in step 3 is now the active task name and you can disregard this step.

If you are using a J2EE application and the compatibility mode is not set, or if you are using a J2EE 1.4 application, you must begin a transaction for the task name to become active. A task name can only be associated with a transaction. Furthermore, it is associated with a transaction when that transaction is begun, and that task name is associated with the transaction for the life of the transaction. Therefore, the task name set above is not active at this point. You must begin a UserTransaction as the following code snippet illustrates:

```
try{
    InitialContext initCtx = new InitialContext();
    userTran = (UserTransaction) initCtx.lookup("java:comp/UserTransaction");
    userTran.begin();
}
catch(Exception e){
}
// . . .
//
```

Notice the resetTaskName() method on the TaskNameManager interface. Resetting the task name has no effect unless called by a J2EE 1.3 application running on a server for which the 5.x Compatibility Mode attribute is selected on the Application Profile Service's console page. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. A call to resetTask( ) should only be used by J2EE 1.3 applications when the 5.x Compatibility mode is set to undo the effects of any setTaskName() method operations and reestablish whatever task name was current when the component began execution. If the setTaskName() method has not been called, the resetTaskName() method has no effect.

## TaskNameManager interface

The TaskNameManager is the programmatic interface to the application profiling function. Because on rare occasions it may be necessary to programmatically set the current task name, the TaskNameManager interface enables both overriding of the current task associated with the thread of execution and resetting of the current task with the original task.

Application profiling enables you to identify particular units of work to the WebSphere Application Server runtime environment. The run time can tailor its support to the exact requirements of that unit of work. Access intent is currently the only runtime component that makes use of the application profiling functionality. For example, you can configure one transaction to load an entity bean with strong update locks and configure another transaction to load the same entity bean without locks.

Application profiling introduces two concepts in order to achieve this function: tasks and profiles.

A *task* is a configurable name for a unit of work. *Unit of work* in this case means either a transaction or an ActivitySession.

A *profile* is simply a mapping of a task to a set of access intent policies that are configured on entity beans. When an invocation on a bean (whether by a finder method, a container managed relationship (CMR) getter, or a dynamic query) requires data to be retrieved from the back end system, the task of the active unit of work associated with the request is used to determine the exact requirement of the transaction. The same bean loads and behaves differently in the context of the task-to-profile mapping. Each profile provides the developer an opportunity to reconfigure the application's access intent.

Except for J2EE 1.3 applications that are executing on a server where the *5.x Compatibility Mode* attribute is selected, this interface cannot be used within Enterprise JavaBeans that are configured for container-managed transactions or container-managed ActivitySessions because units of work can only be associated with a task at the exact time that the unit of work is initiated. The call to set the task name must therefore be started before the unit of work is begun. Units of work cannot be named after they are begun. Calls on this interface during the execution of a container-managed unit of work are simply ignored.

The TaskNameManager interface is available to all J2EE components using the following Java Naming and Directory Interface (JNDI) lookup:

```
java:comp/websphere/AppProfile/TaskNameManager
```

```
package com.ibm.websphere.appprofile;

/**
* The TaskNameManager is the programmatic interface
* to the application profiling function. Using this interface,
* programmers can set the current task name on the
* thread of execution. The task name must have been
* configured in the deployment descriptors as a task
* reference associated with a task. The set task
* name's scope is the duration of the method
* invocation in the EJB and Web components and for
* the duration of the client process, or until the
* resetTaskName() method is invoked.
*/
public interface TaskNameManager {

/**
* Set the thread's current task name to the specified
* parameter. The task name must have been configured as
* a task reference with a corresponding task or the
* IllegalTaskName exception is thrown.
*/
public void setTaskName(String taskName) throws IllegalTaskNameException;

/**
```

```
* Sets the thread's task name to the value that was set
* at, or imported into, the beginning of the method
* invocation (for EJB and Web components) or process
* (for J2EE clients).
*/
public void resetTaskName();

}
```

## Assembling applications for application profiling

To enable application profiling, you must configure tasks, create an application profile, and declaratively configure a unit of work on necessary methods.

### Before you begin

Application profiling enables multiple access intent policies to be configured on the same entity bean, each specified for a particular unit of work. You can use the one of the default policies or create your own. To create your own access intent policy, see the topic, Creating a custom access intent policy, in the assembly tool information center.

### Procedure

1. Configure tasks. Declaratively configure tasks as described in the following topics that are located in the assembly tool information center:
   - Configuring container-managed tasks for Enterprise Java Beans.
   - Configuring container-managed tasks for web components.
   - Configuring container-managed tasks for application clients.

   On rare occasions, you might find it necessary to configure tasks *programmatically*. Application profiling supports this requirement with a simple interface that enables a task name to be set before a unit of work is programmatically initiated. Setting a task name and then initiating a transaction or ActivitySession causes the task to be associated with the new unit of work. This interface cannot be used within Enterprise JavaBeans that are configured for container-managed transactions or container-managed ActivitySessions because units of work can only be associated with a task at the exact time that the unit of work is initiated. The call to set the task name must therefore be invoked before the unit of work is begun. Units of work cannot be named after they are begun. See the topic, Using the TaskNameManager interface.

   **Note:** If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

   For a Version 6.0 client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the launchClient command.
2. Create an application profile. See the assembly tool information center to complete this task.
3. Declaratively configure a unit of work on necessary methods. In step one of this article, you defined a task on a method. The task defined on a method only becomes active when a unit of work is begun on that method's behalf. The method must begin a new unit of work for the configured task to be applied. If the method runs under an imported unit of work, then the configured task on the method is ignored and the task (if any) associated with the imported unit of work is used. If the container begins a new unit of work when the method executes, then it is associated with the configured task name. Therefore, the last step in assembling applications for application profiling is to define a unit of work on any

method that has a task name (and eventually an Application Profile) associated with it. A unit of work can either be a transaction or an ActivitySession. See the topic, Defining container transactions for EJB modules, for a description on how to configure a transaction on an EJB module. The topic, Configuring transactional deployment attributes, describes how to define other transaction attributes. The topic, Using the ActivitySession service, describes how to use and create an ActivitySession unit of work. For more information about the relationships between tasks and units of work, see the topic, Tasks and units of work considerations.

## What to do next

To complete the following tasks using assembly tools see the assembly tool documentation. The following tasks can be done using assembly tools:

- Automatic configuration of application profiling

  The assembly tool includes a static analysis engine that can assist you in configuring application profiling. The tool examines the compiled classes and the deployment descriptor of a Java EE application to determine the entry point of transactions, calculate the set of entities enlisted in each transaction, and determine whether the entities are read or updated during the course of each identified transaction.
- Automatically configure application profiles and tasks.

  Automatically configure application profiling for an application through static analysis.
- Apply profile-scoped access intent policies to entity beans.

  Configure entities with access intent for an application profile.
- Create a custom access intent policy.

  Define a custom access intent policy, which can be configured for Enterprise JavaBeans (EJB) 2.x and 3.0 entity beans.
- Create an application profile.

  An application profile contains a set of access intent policies applied to an application's entity beans. The access intent policies are only applied for requests that are associated with tasks configured on the application profile.
- Configure container-managed tasks for application clients.

  For application clients that programmatically begin either a transaction or ActivitySession only, you must configure an application client's container-managed task to associate requests from the client with an application profile.
- Configure container-managed tasks for Web components.

  For Web components that programmatically set the configured task and then programmatically begin either a transaction or ActivitySession only, you can configure Web components application-managed tasks to associate requests from a servlet or JavaServer Pages (JSP) file with application profiles.
- Configure container-managed tasks for Enterprise JavaBeans.

  For methods that cause a new transaction or ActivitySession to be started either by the container or programmatically by the EJB developer, you can configure an enterprise bean's container-managed tasks to associate requests from the bean with application profiles.
- Configure container-managed tasks for application clients.

  For application clients that programmatically begin either a transaction or ActivitySession only, you must configure an application client's container-managed task to associate requests from the client with an application profile.
- Configure application-managed tasks for Web components.

  For Web components that programmatically begin either a transaction or ActivitySession only, you can configure a Web component's container-managed task to associate requests from a servlet or JSP file with an application profile.
- Configure application-managed tasks for Enterprise JavaBeans.

For Enterprise JavaBeans that programmatically set the configured task and then programmatically begin either a transaction or ActivitySession only, you can configure EJB application-managed tasks to associate requests from the bean with application profiles.

# Chapter 3. Developing Asynchronous beans

This page provides a starting point for finding information about asynchronous beans.

Asynchronous beans and asynchronous scheduling facilities offer performance enhancements for resource-intensive tasks by enabling single tasks to run as multiple tasks.

## Developing work objects, event listeners, and asynchronous scopes

## Developing work objects to run code in parallel

You can run work objects in parallel, or in a different Java Platform, Enterprise Edition (Java EE) context, by wrapping the code in a work object.

### Before you begin

Your administrator must have configured at least one work manager using the administrative console.

### About this task

To run code in parallel, wrap the code in a work object.

### Procedure

1. Create a work object.

   A work object implements the com.ibm.websphere.asynchbeans.Work interface. For example, you can create a work object that dynamically subscribes to a topic and any component that has access to the event source can add an event on demand:

```
class SampleWork implements Work
{
 boolean released;
 Topic targetTopic;
 EventSource es;
 TopicConnectionFactory tcf;

 public SampleWork(TopicConnectionFactory tcf, EventSource es, Topic targetTopic)
 {
  released = false;
  this.targetTopic = targetTopic;
  this.es = es;
  this.tcf = tcf;
 }

 synchronized boolean getReleased()
 {
  return released;
 }

 public void run()
 {
  try
  {
   // setup our JMS stuff.
   TopicConnection tc = tcf.createConnection();
   TopicSession sess = tc.createSession(false, Session.AUTOACK);
   tc.start();

   MessageListener proxy = es.getEventTrigger(MessageListener.class, false);
   while(!getReleased())
   {
```

© Copyright IBM Corp. 2011

```
    // block for up to 5 seconds.
    Message msg = sess.receiveMessage(5000);
    if(msg != null)
    {
     // fire an event when we get a message
     proxy.onMessage(msg);
    }
   }
   tc.close();
  }
  catch (JMSException ex)
  {
   // handle the exception here
   throw ex;
  }
  finally
  {
   if (tc != null)
   {
    try
    {
     tc.close();
    }
    catch (JMSExceptin ex1)
    {
     // handle exception
    }
   }
  }
 }

 // called when we want to stop the Work object.
 public synchronized void release()
 {
  released = true;
 }
}
```

As a result, any component that has access to the event source can add an event on demand, which allows components to subscribe to a topic in a more scalable way than by simply giving each client subscriber its own thread. The previous example is fully explored in the WebSphere Trader Sample. Refer to the Samples section of the Information Center for details.

2. Determine the number of work managers needed by this application component.
3. Look up the work manager or managers using the work manager resource reference (or logical name) in the java:comp namespace. (For more information on resource references, refer to the References topic.)

   ```
   InitialContext ic = new InitialContext();
   WorkManager wm = (WorkManager)ic.lookup("java:comp/env/wm/myWorkManager");
   ```

   The resource reference for the work manager (in this case, `wm/myWorkManager`) must be declared as a resource reference in the application deployment descriptor.
4. Call the WorkManager.startWork() method using the work object as a parameter. For example:

   ```
   Work w = new MyWork(...);
   WorkItem wi = wm.startWork(w);
   ```

   The startWork() method can take a startTimeout parameter. This specifies a hard time limit for the Work object to be started. The startWork() method returns a work item object. This object is a handle that provides a link from the component to the now running work object.
5. [Optional] If your application component needs to wait for one or more of its running work objects to complete, call the WorkManager.join() method. For example:

```
WorkItem wiA = wm.start(workA);
WorkItem wiB = wm.start(workB);
ArrayList l = new ArrayList();
l.add(wiA);
l.add(wiB);
if(wm.join(l, wm.JOIN_AND, 5000)) // block for up to 5 seconds
{

// both wiA and wiB finished
}
else
{

// timeout

// we can check wiA.getStatus or wiB.getStatus to see which, if any, finished.
}
```

This method takes an array list of work items which your component wants to wait on and a flag that indicates whether the component will wait for one or all of the work objects to complete. You also can specify a timeout value.

6. Use the release() method to signal the unit of work to stop running. The unit of work then attempts to stop running as soon as possible. Typically, this action is completed by toggling a flag using a thread-safe approach like the following example:

```
public synchronized void release()
{
 released = true;
}
```

The Work.run() method can periodically examine this variable to check whether the loop exits or not.

## Work objects

A work object is a type of asynchronous bean used by application components to run code in parallel or in a different Java Platform, Enterprise Edition (Java EE) context.

A work object implements the com.ibm.websphere.asynchbeans.Work interface. A work object is essentially a java.lang.Runnable object that is serializable and provides additional methods. For details, refer to the Interface Work in the generated API documentation.

A component wanting to run work in parallel, or in a different Java EE context, locates a work manager in Java™ Naming and Directory Interface (JNDI), then calls the WorkManager.startWork() method using the work object as a parameter.

The startWork() method returns a work item object. This object is a handle that provides a link from the component to the now running work object. The work item object is typically used when the component needs to wait for one or more of its running work objects to complete. The WorkManager.join() method takes an array list of work items that the component wants to wait on, and a flag indicating whether the component will wait for all or one of the work objects to complete. A timeout can be specified, which prevents the component from waiting indefinitely.

The application does not create Java SE Development Kit 6 (JDK 6) threads because they are not managed threads. Plus, these threads are not affiliated with the Java EE environment, which makes them useless inside an application server. In addition, these threads have no Java EE context (for example, a java:comp) and are not authenticated when they fire. Work object threads are fully supported by the application server and have the same properties as other asynchronous beans.

## Example: Creating work objects

You can create a work object that dynamically subscribes to a topic and any component that has access to the event source can add an event on demand.

The following is an example of a work object that dynamically subscribes to a topic:

```
class SampleWork implements Work
{
 boolean released;
 Topic targetTopic;
 EventSource es;
 TopicConnectionFactory tcf;

 public SampleWork(TopicConnectionFactory tcf, EventSource es, Topic targetTopic)
 {
  released = false;
  this.targetTopic = targetTopic;
  this.es = es;
  this.tcf = tcf;
 }

 synchronized boolean getReleased()
 {
  return released;
 }

 public void run()
 {
  try
  {
   // setup our JMS stuff.
   TopicConnection tc = tcf.createConnection();
   TopicSession sess = tc.createSession(false, Session.AUTOACK);
   tc.start();

   MessageListener proxy = es.getEventTrigger(MessageListener.class, false);
   while(!getReleased())
   {
    // block for up to 5 seconds.
    Message msg = sess.receiveMessage(5000);
    if(msg != null)
    {
     // fire an event when we get a message
     proxy.onMessage(msg);
    }
   }
   tc.close();
  }
  catch (JMSException ex)
  {
   // handle the exception here
   throw ex;
  }
  finally
  {
   if (tc != null)
   {
    try
    {
     tc.close();
    }
    catch (JMSExceptin ex1)
    {
     // handle exception
    }
   }
  }
 }

 // called when we want to stop the Work object.
 public synchronized void release()
```

```
 {
  released = true;
 }
}
```

As a result, any component that has access to the event source can add an event on demand, which allows components to subscribe to a topic in a more scalable way than by simply giving each client subscriber its own thread. The previous example is fully explored in the WebSphere Trader Sample. See the Samples section of the Information Center for details.

# Developing event listeners

Application components that listen for events can use the EventSource.addListener() method to register an event listener object (a type of asynchronous bean) with the event source to which the events will be published. An event source also can fire events in a type-safe manner using any interface.

## About this task

Notifications between components within a single EAR file are handled by a special event source. See the Using the application notification service topic for more information about notifications.

## Procedure

1. Create an event listener object, which can be any type. For example, see the following interface code:

```
interface SampleEventGroup
{
  void finished(String message);
}

class myListener implements SampleEventGroup
{
  public void finished(String message)
  {
  // This will be called when we 'finish'.
  }
}
```

2. Register the event listener object with the event source. For example, see the following code:

```
InitialContext ic = ...;
EventSource es = (EventSource)ic.lookup("java:comp/websphere/ApplicationNotificationService");
myListener l = new myListener();
es.addListener(l);
```

   This enables the myListener.finished() method to be called whenever the event is fired. The following code example shows how this event might be fired:

```
InitialContext ic = ...;
EventSource es = (EventSource)ic.lookup("java:comp/websphere/ApplicationNotificationService");
myListener proxy = es.getEventTrigger(myListener.class);
// fire the 'event' by calling the method
// representing the event on the proxy
proxy.finished("done");
```

## Example

You can fire a listenerCountChanged event that produces a proxy for the interface on which the method fires. Calling the method corresponding to the event on the proxy implements the EventSourceEvents interface. The same proxy can be used to send multiple events simultaneously.

The following code example demonstrates how to fire a listenerCountChanged event:

```
// Imagine this snippet inside an EJB or servlet method.
// Make an inner class implementing the required event interfaces.
EventSourceEvents listener = new Object() implements EventSourceEvents.class
{
 void listenerCountChanged(EventSource es, int old, int newCount)
```

```
 {
  try
  {
     InitialContext ic = new InitialContext();
   // Here, the asynchronous bean can access an environment variable of
   // the component which created it.
    int i = (Integer)ic.lookup("java:comp/env/countValue").intValue());
   if(newCount == i)
   {
    // do something interesting
   }
   // call this event when the following code executes:
  }
  catch(NamingException e)
  {
  }
 }
 void listenerExceptionThrown( EventSource es, Object listener,
       String methodName, Throwable exception)
 {
 }
 void unexpectedException(EventSource es, Object runnable, Throwable exception)
 {
 }
}
// register it.
es.addListener(listener);

...

// now fire an event which the previous listener receives.
EventSourceEvents proxy = (EventSourceEvents)
   es.getEventTrigger(EventSourceEvents.class, false);

proxy.listenerCountChanged(es, 0, 1);

// now, fire another event, you can call any of the methods.
proxy.listenerCountChanged(es, 4, 5);
```

The output in this example is a proxy for the interface on which the method fires. Then, call the method corresponding to the event on the proxy. This action causes the same method with the same parameters to be called on any event listeners that implement the EventSourceEvents interface and that were previously registered with the EventSource "es". The same proxy can be used to send multiple events simultaneously.

The boolean parameter on the getEventTrigger() method is `sameTransaction`. When the `sameTransaction` parameter is `false`, a new transaction is started for each event listener invoked and these event listeners can be called in parallel to the caller. However, the event() method is blocked until all of the event listeners are notified. If the `sameTransaction` parameter is `true`, then the current transaction (if any) on the thread is used for all of the event listeners. The event listeners share the transaction of the method that fired the event. For that reason, all event listeners must run serially in an undetermined order. The order that listeners are called is undefined, and the order in which listeners are registered does not act as a guide for the order used at run time. The method on the proxy does not return until all of the event listeners are called, which means that this action is a synchronous operation.

The parameters that references and listeners pass do not interfere with the function of these references, unless you configure the method to do so. For example, event listeners can be used as collaborators and add data to a map, which was a parameter. Each event listener runs on its own transaction, independent of any transaction that is active on the thread. Extreme care must be taken when the `sameTransaction` parameter is `false` because the parameters can be accessed by multiple threads.

## Using the application notification service

During the application lifetime, individual J2EE components (servlets or enterprise beans) within a single EAR file might need to signal each other. There is an event source in the java:comp namespace that is bound into all components within an EAR file that can be used for notification.

### About this task

The JNDI name for this event source, in the java:comp namespace that is bound into all components within an EAR file, is:

```
java:comp/websphere/ApplicationNotificationService
```

Components within the same application can fire asynchronous events and register event listeners using this application notification service. Startup beans can be used to register these event listeners at application startup or they can be registered dynamically at run time.

### Procedure

To have your enterprise bean or servlet use the application notification service, write code similar to the following example:

```
InitialContext ic = new InitialContext();
EventSource appES = (EventSource)
  ic.lookup("java:comp/websphere/ApplicationNotificationService");
// now, the application can add a listener using the EventSource.addListener method.
// MyEventType is an interface.
MyEventType myListener = ...;
AppES.addListener(myListener);

// later another component can fire events as follows
InitialContext ic = new InitialContext();
EventSource appES = (EventSource)
ic.lookup("java:comp/websphere/ApplicationNotificationService");

// This highlights a constant string on the EventSource interface which
// specifies the 'java:comp/websphere/ApplicationNotificationService' string.
ic.lookup(appES.APPLICATION_NOTIFICATION_EVENT_SOURCE)
// now, the application can add a listener using the EventSource.addListener method.
MyEventType proxy = appES.getEventTrigger(MyEventType.class, false);
proxy.someEvent(someArguments);
```

### Example

## Example: Firing a listenerCountChanged event

You can fire a listenerCountChanged event that produces a proxy for the interface on which the method fires. Calling the method corresponding to the event on the proxy implements the EventSourceEvents interface. The same proxy can be used to send multiple events simultaneously.

The following code example demonstrates how to fire a listenerCountChanged event:

```
// imagine this snippet inside an EJB or servlet method.
// Make an inner class implementing the required event interfaces.
EventSourceEvents listener = new Object() implements EventSourceEvents.class
{
 void listenerCountChanged(EventSource es, int old, int newCount)
 {
  try
  {
     InitialContext ic = new InitialContext();
   // Here, the asynchronous bean can access an environment variable of
   // the component which created it.
    int i = (Integer)ic.lookup("java:comp/env/countValue").intValue());
   if(newCount == i)
   {
```

```
    // do something interesting
   }
   // call this event when the following code executes:
  }
  catch(NamingException e)
  {
  }
 }
 void listenerExceptionThrown( EventSource es, Object listener,
       String methodName, Throwable exception)
 {
 }
 void unexpectedException(EventSource es, Object runnable, Throwable exception)
 {
 }
}
// register it.
es.addListener(listener);

...

// now fire an event which the previous listener receives.
EventSourceEvents proxy = (EventSourceEvents)
   es.getEventTrigger(EventSourceEvents.class, false);

proxy.listenerCountChanged(es, 0, 1);

// now, fire another event, you can call any of the methods.
proxy.listenerCountChanged(es, 4, 5);
```

The output in this example is a proxy for the interface on which the method fires. Then, call the method corresponding to the event on the proxy. This action causes the same method with the same parameters to be called on any event listeners that implement the EventSourceEvents interface and that were previously registered with the EventSource "es". The same proxy can be used to send multiple events simultaneously.

The boolean parameter on the getEventTrigger() method is `sameTransaction`. When the `sameTransaction` parameter is `false`, a new transaction is started for each event listener invoked and these event listeners can be called in parallel to the caller. However, the event() method is blocked until all of the event listeners are notified. If the `sameTransaction` parameter is `true`, then the current transaction (if any) on the thread is used for all of the event listeners. The event listeners share the transaction of the method that fired the event. For that reason, all event listeners must run serially in an undetermined order. The order that listeners are called is undefined, and the order in which listeners are registered does not act as a guide for the order used at run time. The method on the proxy does not return until all of the event listeners are called, which means that this action is a synchronous operation.

The parameters that references and listeners pass do not interfere with the function of these references, unless you configure the method to do so. For example, event listeners can be used as collaborators and add data to a map, which was a parameter. Each event listener runs on its own transaction, independent of any transaction that is active on the thread. Extreme care must be taken when the sameTransaction parameter is `false` because the parameters can be accessed by multiple threads.

## Developing asynchronous scopes

`Asynchronous scopes` are units of scoping that comprise a set of alarms, subsystem monitors, and child asynchronous scopes. You can create asynchronous scopes, starting with the parent.

### About this task

Using asynchronous scopes can involve some or all of the following steps:

## Procedure

1. Create asynchronous scopes. Create the parent asynchronous scope object by using a unique parameter name that calls the AsynchScopeManager.createAsynchScope() method. You can store properties in an asynchronous scope object. This storage provides Java 2 Enterprise Edition (J2EE) applications with a way to store a non-serializable state that otherwise cannot be stored in a session bean. You also can create child asynchronous scopes, which is useful for scoping data beneath the parent.
2. Listen for alarm notifications
   a. Create a listener object by implementing the AlarmListener interface. For more information, refer to the AlarmListener interface in the generated API documentation.
   b. Supply this object to the AlarmManager.create() method, as the target for the alarm. The create() method takes the following parameters:
      **Target for the alarm**
      The target on which the fired() method is called when the alarm is fired.
      **Context**
      The context object for the alarm. This object is useful for supplying alarm-specific data to the listener and supports a single listener for multiple alarms.
      **Interval**
      The number of milliseconds before the alarm fires.

      After the specified interval, the alarm fires and the fired() method of the listener is called with the firing alarm as a parameter. The alarm object is returned. By calling methods on this object, you can cancel or reschedule the alarm.
3. Monitor remote systems.
   a. Implement a mechanism for detecting messages sent from the remote system. For example, publish and subscribe messaging.
   b. Create a subsystem manager object by calling the SubsystemMonitorManager.create() method with the following parameters:
      **Name** Each subsystem monitor must have a unique name.
      **Heartbeat interval**
      The expected interval, in milliseconds, between heartbeats.
      **Missed heart beats until stale or suspect**
      The number of heartbeats that can be missed before the subsystem is marked as stale.
      **Missed heart beats until dead**
      The number of heartbeats that can be missed before the system is marked as dead.
   c. Create an object that implements the SubsystemMonitorEvents interface. For more information, see the SubsystemMonitorEvents in the generated API documentation.
   d. Add an instance of this object to the subsystem monitor using the SubsystemMonitor.addListener() method.
   e. Whenever a heartbeat message arrives from the remote system, call the SubsystemMonitor ping() method.

   The subsystem monitor configures alarms to track the heartbeat status of the remote system. When the ping() method is called, the alarms are reset. If an alarm fires, the ping() method is not called; that is, the application did not receive a heartbeat from the monitored subsystem.

## Example

Asynchronous scopes are useful in stateful server applications. An application can have a startup bean that creates an asynchronous scope on a named work manager. The application also might create subsystem monitors to monitor the health of any remote systems on which the application is dependent.

When a client attaches to the server, the application creates a child asynchronous scope that is owned by the application asynchronous scope for the client and named using the client ID. A subsystem monitor for

monitoring the client might be created on the client asynchronous scope. If the client times out, a callback can clean up the client state on the server. Callbacks can be attached to the application subsystem monitors, on behalf of the client. When a remote system becomes unavailable, the client code in the server is notified and an event is sent to the client to warn that a critical remote system has failed. For example, the failure might be a data feed in an electronic trading application.

## Asynchronous scopes

An asynchronous scope (AsynchScope object) is a unit of scoping provided for use with asynchronous beans.

Asynchronous scopes are collections of alarms, subsystem monitors, and child asynchronous scopes that enable a relationship to form. Each asynchronous scope uses a single work manager.

Each AsynchScope object owns and controls the life cycle of the following objects:

**Child asynchronous scopes**
: Each AsynchScope object extends the AsynchScopeManager interface, which is a factory for AsynchScope objects. (For more information on the AsynchScopeManager interface, refer to the generated API documentation). Any asynchronous scope can therefore create named asynchronous scopes (children). Child asynchronous scopes can be useful for scoping data underneath the parent. All of the child asynchronous scopes must be uniquely named. These children are destroyed if the parent asynchronous scope is destroyed.

**Alarms**
: Each asynchronous scope has an associated alarm manager. All of the alarms created by the alarm manager are automatically cancelled if the associated asynchronous scope is destroyed.

**Subsystem monitors**
: Each asynchronous scope has a subsystem monitor manager, which manages a set of subsystem monitors associated with the asynchronous scope. When the asynchronous scope is destroyed, all of the associated subsystem monitors also are destroyed.

In summary, asynchronous scopes can be organized into an acyclic tree. The life cycle of each asynchronous scope is directly coupled to that of its parent asynchronous scope. Each asynchronous scope is associated with a set of alarms and subsystem monitors, and an optional set of child asynchronous scopes. These objects are cancelled and destroyed when the asynchronous scope is destroyed.

### Asynchronous scope state

Each asynchronous scope has an associated map, in which applications can store their state in the form of name and value pairs.

### Asynchronous scope events

Each asynchronous scope is also an event source. Applications can therefore register event listeners against the asynchronous scope. The event listeners can receive notification if, for example, the AsynchScope object is about to be destroyed.

Applications also can use this event source to fire events only to listeners of this asynchronous scope. For example, an AsynchScope object created for a client session might be used to fire asynchronous events to parties interested in that client.

## Alarms

An alarm runs Java Platform, Enterprise Edition (Java EE) context-aware code at a given time interval. Alarm objects are fine-grained, nonpersistent, transient, and can fire at millisecond intervals.

Alarms are run using a thread pool associated with the work manager that owns the associated asynchronous scope. You must create a work manager instance to create an alarm. Refer to the Configuring work managers topic for more information.

The AlarmManager.createAlarm() method takes an application-written object that implements the AlarmListener interface. For more information on the AlarmListener interface, refer to the generated API documentation. The fired method is called when the alarm expires. The createAlarm() method returns a non-serializable handle, which can be used to cancel or reset the alarm. All of the pending alarms are cancelled when its associated AsynchScope object is destroyed.

**best-practices:** The Java SE Development Kit 6 (JDK6 )already has a timer mechanism, so why create a new one? The JDK 6 is a Java Platform, Standard Edition (Java SE) feature that knows nothing about the Java EE environment. Timers fired by the Java SE feature do not run on a managed thread and are therefore unusable inside an application server. These timers also lack a Java EE context (that is, a java:comp value) and are not authenticated when they fire. The asynchronous scope alarms are fully supported by the product and have the same properties as any other asynchronous bean.

**Alarm performance**

The alarm subsystem is designed to handle a large number of alarms. However, do not expect alarms to process heavy loads when they are firing because this activity slows the processing of later alarms. If an alarm needs to process a heavy load, design a work object that is activated by a work manager. This procedure moves the heavy processing to a different thread and enables the alarm threads to process alarms unhampered. All of the alarms owned by asynchronous scopes that are owned by a single work manager share a common thread pool. The properties of this thread pool can be tuned at the work manager level using the administrative console.

## Subsystem monitors

A subsystem monitor is an object that monitors the health of a remote system. It uses an event source to inform all registered listeners of the health of the system.

AdvancedJava Platform, Enterprise Edition (Java EE) applications often rely on remote, non-managed, non-Java EE systems. These remote systems can periodically send clients a message to indicate that they are working. A subsystem monitor is a set of alarms that tracks indicator messages or heart beats from a remote system.

An application creates a subsystem monitor by calling the SubsystemMonitorManager.create() method with the following parameters:

**Name** Each subsystem monitor must be uniquely named.

**Heart beat interval**
The time period, in milliseconds, between arriving heart beat messages.

**Missed heart beats until stale or suspect**
The number of heart beats that can be missed before the subsystem is marked as stale. This designation indicates that the subsystem might be having problems.

**Missed heart beats until dead**
The number of heart beats that can be missed before the system is considered down. The system then is marked as dead.

The subsystem monitor configures alarms to track the heart beat status. Whenever the ping() method is called, the alarms are reset. If an alarm fires, the ping() method has not been called; that is, the application did not receive a heart beat from the monitored subsystem. When the number of **Missed heart beats until stale** value has elapsed without a ping, a stale event is fired. Later, if the number of **Missed heart beats until dead** value elapses without a ping, a dead event is fired. If a ping is received after a stale or dead notification, a fresh event is sent, which indicates that the subsystem is alive again.

Make the **Missed heart beats until dead** value greater or equal to the **Missed heart beats until stale** value. If **Missed heart beats until stale** value equals the **Missed heart beats until dead** value, then a stale event is not published. Only a dead event is published.

You can register a listener that implements the SubsystemMonitorEvents interface for applications that require notification of events. For more information on the SybsystemMonitorEvents interface, refer to the generated API documentation.

Heart beat messages can be transmitted using a variety of mechanisms. The application must call the SubsystemMonitor ping() method whenever a heart beat message arrives from a remote system, but the method used to detect these messages is up to the application. For example, you might use a Java Message Service (JMS) publish or subscribe implementation or even a third-party Java messaging product that does not implement JMS.

### Asynchronous scopes: Dynamic message bean scenario

Java Platform, Enterprise Edition (Java EE) now supports message-driven beans, but the beans are static. This scenario provides information about how to set up the environment to enable the dynamic message bean.

All of the message sources must be known in advance and bound at deployment time. This action is not always viable, especially in fluid messaging environments such as those found in brokerages. Some environments have publish-subscribe topic spaces that are continually changing and clients need servers that can subscribe on demand to an arbitrary topic.

An asynchronous bean application can create a work object that performs a blocking receive on a Java Message Service (JMS) topic and then publishes the message as an event on an application-defined event source. Clients requiring a subscription to that message can add an event listener to the event source. The event source can inform the work object when there are no listeners. Then, the event source can shut down and make the JMS and thread resources available. The work object registers a listener with its own event source. When the count is one again, the work object knows that it is the only listener and it is time to shut down the work object. The WebSphere Trader Sample uses this pattern to dynamically subscribe to JMS topics at run time to gather stock prices. For more information, see the overview of the samples.

How does the server catch clients that disconnect or crash? It creates a subsystem monitor to watch the client and adds an event listener to catch dead events. When a dead event occurs, the server application can clean up the client server state. For example, the server application can remove the client event listener from the dynamic message bean, thereby allowing the server to subscribe to a dynamic topic only when it is needed.

---

# Assembling timer and work managers

# Assembling applications that use work managers and timer managers

The work manager and timer manager objects are both supported for assembling applications that implement the asynchronous bean technology. You can assemble either work managers or time managers.

### Before you begin

Configure at least one work manager or timer manager using the administrative console.

### About this task

Complete the steps to either assemble work managers or time managers.

## Procedure

1. Assemble applications that use asynchronous beans work managers.
2. Assemble applications that use CommonJ work managers.
3. Assemble applications that use CommonJ timer managers.

## Assembling applications that use a CommonJ WorkManager

When a work manager has been configured, if it references a logical work manager it must be bound to a physical work manager using an assembly tool. Then resources can be created and bound to a physical work manager.

### Before you begin

Your administrator needs to configure at least one work manager using the administrative console.

### About this task

If your application references one or more logical work managers, the logical work managers must be bound to one or more physical work managers using an assembly tool, such as Rational Application Developer.

### Procedure

1. Declare a resource reference for each work manager (required action by the application developer). This forms an EAR file. (For more information on resource references, refer to the References. topic)
2. Bind each resource reference to a physical work manager, using an assembly tool, such as Rational Application Developer.
3. Add a resource reference with the type commonj.work.WorkManager to the application deployment descriptor. The application can look up this work manager using its resource reference name in java:comp. Now, you can use an assembly tool or Rational Application Developer to specify which resource references are bound to the physical commonj.work.WorkManager.

   **Attention:** The previous steps outline the same process used for data sources.

## Assembling applications that use timer managers

When a work manager has been configured, if it references a logical work manager it must be bound to a physical work manager using an assembly tool. Then resources can be created and bound to a physical timer.

### Before you begin

Your administrator needs to configure at least one timer manager using the administrative console.

### About this task

If your application references one or more logical timer managers, the logical timer managers must be bound to one or more physical timer managers using an assembly tool, such as the Rational Application Developer.

### Procedure

1. Declare a resource reference for each timer manager (required action by the application developer). This forms an EAR file. (For more information on resource references, refer to the References topic.)
2. Bind each resource reference to a physical timer manager, using an assembly tool.
3. Add a resource reference with the type commonj.timers.TimerManager to the application deployment descriptor. The application then can look up this timer manager using its resource reference name in java:comp. The assembly tool can specify which resource references are bound to a physical timer manager.

**Attention:** The previous steps outline the same process used for data sources.

## Assembling applications that use asynchronous beans work managers

When a work manager has been configured, if it references a logical work manager it must be bound to a physical work manager using an assembly tool. Then resources can be created and bound to a physical work managers.

### Before you begin

Your administrator needs to configure at least one work manager using the administrative console.

### About this task

If your application references one or more logical work managers, the logical work managers must be bound to one or more physical work managers using an assembly tool.

The CommonJ 1.1 interfaces are supported. Both asynchronous beans and CommonJ interfaces can use one configuration work manager object. The type of interface implemented is resolved during the JNDI lookup time. The type of interface used is determined by the one specified in the resource-reference, instead of the one specified in the configuration object. So, there can be one resource-reference for each interface, per configuration object. Each resource-reference lookup returns the appropriate type of instance. For example, there are two resource-references defined for the `wm/MyWorkManager:` `wm/ABWorkMgr` and `wm/CommonJWorkMgr`. The WebSphere Application Server run time returns the correct interface for each resource-reference lookup.

### Procedure

1. Declare a resource reference for each work manager (required action by the application developer). This action results in an EAR file. For more information on resource references, refer to the References topic.
2. Use an assembly tool to bind each resource reference to a physical work manager.
3. Add a resource reference with the type com.ibm.websphere.asynchbeans.WorkManager to the application deployment descriptor. The application then can look up this work manager using its resource reference name in java:comp. The assembly tool or Rational Application Developer then can specify which resource references are bound to a physical work manager.

   **Attention:** Use the same previous steps to configure data sources.

# Chapter 4. Developing batch applications

You can develop a compute-intensive or transactional batch application, deploy it, then submit the batch application using one of the available methods.

## Developing batch applications

This section covers such areas as a procedure for developing batch applications, xJCL elements, and sample batch applications.

## Transactional batch and compute-intensive batch programming models

The product provides a transactional batch programming model and a compute-intensive programming model.

Both the transactional batch and compute-intensive programming models are implemented as Java objects. They are packaged into an enterprise archive (EAR) file for deployment into the application server environment. The individual programming models provide details on how the life cycle of the application and jobs submitted to it are managed by the grid endpoints. Central to all batch applications is the concept of a job to represent an individual unit of work to be run.

**Note:** The Java Platform, Enterprise Edition (Java EE) applications that the application server hosts typically perform short, lightweight, transactional units of work. In most cases, an individual request can be completed with seconds of processor time and relatively little memory. Many applications, however, must complete batch work that is computational and resource intensive. The batch function extends the application server to accommodate applications that must perform batch work alongside transactional applications. Batch work might take hours or even days to finish and uses large amounts of memory or processing power while it runs.

## Developing a simple compute-intensive application

You can write a simple compute-intensive application using a compute-intensive job controller, the command line, or the Apache ANT tool.

### Procedure

- Create a compute-intensive job using a compute-intensive job controller.
  1. Create a compute-intensive job step.
     a. Create a Java class that implements the com.ibm.websphere.ci.CIWork interface.
     b. Implement business logic.
  2. Declare a compute-intensive job controller.
     a. Add a stateless session bean to your deployment descriptor and point to the implementation class that the product provides.

        Do so by specifying com.ibm.ws.ci.CIControllerBean as the bean class. Do this specification only once per compute-intensive application.
     b. Use com.ibm.ws.ci.CIControllerHome for the remote home interface class and com.ibm.ws.ci.CIController for the remote interface class.
  3. Configure the EJB deployment descriptor.
     a. Configure a resource reference on the controller bean to the WorkManager wm/CIWorkManager default of the type commonj.work.WorkManager.
- Create compute-intensive jobs using the command line.
  1. Create a compute-intensive job step.

© Copyright IBM Corp. 2011

a. Create a Java class that implements the com.ibm.websphere.ci.CIWork interface.
b. Implement business logic.

2. Open a command prompt and ensure that the directory where your Java executable program is located is included in your PATH variable so that you can run the Java command.
3. Issue the following command.

```
java -jar pgcbatchpackager.jar -appname=<application name>
 -jarfile=<jarfile containing POJO step classes> -earfile=<name of the output ear file without .ear>
 [-utilityjars=<semicolon separated list of utility jars>] [-debug] [-gridjob]
```

For example for batch jobs, issue

```
java –jar pgcbatchpackager.jar –appname=SimpleCI –jarfile=SimpleCIEJBs.jar
-earfile=SimpleCI –gridjob=true
```

- Create compute-intensive jobs using ANT.
  1. Create the compute-intensive job step.
     a. Create a Java class that implements the com.ibm.websphere.ci.CIWork interface.
     b. Implement business logic.
  2. For a compute-intensive job, ensure that the pgcbatchpackager.jar is on the class path.
  3. Declare the task.

     Use the following command to declare the task:

```
<taskdef name="pgcpackager" classname="com.ibm.ws.batch.packager.PGCPackager"
         classpath="${FEBaseDir}/grid.pgc.packager/build/lib/pgcbatchpackager.jar" />
```

  4. After compiling the Java files in your application, invoke the pgcpackager task.

```
<pgcpackager appname="<appname>" earFile="<location name of EAR file to generate>"
jarfile="location of the POJO jar file" gridJob="true"/>
```

## Results

You have developed a simple compute-intensive application using a compute-intensive job controller, the command line, or ANT.

## What to do next

Install the compute-intensive application and configure WebSphere grid endpoints.

## Compute-intensive programming model

Compute-intensive applications are applications that perform computationally intensive work that does not fit comfortably into the traditional Java Platform, Enterprise Edition (Java EE) request and response paradigm.

### Compute-intensive applications

There are a number of characteristics that can make these applications unsuitable for traditional Java EE programming models:

- The need for asynchronous submission and start of work
- The need for work to run for extended periods of time
- The need for individual units of work to be visible to and manageable by operators and administrators

The compute-intensive programming model provides an environment that addresses these needs. The compute-intensive programming model is centered around two basic concepts:

1. The use of jobs to submit and manage work asynchronously
2. A minor extension to the asynchronous beans programming model to support work that runs for an extended period

The following sections provide additional information about the extensions to the asynchronous beans programming model.

## Controller bean

The controller bean is a stateless session bean defined in the compute-intensive application deployment descriptor that allows the runtime environment to control jobs for the application. The implementation of this stateless session bean is provided by the application server. The application includes the stateless session bean, shown in the following definition, in the deployment descriptor of one of its enterprise bean modules. Exactly one controller bean must be defined for each compute-intensive application. Since the implementation of the controller bean is provided in the application server runtime, application deployers do not request deployment of enterprise beans during deployment of compute-intensive applications.

```
<session id="supply a suitable name here">
   <ejb-name>CIController</ejb-name>
   <home>com.ibm.ws.ci.CIControllerHome</home>
   <remote>com.ibm.ws.ci.CIController</remote>
   <ejb-class>com.ibm.ws.ci.CIControllerBean</ejb-class>
   <session-type>Stateless</session-type>
   <transaction-type>Bean</transaction-type>
   <resource-ref id="WorkManager_ResourceRef">
      <description>
         WorkManager that is used to execute jobs.

      <res-ref-name>wm/CIWorkManager</res-ref-name>
      <res-type>commonj.work.WorkManager</res-type>
      <res-auth>Container</res-auth>
      <res-sharing-scope>Shareable</res-sharing-scope>
```

## Packaging a compute-intensive application

The logic for a compute-intensive application with some number of CIWork objects plus the classes to support those CIWork objects, is packaged in an enterprise bean module in a Java EE application Enterprise Archive (EAR) file. The deployment descriptor for the enterprise bean module must contain the definition of the stateless session bean previously described. If the application itself uses other enterprise beans or resources, then the definitions for those beans and resources might also be in the deployment descriptor. You can use Java EE development tools such as IBM® Rational Application Developer to develop and package compute-intensive applications in the same way that they are used to construct Java EE applications containing enterprise bean modules and asynchronous beans. You can also use the pgcpackager task to package compute-intensive applications.

## Life cycle of a compute-intensive application

A compute-intensive application is started by the application server in the same way as other Java EE applications. If the application defines any start-up beans, then those beans are run when the application server starts. When a job arrives for the application to run, the compute-intensive execution environment invokes the CIControllerBean stateless session bean defined in the application EJB module deployment descriptor. The Java Naming and Directory Interface (JNDI) name of this stateless session bean is specified in the XML Job Control Language (xJCL) for the job. For each job step, the CIControllerBean stateless session bean completes the following actions:

1. Instantiates the application CIWork object specified by the class name element in the xJCL for the job step using the no-argument constructor of the CIWork class.
2. Invokes the setProperties() method of the CIWork object to pass any properties defined in the xJCL for the job step.
3. Looks up the work manager defined in the deployment descriptor of the enterprise bean module and uses it to asynchronously call the run() method of the CIWork object.

If the job is canceled before the run() method returns, then the CIControllerBean invokes the CIWork object release() method on a separate thread. It is up to the developer of the long-running application to arrange for logic in the release() method to cause the run() method to return promptly. The job remains in a *cancel pending* state until the run() method returns.

If the job is not canceled and the run() method returns without returning an exception, then the job completed successfully. If the run() method returns an exception, then the job status is *execution failed*. After the run() method returns either successfully or with an exception, no further calls are made to the CIWork object. All references to the run() method are dropped.

### Compute-intensive job step

Unlike other batch jobs, compute-intensive jobs consist of one job step. This job step is represented by an instance of a class that implements the com.ibm.websphere.ci.CIWork interface. The CIWork interface extends the commonj.Work work interface from the application server asynchronous beans programming model and Java Specification Request (JSR) 237. These extensions consist of two methods that provide a way to pass the job-step-specific properties specified in the job to the CIWork object.

See the API documentation for more details.

To learn about asynchronous beans, go to Using asynchronous beans section of the WebSphere Application Server Information Center.

## Developing a simple transactional batch application

You can write a simple batch application using a batch job controller and Enterprise JavaBeans (EJB) data stream, the command line, or the Apache ANT tool.

### About this task

**Note:** If the batch step uses a batch data stream (BDS) whose data is local to the file system of the application server to which the batch application is deployed, then certain steps must be followed to support job restart scenarios. If such a batch application is deployed to application servers that can run on multiple machines, then there is no guarantee that the restart request is accepted by the machine on which the batch job originally ran. This occurs when the batch application is deployed to a cluster, and if a batch job that runs against such an application is canceled and then restarted. In this scenario, the deployment might send the restart request to an application server that runs on a different machine. Therefore, in cases where file-based affinity is required, you can apply the following solutions to support the job restart scenario:

- Ensure that the data is equally available to every machine on which the batch application can be started. Use a network file system for this example. This action might reduce performance of application.
- Deploy the application on application servers that can only run on the machine where the local data exists. Complete this action by deploying the application to a cluster that exists in a node group that has only one member node.

**Note:** The batch application developer must ensure that transactional work done in the batch step callback methods inherits the global transaction started by the grid endpoints. This action ensures that work performed under a batch step only gets committed at every checkpoint and rolls back if the step fails.

Some commands are split on multiple lines for printing purposes.

## Procedure

- Create batch jobs using a batch job controller and an EJB data stream.
  1. Create batch job steps.
     a. Create a Java class that implements the com.ibm.websphere.BatchJobStepInterface interface.
     b. Implement business logic.

        If your step has one input and one output stream you can alternatively use the Generic batch step of GenericXDBatchStep.
  2. Create batch data streams.
     a. Create a Java Class that implements the interface com.ibm.websphere.batch.BatchDataStream.

        Batch data streams are accessed from the business logic, for example, from the batch job steps by calling BatchDataStreamMgr with jobID and stepID. JobID and stepID are retrieved from the step bean properties list using keys BatchConstants.JOB_ID and BatchConstants.STEP_ID.
     b. Map BatchConstants.JOB_ID to com.ibm.websphere.batch.JobID and map BatchConstants.STEP_ID to com.ibm.websphere.batch.StepID.

        You should already have access to the BatchConstants class.

        The batch datastream framework provides several ready-to-use patterns to work with different types of datastreams such as file and database. To use the batch datastream framework, complete the following steps.

        1) Identify the data stream type with which you want to operate, such as TextFile, ByteFile, JDBC, or z/OS® stream.
        2) Identify whether you would read from the stream or write to the stream.
        3) See the table in the batch data stream framework and patterns. Select the class from the supporting classes column that matches your data stream type and operation. For example, if you want to read data from a text file, then select TextFileReader.
        4) Implement the interface listed in the pattern name column that corresponds to the supporting class you selected in the previous step. The supporting class handles all the book keeping activities related to the stream and the batch programming model. The implementation class focuses on the stream processing logic.
        5) Declare the supporting class and your implementation class in the xJCL.
        6) Repeat this procedure for each datastream required in your step.
  3. Define batch data streams in xJCL.

```
<batch-data-streams>
   <bds>
<logical-name>inputStream</logical-name>
<props>
     <prop name="PATTERN_IMPL_CLASS" value="MyBDSStreamImplementationClass"/>
<prop name="file.encoding" value="8859_1"/>
     <prop name="FILENAME" value="${inputDataStream}" />
     <prop name="PROCESS_HEADER" value="true"/>
     <prop name="AppendJobIdToFileName" value="true"/> </props>
<impl-class>com.ibm.websphere.batch.devframework.datastreams.patterns.FileByteReader
</impl-class>
</bds>
```

     The PATTERN_IMPL_CLASS class denotes the user implementation of the BDS framework pattern and the impl-class property denotes the supporting class.
  4. Declare a batch job controller.
     a. Add a stateless session bean to your deployment descriptor and point to the implementation class that the product provides. Do so by specifying `com.ibm.ws.batch.BatchJobControllerBean` as the bean class. Do this specification only once per batch application.
     b. Use `com.ibm.ws.batch.BatchJobControllerHome` for the remote home interface class and `com.ibm.ws.batch.BatchJobController` for the remote interface class.
  5. Configure the EJB deployment descriptor.

a. Configure a resource reference on the Controller bean to the default WorkManager wm/BatchWorkManager of the type commonj.work.WorkManager.

**Note:** You must declare the deployment descriptor of the batch controller bean in the Enterprise JavaBeans (EJB) deployment descriptor of a batch application. Only one controller bean can be defined per batch application.

- Create batch jobs using the command line.
  1. Create batch job steps.
     a. Create a Java class that implements the com.ibm.websphere.BatchJobStepInterface interface.
     b. Implement business logic.

        If your step has exactly one input and one output stream you could alternatively use the Generic batch step of GenericXDBatchStep.
  2. Create batch data streams.
     a. Create a Java Class that implements the interface com.ibm.websphere.batch.BatchDataStream.

        Batch data streams are accessed from the business logic, for example, from the batch job steps by calling BatchDataStreamMgr with jobID and stepID. JobID and stepID are retrieved from the step bean properties list using keys BatchConstants.JOB_ID and BatchConstants.STEP_ID.
     b. Map BatchConstants.JOB_ID to com.ibm.websphere.batch.JobID and map BatchConstants.STEP_ID to com.ibm.websphere.batch.StepID.

        You should already have access to the BatchConstants class.

        The batch datastream framework provides several ready-to-use patterns to work with different types of datastreams such as file and database. To use the batch datastream framework, complete the following steps.

        1) Identify the data stream type with which you want to operate, such as TextFile, ByteFile, JDBC, or z/OS stream.
        2) Identify whether you would read from the stream or write to the stream.
        3) See the table in the batch data stream framework and patterns. Select the class from the supporting classes column that matches your data stream type and operation. For example, if you want to read data from a text file, then choose TextFileReader.
        4) Implement the interface listed in the pattern name column that corresponds to the supporting class you selected in the previous step. The supporting class handles all the book keeping activities related to the stream and the batch programming model. The implementation class focuses on the stream processing logic.
        5) Declare the supporting class and your implementation class in the xJCL.
        6) Repeat this procedure for each datastream required in your step.
  3. Open a command prompt and ensure that Java is on the path.
  4. Issue the following command, all on a single line.

```
java -cp ${WAS_INSTALL_ROOT}/plugins/com.ibm.ws.batch.runtime.jar
com.ibm.ws.batch.packager.WSBatchPackager
  -appname=<Application_Name>
  -jarfile=<jarfile containing the POJO batch steps>
  -earfile=<name of the output EAR file without the .ear extension>
  [-utilityjars=<semicolon separated list of utility jars>]
  [-debug]
  [-gridJob]
```

     For example, for batch jobs, issue

```
java -cp ${WAS_INSTALL_ROOT}/plugins/com.ibm.ws.batch.runtime.jar
com.ibm.ws.batch.packager.WSBatchPackager
  -appname=XDCGIVT
  -jarfile=XDCGIVTEJBs.jar
  -earfile=XDCGIVT
```

- Create batch jobs using ANT.

1. Create batch job steps.
   a. Create a Java class that implements the com.ibm.websphere.BatchJobStepInterface interface.
   b. Implement business logic.

      If your step has exactly one input and one output stream you could alternatively use the Generic batch step of GenericXDBatchStep.
2. Create batch data streams.
   a. Create a Java Class that implements the interface com.ibm.websphere.batch.BatchDataStream.

      Batch data streams are accessed from the business logic, for example, from the batch job steps by calling BatchDataStreamMgr with jobID and stepID. JobID and stepID are retrieved from the step bean properties list using keys BatchConstants.JOB_ID and BatchConstants.STEP_ID.
   b. Map BatchConstants.JOB_ID to com.ibm.websphere.batch.JobID and map BatchConstants.STEP_ID to com.ibm.websphere.batch.StepID.

      You should already have access to the BatchConstants class.

      The batch datastream framework provides several ready-to-use patterns to work with different types of datastreams such as file and database. To use the batch datastream framework, complete the following steps.
      1) Identify the data stream type with which you want to operate, such as TextFile, ByteFile, JDBC, or z/OS stream.
      2) Identify whether you would read from the stream or write to the stream.
      3) See the table in the batch data stream framework and patterns. Select the class from the supporting classes column that matches your data stream type and operation. For example, if you want to read data from a text file, then select TextFileReader.
      4) Implement the interface listed in the pattern name column that corresponds to the supporting class you selected in the previous step. The supporting class handles all the book keeping activities related to the stream and the batch programming model. The implementation class focuses on the stream processing logic.
      5) Declare the supporting class and your implementation class in the xJCL.
      6) Repeat this procedure for each datastream required in your step.
3. For a batch job, ensure the com.ibm.ws.batch.runtime.jar file is on the class path.
4. Declare the task.

   Use the following command to declare the task:

   ```
   <taskdef name="pgcpackager" classname="com.ibm.ws.batch.packager.PGCPackager"
     classpath="${WAS_INSTALL_ROOT}/plugins/com.ibm.ws.batch.runtime.jar" />
   ```
5. After compiling the Java files in your application, invoke the WSBatchPackager task.

   ```
   <WSBatchPackager appname="<appname>" earFile="<location name of EAR file to generate>"
   jarfile="location of the POJO jar file"/>
   ```

## Results

You have developed a simple transactional batch application using a batch job controller and Enterprise JavaBeans (EJB) data stream, the command line, or the ANT tool.

## What to do next

Install the compute-intensive application and configure WebSphere grid endpoints.

## Components of a batch application

The batch application developer and the batch run time environment provide the components of a batch application.

The following tables describe the components of a batch application.

*Table 1. Components of a batch application that are provided by the batch application developer. The table includes the component, type, implementation, and provider.*

| Component | Type | Implementation | Provider |
|---|---|---|---|
| Batch job step | POJO | com.ibm.websphere.BatchJobStepInterface | Batch application |
| Checkpoint algorithm | POJO | com.ibm.wsspi.batchCheckpointAlgorithm | Batch application (can use runtime-provided implementation instead) |
| Results algorithm | POJO | com.ibm.wsspi.batchResultsAlgorithm | Batch application (can use runtime-provided implementation instead) |

*Table 2. Components of a batch application that are provided by the batch run time environment. The table includes the component, type, implementation, and provider.*

| Component | Type | Implementation | Provider |
|---|---|---|---|
| Batch job controller | Session bean | | Batch run time environment |
| Checkpoint algorithm | POJO | | Batch run time environment (applications can provide their own) |
| Results algorithm | POJO | | Batch run time environment (applications can provide their own) |

## The batch programming model

Batch applications are Enterprise JavaBeans (EJB) based Java 2 Platform Enterprise Edition (J2EE) applications. These applications conform to a few well-defined interfaces that allow the batch runtime environment to manage the start of batch jobs destined for the application.

**Batch job steps**

A batch job can be composed of one or more batch steps. All steps in a job are processed sequentially. Dividing a batch application into steps allows for separation of distinct tasks in a batch application. You can create batch steps by implementing the com.ibm.websphere.batch.BatchJobStepInterface interface. This interface provides the business logic of the batch step that the batch run time starts to run the batch application.

**Batch controller bean**

A batch application includes a stateless session bean that the product run time provides. This stateless session bean acts as a job step controller. The controller stateless session bean is declared in the application deployment descriptor once per batch application.

**Batch data streams**

Methods on the BatchDataStream interface allow the batch runtime environment to manage the data stream being used by a batch step. For example, one of the methods retrieves current cursor information from the stream to track how much data has been processed by the batch step.

**Checkpoint algorithms**

The batch runtime environment uses checkpoint algorithms to decide how often to commit global transactions under which batch steps are started. The XML Job Control Language (xJCL) definition of a batch job defines the checkpoint algorithms to be used. Properties specified for checkpoint algorithms in xJCL allow for checkpoint behavior, such as transaction timeouts and checkpoint intervals, to be customized for batch steps. The product provides time-based and record-based checkpoint algorithms. A checkpoint algorithm SPI is also provided for building additional custom checkpoint algorithms.

**Results algorithm**

Results algorithms are an optional feature of the batch programming model. Results algorithms are applied to batch steps through XML Job Control Language (xJCL). The algorithms are used to manipulate the return codes of batch jobs. Additionally, these algorithms are place holders for triggers based on step return codes.

**Batch job return codes**

Batch job return codes fall into two groups named *system* and *user*. System return codes are defined as negative integers. User application return codes are defined as positive integers. Both

system and user ranges include the return code of zero (0). If a user application return code is specified in the system return code range, a warning message is posted in the job and system logs.

***Batch job steps:***

You can separate tasks of a batch application into batch steps. Batch steps are implemented as Plain Old Java Object (POJO) classes that implement the interface, com.ibm.websphere.batch.BatchJobStepInterfance. Batch job steps are performed sequentially.

Callback methods in the BatchJobStepInterface allow the grid endpoints to run batch steps when it runs a batch job.

A batch step contains the batchable business logic to run for a portion of the batch job. Typically, a batch step contains code to read a record from a batch data stream, perform business logic with that record and then continue to read the next record. The processJobStep method of a batch step class is called by the grid endpoints in a batch loop. This method contains all the logic that can be batched to perform on data.

The grid endpoints invoke batch step class methods in a global transaction. This global transaction is managed by the grid endpoints. The behavior of the transaction, such as transaction timeout or transaction commit interval, is controlled by the checkpoint algorithm associated with the batch job to which the step belongs.

The following grid endpoints callback methods exist on the BatchJobStepInterface that are invoked by the grid endpoints:

*Table 3. Callback methods for grid endpoints. The table includes the callback method and a description.*

| Callback method | Description |
|---|---|
| setProperties(java.util.Properties properties) | Makes properties defined in XML Job Control Language (xJCL) available to batch step in a java.util.Properties object. This method is invoked in a global transaction. |
| void createJobStep() | Indicates to the step that it has been initialized. Initialization logic, such as retrieving a handle to a batch data stream, can be placed here. This method is invoked in a global transaction. |
| int processJobStep() | Repeatedly invoked by grid endpoints in a batch loop until the return code integer of this method indicates that the step has finished processing. Review BatchConstants in the batch API to see which return codes can be returned. A return code of BatchConstants.STEP_CONTINUE signals to the grid endpoints to continue calling this method in the batch loop. A return code of BatchConstants.STEP_COMPLETE indicates to the grid endpoints that the step has finished and to call destroyJobStep. |
| int destroyJobStep() | Indicates to the step that completion has occurred. The integer return code of this method is arbitrary and can be chosen by the batch application developer. This return code is saved in the grid endpoints database and represents the return code of the batch step. If the results algorithm is associated with the batch job, then this return code is passed to it. If there is a return code-based conditional logic in the xJCL of the batch job, then the grid endpoints use this return code to evaluate that logic. |

The getProperties() method on the BatchJobStepInterface is not currently called by the grid endpoints. The method is included in the interface for symmetry and possible later use.

***Batch return codes:***

The batch job return code is retrieved by using the getBatchJobRC EJB interface, the get BatchJobRC web services interface, or the lrcmd getBatchJobRC command option.

The following table lists the system batch job return codes that the batch environment uses. Do not confuse the batch job return code with either the job status constants (see the com.ibm.websphere.longrun.JobStatusConstants API) or the job scheduler constants (see the com.ibm.websphere.longrun.JobSchedulerConstants API). The JobStatusConstants represent the status of the job such as submitted, ended, restartable, canceled, or execution failed.

The job status can be obtained by using the getJobStatus EJB interface, the getJobStatus web services interface, or through the job management console. The JobSchedulerConstants represent operating conditions returned by the job scheduler on requests involving multiple jobs. For example,

```
int[] cancelJob( String[] jobid ))
```

. These conditions include:

1. Job does not exist
2. Job is in an invalid state
3. Database exception has occurred.

*Table 4. Batch job return codes. The table includes each return code with an explanation.*

| Return code | Explanation |
|---|---|
| 0 | Job ended normally |
| -1 | Internal protocol error - WSGrid utility |
| -2 | Input parameter error - WSGrid utility |
| -4 | Job was suspended |
| -8 | Job was canceled |
| -10 | Job was forcibly canceled (z/OS only) |
| -12 | Job failed and is in restartable state |
| -14 | Job failed and is in execution failed state** |
| -16 | Catastrophic failure - WSGrid utility |

**Note:** This return code value does not apply in the case where the application returns BatchConstants.STEP_COMPLETE_EXECUTION_FAILED from the processJobStep method. In this case, the return code is determined by the application.

There are two options that are used to report an error in a batch application. The first option is for the application to produce an exception when an error is encountered. This results in termination of the job with a batch job return code of -12 and a batch job status of

```
restartable
```

. The second option is for the application to return a BatchConstants.STEP_COMPLETE_EXECUTION_FAILED return code (see the

com.ibm.websphere.batch.BatchConstants API) from the processJobStep method and return an application-specific error return code from the destroyJobStep method. This results in termination of the job and a batch job status of

```
execution failed
```

. The step return code set in the destroyJobStep method is passed to any results algorithm specified on the job step and is used to influence the return code of the job to indicate the specific cause of the failure.

***Batch controller bean:***

In its deployment descriptor, a batch application is required to declare a special stateless session bean. This bean acts as a batch job controller.

Each application can include only a single controller bean. You can only include a controller bean in a single work class, and a batch application can only have a single work class defined. This single work class is created when the application is installed. You can associate this work class with any service policy that has discretionary or queue-time goal type. The implementation of this bean is provided by WebSphere Application Server, not by the batch application. The bean must be declared in the batch application deployment descriptor. Only one controller bean per batch application can be defined. The resource references and EJB references declared on the controller bean are available to batch data streams of the batch application in which the controller bean is declared. For example, if a batch data stream in the application needs access to a WebSphere Application Server data source, then a resource reference to that data source can be declared on the controller bean, and the batch data stream can look up the data source at run time in the java:comp/env name space.

**Restrictions**:

- The home interface must be com.ibm.ws.batch.BatchJobControllerHome.
- The remote interface must be com.ibm.ws.batch.BatchJobController.
- The EJB class must be com.ibm.ws.batch.BatchJobControllerBean.
- The transaction type can be bean or container.
- The session type must be stateless.
- There can be at most one batch controller stateless session bean per batch application.

The following example deployment descriptor illustrates a batch controller stateless session bean:

```
<session id="BatchController>
    <ejb-name>BatchController</ejb-name>
    <home>com.ibm.ws.batch.BatchJobControllerHome</home>
    <remote>com.ibm.ws.batch.BatchJobController</remote>
    <ejb-class>com.ibm.ws.batch.BatchJobControllerBean</ejb-class>
    <session-type>Stateless</session-type>
    <transaction-type>Bean</transaction-type>
    <resource-ref id="ResourceRef_1117024737807">
            <description></description>
            <res-ref-name>wm/BatchWorkManager</res-ref-name>
            <res-type>commonj.work.WorkManager</res-type>
            <res-auth>Container</res-auth>
            <res-sharing-scope>Shareable</res-sharing-scope>
        </resource-ref>
</session>
```

***Batch data streams:***

Batch data streams (BDS) are Java objects that provide an abstraction for the data stream processed by a batch step. A batch step can have one or more BDS objects associated with it. The grid endpoints make the BDS associated with the batch step available at run time. The grid endpoints also manages the life cycle of a BDS by invoking batch-specific callbacks.

A BDS object implements the com.ibm.websphere.batch.BatchDataStream interface. This interface is server agnostic. The implementing object can retrieve data from any type of data source, for example, files and databases. Call back methods on the BatchDataStream interface allow the grid endpoints to manage the BDS at run time. One of the key features of a BDS is its capability to convey its current position in the stream to the grid endpoints, and the capability to move itself to a given location in the data stream. This feature allows the grid endpoints to record (in the grid endpoints database) how much data a batch step has processed. This information is recorded on every checkpoint. Therefore, the grid endpoints can restart a batch job from a recorded position in the data stream if the job is canceled or fails in a recoverable manner.

The following main methods exist for the BatchDataStream interface. See the API for the BatchDataStream interface for additional information.

- void open(): Called by grid endpoints to open the BDS
- void close(): Called by grid endpoints to close the BDS
- void initialize(String ilogicalname, String ijobstepid): Called by grid endpoints to initialize the BDS and let it know its logical name and batch step ID.
- String externalizeCheckpointInformation(): Called by grid endpoints right before a checkpoint to record the current cursor of the BDS
- void internalizeCheckpointInformation(String chkpointInfo(): Called by grid endpoints to inform the BDS of the previously recorded cursor, chkpointInfo. Typically, the positionAtCurrentCheckpoint is called after this call to move the BDS to this cursor.
- void positionAtCurrentCheckpoint(): Called by grid endpoints after calling internalizeCheckpointInformation to move the BDS to the cursor indicated by the chkpointInfo passed in through the internalizeCheckpointInformation call.

The BatchDataStream interface does not have methods for retrieving or writing data. There are no getNextRecord and putNextRecord methods defined on the interface that a batch step calls to read or write to the BDS object. Methods for passing data between the batch step and the BDS object are left up to the implementation of the BDS object. Review the batch Samples that this product supports to see examples of how to implement batch data streams.

**Transaction environment**

All methods of a BDS object are called in a global transaction. There is no guarantee that any consecutive method calls made to a BDS object happen in the same transaction because the transaction is owned by the grid endpoints, not the BDS object.

***Checkpoint algorithms:***

The grid endpoints use checkpoint algorithms to determine when to commit global transactions under which batch steps are invoked. These algorithms are applied to a batch job through the XML Job Control Language (xJCL) definition. Properties specified for checkpoint algorithms in xJCL allow for checkpoint behavior, such as transaction timeouts and checkpoint intervals, to be customized for batch steps. The product provides both a time-based checkpoint algorithm and a record-based algorithm, and defines a service provider interface (SPI) for building additional custom checkpoint algorithms.

On each batch step iteration of the processJobStep method, the common batch container consults the checkpoint algorithm applied to that step if it commits the global transaction or not. Call back methods on the checkpoint algorithms allow the common batch container to inform the algorithm when a global transaction is committed or started. This behavior enables the algorithm to tracks the global transaction life cycle. On each iteration of the processJobStep method, the common batch container calls the

ShouldCheckpointBeExecuted callback method on the algorithm to determine if the transaction is committed. The algorithm controls the checkpoint interval through this method.

Review the batch API for the checkpoint algorithm SPI, located in the Information Center reference section, for the checkpoint algorithm SPI that you can use to create custom checkpoint algorithms. The class name is com.ibm.wsspi.batch.CheckpointPolicyAlgorithm.

The product supports two checkpoint algorithms: the time-based algorithm and the record based algorithm. Both are explained in the following sections.

**Time-based algorithm**

The time-based checkpoint algorithm commits global transactions at a specified time interval. The following example declares a time-based algorithm in xJCL:

```
<checkpoint-algorithm name="timebased">
     <classname>com.ibm.wsspi.batch.checkpointalgorithms.timebased</classname>
     <props>
           <prop name="interval" value="15" />
           <prop name="TransactionTimeOut" value="30" />
     </props>
</checkpoint-algorithm>
```

The units of interval and TransactionTimeOut properties in the previous example are expressed in seconds.

**Record-based algorithm**

The record-based checkpoint algorithm commits global transactions at a specified number of iterations of the processJobStep method of batch step. Each call to the processJobStep method is treated as iterating through one record. The processJobStep method can retrieve multiple records from a batch data stream on each call. However, for this checkpoint algorithm one record is the equivalent one call to the processJobStep method.

The following example declares a record-based algorithm in xJCL:

```
<checkpoint-algorithm name="recordbased">
     <classname>com.ibm.wsspi.batch.checkpointalgorithms.recordbased</classname>
     <props>
           <prop name="recordcount" value="1000" />
           <prop name="TransactionTimeOut" value="60" />
     </props>
</checkpoint-algorithm>
```

The unit of the TransactionTimeOut property in the previous example is expressed in seconds.

If not specified in xJCL, the default transaction timeout is 60 seconds and the default record count is 10000.

**Applying a checkpoint algorithm to a batch step**

Checkpoint algorithms are applied to a batch job through xJCL. You can declare multiple checkpoint algorithms in xJCL, and you can apply a different algorithm to each batch step. You can apply no more than one checkpoint algorithm to a batch step.

The following example applies checkpoint algorithms in xJCL:

```
<job name="PostingsSampleEar">

<checkpoint-algorithm name="timebased">
     <classname>com.ibm.wsspi.batch.checkpointalgorithms.timebased</classname>
```

```
     <props>
           <prop name="interval" value="15" />
           <prop name=" TransactionTimeOut" value="30" />
     </props>
</checkpoint-algorithm>

<checkpoint-algorithm name="recordbased">
     <classname>com.ibm.wsspi.batch.checkpointalgorithms.recordbased</classname>
     <props>
           <prop name="recordcount" value="1000" />
           <prop name="TransactionTimeOut" value="60" />
     </props>
</checkpoint-algorithm>

<job-step name="Step1">
     <checkpoint-algorithm-ref name="timebased" />
</job-step>

<job-step name="Step2">
     <checkpoint-algorithm-ref name="recordbased" />
</job-step>
</job>
```

***Results algorithms:***

Results algorithms are an optional feature of the batch programming model.

A results algorithm allows for two types of actions to occur at the end of a batch step:

- To influence the return code of the batch job based on the return code of the batch step that just ended. There are two types of return codes: The return code of an individual batch step and the return code of the batch job to which the step belongs.
- To provide a place holder for triggers or actions to take based on various step return codes.

Results algorithms are applied to a batch job through XML Job Control Language (xJCL). These algorithms are declared in xJCL and then applied to batch steps.

At the end of a batch step, the grid endpoints check the xJCL of the batch job to determine which results algorithm to invoke. For each results algorithm specified, the grid endpoints pass to the algorithm the return code of the batch step, which is the integer returned by the destroyJobStep method of the step, and the current return code of the batch job in the grid endpoints database. The results algorithm can then act based on the return codes passed in. The algorithm then passes a return code for the batch job back to the grid endpoints, which is persisted to the grid endpoints database as the current return code of the batch job. This return code can be the same as the return code that the grid endpoints passed to the results algorithm initially, or the return code can be different, depending on logic coded into the results algorithm. If a results algorithm is not specified on a batch step, the job return code is that of the results algorithm from the previous step. If no results algorithms are specified, the job return code is zero (0).

A results algorithm system programming interface (SPI) is also provided, which you can use to write your own algorithms and apply them to batch jobs.

**The jobsum results algorithm**

The jobsum results algorithm returns the highest return code of job steps to the grid endpoints. For example, there are three steps in the job (step1, step2, step3) where the following conditions exist:

- step1 returned 5
- step2 returned 8
- step3 returned 2. The jobsum algorithm ensures that 8 is passed to the grid endpoints as the final return code of the job.

**Example of applying a jobsum and custom results algorithm to steps**

```
<job name="PostingSampleEar">

  <results-algorithms>
     <results-algorithm name="jobsum">
        <classname>com.ibm.wsspi.resultsalgorithms.jobsum</classname>
  </results-algorithm>

     <results-algorithm name="custom_algorithm">
           <classname>my_custom_algorithm</classname>
     </results-algorithm>

</results-algorithms>

<job-step name="Step1">

     <results-ref name="jobsum">
  </job-step>

<job-step name="Step2">

     <results-ref name="custom_algorithm">
  </job-step>

</job>
```

# Using the batch data stream (BDS) framework

This topic shows you an example of how to use the batch data stream (BDS) framework.

## Before you begin

Identify the correct pattern to use. Select a pattern based on what type of data stream you need. For example, if you want to read text from a file, then select the FileReaderPattern. See “Batch data stream framework and patterns” on page 45 for a selection of patterns.

## Procedure

1. Implement the pattern interface:

```
<codeblock>package com.ibm.websphere.samples;

import java.io.BufferedReader;
import java.io.IOException;
import java.util.Properties;

import com.ibm.websphere.batch.devframework.configuration.BDSFWLogger;
import com.ibm.websphere.batch.devframework.datastreams.patternadapter.FileReaderPattern;

// Implement the FileReaderPattern
public class TransactionListStream implements FileReaderPattern {
 private Properties properties;
 private BDSFWLogger logger;

/**
   Save properties specified in the xJCL
*/

 public void initialize(Properties props) {
// create logger
  logger = new BDSFWLogger(props);

  if (logger.isDebugEnabled())
   logger.debug("entering TransactionListInputStream.initialize()");
  properties = props;
```

```
    }

   // This method is where you should add the business logic of processing the read //string
    public Object fetchRecord(BufferedReader reader) throws IOException {
     String str = null;
     Posting posting = null;
     if (logger.isDebugEnabled())
   logger.debug("Entering TransactionListInputStream.fetchRecord");
     if(reader.ready()) {
      str = reader.readLine();
     }
     if(str != null) {

      posting = _generateRecord(str);

     }

     if (logger.isDebugEnabled())
      logger.debug("Exiting TransactionListInputStream.fetchRecord with " + posting);
     return posting;

    }
    // Helper method that parses the read string and creates an internal object for use
    // by other parts of the code
    private Posting _generateRecord(String str) {
     Posting post = null;
     String [] tokens = str.split(",", 3);

     if(tokens.length == 3) {

      String txTypeStr = tokens[0];
      String actNoStr = tokens[1];
      String amtStr = tokens[2];

      int txType = Integer.parseInt(txTypeStr);
      double amt = Double.parseDouble(amtStr);
      post = new Posting(txType,actNoStr,amt);

     } else {
      logger.error("Invalid csv string" + str);
     }
     if(logger.isDebugEnabled())
      logger.debug("Loaded posting record " + post);
     return post;
    }
    public void processHeader(BufferedReader reader) throws IOException {
     // NO OP for this sample

    }

   }
   </codeblock>
```

2. Reference the class that you created in the previous step, along with the supporting class in the xJCL.

## xJCL example

```
<codeblock><batch-data-streams>
  <bds>
          <logical-name>txliststream</logical-name>
          <props>
<prop name="IMPLCLASS" value= "com.ibm.websphere.samples.TransactionListStream"/>
             <prop name="FILENAME" value="/opt/inputfile.txt"/>
             <prop name="debug" value="true"/>
          </props>
```

```
<impl-class> com.ibm.websphere.batch.devframework.datastreams.patterns.TextFileReader </impl-class>
 </bds>
</batch-data-streams>

</codeblock>
```

## What to do next

Install the application.

## Batch data stream framework and patterns

The batch environment provides a batch data stream (BDS) framework that includes pre-built code to work with streams such as text, byte, database, and data sets. You can implement an interface where the business logic for processing the stream is added. The pre-built code manages actions such as opening, closing, and externalizing and internalizing checkpoints.

### BDS framework patterns

A BDS framework pattern is a simple Java TM interface for a particular type of data stream that a user implements to insert business logic. The BDS framework has several supporting classes for each pattern that do most of the mundane tasks related to stream management. The following table shows the patterns that the batch environment provides:

*Table 5. BDS framework patterns. The table includes the pattern name, description, and supporting classes.*

| Pattern name | Description | Supporting classes |
|---|---|---|
| "JDBCReaderPattern" on page 46 | Used to retrieve data from a database using a JDBC connection. | • LocalJDBCReader<br>• JDBCReader<br>• CursorHoldableJDBCReader |
| "JDBCWriterPattern" on page 48 | Used to write data to a database using a JDBC connection. | • LocalJDBCWriter<br>• JDBCWriter |
| "ByteReaderPattern" on page 50 | Used to read byte data from a file. | FileByteReader |
| "ByteWriterPattern" on page 51 | Used to write byte data from a file. | FileByteWriter |
| "FileReaderPattern" on page 53 | Used to read a text file. | TextFileReader |
| "FileWriterPattern" on page 54 | Used to write to a text file. | TextFileWriter |
| | Used to read a z/OS data set. | • ZFileStreamOrientedTextReader<br>• ZFileStreamOrientedByteReader<br>• ZFileRecordOrientedDataReader |
| | Used to write to a z/OS data set. | • ZFileStreamOrientedTextWriter<br>• ZFileStreamOrientedByteWriter<br>• ZFileRecordOrientedDataReader |
| "JPAReaderPattern" on page 55 | Used to retrieve data from a database using OpenJPA | JPAReader |
| "JPAWriterPattern" on page 57 | Used to write data to a database using a Java Persistence API (JPA) connection. | JPAWriter |

### BDS framework steps

BDS framework steps minimize the amount of work to create a batch step by performing the bookkeeping tasks related to step management and delegating the business logic to a class implemented by the user.

*Table 6. BDS framework steps. The table includes the framework step and description.*

| Step | Description |
|---|---|
| "Implementing the generic batch step (GenericXDBatchStep)" on page 61 | A simple step that uses one input and one output stream. |
| "Implementing the error tolerant step" on page 62 | A simple step that uses one input, one output stream, and one error stream. |

## ThresholdPolicies

*Table 7. ThresholdPolicies. The table includes the step and description.*

| Step | Description |
|---|---|
| "Declaring the record based threshold policy (RecordBasedThresholdPolicy)" on page 64 | This policy provides a batch implementation of the ThresholdPolicy interface. |
| "Declaring the percentage-based threshold policy (PercentageBasedThresholdPolicy)" on page 64 | This policy provides a batch implementation of the ThresholdPolicy interface |

### *JDBCReaderPattern:*

This pattern is used to retrieve data from a database using a Java Database Connectivity (JDBC) connection.

#### Supporting classes

1. CursorHoldableJDBCReader

   This class is referenced when the usage pattern of your JDBC input stream retrieves a set of results at the beginning of the step, and then iterates over them throughout the step-processing logic. The CursorHoldableJDBCReader uses a stateful session bean with a cursor holdable, non-XA data source. A cursor holdable JDBCReader is a pattern that is implemented in such a way that the cursor is not lost when the transaction is committed. As a result, ResultSets do not need to be repopulated after every checkpoint, which improves performance. To use CursorHoldableJDBCReader, package the CursorHoldableSessionBean in your application. To create the package, add the `nonxadsjndiname=`*`jndi_name_of_a_non-XA_data_source_to_database`* property to the properties file that is used by the BatchPackager. For example, `nonxadsjndiname=jdbc/nonxads`. If you want to add multiple non-XA data sources enter the following: `nonxadsjndiname=<jndi name1>;<jndi name2>...`

   **Restriction:** Currently, the resource reference name of the JDBC data source is the same as the Java Naming and Directory Interface (JNDI) name.

2. JDBCReader

   This class is referenced when the usage pattern of your JDBC input stream retrieves a single result from a query, which is used and discarded after every iteration of the step.

3. LocalJDBCReader

   This class is referenced when data is read from a local database.

#### Required properties

The following properties are required for the pattern.

*Table 8. Required properties. The table includes each required property, its value, and whether the LocalJDBCReader class, the CursorHoldableJDBCReader class, or the JDBCReader class is applicable.*

| Property | Value | LocalJDBCReader | CursorHoldableJDBCReader | JDBCReader |
|---|---|---|---|---|
| PATTERN_IMPL_CLASS | Class implementing JDBCReaderPattern interface | Applicable | Applicable | Applicable |
| ds_jndi_name | Datasource JNDI name. | Applicable | Not applicable | Applicable |

*Table 8. Required properties (continued). The table includes each required property, its value, and whether the LocalJDBCReader class, the CursorHoldableJDBCReader class, or the JDBCReader class is applicable.*

| Property | Value | LocalJDBCReader | CursorHoldableJDBCReader | JDBCReader |
|---|---|---|---|---|
| jdbc_url | The JDBC URL. For example, `jdbc:derby:C:\\mysample\\CREDITREPORT`. | Applicable | Not applicable | Not applicable |
| jdbc_driver | The JDBC driver. For example, `org.apache.derby.jdbc.EmbeddedDriver` | Applicable | Not applicable | Not applicable |
| userid | The user ID for the database. For example, `Myid` | Applicable | Not applicable | Not applicable |
| pswd | User password. For example, `mypwd`. LocalJDBCReader only. | Applicable | Not applicable | Not applicable |

## Optional properties

The following properties are optional for the pattern.

*Table 9. Optional properties. The table includes each optional property, its value and description, and whether the LocalJDBCReader class, the CursorHoldableJDBCReader class, or the JDBCReader class is applicable.*

| Property name | Value | Description | LocalJDBCReader | CursorHoldableJDCReader | JDBCReader |
|---|---|---|---|---|---|
| debug | true or false (default is false) | Enables detailed tracing on this batch datastream. | Applicable | Applicable | Applicable |
| EnablePerformanceMeasurement | true or false (default is false) | Calculates the total time spent in the batch data-streams and the processRecord method, if you are using the GenericXDBatchStep. | Applicable | Applicable | Applicable |
| EnableDetailedPerformanceMeasurement | true or false (default is false) | Provides a more detailed breakdown of time spent in each method of the batch data-streams. | Applicable | Applicable | Applicable |

## Interface definition

```
public interface JDBCReaderPattern {

 /**
  * This method is invoked during the job setup phase.
  *
  * @param props properties provided in the xJCL
  */

 public void initialize(Properties props);

 /**
  * This method should retrieve values for the various columns for the current row from the given resultset
   * object. Typically this data would be used to populate an intermediate object which would be returned
  * @param resultSet
  * @return
  */
 public Object fetchRecord(ResultSet resultSet);

 /**
  * This method should return a SQL query that will be used during setup of the stream to retrieve all
   * relevant data that would be processed part of the job steps
  * @return object to be used during process step.
  */
 public String getInitialLookupQuery();

 /**
```

```
  * This method gets called during Job Restart. The restart token should be used to create an SQL query
   * that will retrieve previously unprocessed records. Typically the restart token would be the primary
   * key in the table and the query would get all rows with
  * primary key value > restarttoken
  * @param restartToken
  * @return The restart query
  */
 public String getRestartQuery(String restartToken);

 /**
  * This method gets called just before a checkpoint is taken.
  * @return The method should return a string value identifying the last record read by the stream.
  */
 public String getRestartTokens();

}
```

### CursorHoldableJDBCReader xJCL example

```
<batch-data-streams>
<bds>
<logical-name>inputStream</logical-name>
<props>
<prop name="PATTERN_IMPL_CLASS" value="com.ibm.websphere.batch.samples.tests.bds.EchoReader"/>
<prop name="ds_jndi_name" value="jdbc/fvtdb"/>
<prop name="debug" value="true"/>
<prop name="DEFAULT_APPLICATION_NAME" value="XDCGIVT"/>
</props>
<impl-class>com.ibm.websphere.batch.devframework.datastreams.patterns.CursorHoldableJDBCReader</impl-class>
</bds>
</batch-data-streams>
```

### LocalJDBCReader xJCL example

```
<batch-data-streams>
<bds>
<logical-name>inputStream</logical-name>
<props>
<prop name="PATTERN_IMPL_CLASS" value="com.ibm.websphere.batch.samples.tests.bds.EchoReader"/>
<prop name="jdbc_url" value="jdbc:derby:C:\\mysample\\CREDITREPORT"/>
<prop name="jdbc_driver" value="org.apache.derby.jdbc.EmbeddedDriver"/>
<prop name="user_id" value="myuserid"/>
<prop name="pswd" value="mypswd"/>
<prop name="debug" value="true"/>
</props>
<impl-class>com.ibm.websphere.batch.devframework.datastreams.patterns.LocalJDBCReader</impl-class>
</bds>
</batch-data-streams>
```

### *JDBCWriterPattern:*

This pattern is used to write data to a database using a JDBC connection.

### Supporting classes

1. JDBCWriter
2. LocalJDBCWriter

### Required properties

The following properties are required for the pattern.

*Table 10. Required properties. The table includes the name and value of each required property for the pattern.*

| Property name | Value | LocalJDBCWriter | JDBCWriter |
|---|---|---|---|
| PATTERN_IMPL_CLASS | Class implementing JDBCWriterPattern interface | Applicable | Applicable |
| ds_jndi_name | Datasource JNDI name. | Applicable | Not applicable |

*Table 10. Required properties (continued). The table includes the name and value of each required property for the pattern.*

| Property name | Value | LocalJDBCWriter | JDBCWriter |
|---|---|---|---|
| jdbc_url | The JDBC URL. For example, `jdbc:derby:C:\\mysample\\CREDITREPORT`. | Applicable | Not applicable |
| jdbc_driver | The JDBC driver. For example, `org.apache.derby.jdbc.EmbeddedDriver` | Applicable | Not applicable |
| user_id | The user ID for the database. For example, `Myid` | Applicable | Not applicable |
| pswd | User password. For example, `mypwd`. LocalJDBCReader only. | Applicable | Not applicable |

## Optional properties

The following properties are optional for the pattern.

*Table 11. Optional properties. The table includes the name, value, and description of each optional property for the pattern.*

| Property name | Value | Description | LocalJDBCReader | JDBCWriter |
|---|---|---|---|---|
| debug | true or false (default is false) | Enables detailed tracing on this batch datastream. | Applicable | Applicable |
| EnablePerformanceMeasurement | true or false (default is false) | Calculates the total time spent in the batch data-streams and the processRecord method, if you are using the GenericXDBatchStep. | Applicable | Applicable |
| EnableDetailedPerformanceMeasurement | true or false (default is false) | Provides a more detailed breakdown of time spent in each method of the batch data-streams. | Applicable | Applicable |
| batch_interval | Default value is 20. Make the value less than the checkpoint interval for record-based checkpointing. | Denotes the number of SQL updates to batch before committing. | Applicable | Applicable |

## Interface definition

```
public interface JDBCWriterPattern {

 public void initialize(Properties props);

 /**
  * This is typically an Update query used to write data into the DB
  * @return
  */
 public String getSQLQuery();

 /**
  * The parent class BDSJDBCWriter creates a new preparedstatement and
  * passes it to this method. This method populates the preparedstatement
  * with appropriate values and returns it to the parent class for execution
  * @param pstmt
  * @param record
  * @return
  */
 public PreparedStatement writeRecord(PreparedStatement pstmt, Object record);
}
```

## JDBCWriter xJCL example

```
<batch-data-streams>
<bds>
<logical-name>outputStream</logical-name>
<props>
<prop name="PATTERN_IMPL_CLASS" value="com.ibm.websphere.batch.samples.tests.bds.EchoWriter"/>
<prop name="ds_jndi_name" value="jdbc/fvtdb"/>
```

```
<prop name="debug" value="true"/>
</props>
<impl-class>com.ibm.websphere.batch.devframework.datastreams.patterns.JDBCWriter</impl-class>
</bds>
</batch-data-streams>
```

### LocalJDCBWriter xJCL example

```
<batch-data-streams>
<bds>
<logical-name>outputStream</logical-name>
<props>
<prop name="PATTERN_IMPL_CLASS" value="com.ibm.websphere.batch.samples.tests.bds.EchoWriter"/>
<prop name="jdbc_url" value="jdbc:derby:C:\\mysample\\CREDITREPORT"/>
<prop name="jdbc_driver" value="org.apache.derby.jdbc.EmbeddedDriver"/>
<prop name="user_id" value="myuserid"/>
<prop name="pswd" value="mypswd"/>
<prop name="debug" value="true"/>
</props>
<impl-class>com.ibm.websphere.batch.devframework.datastreams.patterns.LocalJDBCWriter</impl-class>
</bds>
</batch-data-streams>
```

### *ByteReaderPattern:*

This pattern is used to read byte data from a file.

### Supporting classes

The FileByteReader class provides the logic for opening and reading byte data from the given file.

### Required properties

The following properties are required for the pattern.

*Table 12. Required properties. The table includes the name and value of each required property for the pattern.*

| Property name | Value |
|---|---|
| PATTERN_IMPL_CLASS | Class implementing ByteReaderPattern interface |
| FILENAME | Complete path to the input file |

### Optional properties

The following properties are optional for the pattern.

*Table 13. Optional properties. The table includes the name, value, and description of each optional property for the pattern.*

| Property name | Value | Description |
|---|---|---|
| debug | true or false (default is false) | Enables detailed tracing on this batch data stream. |
| EnablePerformanceMeasurement | true or false (default is false) | Calculates the total time spent in the batch data streams and the processRecord method, if you are using the GenericXDBatchStep. |
| EnableDetailedPerformanceMeasurement | true or false (default is false) | Provides a more detailed breakdown of time spent in each method of the batch data streams. |
| file.encoding | Encoding of the file. | For example, 8859_1 |
| AppendJobIdToFileName | true or false (default is false) | Appends the JobID to the file name before loading the file. |

### Interface definition

```
public interface ByteReaderPattern {

 /**
  * Is called by the framework during Step setup stage
  * @param props
  */
 public void initialize(Properties props);

 /**
  *
  * @param reader
  * @throws IOException
  */

 public void processHeader(BufferedInputStream reader) throws IOException;

 /**
  * Get the next record from the input stream
  * @param reader
  * @return
  * @throws IOException
  */
 public Object fetchRecord(BufferedInputStream reader) throws IOException;
}
```

### xJCL example

```
<batch-data-streams>
<bds>
<logical-name>inputStream</logical-name>
<props>
<prop name="PATTERN_IMPL_CLASS" value="com.ibm.websphere.batch.samples.tests.bds.EchoReader"/>
<prop name="file.encoding" value="8859_1"/>
<prop name="FILENAME" value="/opt/txlist.txt" />
<prop name="debug" value="true"/>
</props>
<impl-class>com.ibm.websphere.batch.devframework.datastreams.patterns.FileByteReader</impl-class>
</bds>
</batch-data-streams>
```

### *ByteWriterPattern:*

This pattern is used to write byte data to a file.

### Supporting classes

The FileByteWriter class provides the logic to open and write bytes to the given file. It can either append or overwrite existing content, depending on the properties specified. During a restart, the file is always opened in append mode.

### Required properties

The following properties are required for the pattern.

*Table 14. Required properties. The table includes the name and value of each required property for the pattern.*

| Property name | Value |
|---|---|
| PATTERN_IMPL_CLASS | Class implementing ByteWriterPattern interface |
| FILENAME | Complete path to the input file |

### Optional properties

The following properties are optional for the pattern.

*Table 15. Optional properties. The table includes the name, value, and description of each optional property for the pattern.*

| Property name | Value | Description |
|---|---|---|
| debug | true or false (default is false) | Enables detailed tracing on this batch datastream. |
| EnablePerformanceMeasurement | true or false (default is false) | Calculates the total time spent in the batch data-streams and the processRecord method, if you are using the GenericXDBatchStep. |
| EnableDetailedPerformanceMeasurement | true or false (default is false) | Provides a more detailed breakdown of time spent in each method of the batch data-streams. |
| file.encoding | Encoding of the file | For example, 8859_1 |
| AppendJobIdToFileName | true or false (default is false) | Appends the JobID to the file name before loading the file. |
| append | true or false (default is true) | Determines whether to open the file in append mode.<br>**Important:** During a restart, the file is always opened in append mode. |

### Interface definition

```
public interface ByteWriterPattern {

 /**
  * Invoked during the step setup phase
  * @param props
  */
 public void initialize(Properties props);

 /**
  * Writes the given object onto the given outputstream. Any processing
  * that needs to be done before writing can be added here
  * @param out
  * @param record
  * @throws IOException
  */
 public void writeRecord(BufferedOutputStream out, Object record) throws IOException;

 /**
  * Write header information if any
  * @param out
  * @throws IOException
  */
 public void writeHeader(BufferedOutputStream out) throws IOException;

         /**
  * This method can be optionally called during process step to explicity
  * initialize and write the header.
  * @param header
  */
 public void writeHeader(BufferedOutputStream out, Object header) throws IOException;
}
```

### xJCL example

```
<batch-data-streams>
<bds>
<logical-name>outputStream</logical-name>
<props>
     <prop name="PATTERN_IMPL_CLASS" value="com.ibm.websphere.batch.samples.tests.bds.EchoWriter"/>
     <prop name="file.encoding" value="8859_1"/>
     <prop name="FILENAME" value="/opt/txlist.txt" />
     <prop name="debug" value="true"/>
```

```
</props>
<impl-class>com.ibm.websphere.batch.devframework.datastreams.patterns.FileByteWriter</impl-class>
</bds>
</batch-data-streams>
```

### *FileReaderPattern:*

This pattern is used to read text data from a file.

#### Supporting classes

The TextFileReader class provides the logic to open and read text data line by line.

#### Required properties

The following properties are required for the pattern.

*Table 16. Required properties. The table includes the name and value of each required property for the pattern.*

| Property name | Value |
|---|---|
| PATTERN_IMPL_CLASS | Class implementing FileReaderPattern interface |
| FILENAME | Complete path to the input file |

#### Optional properties

The following properties are optional for the pattern.

*Table 17. Optional properties. The table includes the name, value, and description of each optional property for the pattern.*

| Property name | Value | Description |
|---|---|---|
| debug | true or false (default is false) | Enables detailed tracing on this batch datastream. |
| EnablePerformanceMeasurement | true or false (default is false) | Calculates the total time spent in the batch data-streams and the processRecord method, if you are using the GenericXDBatchStep. |
| EnableDetailedPerformanceMeasurement | true or false (default is false) | Provides a more detailed breakdown of time spent in each method of the batch data-streams. |
| file.encoding | Encoding of the file. | For example, 8859_1 |
| AppendJobIdToFileName | true or false (default is false) | Appends the JobID to the file name before loading the file. |

#### Interface definition

```
public interface FileReaderPattern {

 /**
  * Invoked during the step setup phase
  * @param props
  */
 public void initialize(Properties props);
 /**
  * This method is invoked only once. It should be used
  * to read any header data if necessary.
  * @param reader
  * @throws IOException
  */
 public void processHeader(BufferedReader reader) throws IOException;

 /**
  * This method should read the next line from the reader
  * and return the data in suitable form to be processed
  * by the step.
  * @param reader
```

```
  * @return
  * @throws IOException
  */
 public Object fetchRecord(BufferedReader reader) throws IOException;

   /**
    * This method can be optionally invoked from the process step
    * to obtain the header data that was previously obtained during the processHeader
    * call
    * @return
    */

     public Object fetchHeader();
}
```

### xJCL example

```
<batch-data-streams>
<bds>
<logical-name>inputStream</logical-name>
<props>
     <prop name="PATTERN_IMPL_CLASS" value="com.ibm.websphere.batch.samples.tests.bds.EchoReader"/>
     <prop name="file.encoding" value="8859_1"/>
     <prop name="FILENAME" value="/opt/txlist.txt" />
     <prop name="debug" value="true"/>
</props>
<impl-class>com.ibm.websphere.batch.devframework.datastreams.patterns.TextFileReader</impl-class>
</bds>
</batch-data-streams>
```

### *FileWriterPattern:*

The FileWriterPattern pattern is used to write text data to a file.

### Supporting classes

The TextFileWriter class provides the logic to open and write string data to the given file. The file is opened either in append or overwrite mode, depending on the properties specified. The file is always opened in append mode during a job restart.

### Required properties

The following properties are required for the pattern.

*Table 18. Required properties. The table includes the name and value of each required property for the pattern.*

| Property name | Value |
|---|---|
| PATTERN_IMPL_CLASS | Class that implements the FileWriterPattern interface |
| FILENAME | Complete path to the input file |

### Optional properties

The following properties are optional for the pattern.

*Table 19. Optional properties. The table includes the name, value, and description of each optional property for the pattern.*

| Property name | Value | Description |
|---|---|---|
| debug | true or false (default is false) | Enables detailed tracing on this batch datastream. |
| EnablePerformanceMeasurement | true or false (default is false) | Calculates the total time spent in the batch data-streams and the processRecord method, if you are using the GenericXDBatchStep. |
| EnableDetailedPerformanceMeasurement | true or false (default is false) | Provides a more detailed breakdown of time spent in each method of the batch data-streams. |

*Table 19. Optional properties (continued). The table includes the name, value, and description of each optional property for the pattern.*

| Property name | Value | Description |
|---|---|---|
| file.encoding | Encoding of the file | For example, 8859_1 |
| AppendJobIdToFileName | true or false (default is false) | Appends the JobID to the file name before loading the file. |
| append | true or false (default is true) | Determines whether to open the file in append mode.<br>**Important:** During a restart, the file is always opened in append mode. |

### Interface definition

```
public interface FileWriterPattern {

 /**
  * Invoked during step setup phase
  * @param props
  */
 public void initialize(Properties props);

 /**
  * This method should write the given record
  * object to the bufferedwriter.
  * @param out
  * @param record
  * @throws IOException
  */
 public void writeRecord(BufferedWriter out, Object record) throws IOException;

 /**
  * This method is invoked only once just after the bufferedwriter
  * is opened. It should be used to write any header information
  * @param out
  * @throws IOException
  */
 public void writeHeader(BufferedWriter out) throws IOException;

        /**
  * This method can be optionally called during process step to explicity
  * initialize and write the header.
  * @param header
  * @throws IOException
  */
 public void writeHeader(BufferedWriter out, Object header) throws IOException;

}
```

### xJCL sample

```
<batch-data-streams>
<bds>
<logical-name>outputStream</logical-name>
<props>
     <prop name="PATTERN_IMPL_CLASS" value="com.ibm.websphere.batch.samples.tests.bds.EchoWriter"/>
     <prop name="file.encoding" value="8859_1"/>
     <prop name="FILENAME" value="/opt/txlist.txt" />
     <prop name="debug" value="true"/>
</props>
<impl-class>com.ibm.websphere.batch.devframework.datastreams.patterns.TextFileWriter</impl-class>
</bds>
</batch-data-streams>
```

### *JPAReaderPattern:*

This pattern is used to retrieve data from a database using OpenJPA.

### Supporting classes

The JPAReader class performs the tasks of obtaining an entity manager, running user provided queries, and iterating over the results of the query. A `persistence.xml` file needs to be packaged with the user application.

### Required properties

The following properties are required for the pattern.

*Table 20. Required properties. The table includes the name and value of each required property for the pattern.*

| Property name | Value |
|---|---|
| PATTERN_IMPL_CLASS | Class implementing JPAReader Pattern interface |
| PERSISTENT_UNIT | The OpenJPA persistent unit name. |

### Optional properties

The following properties are optional for the pattern.

*Table 21. Optional properties. The table includes the name, value, and description of each optional property for the pattern.*

| Property name | Value | Description |
|---|---|---|
| debug | true or false (default is false) | Enables detailed tracing on this batch data stream. |
| openjpa.Log | `DefaultLevel=WARN,SQL=TRACE` | JPA log settings |
| EnablePerformanceMeasurement | true or false (default is false) | Calculates the total time spent in the batch data streams and the processRecord method, if you are using the GenericXDBatchStep. |
| EnableDetailedPerformanceMeasurement | true or false (default is false) | Provides a more detailed breakdown of time spent in each method of the batch data streams. |

### Interface definition

```
public interface JPAReaderPattern {

 /**
  * This method is invoked during the job setup phase.
  *
  * @param props properties provided in the xJCL
  */

 public void initialize(Properties props);

 /**
  * This method should retrieve values for the various columns for the current row from
   * the given Iterator object. Typically this data would be used to populate an intermediate
   * object which would be returned.
  * @param listIt
  * @return
  */
 public Object fetchRecord(Iterator listIt);

 /**
  * This method should return a JPQL query that will be used during setup of the stream to
   * retrieve all relevant data that would be processed part of the job steps.
  * @return object to be used during process step.
  */
 public String getInitialLookupQuery();

 /**
  * This method gets called during Job Restart. The restart token should be used to create
   * a JPQL query that retrieves previously unprocessed records. Typically the restart token
   * is the primary key in the table and the query would get all rows with
  * primary key value > restarttoken
```

```
 * @param restartToken
 * @return The restart query
 */
public String getRestartQuery(String restartToken);

/**
 * This method gets called just before a checkpoint is taken.
 * @return The method should return a string value identifying the last record read by the stream.
 */
public String getRestartTokens();

}
```

### xJCL example

```
<batch-data-streams>
<bds>
<logical-name>inputStream</logical-name>
<props>
<prop name="PERSISTENT_UNIT" value="hellojpa"/>
<prop name="debug" value="true"/>
<prop name="PATTERN_IMPL_CLASS" value="com.ibm.websphere.samples.JPAInputStream"/>
</props>
<impl-class>com.ibm.websphere.batch.devframework.datastreams.patterns.JPAReader</impl-class>
</bds>
</batch-data-streams>
```

### *JPAWriterPattern:*

This pattern is used to write data to a database using a Java Persistence API (JPA) connection.

### Supporting classes

The JPAWriter class implements the basic JPA operations of obtaining an EntityManager class and joining, beginning, and committing transactions. By default the JPAWriter joins an existing global transaction.

Package a `persistence.xml` file that sets the transaction-type attribute to `JTA` and declares a jta-data-source element. Optionally configure the JPAWriter class to begin and commit transactions in synchronization with the global transactions. These transactions are used with non-jta-data-source elements and connection URLs. In this case the `persistence.xml` file sets the transaction-type to `RESOURCE_LOCAL` and declare a non-jta-data-source element or connection URLs.

### Required properties

The following properties are required for the pattern.

*Table 22. Required properties. The table includes the name and value of each required property for the pattern.*

| Property name | Value |
|---|---|
| PATTERN_IMPL_CLASS | Class implementing JPAWriterPattern interface |
| PERSISTENT_UNIT | The OpenJPA persistent unit name |
| *JPA properties that you set on the EntityManager class* | *The value of these properties* |

### Optional properties

The following properties are optional for the pattern.

*Table 23. Optional properties. The table includes the name, value, and description of each optional property for the pattern.*

| Property name | Value | Description |
|---|---|---|
| debug | true or false (The default is false.) | Enables detailed tracing on this batch data stream. |
| use_JTA_transactions | true or false (The default is true.) | If you use the non-jta-data-source element or connection URLs, set the value to `false`. |
| EnablePerformanceMeasurement | true or false (The default is false.) | Calculates the total time spent in the batch data-streams and the processRecord method, if you are using the GenericXDBatchStep. |

### Interface definition

```
public interface JPAWriterPattern {

 /**
  * This method is invoked during create job step to allow the JPAWriter stream to
  * initialize.
  * @param props Properties passed via xJCL
  */
public void initialize(Properties props);

 /**
  * This method is invoked to actually persist the passed object to the database
  * using JPA EntityManager
  * @param manager
  * @param record
  */
 public void writeRecord(EntityManager manager, Object record);
}
```

### xJCL example

```
<batch-data-streams>
<bds>
<logical-name>outputStream</logical-name>
<props>
<prop name="PATTERN_IMPL_CLASS" value="com.ibm.websphere.batch.samples.tests.bds.EchoWriter"/>
<prop name="PERSISTENT_UNIT" value="mypersistentU"/>
<prop name="debug" value="true"/>
</props>
<impl-class>com.ibm.websphere.batch.devframework.datastreams.patterns.JPAWriter</impl-class>
</bds>
</batch-data-streams>
```

### *PureQueryWriterPattern:*

Use this pattern to write data to a database using IBM Optim™ pureQuery Runtime. The batch data stream (BDS) framework completes the administrative tasks of opening and closing connections.

### Supporting classes

The PureQueryWriter class implements the basic operations of opening and closing database connections, obtaining the PureQuery data interface, and batching operations.

### Required properties

The following properties are required for the pattern.

*Table 24. Required properties. The table includes the name and value of each required property for the pattern.*

| Property name | Value |
|---|---|
| PATTERN_IMPL_CLASS | Class implementing PureQueryWriterPattern interface |
| PQ_DATA_BEAN_INTERFACE | PureQuery data bean interface |
| ds_jndi_name | Java Naming and Directory Interface (JNDI) name of the data source to access the database |

### Optional properties

The following properties are optional for the pattern.

*Table 25. Optional properties. The table includes the name, value, and description of each optional property for the pattern.*

| Property name | Value | Description |
|---|---|---|
| debug | true or false (The default is false.) | Enables detailed tracing on this batch data stream. |
| DB_SCHEMA | null | Database schema name |
| EnablePerformanceMeasurement | true or false (The default is false.) | Calculates the total time spent in the batch data-streams and the processRecord method, if you are using the GenericXDBatchStep |
| force_connection_recycle | false | Forces the connection to be closed and reopened during checkpoint processing |
| Batch_interval | 20 | Number of operations to batch |

### Interface definition

The PureQueryWriterPattern Interface definition shows the methods that you must implement to support the PureQueryWriterPattern interface.

```
public interface PureQueryWriterPattern {

 public void initialize(Properties props);

 /**
   * The parent class passes the record to be written, the data interface, or the data interface
   * user method in order to update the database. The application might use the data interface to
   * run the pureQuery API method for in-line style or the data interface method for annotation style.
     * The parent class passes the record to be written and the
  * Data interface that may be used by the application to execute the pureQuery API method
   * (for in-line style ) or the Data interface user method ( for annotation style ) in order
   * to update the database.
  * @param
  * @param record
  * @return
  */
 public void writeRecord(Data dataInterface, Object record);
}
```

### xJCL example

The example shows xJCL that you can use to define a batch data stream which implements the PureQueryWriterPattern interface in your application.

```
<batch-data-streams>
<bds>
   <logical-name>outputStream</logical-name>
   <props>
    <prop name="PATTERN-IMPL-CLASS" value="com.ibm.MyWriterPattern"/>
          <prop name="jdbc_url" value="jdbc:derby:C:\\mysample\\CREDITREPORT"/>
           <prop name="jdbc_driver" value="org.apache.derby.jdbc.EmbeddedDriver"/>
```

```
          <prop name="user_id" value="myid"/>
          <prop name="pswd" value="mypwd"/>
          <prop name="debug" value="true"/>
          <prop name="DB_SCHEMA" value="PQDS"/>
         <prop name="PQ_DATA_BEAN_INTERFACE" value="com.ibm..MyEmployeeData"/>
   </props>
     <impl-class>com.ibm.websphere.batch.devframework.datastreams.patterns.PureQueryWriter</impl-class>
   </bds>
</batch-data-streams>
```

***PureQueryReaderPattern:***

Use this pattern is used to read data from a database using IBM Optim pureQuery Runtime. The batch data stream (BDS) framework completes the administrative tasks of opening and closing connections.

### Supporting classes

The PureQueryReader class implements the basic operations of opening and closing database connections and obtaining the IBM Optim pureQuery Runtime data.

### Required properties

The following properties are required for the pattern.

*Table 26. Required properties. The table includes the name and value of each required property for the pattern.*

| Property name | Value |
|---|---|
| PATTERN_IMPL_CLASS | Class implementing PureQueryReaderPattern interface |
| PQ_DATA_BEAN_INTERFACE | PureQuery data bean interface |
| ds_jndi_name | Java Naming and Directory Interface (JNDI) name of the data source to access the database |

### Optional properties

The following properties are optional for the pattern.

*Table 27. Optional properties. The table includes the name, value, and description of each optional property for the pattern.*

| Property name | Value | Description |
|---|---|---|
| debug | true or false (The default is false.) | Enables detailed tracing on this batch data stream |
| DB_SCHEMA | null | Database schema name |
| EnablePerformanceMeasurement | true or false (The default is false.) | Calculates the total time spent in the batch data-streams and the processRecord method, if you are using the GenericXDBatchStep |

### Interface definition

The PureQueryReaderPattern Interface definition shows the methods that you must implement to support the PureQueryReaderPattern interface.

```
public interface PureQueryReaderPattern
{

 /**
  * This method is called by the batch container during step setup. The properties passed
  * in are the ones that you provide in the xJCL BDS level properties.
  * @param properties
  */
    public  void initialize(Properties properties);

    /**
```

```
     * Invoked by the container during each iteration of the batch loop. This code obtains
     * the next record using the given iterator object.
     * @param iterator
     * @return
     */
    public  Object fetchRecord(Iterator iterator);

    /**
     * Returns the iterator based on the passed data object that is used to iterate
     * over the records
     * @param data
     * @return
     */
    public  Iterator getInitialIterator(Data data);

    /**
     * Returns the iterator based on the passed data object repositioned based on the restart
     * token of restartToken.
     * @param data
     * @param s
     * @return
     */
    public  Iterator getRestartIterator(Data data, String restartToken);

    /**
     * Invoked before a checkpoint is taken to save the restart token that is used in case
     * of a restart
     * @return
     */
    public  String getRestartTokens();
}
```

### xJCL example

The example shows xJCL that you can use to define a batch datastream which implements the PureQueryReaderPattern interface in your application.

```
<batch-data-streams>
<bds>
   <logical-name>outputStream</logical-name>
   <props>
    <prop name="IMPLCLASS" value="com.ibm.MyWriterPattern"/>
               <prop name="ds_jndi_name" value="jdbc/crreport"/>
               <prop name="debug" value="true"/>
               <prop name="DB_SCHEMA" value="PQDS"/>
               <prop name="PQ_DATA_BEAN_INTERFACE" value="com.ibm.MyEmployeeData"/>
    </props>
    <impl-class>com.ibm.websphere.batch.devframework.datastreams.patterns.PureQueryReader</impl-class>
  </bds></batch-data-streams>
```

## Implementing the generic batch step (GenericXDBatchStep)

A generic batch step works with one input and one output stream. This step during each iteration of the batch loop reads a single entry from the BDS Input Stream passes it to the BatchRecordProcessor for processing. The BatchRecordProcessor returns the processed data which is then passed to the BDS output stream.

### About this task

Use the following properties to implement the generic batch step.

*Table 28. Required properties. The table includes the property name, property value, and property description.*

| Property name | Value | Description |
|---|---|---|
| BATCHRECORDPROCESSOR | Java class name | Class implementing the BatchRecordProcessor interface |

*Table 29. Optional properties. The table includes the property name, property value, and property description.*

| Property | Value | Description |
|---|---|---|
| debug | true or false (default is false) | Enable tracing and debugging on the step |
| EnablePerformanceMeasurement | true or false (default is false) | Measure time spent within the step |

### Procedure

1. Implement the interfacecom.ibm.websphere.batch.devframework.steps.technologyadapters.BatchRecordProcessor to provide the business logic for the step. In the xJCL for the step, declare a property BATCHRECORDPROCESSOR with the value set to the implementation of the interface. For example:

```
...
<props>
 <prop name="BATCHRECORDPROCESSOR"
    value="com.ibm.websphere.batch.samples.tests.steps.InfrastructureVerificationTest"/>
</props>
...
```

2. Set the BDS input stream logical name to inputStream and a BDS output stream logical name to outputStream. The logical names are declared in the xJCL. For example:

```
<batch-data-streams>
   <bds>
 <logical-name>inputStream</logical-name>
 <props>
        ....
   </bds>
    <bds>
 <logical-name>outputStream</logical-name>
 <props>
 ...
   </bds>
</batch-data-streams>
```

3. While using the BatchPackager for packaging, the application for the job step class, jobstepclass, must be set to com.ibm.websphere.batch.devframework.steps.technologyadapters.GenericXDBatchStep. For example:

```
ejbname.1=IVTStep1
jndiname.1=ejb/GenericXDBatchStep
jobstepclass.1=com.ibm.websphere.batch.devframework.steps.technologyadapters.GenericXDBatchStep
```

## Implementing the error tolerant step

An error tolerant generic batch step works with one input, one output stream, and one error stream. This step during each iteration of the batch loop reads a single entry from the batch data stream (BDS) input stream and passes it to the BatchRecordProcessor property for processing.

### Before you begin

The BatchRecordProcessor property might either return a valid data object or a null value in a tolerable error. If the returned value is null, the record read from the input stream is logged on to the error stream and the invalidRecordEncountered method is invoked on the ThresholdPolicy interface. The threshold policy determines whether the error tolerance threshold has been reached. If so, it returns STEP_CONTINUE_FORCE_CHECKPOINT_BEFORE_PROCESSING_CANCEL, which forces a checkpoint and puts the job in the restartable state. Otherwise, the job continues as normal. If the data returned by BatchRecordProcessor.processRecord is valid, then the data is passed to the BDS output stream.

## About this task

Use the following properties to implement the error tolerant step.

*Table 30. Required properties. The table includes the property name, value, and description.*

| Property name | Value | Description |
|---|---|---|
| threshold_policy | Java class name | Class implementing the com.ibm.websphere.batch.devframework.thresholdpolicies.ThresholdPolicy interface |
| BATCHRECORDPROCESSOR | Java class name | Class implementing the BatchRecordProcessor interface |

*Table 31. Optional properties. The table includes the property name, value, and description.*

| Property | Value | Description |
|---|---|---|
| debug | true or false (default is false) | Enable tracing and debugging on the step |
| EnablePerformanceMeasurement | true or false (default is false) | Measure time spent within the step |

## Procedure

1. Implement the interface`com.ibm.websphere.batch.devframework.steps.technologyadapters.BatchRecordProcessor` to provide the business logic for the step. In the xJCL for the step, declare a property BATCHRECORDPROCESSOR with the value set to the implementation of the interface. For example:

```
...
<props>
 <prop name="BATCHRECORDPROCESSOR"
    value="com.ibm.websphere.batch.samples.tests.steps.InfrastructureVerificationTest"/>
</props>
...
```

2. Implement the interface com.ibm.websphere.batch.devframework.thresholdpolicies.ThresholdPolicy to provide the threshold policy for the step. You can also use the product implementations such as com.ibm.websphere.batch.devframework.thresholdpolicies.PercentageBasedThresholdPolicy or com.ibm.websphere.batch.devframework.thresholdpolicies.RecordBasedThresholdPolicy. Declare the ThresholdPolicy to use in the xJCL as shown in the following code snippet:

```
...
<props>
  <prop name="threshold_policy"
    value="com.ibm.websphere.batch.devframework.thresholdpolicies.PercentageBasedThresholdPolicy"/>
</props>
...
```

3. Set the BDS input stream logical name to `inputStream` and a BDS output stream logical name to `outputStream` and the BDS output stream for errors to `errorStream`. The logical names are declared in the xJCL. For example:

```
<batch-data-streams>
   <bds>
 <logical-name>inputStream</logical-name>
 <props>
        ....
   </bds>
    <bds>
 <logical-name>outputStream</logical-name>
 <props>
 ...
    </bds>
    <bds>
 <logical-name>errorStream</logical-name>
 <props>
 ...
     </bds>
</batch-data-streams>
```

4. While using the BatchPackager for packaging, the application for the job step class, jobstepclass, must be set to com.ibm.websphere.batch.devframework.steps.technologyadapters.ThresholdBatchStep. For example:

```
ejbname.1=IVTStep1
jndiname.1=ejb/MyThresholdBatchStep
jobstepclass.1=com.ibm.websphere.batch.devframework.steps.technologyadapters.ThresholdBatchStep
```

## Declaring the percentage-based threshold policy (PercentageBasedThresholdPolicy)

This policy provides a batch implementation of the ThresholdPolicy interface.

### Before you begin

The percentageBasedThresholdPolicy is applicable only if the ThresholdBatchStep is used. It calculates the percentage of the number of error records processed to the total number processed. If the result is greater than the threshold, it forces the job to go into restartable state.

### About this task

Optionally use the following properties when you declare the percentage-based threshold policy.

*Table 32. Optional properties. The table includes the property name, property value, and property description.*

| Property | Value | Description |
|---|---|---|
| debug | true or false (default is false) | Enable tracing and debugging on the step |
| minimum_threshold_sample_size | Integer value (default is 20) | The minimum number of records to process before checking for threshold breach. |
| threshold_threshold | Double value (default is 0.1) | The acceptable percentage of errors. |

### Procedure

Declare the threshold policy to use in the xJCL as a property of the step as follows:

```
...
<props>
 <prop name="threshold_policy"
   value="com.ibm.websphere.batch.devframework.thresholdpolicies.PercentageBasedThresholdPolicy"/>
</props>
...
```

## Declaring the record based threshold policy (RecordBasedThresholdPolicy)

This policy provides a batch implementation of the ThresholdPolicy interface.

### Before you begin

The record based threshold policy of RecordBasedThresholdPolicy is applicable only if the threshold batch step of ThresholdBatchStep is used. It counts the number of error records processed. If the result is greater than the threshold, it forces the job to go into restartable state.

### About this task

Optionally use the following properties when you declare the record based threshold policy.

*Table 33. Optional properties. The table includes the property name, property value, and property description.*

| Property | Value | Description |
|---|---|---|
| debug | true or false (default is false) | Enable tracing and debugging on the step |
| minimum_threshold_size | Integer value (default is 20) | The minimum number of records to process before checking for threshold breach. |

*Table 33. Optional properties (continued). The table includes the property name, property value, and property description.*

| Property | Value | Description |
|---|---|---|
| error_threshold | Double value (default is 100) | The number of error records. |

### Procedure

Declare the threshold policy to use in the xJCL as a property of the step as follows:

```
...
<props>
 <prop name="threshold_policy"
       value="com.ibm.websphere.batch.devframework.thresholdpolicies.RecordBasedThresholdPolicy"/>
</props>
...
```

# Deploying batch applications

This section covers such areas as packaging Enterprise JavaBeans (EJB) 3.0 modules and installing batch applications.

## Packaging EJB 3.0 modules in a batch application using Rational Application Developer

Use Rational Application Developer 8.0.1 or later to package Enterprise JavaBeans (EJB) 3.0 modules.

### Before you begin

Develop a batch application.

### Procedure

1. Import your batch application EAR file into Rational Application Developer. Click **File** > **Import**.
   a. Select **Java EE - EAR file**. Click **Next**.
   b. Enter the location of your EAR file in the EAR file field.
   c. Set the Target run time to a WebSphere Application Server Version 8 run time.
   d. Clear everything on the **EAR Module and Utility JAR Projects** page (third page).
   e. Click **Finish**.
2. Link in your EJB 3.0 JAR file.
   a. Right-click on the newly created EAR project.
   b. Select **Properties** > **Java EE Module Dependencies**
   c. Click **Add External JARs...**.
   d. Select your EJB3 JAR file.
   e. Click **OK**.
3. Export your EAR file.
   a. Right-click on the EAR project.
   b. Click **Export** > **EAR file**.
   c. Enter a value in the **Destination** field.
   d. Click **Finish**.

## Installing the batch application

Now you can install the batch application itself. The batch application is installed exactly like Java Platform, Enterprise Edition (Java EE) transactional applications.

### Before you begin

Develop a compute-intensive application or a transactional batch application. You can develop a compute intensive application using a compute-intensive job controller, the command line, or the Apache ANT tool. You can develop a transactional batch application using a batch job controller and Enterprise JavaBeans (EJB) data stream, the command line, or the ANT tool.

### About this task

When mapping modules of the batch application to servers, select the server or cluster that you created previously for the enterprise bean modules that contain the logic for a batch job.

### Procedure

See the topic on installing applications for details on how to install your batch application.

### What to do next

Configure the job scheduler and submit batch jobs using the job scheduler.

## Submitting batch jobs

You can submit batch applications using the job scheduler Enterprise JavaBeans (EJB) interface or the job scheduler web services interface.

## xJCL elements

Jobs are expressed using an Extensible Markup Language XML dialect called xJCL (XML Job Control Language). This dialect has constructs for expressing all of the information needed for both compute-intensive and batch jobs, although some elements of xJCL are only applicable to compute-intensive or batch jobs. See the xJCL provided with the Sample applications, the xJCL table, and xJCL XSD schema document for more information about xJCL. The xJCL definition of a job is not part of the batch application, but is constructed separately and submitted to the job scheduler for to run. The job scheduler uses information in the xJCL to determine where and when to run the job.

### xJCL elements

The following table summarizes the xJCL elements.

*Table 34. xJCL elements. The table includes xJCL elements, whether each xJCL element applies to compute-intensive or batch jobs, and subelements, attributes, and descriptions for each xJCL element.*

| Element | Java Platform, Enterprise Edition (Java EE) Compute-intensive | Java EE Batch | Subelement | Attributes | Description |
|---|---|---|---|---|---|
| job | Y | Y | | | Scopes the description of a batch job. |
| job | Y | Y | | name | Name of the job. This name must match the name of the batch application |
| job | Y | Y | | accounting | Optional accounting information attribute. |
| job | Y | Y | | class | Optional job class attribute, which identifies the job class under which the job runs. |

*Table 34. xJCL elements (continued). The table includes xJCL elements, whether each xJCL element applies to compute-intensive or batch jobs, and subelements, attributes, and descriptions for each xJCL element.*

| Element | Java Platform, Enterprise Edition (Java EE) Compute-intensive | Java EE Batch | Subelement | Attributes | Description |
|---|---|---|---|---|---|
| job | Y | Y | | default-application-name | The application name to be used when no job step application-name attribute is found. |
| job | Y | Y | jndi-name | | JNDI name that is given to the job controller stateless session bean when the batch application is deployed into WebSphere Application Server. |
| job | Y | Y | job-scheduling criteria | required-capability | The required-capability of the job, which must be defined on an endpoint for the job to be dispatched to that endpoint. |
| job | Y | Y | step-scheduling criteria | See step-scheduling-criteria element | |
| job | N | Y | checkpoint algorithm | See checkpoint-algorithm element | |
| job | N | Y | results-algorithm | See results-algorithms element | |
| job | Y | Y | substitution-props++ | See prop element | The required-capability of the job, which must be defined on an endpoint for the job to be dispatched to that endpoint |
| job-step | Y* | Y | | name | Optional name of the step. This information is returned on operational commands. |
| job-step | Y* | Y | | application-name | Optional name of the application run by the step. The attribute name is used if application-name is omitted and the job level attribute default-application-name is omitted. |
| job-step | N | Y | step-scheduling | See step-scheduling element | Allows for conditional logic based on return codes of steps that determines whether the batch step is invoked. |
| job-step | Y | Y | classname | | Fully-qualified name of class that implements the compute intensive job. |
| job-step | Y | N | checkpoint-algorithm-ref | | Specifies the checkpoint algorithm to use for the batch job step. |
| job-step | N | Y | results-ref | See results-ref element | Specifies the results algorithm to use for the conditional batch job step execution. |
| job-step | N | Y | batch-data-streams | See batch-data-streams element | A sequence of bds elements. Each bds is the configuration information necessary to create a batch data stream. |
| job-step | Y | Y | props | See props element | Name-value properties to pass to the step. |
| job-step | N | N | exec | See exec element | Identifies the executable associated with the job step. |
| job-step | N | N | env-entries | See env-entries element | Identifies the environmental properties associated with the job step. |
| prop | Y | Y | | | Single instance of a name value pair, that serves as a property. |
| prop | Y | Y | | name | Name of the property. |
| prop | Y | Y | | value | Value of the property. |

*Table 34. xJCL elements (continued). The table includes xJCL elements, whether each xJCL element applies to compute-intensive or batch jobs, and subelements, attributes, and descriptions for each xJCL element.*

| Element | Java Platform, Enterprise Edition (Java EE) Compute-intensive | Java EE Batch | Subelement | Attributes | Description |
|---|---|---|---|---|---|
| props | Y | Y | prop | See prop element | |
| env-entries | N | N | | | Series of prop elements that are used to pass name-value pair properties to steps, bds, checkpoint algorithms, and results algorithms. |
| env-entries | N | N | env-var | See env-var element | |
| exec | N | N | | | Series of prop elements that are used to pass name-value pair properties to steps, bds, checkpoint algorithms, and results algorithms. |
| exec | N | N | | executable | The name of the executable associated with the job step. |
| exec | N | N | arg | See line element | |
| line | N | N | | | Command-line arguments passed to the job step executable. |
| bds | N | Y | | | Single instance of a batch data stream implementation made available to the batch job. |
| bds | N | Y | logical-name | | A string that is embedded in batch step, which uses it to query the batch runtime environment for a specific batch data stream instance. |
| bds | N | Y | impl-class | | Fully- qualified class name of the batch data stream implementation class. |
| bds | N | Y | props | See props elements | List of properties that are passed to the batch data stream implementation class. |
| batch-data-streams | N | Y | | | Series of bds elements |
| batch-data-streams | N | Y | bds | See bds element | |
| step-scheduling | N | Y | | | Applies to job-steps to create return code-based conditional flows for a batch job. Compares values of return codes defined for this batch job to decide whether a step is invoked or not while processing a batch job. The values of return codes are compared using the returncode-expression element. |
| step-scheduling | N | Y | returncode-expression | see returncode-expression | Returncode- expression to evaluate. |
| step-scheduling | N | Y | | condition | If there is more than one returncode-expression element in the step-scheduling element, conditional operators are applied to them. Conditional operators supported are: AND, OR. |
| returncode-expression | N | Y | | | Used under step-scheduling tags to decide whether a batch job step runs based on return codes of other job steps. |
| returncode-expression | N | Y | | step | Name of step whose return code is to be compared in this expression. |

*Table 34. xJCL elements (continued). The table includes xJCL elements, whether each xJCL element applies to compute-intensive or batch jobs, and subelements, attributes, and descriptions for each xJCL element.*

| Element | Java Platform, Enterprise Edition (Java EE) Compute-intensive | Java EE Batch | Subelement | Attributes | Description |
|---|---|---|---|---|---|
| returncode-expression | N | Y | | operator | Operator to use for the return code expression. The supported operators are eq for equals, lt for less than, gt for greater than, le for less than or equal to, and ge for greater than or equal to. |
| returncode-expression | N | Y | | value | The value with which to compare the return code. |
| step-scheduling-criteria | N | Y | | | Describes the sequence in which the job steps are processed. Currently sequential scheduling is supported; for example, steps get invoked in the order in which they exist in xJCL. |
| step-scheduling-criteria | N | Y | scheduling-mode | | Sequence in which to invoke steps, only possible value is sequential right now. |
| checkpoint-algorithm | N | Y | | | Declares a checkpoint algorithm that can be used for a batch job step. |
| checkpoint-algorithm | N | Y | | name | Name of algorithm. |
| checkpoint-algorithm | N | Y | classname | | Class that implements this algorithm. |
| checkpoint-algorithm | N | Y | props | See props element | Sequence of prop elements for the checkpoint algorithm. |
| checkpoint-algorithm-ref | N | Y | | | Reference to a checkpoint algorithm element. |
| checkpoint-algorithm-ref | N | Y | | name | Name of checkpoint algorithm to which you are referring. |
| checkpoint-algorithm-ref | N | Y | props | See props element. | Sequence of prop elements for the checkpoint algorithm. |

++ The xJCL element substitution-props is discussed in the following section.

## xJCL substitution-props

The job xJCL can contain symbolic variables. A symbolic variable is an expression of the form ${variable-name}, which is found outside a comment in an otherwise well-formed document. For example:

```
<checkpoint-algorithm-ref name="${checkpoint}" />
```

The xJCL element, substitution-props, defines a default name and value pairs for symbolic variables. Following is an example of the substitution-props element, taken from the postingSampleXJCL.xml document:

```
<substitution-props>
<prop name="wsbatch.count" value="5" />
<prop name="checkpoint" value="timebased" />
<prop name="checkpointInterval" value="15" />
<prop name="postingsDataStream" value="${was.install.root}${file.separator}temp${file.separator}postings" />
</substitution-props>
```

Substitution for symbolic variables occurs at run time. At run time, the string ${variable-name} is replaced with the value of the property when the xJCL is submitted for execution. Using the properties in the previous example, the string ${checkpoint} is replaced with the string time-based before the job is submitted.

Symbolic variables can be indirect. For example: name=FILENAME value=${${filename}} used with the name/value pair filename=postingsDataStream yields the same result as specifying name=FILENAME value=${postingsDataStream}.

Symbolic variables can also be compound. For example, name=postingsDataStream value=${was.install.root}${file.separator}temp${file.separator}postings.

The name/value pairs do not have to be defined in the job document substitution-props element. The props name and value pairs defined in the substitution-props element are default values for the named variables. If not defined in the substitution-props element, name/value pairs must be either passed in via the job scheduler APIs when the job is submitted or defined in the system properties for the JVM. Every symbolic variable defined in the body of a job document must be resolved for the xJCL to be considered valid. Every name/value pair defined in the job document must resolve to a symbolic variable which is found in the body of the xJCL for the xJCL to be considered valid.

If name/value pairs are both defined in the xJCL document and passed to the job scheduler APIs at job submission time, the name/value pairs passed via the Job Scheduler APIs override the default values defined in the xJCL document. If name/value pairs are neither passed in via the job scheduler APIs nor defined as defaults in the xJCL document, name/value pairs for the symbolic variables must be defined in the system JVM properties for the xJCL to be considered valid.

Symbolic variables are resolved by the job scheduler before job submission, except for the following special variables, which are resolved at the grid endpoint. The following special variables all must be defined as JVM system properties. They are:

- `${was.install.root}`
- `${user.install.root}`
- `${agent.home}`

## The batch job state table

As the job scheduler and grid endpoint process a grid batch job, the job state updates in the job scheduler database. The diagram shows the relationship between states, and the following table lists the possible batch job states and the events that trigger transitions between states. You can view the current state of a batch job from the job management console, or retrieve it using the command line or Enterprise JavaBeans (EJB) interface. If a failure occurs before a batch step initializes, then the batch job goes into execution failed state. Otherwise, it goes into restartable state.

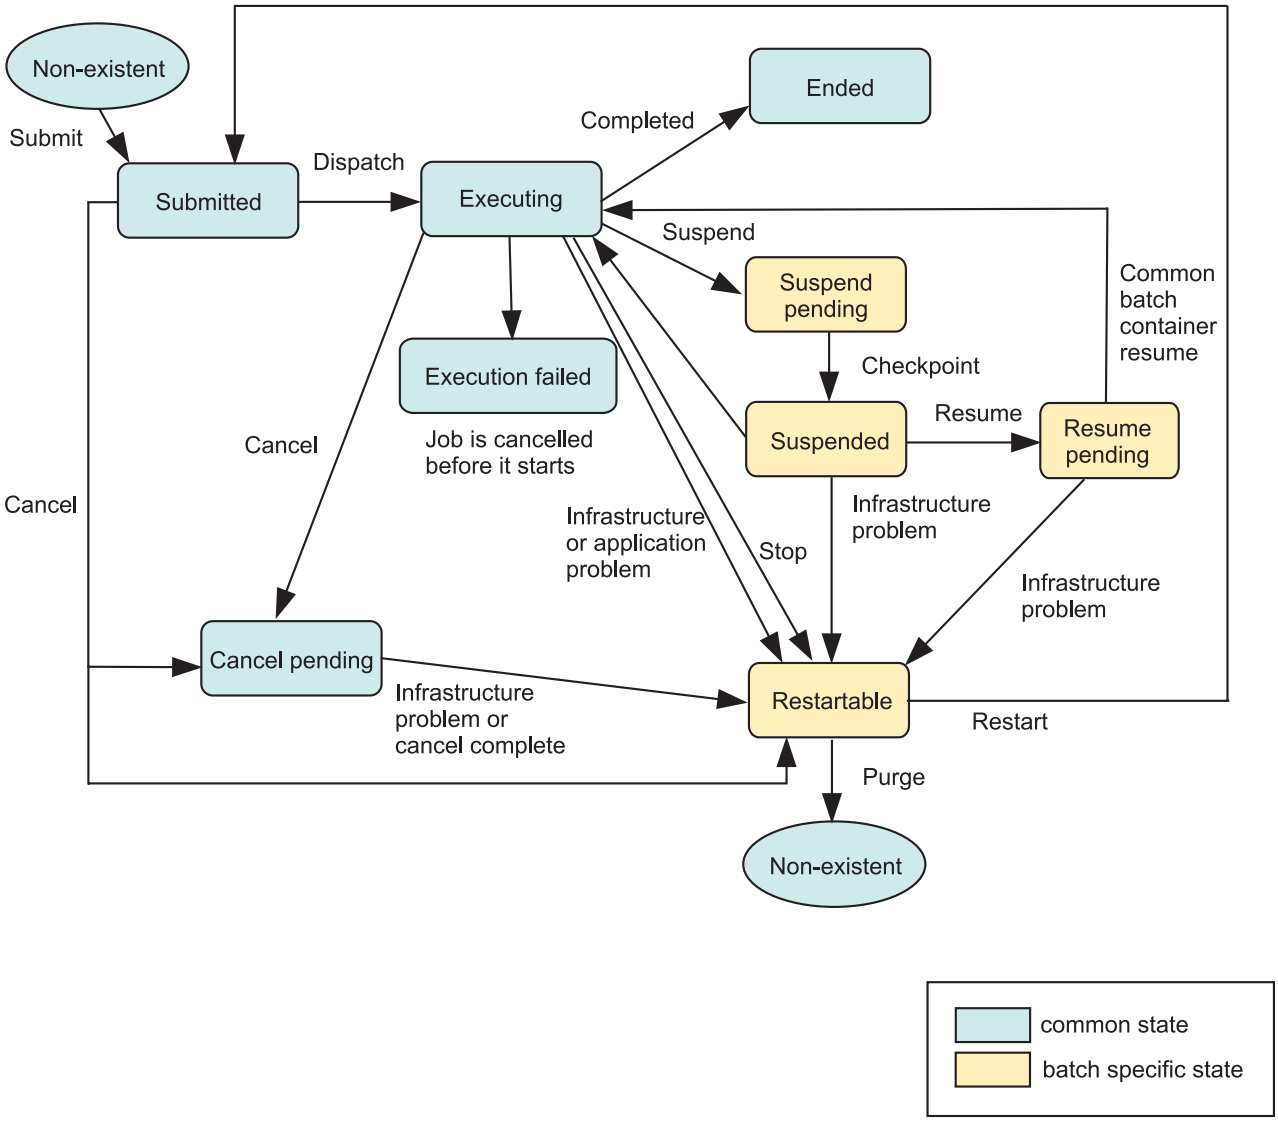

*Table 35. Batch job states. The table includes each batch start state with its client command, system action, special condition, return code, and end state.*

| Start State | Client Command | SystemAction | Special Condition | Numeric return codes | End State |
|---|---|---|---|---|---|
| non-existent (delayed submit) | submit | n/a | Not applicable | | pending submit |
| non-existent | submit | n/a | Not applicable | | submitted |
| submitted | n/a | dispatch | Not applicable | 0 | executing |
| submitted | cancel | n/a | Not applicable | 0 | restartable |
| executing | stop | n/a | Not applicable | 0 | restartable |
| executing | cancel | n/a | Not applicable | 4 | cancel_pending |
| executing | n/a | caught application error* | Not applicable | 4 | restartable |
| executing | n/a | n/a | Infrastructure problem** | 4 | restartable/unknown |
| executing | suspend | n/a | Not applicable | 4 | suspend_pending |
| executing | n/a | job completed | Not applicable | 4 | ended |
| executing | n/a | n/a | Infrastructure problem in job setup*** | 4 | restartable |
| suspend_pending | n/a | checkpoint | Not applicable | 2 | suspended |
| suspend_pending | n/a | n/a | Infrastructure problem** | 2 | restartable/unknown |

*Table 35. Batch job states (continued). The table includes each batch start state with its client command, system action, special condition, return code, and end state.*

| Start State | Client Command | SystemAction | Special Condition | Numeric return codes | End State |
|---|---|---|---|---|---|
| suspended | resume | n/a | n/a | 5 | resume_pending |
| suspended | cancel | n/a | n/a | 5 | cancel_pending |
| suspended | Not applicable | n/a | Infrastructure problem** | 5 | restartable/unknown |
| resume_pending | Not applicable | job resumed | Not applicable | 2 | executing |
| resume_pending | Not applicable | Not applicable | Infrastructure problem** | 2 | restartable/unknown |
| restartable | restart | Not applicable | Not applicable | 8 | submitted |
| cancel_pending | Not applicable | job canceled | Not applicable | 1 | restartable |
| cancel_pending | Not applicable | Not applicable | Infrastructure problem** | 1 | restartable/unknown |
| restartable | purge | Not applicable | Not applicable | 8 | non-existent |
| execution_failed | purge | Not applicable | Not applicable | 9 | non-existent |
| ended | purge | Not applicable | Not applicable | 7 | non-existent |

*Table 36. Notes for the batch job states table. The table includes each note with a description.*

| Note | Description |
|---|---|
| * Application error | The batch application failed at run time. The grid endpoints detected this failure. |
| ** Infrastructure problem | An unexpected error has occurred. See the following example for infrastructure problem in job setup. |
| *** Infrastructure problem in job setup | An unexpected error that occurs when a batch job is set up for the first time by the grid endpoints. For example, if there is an unexpected database failure, the job goes into execution_failed state.<br><br>In this condition, the batch job is run for the first time and no steps are processed yet. Batch jobs go into the restartable state under most failure conditions so that they can restart from checkpointed positions if the failure condition can be overcome. However, in this instance of a failure condition, a batch job goes into execution_failed state and cannot be restarted. Since this situation is a job setup scenario and work is not yet processed by the batch job, batch work is not lost as a result of failure.<br><br>If jobs are in a non-final state on the endpoint, the scheduler puts the jobs into an unknown state under two conditions. The conditions are that the endpoint loses communications or the endpoint goes down. If the endpoint comes back up, the scheduler synchronizes the job status with the endpoint. If the endpoint goes down, all batch jobs are put into a restartable state and all compute- intensive jobs in an execution failed state. If the endpoint has only lost communication with the scheduler and the jobs continue to run, the scheduler updates its status. The status update is the final state of the jobs running on the endpoint at that point. |

# Submitting batch jobs using the job scheduler EJB interface

The job scheduler Enterprise JavaBeans (EJB) interface is used to programmatically submit and manipulate a batch job. You can use the EJB interface with the base scheduler in WebSphere Application Server to perform calendar-based submission of a batch job.

## Before you begin

The job scheduler supports programmatic access to its functions over both an EJB interface for Java Platform, Enterprise Edition (Java EE) applications and a web services interface for both Java EE and non-Java EE applications. The EJB interface for the job scheduler is described by the interfaces found in the API documentation. Consult this documentation for further information.

Develop and install your batch applications.

## About this task

This topic describes how to submit a batch job to the job scheduler using the base scheduler in WebSphere Application Server. It includes a code example that demonstrates how to invoke the job scheduler EJB.

## Procedure

1. Create and configure a scheduler. Read about how to create and configure a scheduler in the topic on developing and scheduling tasks.
2. Create a scheduler task for submitting batch work.

   This scheduler task invokes the job scheduler EJB to submit a batch job. Read the instructions for creating a task that invokes an EJB in the topic on developing a task that calls a session bean. This topic also includes instructions for using the calendaring feature of the WebSphere scheduler. The following example demonstrates on how to invoke the job scheduler EJB:

```
// These are the import statements needed by the task
import javax.naming.*;

import com.ibm.websphere.longrun.JobScheduler;
import com.ibm.websphere.longrun.JobSchedulerHome

private JobSchedulerHome zjsHome = null;
private JobScheduler zjs = null;

public void process(TaskStatus task) ()
try{

     //Ensure that the xJCL can be placed in a string, for example, by reading an xJCL
     //File into a string
     String xJCL = <xJCL as a string>;

     //Obtain cell-level naming context
     InitialContext ctxt = new InitialContext();
     Hashtable env = new Hashtable();

     env.put (Context.INITIAL_CONTEXT_FACTORY,
     "com.ibm.websphere.naming.WsnInitialContextFactory");

     env.put(Context.PROVIDER_URL,"corbaloc:rir:/NameServiceCellRoot");
     ctxt = new InitialContext(env);

     //To look up the LRS EJB from the cell context in the namespace,
     //The name context to the application server or cluster to which the LRS
     //Application is deployed has to be provided
     //Eg: "nodes/myNode/servers/myServer" or "clusters/myCluster".

     String longRunningContext = <long_running_context>;

     zjsHome = (JobSchedulerHome) ctxt.lookup(longRunningContext +
     "/ejb/com/ibm/websphere/longrun/JobSchedulerHome");
     zjs = zjsHome.create();
     zjs.submitJob( xJCL );

}catch (Exception e) {
System.out.println(e.getMessage());
}
```

3. Run the program to submit batch work.

   Read the topic on submitting a task to a scheduler.

## The job scheduler EJB interfaces

The job scheduler Enterprise JavaBeans (EJB) interface is used to programmatically submit a batch job to the job scheduler and manipulate the job.

The following code is the remote interface to the job scheduler EJB. The code produces application programming interfaces.

Some code is split on multiple lines for printing purposes.

```
/**
 * This is the remote interface for the Job Scheduler EJB.
 * Clients of this interface can programmatically submit and manipulate
 * jobs to the Job Scheduler. Code similar to the following can be used to lookup and invoke
 * the remote Job Scheduler EJB interface:
 * <p>
 *
 * InitialContext ctxt = new InitialContext(); <br>
 * Hashtable env = new Hashtable(); <br>
 *
 * env.put (Context.INITIAL_CONTEXT_FACTORY,
 * "com.ibm.websphere.naming.WsnInitialContextFactory"); <br>
 * env.put(Context.PROVIDER_URL,
 * "corbaloc:iiop:<schedulerHostName>:<schedulerBootstrapPort>/NameServiceCellRoot"); <br>
 * ctxt = new InitialContext(env); <br>
 *
 * // In order to lookup the Job Scheduler EJB from the cell context in the namespace, <br>
 * // the name context to the application server or cluster to which the Job Scheduler  <br>
 * // application is deployed has to be provided. <br>
 * // Eg: "nodes/myNode/servers/myServer" or "clusters/myCluster". <br> <br>
 *
 * String jobSchedulerContext = clusters/myCluster; <br> <br>
 *
 * JobSchedulerHome zjsHome = (JobSchedulerHome)
 *      PortableRemoteObject.narrow(ctxt.lookup(jobSchedulerContext +
 *      "/ejb/com/ibm/websphere/longrun/JobSchedulerHome"),JobSchedulerHome.class); <br>
 *
 * JobScheduler js = zjsHome.create(); <br>
 *
 *
 *
 * @ibm-api
 */
public interface JobScheduler extends javax.ejb.EJBObject {

    /**
     * Note: The following code is not supported.
     * Submits the specified job, saved in the xJCL repository, to the job scheduler
     * @param job  The name of the job that was stored to the xJCL repository

}
```

# Submitting batch jobs using the job scheduler web services interface

The job scheduler web services interface is used to programmatically submit and manipulate a batch job.

## Before you begin

The job scheduler supports programmatic access to its functions over both an EJB interface for Java Platform, Enterprise Edition (Java EE) applications and a web services interface for both Java EE and non-Java EE applications. The Web Services Description Language (WSDL) describes the web services interface for the job scheduler that is listed under the job scheduler web services interface.

Develop and install your batch applications.

## About this task

This topic describes how to submit a batch job to the job scheduler. It includes a code example that demonstrates how to invoke the job scheduler web services interface.

## Procedure

1. Create a program for submitting batch work.

   The following example demonstrates how to invoke the job scheduler web services interface to submit a batch job.

Some statements are split on multiple lines for printing purposes.

```
import javax.xml.namespace.QName;
 import javax.xml.rpc.Call;
 import javax.xml.rpc.ParameterMode;
 import javax.xml.rpc.Service;
 import javax.xml.rpc.ServiceException;
 import javax.xml.rpc.ServiceFactory;
 import javax.xml.rpc.encoding.XMLType;

    Call call = null;
 String lrsHostName = "localhost";
 String lrsPort = "9080";

 private String readXJCL() throws FileNotFoundException, IOException {
  // Code to read xJCL file into a String
 }

      public void submitJob() {
       String endPoint =
          "http://"+lrsHostName+":"+lrsPort+"/LongRunningJobSchedulerWebSvcRouter/
            services/JobScheduler";
       try {
           ServiceFactory serviceFactory = ServiceFactory.newInstance();
           Service service = serviceFactory.createService(new
              QName("http://longrun.websphere.ibm.com", "JobSchedulerService"));

           call = (Call) service.createCall();
        call.setProperty(Call.ENCODINGSTYLE_URI_PROPERTY,
            "http://schemas.xmlsoap.org/soap/encoding/");
        call.setProperty(Call.OPERATION_STYLE_PROPERTY, "wrapped");
        call.setPortTypeName(new
            QName("http://longrun.websphere.ibm.com", "JobSchedulerService"));
        call.setTargetEndpointAddress(endPoint);

        //remove all parameters from call object
        call.removeAllParameters();
        call.setReturnType(XMLType.SOAP_STRING, null);
        call.addParameter("arg", XMLType.SOAP_STRING, ParameterMode.IN);
        call.setOperationName(new QName("http://longrun.websphere.ibm.com","submitJob"));

   String xjcl = readXJCL(); // Method to read xJCL file into a string

        call.invoke(new Object[] {xjcl});
       } catch (ServiceException se) {
        System.out.println("Service Exception: " + se.getMessage());
        se.printStackTrace();
       } catch (java.rmi.RemoteException re) {
        System.out.println("Remote Exception: " + re.getMessage());
        re.printStackTrace();
       }
      }
```

2. Run the program to submit batch work.

## The job scheduler web services interface

The job scheduler for web services provides the following interfaces for programmatically submitting and manipulating a batch job from a web services client program:

The following code is the contents of the Web Services Description Language (WSDL) file.

Some code is split on multiple lines for printing purposes.

```
<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions
targetNamespace="http://longrun.websphere.ibm.com"

# Chapter 5. Developing applications that use the Bean Validation API

The Bean Validation API is introduced with the Java Enterprise Edition 6 platform as a standard mechanism to validate Enterprise JavaBeans in all layers of an application, including, presentation, business and data access. Before the Bean Validation specification, the JavaBeans were validated in each layer. To prevent the reimplementation of validations at each layer, developers bundled validations directly into their classes or copied validation code, which was often cluttered. Having one implementation that is common to all layers of the application simplifies the developers work and saves time.

## Bean Validation

The Bean Validation API is introduced with the Java Enterprise Edition 6 platform as a standard mechanism to validate JavaBeans in all layers of an application, including presentation, business, and data access.

Before the Bean Validation specification, JavaBeans were validated in each layer. To prevent the reimplementation of validations at each layer, developers bundled validations directly into their classes or copied validation code, which was often cluttered. Having one implementation that is common to all layers of the application simplifies the developers work and saves time.

The Bean Validation specification defines a metadata model and an API that are used to validate JavaBeans for data integrity. The metadata source is the constraint annotations defined that can be overridden and extended using XML validation descriptors. The set of APIs provides an ease of use programming model allowing any application layer to use the same set of validation constraints. Validation constraints are used to check the value of annotated fields, methods, and types to ensure that they adhere to the defined constraint.

Constraints can be built in or user-defined. Several built-in annotations are available in the javax.validation.constraints package. They are used to define regular constraint definitions and for composing constraints. For a list of built-in constraints, see the topic, “Bean validation built-in constraints” on page 162. For more details about the Bean Validation metadata model and APIs see the JSR 303 Bean Validation specification document.

The following example is a simple Enterprise JavaBeans (EJB) class that is decorated with built-in constraint annotations.

```
public class Home  {
   @Size(Max=20)
    String builder;
    @NotNull @Size(Max=20)
    String address;

    public String getAddress() {
         return address;
    }

    public String getBuilder() {
         return address;
    }
    public String setAddress(String newAddress) {
         return address = newAddress;
    }

    public String setBuilder(String newBuilder) {
         return builder = newBuilder;
    }
}
```

© Copyright IBM Corp. 2011

The @Size annotations on builder and address specify that the string value assigned should not be greater 20 characters. The @NotNull annotation on address indicates that it cannot be null. When the Home object is validated, the builder and address values are passed to the validator class defined for the @Size annotation. The address value is also be passed to the @NotNull validator class. The validator classes handle checking the values for the proper constraints and if any constraint fails validation, a ConstraintViolation object is created, and is returned in a set to the caller validating the Home object.

## Validation APIs

The javax.validation package contains the bean validation APIs that describe how to programmatically validate JavaBeans.

ConstraintViolation is the class describing a single constraint failure. A set of ConstraintViolation classes is returned for an object validation. The constraint violation also exposes a human readable message describing the violation.

ValidationException are raised if a failure happens during validation.

The Validator interface is the main validation API and a Validator instance is the object that is able to validate the values of the Java object fields, methods, and types. The bootstrapping API is the mechanism used to get access to a ValidatorFactory that is used to create a Validator instance. For applications deployed on the product, bootstrapping is done automatically. There are two ways for applications to get the validator or the ValidatorFactory. One way is injection, for example, using the @Resource annotation, and the other way is the java: lookup.

The following example uses injection to obtain a ValidatorFactory and a Validator:

```
@Resource ValidatorFactory _validatorFactory;
@Resource Validator _validator;
```

**Attention:** When using @Resource to obtain a Validator or ValidatorFactory, the authenticationType and shareable elements must not be specified.

The following example uses JNDI to obtain a ValidatorFactory and a Validator:

```
ValidatorFactory validatorFactory = (ValidatorFactory)context.lookup("java:comp/ValidatorFactory");
Validator validator = (Validator)context.lookup("java:comp/Validator");
```

## Constraint metadata request APIs

The metadata APIs support tool providers, provides integration with other frameworks, libraries, and Java Platform, Enterprise Edition technologies. The metadata repository of object constraints is accessed through the Validator instance of a given class.

## XML deployment descriptors

Besides declaring constraints in annotations, support exists for using XML to declare your constraints.

The validation XML description is composed of two kinds of xml files. The META-INF/validation.xml file describes the bean validation configuration for the module. The other XML file type describes constraints declarations and closely matches the annotations declaration method. By default, all constraint declarations expressed through annotations are ignored for classes described in XML. It is possible to force validation to use both the annotations and the XML constraint declarations by using the ignore-annotation="false" setting on the bean. The product ensures that application modules deployed containing a validation.xml file and constraints defined in XML files are isolated from other module validation.xml and constraint files by creating validator instances specific to the module containing the XML descriptors.

## Advanced bean validation concepts

The Bean Validation API provides a set of built-in constraints and an interface that enables you to declare custom constraints. This is accomplished by creating constraint annotations and declaring an annotation on a bean type, field, or property. Composing constraints is also done by declaring the constant on another constraint definition.

### Custom constraint and validator example

The following example shows creating a CommentChecker constraint that is defined to ensure a comment string field is not null. The comment text is enclosed by brackets, such as [*text*].

```
package com.my.company;
    import java.lang.annotation.Documented;
    import java.lang.annotation.Retention;
    import java.lang.annotation.Target;
    import static java.lang.annotation.ElementType.METHOD;
    import static java.lang.annotation.ElementType.FIELD;
    import static java.lang.annotation.RetentionPolicy.RUNTIME;

    import javax.validation.Constraint;
    import javax.validation.Payload;
    @Documented
    @Constraint(validatedBy = CommentValidator.class)
    @Target({ METHOD, FIELD })
    @Retention(RUNTIME)
    public @interface CommentChecker {
           String message() default "The comment is not valid.";
           Class<?>[] groups() default {};
           Class<? extends Payload>[] payload() default {};
     ...}
```

The next example shows the constraint validator that handles validating elements with the @CommentChecker annotation. The constraint validator implements the ConstraintValidator interface provided by the Bean Validation API.

```
package com.my.company
import javax.validation.ConstraintValidator;
import javax.validation.ConstraintValidatorContext;
public class CommentValidator implements ConstraintValidator<CommentChecker, String> {
    public void initialize(CommentChecker arg0) {
    }
    public boolean isValid(String comment, ConstraintValidatorContext context) {
        if (comment == null) {
            // Null comment is not allowed, fail the constraint.
            return false;
        }
        if (!comment.contains("[") && !comment.contains("]")) {
            // Can't find any open or close brackets, fail the constraint
            return false;
        }
        // Ignore leading and trailing spaces
        String trimmedComment = comment.trim();
        return // validate '[' prefix condition
               trimmedComment.charAt(0) == '[' &&
               // validate ']' suffix condition
               trimmedComment.charAt(trimmedComment.size()-1) == ']';
    }
}
```

After the @CommentChecker is defined, it can be used to ensure that the comment string field is a valid comment based on the CommentValidator isValid() implementation. The following example shows the use of the @CommentChecker constraint. When the myChecker bean is validated, the comment string is validated by the CommentValidator class to ensure the constraints defined are met.

```
package com.my.company;
public myChecker {

    @CommentChecker
    String comment = null;
    ...
}
```

**Using a different bean validation provider**

The product provides a specific bean validation provider, but it might be necessary for an application to use or require another provider.

This method can be accomplished by using the validator methods to set the provider programmatically and create a validation factory. Or, by using the validation.xml default-provider element. The specific provider that is defined and used to create the validation factory and not the default provider provided by the application server in the default implementation. If you want to ensure that the user-provided implementation does not conflict with the default implementation, the server or application class loading parameter, the class loader order should be set to be loaded with local class loader first (parent last). See additional information in the class loading documentation on how to set this setting.

**Validation.xml deployment descriptor and class loading**

The Bean Validation specification indicates that if more than one validation.xml file is found in the class path, a ValidationException occurs. However, WebSphere Application Server supports an environment where multiple teams develop modules that are assembled and deployed into the Application Server together. In this environment, all EJB modules within an application are loaded with the same class loader and it is possible to configure the application class loaders so that all EJB and web archive (WAR) modules are loaded by a single class loader. Because of this, the product provides support for multiple validation.xml files in the same class path.

When an application using bean validation and XML descriptors contains multiple EJB modules and web modules, each validation.xml file is associated with a validation factory that is specific to that module. In this environment, any constraint-mapping elements that are defined are only looked up in the module where the validation.xml file is defined. For example, if an EJB module building.jar contains a META-INF/validation.xml file and the validation.xml file defined the following constraints, both the META-INF/constraints-house.xml and META-INF/constraints-rooms.xml files must also be located in the building.jar file:

```
<constraint-mapping>META-INF/constraints-house.xml</constaint-mapping>
<constraint-mapping>META-INF/constraints-rooms.xml</constraint-mapping>
```

The exception to this behavior is when all bean validation constraints classes and configuration are visible to all application modules. It is the case where a single validation.xml file is defined in an EAR file and no other validation.xml files are visible a modules class path. In this environment any module creating a validator factory or validator uses the same validation.xml file. This makes it possible for other modules to create a validator factory that uses the validation.xml file of another module as long the class path has been configured so that both modules are visible on the same class path and only one validation.xml file is visible.

For a more detailed understanding about the Bean Validation APIs and metadata see the JSR 303 Bean Validation specification document.

## Bean validation built-in constraints

Use this information to look up information about Bean Validation API built-in constraints.

The Bean Validation API is supported by constraints that are primarily expressed through annotations. The constraints are added to a class, field, or method of an Enterprise JavaBeans (EJB) component. The annotated element value is checked by the constraint.

Constraints can be built in or user defined. Several built-in annotations are available in the javax.validation.constraints package. They are used to define regular constraint definitions and for composing constraints.

The following table is a list of constraints and usage.

*Table 37. Bean validation built-in constraints. Bean validation built-in constraints*

| Constraint | Usage |
|---|---|
| @Null | Specifies that the configuration property decorated with this annotation must have a null value. This constraint accepts any type. |
| @NotNull | Specifies that the configuration property decorated with this annotation must not have a null value. That is, the property is required. This constraint accepts any type. |
| @AssertTrue | Specifies that the configuration property decorated with this annotation must be true. Supported value types are boolean and Boolean. Null elements are considered valid. |
| @AssertFalse | Specifies that the configuration property decorated with this annotation must be false. Supported value types are boolean and Boolean. Null elements are considered valid. |
| @Min | Specifies that the configuration property decorated with this annotation must have a value greater than or equal to the specified minimum. Supported value types are BigDecimal, BigInteger, byte, short, int, long and their respective wrappers. Null elements are considered valid. |
| @Max | Specifies that the configuration property decorated with this annotation must have a value less than or equal to the specified maximum. Supported value types are BigDecimal, BigInteger, byte, short, int, long and their respective wrappers. Null elements are considered valid. |
| @DecimalMin | Specifies that the configuration property decorated with this annotation must have a value higher or equal to the specified minimum. Supported value types are BigDecimal, BigInteger, String, byte, short, int, long and their respective wrappers. Null elements are considered valid. |
| @DecimalMax | Specifies that the configuration property decorated with this annotation must have a value lower or equal to the specified maximum. Supported value types are BigDecimal, BigInteger, String, byte, short, int, long and their respective wrappers. Null elements are considered valid. |
| @Size | Specifies that the configuration property decorated with this annotation must have a value between the specified boundaries (included). Supported value types are String (string length is evaluated), Collection (collection size is evaluated), Map (map size is evaluated), Array (array length is evaluated). Null elements are considered valid. |
| @Digits | Specifies that the configuration property decorated with this annotation must have a value within accepted range. Supported value types are BigDecimal, BigInteger, String, byte, short, int, long and their respective wrappers. Null elements are considered valid. |
| @Past | Specifies that the configuration property decorated with this annotation must have a date in the past. Now is defined as the current time according to the virtual machine. The calendar is used if the compared type is of type Calendar and the calendar is based on the current timezone and the current locale. Supported value types are java.util.Date, java.util.Calendar. Null elements are considered valid. |
| @Future | Specifies that the configuration property decorated with this annotation must have a date in the future. Now is defined as the current time according to the virtual machine. The calendar is used if the compared type is of type Calendar and the calendar is based on the current timezone and the current locale. Supported value types are java.util.Date, java.util.Calendar. Null elements are considered valid. |
| @Pattern | Specifies that the configuration property decorated with this annotation must match the following regular expression. The regular expression follows the Java regular expression conventions java.util.regex.Pattern. Supported type value is String. Null elements are considered valid. |
| | |

# Using bean validation in the product

The Java Enterprise Edition (Java EE) 6 specification includes the Bean Validation API that is a standard mechanism for validating JavaBeans in all layers of an application.

## About this task

Before the Bean Validation specification, JavaBeans were validated in each layer. To prevent the reimplementation of validations at each layer, developers bundled validations directly into their classes or copied validation code, which was often cluttered. Having one implementation that is common to all layers of the application simplifies the developers work and saves time.

Bean validation is common to all layers of an application. Specifically, web applications have the following layers:

- Presentation

  This layer represents how the user interacts with the application and might be built on a thin client or rich client.

- Business

  This layer coordinates the application, processes commands, makes logical decisions and evaluations and performs calculations. It also moves and processes data between the two other layers. The EJB contains business logic in WebSphere Application Server.

- Data access

  Your data is stored and retrieved from a database or file system at this layer. The business layer processes the data and sends it in usable form to the user interface. WebSphere Application Server supports several databases and methods of retrieving data. This layer also defines persistence.

For WebSphere Application Server, these layers are built and administered with several components in the product that are necessary for developing and deploying applications.

**Note:** The product provides support for the Bean Validation API in the Java Platform, Enterprise Edition (Java EE) environment by providing a bean validation service in multiple Java EE technologies including Java Servlets, Enterprise JavaBeans, Java Persistence API (JPA) 2.0, Java EE Connector API (JCA) 1.6 and Java ServerFaces (JSF) 2.0. Bean validation provides these technologies a way to maintain data integrity in an integrated and standard environment.

Enterprise application development involves multiple teams developing numerous applications and modules that are assembled and deployed in an application server environment. The product ensures that each application and module data is validated independently. Validation is performed using only the constraints defined for the application and module.

## What to do next

- Data access resources:

  Bean validation in RAR modules.

  The product validates resource adapter archive (RAR) Enterprise JavaBeans (EJB) constraints in compliance with the JCA version 1.6 specification. Resource adapters can use the built-in bean validation constraint annotations or provide a bean validation XML configuration to specify the validation requirements of resource adapter configuration properties to the application server.

- Using bean validation in JPA

  A new feature defined by the JPA 2.0 specification is the ability to seamlessly integrate with the Bean Validation API. With minimal effort, JPA 2.0 can be coupled with the validation provider for runtime data validation. By combining these two technologies, you get a standardized persistence solution with the added ability to perform standardized data validation.

- Using bean validation with JSF

  JSF previously was able do bean validation, but now it provides built-in support of the Bean Validation specification.

- Using bean validation in web container

  The web container provides an instance of ValidatorFactory and makes it available to JSF implementations by storing it in a servlet context attribute named javax.faces.validator.beanValidator.ValidatorFactory.

- Using bean validation with the embeddable container.

  To use bean validation with the embeddable EJB container, the javax.validation classes must exist in the class path. That can be done in one of two ways:

– Include the JPA thin client that is located in the directory ${*WAS_INSTALL_ROOT*}\runtimes\com.ibm.ws.jpa.thinclient_8.0.0.jar in the class path. See the topic, Running an embeddable container, and the information about JPA, for more information.
– Include a third party bean validation provider Java archive (JAR) file in the class path of the embeddable EJB container run time.

## Bean validation in RAR modules

WebSphere Application Server validates resource adapter archive (RAR) JavaBeans constraints in compliance with the Java Connector Architecture (JCA) version 1.6 specification.

Resource adapters can specify the validation requirements of configuration properties to the Application Server through annotations in the source code of the resource adapter, constraint specifications in a resource adapter validation descriptor, or a mixture of both. In specifying these constraints, resource adapters can use the built-in bean validation constraints supplied with the Application Server, custom bean validation constraints supplied either by the application developer or a third party, or a mixture of both. Resource adapter developers can apply constraints to the fields and JavaBeans-compliant properties of the following JCA types:

- ResourceAdapter
- ManagedConnectionFactory
- ActivationSpec
- AdministeredObject

At run time, the application server creates instances of bean types declared by the resource adapter. Each instance is validated immediately upon setting its configuration properties, before placing the instance into service.

When validating a RAR bean, the Application Server creates an instance of a validator factory according to the bean validation deployment descriptor discovered by the Application Server. A validator instance is then obtained from the factory and used to validate the bean instance.

If validation fails, the Application Server throws a constraint violation exception and reports all violations to the system log. The effects of the exception for each RAR bean type and problem determination information are documented in the topic, Troubleshooting bean validation in RAR modules.

**Note:** The Bean Validation specification requires that no more than one `validation.xml` is visible on the class path. This requirement is violated whenever two or more stand-alone RARs provide a validation descriptor. See the section, "RAR bean validation descriptor" in this topic, for more information. When more than one `validation.xml` is visible to the Application Server class loaders, the Application Server or application modules might fail to acquire the default ValidatorFactory and subsequently cannot perform bean validation. For example, the server cannot validate beans of a RAR embedded in an application whenever the embedded RAR lacks a validation configuration, and two or more stand-alone RARs provide configurations. To avoid trouble, install stand-alone RARs that provide a bean validation descriptor as isolated whenever possible.

### Built-in constraint annotations

**Note:** Use built-in constraint annotations to specify the range and mandatory attributes of configuration properties rather than provide custom annotations for the same purpose. The following constraints are useful, but you can use all bean validation built-in constraints. See the topic Bean validation built-in constraints for a complete list of the constraints.

- @Min

  Specifies the minimum value of the configuration property decorated with this annotation. The value must be greater than or equal to the specified minimum.
- @Max

Specifies the maximum value of the configuration property decorated with this annotation. The value must less than or equal to the specified maximum.

- @Size

  Specifies the range of values of the configuration property decorated with this annotation. The value must be greater than or equal to the specified minimum and be less than or equal to the specified maximum.

- @NotNull

  Specifies the value of the configuration property decorated with this annotation must not be null. That is, the property is required.

The following example is a RAR bean class that is decorated with built-in constraint annotations.

The value of the serverName configuration property must not be null, and the value of the instanceCount property must be at least 1 when the Application Server creates and configures an instance of the MyConnector class. Otherwise, a constraint validation exception occurs and, in the case of ResourceAdapter bean, the resource adapter fails to start. See the topic Troubleshooting bean validation in RAR modules for more information.

```
package com.my.company;

@Connector(...)
public class MyConnector implements ResourceAdapter, Serializable
{
 @ConfigProperty(type=java.lang.String.class,defaultValue="WAS")
 private String serverName;

 @NotNull()
 public String getServerName() {return serverName;}

 private Integer instanceCount = 0;

 @Min(value=1)
 public Integer getInstanceCount() {return instanceCount;}
 ...
```

## RAR bean validation descriptor

Bean validation constraints can be declared through an XML descriptor supplied by a RAR module. In the simplest case, a RAR validation descriptor consists of the validation configuration declared in the validation.xml file and zero or more XML files that declare RAR bean validation constraints. Files containing constraint declarations are specified in the constraint-mapping elements of the validation configuration (validation.xml).

You must package the validation descriptor in the META-INF directory of a RAR module. Any custom constraint annotation classes that are declared in the validation descriptor must also be packaged in the RAR module.

The following example is a simple RAR validation descriptor that declares constraint metadata like the code shown in the section, "Built-in constraint annotations."

```
<?xml version="1.0" encoding="UTF-8"?>
<validation-config
  xmlns="http://jboss.org/xml/ns/javax/validation/configuration"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://jboss.org/xml/ns/javax/validation/configuration validation-configuration-1.0.xsd">
<constraint-mapping>META-INF/constraints.xml</constraint-mapping>
</validation-config>
```

The constraints XML file is also located in the META-INF directory and looks like the following:

```
<constraint-mappings
 xmlns="http://jboss.org/xml/ns/javax/validation/mapping"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://jboss.org/xml/ns/javax/validation/mapping validation-mapping-1.0.xsd">
<default-package>com.my.company</default-package>
<bean class="MyConnector" ignore-annotations="true">
 <field name="serverName">
  <valid/>
  <!-- @NotNull() -->
```

```
  <constraint annotation="javax.validation.constraints.NotNull">
   <message>Value is not null</message>
  </constraint>
 </field>
 <field name="instanceCount">
  <valid/>
  <!-- @Min(1) -->
  <constraint annotation="javax.validation.constraints.Min">
    <message>Minimum possible value is 1</message>
    <element name="value">1</element>
   </constraint>
  </field>
 </bean>
<constraint-mapping>
```

The packaged RAR module, `MyResourceAdapter.rar`, looks like the following:

```
my/
  company/
    MyConnector.class
. . .
META-INF
  /validation.xml
  /constraints.xml
```

### Third-party bean validation

WebSphere Application Server supports using different bean validation implementations. If a resource adapter requires a bean validation implementation different from the implementation that is provided by the product, and the RAR provides the bean validation implementation, you must package the JAR file that contains the bean validation implementation in the RAR module root directory.

The RAR module must also contain a single validation configuration descriptor (`validation.xml`), which can be packaged in the META-INF directory of the RAR module, or in the `META-INF/services` directory of the bean validation JAR file, but not both.

### RAR bean validation configuration discovery

When validating RAR beans, the Application Server bootstraps the bean validation configuration, specific to the RAR, according to the bean validation descriptor supplied in the RAR META-INF directory. If the descriptor does not exist, the server bootstraps the configuration using the first validation descriptor discovered in the RAR class loading context, such as that supplied in a third-party bean validation that is packaged in the RAR. Finally, the server uses the default validation configuration provided by the product.

The server then creates a validator factory specific to the discovered bean validation configuration and uses this factory to create validator instances for validating the RAR bean instances. When you deploy a RAR that supplies a bean validation descriptor, you must take additional steps to ensure that the class loader that loads the RAR loads the bean validation descriptor and classes packaged in the RAR.

For an embedded RAR, after you have deployed the application that embeds the RAR, you must set the delegation mode of the application class loader to Parent-Last (Child-First). See the topic Configuring application class loaders for more information.

For a stand-alone RAR, you must install the RAR as an isolated resource provider. See the topic Resource Adapter settings for more information.

## Bean validation in JPA

Data validation is a common task that occurs in all layers of an application, including persistence. The Java Persistence API (JPA) 2.0 provides support for the Bean Validation API so that data validation can be done at run time. This topic includes a usage scenario where bean validation is used in the JPA environment of a sample digital image gallery application.

The Bean Validation API provides seamless validation across technologies on Java Enterprise Edition 6 (Java EE 6) and Java Platform, Standard Edition (JSE) environments. In addition to JPA 2.0, these technologies include JavaServer Faces (JSF) 2.0 and Java EE Connector Architecture (JCA) 1.6. You can read more about bean validation in the topic, Bean Validation API.

There are three core concepts of bean validation: constraints, constraint violation handling, and the validator. If you are running applications in an integrated environment like JPA, there is no need to interface directly with the validator.

Validation constraints are annotations or XML code that are added to a class, field, or method of a JavaBeans component. Constraints can be built in or user-defined. They are used to define regular constraint definitions and for composing constraints. The built-in constraints are defined by the bean validation specification and are available with every validation provider. For a list of built-in constraints, see the topic, Bean validation built-in constraints. If you need a constraint different from the built-in constraints, you can build your own user-defined constraint.

## Constraints and JPA

The following usage scenario illustrates how a built-in constraint is used in the JPA architecture of a sample digital image gallery application.

In the first code example, a built-in constraint is added to a simple entity of the JPA model called *image*. An image has an ID, image type, file name, and image data. The image type must be specified and the image file name must include a valid JPEG or GIF extension. The code shows the annotated image entity with some built-in bean validation constraints applied.

```
package org.apache.openjpa.example.gallery.model;

import javax.persistence.Entity;
import javax.persistence.EnumType;
import javax.persistence.Enumerated;
import javax.persistence.GeneratedValue;
import javax.persistence.Id;
import javax.validation.constraints.NotNull;
import javax.validation.constraints.Pattern;

@Entity
public class Image {

    private long id;
    private ImageType type;
    private String fileName;
    private byte[] data;

    @Id
    @GeneratedValue
    public long getId() {
        return id;
    }

    public void setId(long id) {
        this.id = id;
    }

    @NotNull(message="Image type must be specified.")
    @Enumerated(EnumType.STRING)
    public ImageType getType() {
        return type;
    }

    public void setType(ImageType type) {
        this.type = type;
    }
```

```
    @Pattern(regexp = ".*\\.jpg|.*\\.jpeg|.*\\.gif",
        message="Only images of type JPEG or GIF are supported.")
    public String getFileName() {
        return fileName;
    }

    public void setFileName(String fileName) {
        this.fileName = fileName;
    }

    public byte[] getData() {
        return data;
    }

    public void setData(byte[] data) {
        this.data = data;
    }
}
```

The Image class uses two built-in constraints, @NotNull and @Pattern. The @NotNull constraint ensures that an ImageType element is specified and the @Pattern constraint uses regular expression pattern matching to ensure that the image file name is suffixed with a supported image format. Each constraint has corresponding validation logic that gets started at run time when the image entity is validated. If either constraint is not met, the JPA provider throws a ConstraintViolationException with the defined message. The JSR-303 specification also makes provisions for the use of a variable within the message attribute. The variable references a keyed message in a resource bundle. The resource bundle supports environment-specific messages and globalization, translation, and multicultural support of messages.

You can create your own custom validator and constraints. In the previous example, the Image entity used the @Pattern constraint to validate the file name of the image. However, it did not check constraints on the actual image data itself. You can use a pattern-based constraint; however, you do not have the flexibility that you would if you created a constraint specifically for checking constraints on the data. In this case you can build a custom method-level constraint annotation. The following is a custom or user-defined constraint called ImageContent.

```
package org.apache.openjpa.example.gallery.constraint;

import java.lang.annotation.Documented;
import java.lang.annotation.Retention;
import java.lang.annotation.Target;
import static java.lang.annotation.ElementType.METHOD;
import static java.lang.annotation.ElementType.FIELD;
import static java.lang.annotation.RetentionPolicy.RUNTIME;

import javax.validation.Constraint;
import javax.validation.Payload;

import org.apache.openjpa.example.gallery.model.ImageType;

@Documented
@Constraint(validatedBy = ImageContentValidator.class)
@Target({ METHOD, FIELD })
@Retention(RUNTIME)
public @interface ImageContent {
     String message() default "Image data is not a supported format.";
     Class<?>[] groups() default {};
  Class<? extends Payload>[] payload() default {};
  ImageType[] value() default { ImageType.GIF, ImageType.JPEG };
}
```

Next, you must create the validator class, ImageContentValidator. The logic within this validator gets implemented by the validation provider when the constraint is validated. The validator class is bound to the constraint annotation through the validatedBy attribute on the @Constraint annotation as shown in the following code:

```
package org.apache.openjpa.example.gallery.constraint;
import java.util.Arrays;
import java.util.List;
import javax.validation.ConstraintValidator;
import javax.validation.ConstraintValidatorContext;
import org.apache.openjpa.example.gallery.model.ImageType;
/**
 * Simple check that file format is of a supported type
 */
public class ImageContentValidator implements ConstraintValidator<ImageContent, byte[]> {
    private List<ImageType> allowedTypes = null;
    /**
     * Configure the constraint validator based on the image
     * types it should support.
     * @param constraint the constraint definition
     */
    public void initialize(ImageContent constraint) {
        allowedTypes = Arrays.asList(constraint.value());
    }
    /**
     *Validate a specified value.
     */
    public boolean isValid(byte[] value, ConstraintValidatorContext context) {
        if (value == null) {
            return false;
        }
        // Verify the GIF header is either GIF87 or GIF89
        if (allowedTypes.contains(ImageType.GIF)) {
            String gifHeader = new String(value, 0, 6);
            if (value.length >= 6 &&
                (gifHeader.equalsIgnoreCase("GIF87a") ||
                 gifHeader.equalsIgnoreCase("GIF89a"))) {
                return true;
            }
        }
        // Verify the JPEG begins with SOI and ends with EOI
        if (allowedTypes.contains(ImageType.JPEG)) {
            if (value.length >= 4 &&
                value[0] == 0xff && value[1] == 0xd8 &&
                value[value.length - 2] == 0xff && value[value.length -1] == 0xd9) {
                return true;
            }
        }
        // Unknown file format
        return false;
    }
}
```

Apply this new constraint to the getData() method on the Image class; for example:

```
@ImageContent
    public byte[] getData() {
        return data;
    }
```

When validation of the data attribute occurs, the isValid() method in the ImageContentValidator is started. This method contains logic for performing simple validation of the format of the binary image data. A potentially overlooked feature in the ImageContentValidator is that it can also validate for a specific image type. By definition, it accepts JPEG or GIF formats, but it can also validate for a specific format. For example, by changing the annotation to the following code example, the validator is instructed to only permit image data with valid JPEG content:

```
@ImageContent(ImageType.JPEG)
    public byte[] getData() {
        return data;
    }
```

*Type-level* constraints are also a consideration because you might need to validate combinations of attributes on an entity. In the previous examples validation constraints were used on individual attributes. Type-level constraints make it possible to provide collective validation. For example, the constraints applied to the image entity validate that an image type is set (not null), the extension on the image file name is of a supported type, and the data format is correct for the indicated type. But, for example, it does not collectively validate that a file named `img0.gif` is of type GIF and the format of the data is for a valid GIF file image. For more information about type-level constraints, see the white paper, OpenJPA Bean Validation Primer, and the section "Type-level constraints."

## Validation groups

Bean validation uses validation groups to determine what type of validation and when validation occurs.

There are no special interfaces to implement or annotations to apply to create a validation group. A validation group is denoted by a class definition.

**Note:** When using groups, use simple interfaces. Using a simple interface makes validation groups more usable in multiple environments. Whereas, if a class or entity definition is used as a validation group, it might pollute the object model of another application by bringing in domain classes and logic that do no make sense for the application. By default, if a validation group or multiple groups is not specified on an individual constraint, it is validated using the javax.validation.groups.Default group. Creating a custom group is as simple as creating a new interface definition.

For more information about validation groups, read the white paper, OpenJPA Bean Validation Primer, and the section "Validation groups."

## JPA domain model

In addition to the Image entity are Album, Creator and Location persistent types. An Album entity contains a reference to collection of its Image entities. The Creator entity contains a reference to the album entities that the image Creator contributed to and a reference to the Image entities created. This provides full navigational capabilities to and from each of the entities in the domain. An embeddable location, has been added to image to support storing location information with the image.

The Album and Creator entities have standard built-in constraints. The embeddable location is more unique in that it demonstrates the use of the @Valid annotation to validate embedded objects. To embed location into an image, a new field and corresponding persistent properties are added to the Image class; for example:

```
private Location location;

    @Valid
    @Embedded
    public Location getLocation() {
        return location;
    }

    public void setLocation(Location location) {
        this.location = location;
    }
```

The @Valid annotation provides chained validation of embeddable objects within a JPA environment. Therefore, when image is validated, any constraints on the location it references are also validated. If @Valid is not specified, the location is not validated. In a JPA environment, chained validation through

@Valid is only available for embeddable objects. Referenced entities and collections of entities are validated separately to prevent circular validation.

## Bean validation and the JPA environment

The JPA 2.0 specification makes integration with the Bean Validation API simple. In a JSE environment, bean validation is enabled by default when you provide the Bean Validation API and a bean validation provider on your runtime class path. In a Java EE 6 environment, the application server includes a bean validation provider so there is no need to bundle one with your application. In both environments, you must use a Version 2.0 `persistence.xml` file.

A Version 1.0 `persistence.xml` provides no means to configure bean validation. Requiring a Version 2.0 `persistence.xml` prevents a pure JPA 1.0 application from incurring the validation startup and runtime costs. This is important given that there is no standard means for a 1.0-based application to disable validation. In a Java EE 6 environment, enable validation in an existing 1.0 application by modifying the root element of your `persistence.xml` file. The following example represents the `persistence.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<persistence xmlns="http://java.sun.com/xml/ns/persistence"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/persistence
    http://java.sun.com/xml/ns/persistence/persistence_2_0.xsd"
    version="2.0" >
...
</persistence>
```

### Validation modes

Bean validation provides three modes of operation within the JPA environment:

- Auto

  Enables bean validation if a validation provider is available within the class path. Auto is the default.
- Callback

  When callback mode is specified, a bean validation provider must be available for use by the JPA provider. If not, the JPA provider throws an exception upon instantiation of a new JPA entity manager factory.
- None

  Disables bean validation for a particular persistence unit.

Auto mode simplifies deployment, but can lead to problems if validation does not take place because of a configuration problem.

**Note:** Use either none or callback mode explicitly for consistent behavior.
Also, if none is specified, JPA optimizes at startup and does not attempt to perform unexpected validation. Explicitly disabling validation is especially important in a Java EE 6 environment where the container is mandated to provide a validation provider. Therefore, unless specified, a JPA 2.0 application started in a container has validation enabled. This process adds additional processing during life cycle events.

There are two ways to configure validation modes in JPA 2.0. The simplest way is to add a validation-mode element to the `persistence.xml` with the wanted validation mode as shown in the following example:

```
 <persistence-unit name="auto-validation">
          ...
    <!-- Validation modes: AUTO, CALLBACK, NONE -->
    <validation-mode>AUTO</validation-mode>
    ...
  </persistence-unit>
```

The other way is to configure the validation mode programmatically by specifying the javax.persistence.validation.mode property with value auto, callback, or none when creating a new JPA entity manager factory as shown in the following example:

```
Map<String, String> props = new HashMap<String, String>();
  props.put("javax.persistence.validation.mode", "callback");
        EntityManagerFactory emf =
            Persistence.createEntityManagerFactory("validation", props);
```

### Validation in the JPA life cycle

Bean validation within JPA occurs during JPA life cycle event processing. If enabled, validation occurs at the final stage of the PrePersist, PreUpdate, and PreRemove life cycle events. Validation occurs only after all user-defined life cycle events, since some of those events can modify the entity that is being validated. By default, JPA enables validation for the default validation group for PrePersist and PreUpdate life cycle events. If you must validate other validation groups or enable validation for the PreRemove event, you can specify the validation groups to validate each life cycle event in the `persistence.xml` as shown in the following example:

```
<persistence-unit name="non-default-validation-groups">
  <class>my.Entity</class>
  <validation-mode>CALLBACK</validation-mode>
  <properties>
   <property name="javax.persistence.validation.group.pre-persist"
       value="org.apache.openjpa.example.gallery.constraint.SequencedImageGroup"/>
   <property name="javax.persistence.validation.group.pre-update"
       value="org.apache.openjpa.example.gallery.constraint.SequencedImageGroup"/>
   <property name="javax.persistence.validation.group.pre-remove"
       value="javax.validation.groups.Default"/>
  </property>
 </persistence-unit>
```

The following example shows various stages of the JPA life cycle, including persist, update, and remove:

```
EntityManagerFactory emf =
            Persistence.createEntityManagerFactory("BeanValidation");
        EntityManager em = emf.createEntityManager();

        Location loc = new Location();
        loc.setCity("Rochester");
        loc.setState("MN");
        loc.setZipCode("55901");
        loc.setCountry("USA");

        // Create an Image with non-matching type and file extension
        Image img = new Image();
        img.setType(ImageType.JPEG);
        img.setFileName("Winter_01.gif");
        loadImage(img);
        img.setLocation(loc);

        // *** PERSIST ***
        try {
            em.getTransaction().begin();
            // Persist the entity with non-matching extension and type
            em.persist(img);
        } catch (ConstraintViolationException cve) {
            // Transaction was marked for rollback, roll it back and
            // start a new one
            em.getTransaction().rollback();
            em.getTransaction().begin();
            // Fix the file type and re-try the persist.
            img.setType(ImageType.GIF);
            em.persist(img);
            em.getTransaction().commit();
        }
```

```
        // *** UPDATE ***
        try {
            em.getTransaction().begin();
            // Modify the file name to a non-matching file name
            // and commit to trigger an update
            img.setFileName("Winter_01.jpg");
            em.getTransaction().commit();
        }  catch (ConstraintViolationException cve) {
            // Handle the exception.  The commit failed so the transaction
            // was already rolled back.
            handleConstraintViolation(cve);
        }
        // The update failure caused img to be detached. It must be merged back
        // into the persistence context.
        img = em.merge(img);

        // *** REMOVE ***
        em.getTransaction().begin();
        try {
            // Remove the type and commit to trigger removal
            img.setType(ImageType.GIF);
            em.remove(img);
        }  catch (ConstraintViolationException cve) {
            // Rollback the active transaction and handle the exception
            em.getTransaction().rollback();
            handleConstraintViolation(cve);
        }
        em.close();
        emf.close();
```

## Exceptions

Validation errors can occur in any part of JPA life cycle.

If one or more constraints fail to validate during a life cycle event, a ConstraintViolationException is thrown by the JPA provider. The ConstraintViolationException thrown by the JPA provider includes a set of ConstraintViolations that occurred. Individual constraint violations contain information regarding the constraint, including: a message, the root bean or JPA entity, the leaf bean which is useful when validating JPA embeddable objects, the attribute which failed to validate, and the value that caused the failure. The following is a sample exception handling routine:

```
private void handleConstraintViolation(ConstraintViolationException cve) {
      Set<ConstraintViolation<?>> cvs = cve.getConstraintViolations();
   for (ConstraintViolation<?> cv : cvs) {
     System.out.println("------------------------------------------------");
           System.out.println("Violation: " + cv.getMessage());
           System.out.println("Entity: " + cv.getRootBeanClass().getSimpleName());
           // The violation occurred on a leaf bean (embeddable)
           if (cv.getLeafBean() != null && cv.getRootBean() != cv.getLeafBean()) {
              System.out.println("Embeddable: " +
cv.getLeafBean().getClass().getSimpleName());
           }
           System.out.println("Attribute: " + cv.getPropertyPath());
           System.out.println("Invalid value: " + cv.getInvalidValue());
      }
    }
```

Constraint violation processing is typically simple when using attribute-level constraints. If you are using a type-level validator with type-level constraints, it can be more difficult to determine which attribute or combination of attributes failed to validate. Also, the entire object is returned as the invalid value instead of an individual attribute. In cases where specific failure information is required, use of an attribute-level constraint or a custom constraint violation might be provided as described in the Bean Validation specification.

## Sample

The JPA model and image gallery application usage scenario provided in this topic can be implemented through a sample that is provided in the white paper, OpenJPA Bean Validation primer.

# Chapter 6. Developing Client applications

This page provides a starting point for finding information about application clients and client applications. Application clients provide a framework on which application code runs, so that your client applications can access information on the application server.

For example, an insurance company can use application clients to help offload work on the server and to perform specific tasks. Suppose an insurance agent wants to access and compile daily reports. The reports are based on insurance rates that are located on the server. The agent can use application clients to access the application server where the insurance rates are located. More introduction...

## Developing client applications

A *client application* performs business logic and makes use of the framework provided by an underlying *client*. Developing the code for a client application depends on the objects and functions you want to exploit, and the programming model that you want to use.

### Before you begin

Install the software development resources needed to develop client applications for use with WebSphere Application Server. During code development, you do not need access to the WebSphere Application Server. However, to assemble some types of client applications you need to install files for the client that provides the framework for the client application. Instead of installing WebSphere Application Server you can install the Application Client feature, which provides the same resources and clients to aid development of client applications.

### About this task

To use a client application to access a remote object on an application server, develop your client application code as described in the following steps and the related topics. These topics only describe the client-specific considerations; they do not describe general client programming models, which you should already be familiar with. Samples for different types of client applications are provided with the Application Client.

### Procedure

1. Choose the type of client that you want to use as a framework for your client application. Decision factors for choosing a client include whether you want to run a client application on Java EE or J2SE; whether you want ease of use with a small installation footprint or full-function with medium-large footprint; and whether you need licence to copy or redistribute the client. For more information about choosing the type of client, see “Choosing a type of client” on page 178.
2. Develop the client application code. The following substeps are a high-level general procedure. Information specific to a type of client is given in the related tasks.
   a. Create an instance of the object that you want to access on the remote server. You can use full Java Naming and Directory Interface (JNDI) support to get a suitable reference to administered objects from the server's JNDI namespace. Alternatively, you can get suitable references to objects programmatically without using JNDI.

      Using the javax.naming.InitialContext class, the client application program uses the lookup operation to access the Java Naming and Directory Interface (JNDI) namespace. The InitialContext class provides the lookup method to locate resources.

      You can compare the use of JNDI and programmatic techniques by looking at the samples provided for the Java EE client and Java thin client in an Application Client installation (for example, in `C:\wac70\samples\src\`):

© IBM Corporation 2009

- Java EE client use of JNDI for BasicCalculatorHome: `TechnologySamplesJ2EEClient\BasicCalculator\com\ibm\websphere\samples\technologysamples\basiccalcclient\BasicCalculatorClientJ2EE.java`
- Java thin client programmatic retrieval of BasicCalculatorHome: `TechnologySamplesThinClient\BasicCalculator\com\ibm\websphere\samples\technologysamples\basiccalcthinclient\BasicCalculatorClientThin.java`

b. Create a connection to the server. If the server runs with security enabled, you can configure secure connections.

c. Work with the objects to perform your business requirements. For example, send and receive JMS messages, update database entries, handle error conditions, and close resources used.

3. Compile or assemble the client application. This creates the JAR or EAR file that you can deploy to make the client application available for use.

   To compile your client application, include the JAR files needed in the CLASSPATH setting for the javac command; for example, any extra JAR files for the client application's own classes, JAR files for IBM Thin clients used, and JAR files for JDBC provider classes.

   **Attention:** IBM-provided clients are not packaged with JDBC provider classes. For example, the WebSphere Application Server Version 7.0 Java Thin application client is not packaged with Apache Derby 10.2 classes. If your client application needs to use a database class (such as through the JNDI lookup of a datasource), you must obtain the class files from the database provider and make them available when compiling and running the client application.

### What to do next

After you develop a client application, deploy it into the environment you want it to run.

## Choosing a type of client

A *client* provides the framework for client applications that run separately from your application server.

### About this task

Decision factors for choosing a client include whether you want to run a client application on Java Platform, Enterprise Edition (Java EE) or Java Platform, Standard Edition (J2SE) ; whether you want ease of use with a small installation footprint or full-function with medium to large footprint; and whether you need licence to copy or redistribute the client.

A usual first decision to make is do you want a client application that runs on Java EE or J2SE?. This leads you to choose from the main types of clients, as described in this topic. Otherwise, if you want to run an ActiveX program, or a Java applet, to interact with enterprise beans on WebSphere Application Server, your decision is only for one of those types of client.

### Procedure

- J2SE

  If you want to run a lightweight client application, without the resource and processing cost of the Java EE platform for WebSphere Application Server on the client machine, then choose either the Java thin client or the stand-alone thin clients to run on J2SE.

  – If you want a client with a small installation footprint, that you can embed into your application, and that runs under an IBM, Sun, or HP-UX JRE, choose the stand-alone clients. Each client is an embeddable single jar with small footprint; for example, the Thin Client for JMS with WebSphere Application Server, `com.ibm.ws.sib.client.thin.jms_7.0.0.jar` needs about 2 MB of disk space. For notable restrictions of stand-alone clients, see the client comparison table in Client applications.

  – If you want a full-function client with medium to large footprint, that runs under the IBM JRE supplied, choose the Java thin client.

- If you run your client application to use the installed files of Application Client for WebSphere Application Server, you need about 400 MB of disk space (as part of the Application Client installation). Choose this option if you intend to copy and redistribute the Java thin client, within your licensing agreement.
- If you run your client application to use the installed files of the WebSphere Application Server, you need about 1 GB of disk space (as part of the Application Server installation). Choose this option if you do not mind the larger footprint, and you want maintenance support for the Java thin client.

However, the thin clients running on J2SE do not support a Java EE container that provides easy access to system services for object resolution, security, Reliability Availability and Servicability (RAS), and other services. Also, thin clients running on J2SE do not initialize any of the services that the client application might require.

- Java EE

  If you want to run a Java client application that makes full use of the Java EE platform features of WebSphere Application Server, then choose the Java EE client.

  – If you run your client application to use the installed files of Application Client for WebSphere Application Server, you need about 400 MB of disk space (as part of the Application Client installation). Choose this option if you intend to copy and redistribute the Java EE client, within your licensing agreement.
  – If you run your client application to use the installed files of the WebSphere Application Server, you need about 1 GB of disk space (as part of the Application Server installation). Choose this option if you do not mind the larger footprint, and you want maintenance support for the Java EE client.

  The Java EE client provides a container that client applications can use to access system services. The Java EE client also initializes the runtime environment for client applications.
- ActiveX to Enterprise JavaBeans (EJB) Bridge

  If you want ActiveX programs to access enterprise beans on WebSphere Application Server, choose this client.
- Applet client

  If you want a browser-based Java client application program that provides a richer and more robust environment than the one offered by the Applet > Servlet > enterprise bean model, choose this client.

### What to do next

Develop your client application to use the type of client that you have chosen.

## Installing, updating, rolling back, and uninstalling the Application Client for IBM WebSphere Application Server

IBM Installation Manager is a common installer for many IBM software products that you use to install, update, roll back, and uninstall the Application Client for IBM WebSphere Application Server.

### Before you begin

**Note:** Application Client for IBM WebSphere Application Server is now installed by Installation Manager rather than by the programs based on InstallShield MultiPlatform (ISMP) that are used to install and uninstall previous versions.

Before you start to use the installation tools, prepare for choosing and installing the variety of options and features provided by the Application Client. Read through all the steps in this article and read the related topics before installing the Application Client:

It is recommended that you have 350 MB of temporary disk space available before starting the installation.

**Restrictions:**

- Solaris The Installation Manager GUI is not supported on Solaris 10 x64 systems. Perform the following actions to install or uninstall the product on these systems:
  - Use the Installation Manager GUI on a supported system to record a response file that will allow you to install or uninstall the product silently.
  - Edit the recorded response file if necessary.
  - Use the response file to install or uninstall the product silently on your system.
- Linux For any Linux system that is enabled for Security Enhanced Linux (SELinux), such as Red Hat Enterprise Linux Version 5 or SUSE Linux Enterprise Server Version 11, you must identify the Java shared libraries in the Installation Manager Version 1.4.3 or earlier installation image to the system. Also, you must identify the Java shared libraries in the Installation Manager Version 1.4.3 or earlier installation after it has been installed. For example:

```
chcon -R -t texrel_shlib_t ${IM_Image}/jre_5.0.3.sr8a_20080811b/jre/bin
chcon -R -t texrel_shlib_t ${IM_Install_root}/eclipse/jre_5.0.3.sr8a_20080811b/jre/bin
```

- Application Client for WebSphere Application Server ships only with the 32-bit WebSphere Application Server.
- Installation Manager console mode, which is included in Installation Manager Version 1.4.3 and later, does not work with WebSphere Application Server Version 8.0 offerings.

## About this task

The Application Client provides resources and clients to aid development of client applications for use with WebSphere Application Server. The Application Client is a source for the clients (as runtime frameworks) for client applications, either to run on the Application Client machine or to be distributed with client applications that are to run on other machines.

To assemble some types of client applications, you need to install the client that provides the framework for the client application. Instead of installing WebSphere Application Server, you can install the Application Client feature, which provides the same resources and clients to aid development of client applications.

Similarly, running some types of client applications for use with WebSphere Application Server requires that the associated client is deployed with the client application. For client applications that only need a small fraction of the Application Client, you can install the Application Client onto a convenient machine, such as the machine used to develop the client application, then package the client application with only the clients that it needs. For example, this means that a standalone client application is deployed on only the required fraction of the clients provided with the Application Client.

Perform one of these procedures to install, update, roll back, or uninstall the Application Client for IBM WebSphere Application Server.

## Procedure

- “Installing the Application Client using the GUI” on page 182
- “Installing the Application Client silently” on page 187
- “Installing and removing features in the Application Client” on page 197
- “Installing fix packs on the Application Client” on page 203
- “Uninstalling fix packs from the Application Client using the Installation Manager GUI” on page 204
- “Uninstalling the Application Client using the GUI” on page 204
- “Uninstalling the Application Client silently” on page 205

## Results

**Notes on logging and tracing:**

- An easy way to view the logs is to open Installation Manager and go to **File > View Log**. An individual log file can be opened by selecting it in the table and then clicking the **Open log file** icon.
- Logs are located in the `logs` directory of Installation Manager's application data location. For example:
  - Windows **Administrative installation:**

```
C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager\logs
```

  - Windows **Non-administrative installation:**

```
C:\Documents and Settings\user_name\Application Data\IBM\Installation Manager\logs
```

  - AIX HP-UX Linux Solaris **Administrative installation:**

```
/var/ibm/InstallationManager/logs
```

  - AIX HP-UX Linux Solaris **Non-administrative installation:**

```
user_home/var/ibm/InstallationManager/logs
```

- The main log files are time-stamped XML files in the `logs` directory, and they can be viewed using any standard web browser.
- The `log.properties` file in the `logs` directory specifies the level of logging or tracing that Installation Manager uses. To turn on tracing, for example, create a `log.properties` file with the following content:

```
com.ibm.ws=DEBUG
com.ibm.cic.agent.core.Engine=DEBUG
global=DEBUG
```

  Restart Installation Manager as necessary, and Installation Manager outputs traces.

**Notes on troubleshooting:**

- HP-UX By default, some HP-UX systems are configured to not use DNS to resolve host names. This could result in Installation Manager not being able to connect to an external repository.

  You can ping the repository, but nslookup does not return anything.

  Work with your system administrator to configure your machine to use DNS, or use the IP address of the repository.
- In some cases, you might need to bypass existing checking mechanisms in Installation Manager.
  - On some network file systems, disk space might not be reported correctly at times; and you might need to bypass disk-space checking and proceed with your installation.

    To disable disk-space checking, specify the following system property in the `config.ini` file in *IM_install_root*`/eclipse/configuration` and restart Installation Manager:

```
cic.override.disk.space=sizeunit
```

    where *size* is a positive integer and *unit* is blank for bytes, k for kilo, m for megabytes, or g for gigabytes. For example:

```
cic.override.disk.space=120 (120 bytes)
cic.override.disk.space=130k (130 kilobytes)
cic.override.disk.space=140m (140 megabytes)
cic.override.disk.space=150g (150 gigabytes)
cic.override.disk.space=true
```

    Installation Manager will report a disk-space size of Long.MAX_VALUE. Instead of displaying a very large amount of available disk space, N/A is displayed.

– To bypass operating-system prerequisite checking, add `disableOSPrereqChecking=true` to the `config.ini` file in *IM_install_root*`/eclipse/configuration` and restart Installation Manager.

If you need to use any of these bypass methods, contact IBM Support for assistance in developing a solution that does not involve bypassing the Installation Manager checking mechanisms.

- For more information on using Installation Manager, read the IBM Installation Manager Information Center.

  Read the release notes to learn more about the latest version of Installation Manager. To access the release notes, complete the following task:

  – Windows Click **Start > Programs > IBM Installation Manager > Release Notes**.

  – AIX HP-UX Linux Solaris Go to the documentation subdirectory in the directory where Installation Manager is installed, and open the `readme.html` file.

## Installing the Application Client using the GUI

You can use the Installation Manager GUI to install the Application Client.

### Before you begin

**Install Installation Manager:**

1. Perform one of the following procedures:
   - If you want to use the Installation Manager that is included with this product, perform the following actions:
     a. Obtain the necessary files from the physical media or the web.

        There are three basic options for obtaining and installing the product.

        – **Access the physical media, and use local installation**

          You can access the product repositories on the product media.

          1) Install Installation Manager on your system.

             You can install Installation Manager using the product media, using a file obtained from the Passport Advantage® site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager website.

          2) Use Installation Manager to install the product from the product repositories on the media.

        – **Download the files from the Passport Advantage site, and use local installation**

          Licensed customers with a Passport Advantage ID and password can download the necessary product repositories from the Passport Advantage site.

          1) Download the files from the Passport Advantage site.

          2) Install Installation Manager on your system.

             You can install Installation Manager using the product media, using a file obtained from the Passport Advantage site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager website.

          3) Use Installation Manager to install the product from the downloaded repositories.

        – **Access the live repositories, and use web-based installation**

          If you have a Passport Advantage ID and password, you can install the product from the web-based repositories.

          1) Install Installation Manager on your system.

You can install Installation Manager using the product media, using a file obtained from the Passport Advantage site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager website.

2) Use Installation Manager to install the product from the web-based repository located at

`http://www.ibm.com/software/repositorymanager/com.ibm.websphere.APPCLIENT.v80`

Whenever possible, you should use the remote web-based repositories so that you are accessing the most up-to-date installation files.

**Notes:**

- If you do not have a Passport Advantage ID and password, you must install the product from the product repositories on the media or local repositories.
- With the Packaging Utility, you can create and manage packages for installation repositories. You can copy multiple packages into one repository or copy multiple disks for one product into a repository. You can copy packages from Passport Advantage into a repository for example. For more information on the Packaging Utility, go to the IBM Installation Manager Information Center.

b. Change to the location containing the Installation Manager installation files, and run one of the following commands:

**Administrative installation:**

- Windows `install.exe`
- AIX HP-UX Linux Solaris `./install`

**Non-administrative installation:**

- Windows `userinst.exe`
- AIX HP-UX Linux Solaris `./userinst`

**Group-mode installation:**

AIX HP-UX Linux Solaris `./groupinst`

**Notes on group mode:**

- Group mode allows multiple users to use a single instance of IBM Installation Manager to manage software packages.
- Windows Group mode is not available on Windows operating systems.
- If you do not install Installation Manager using group mode, you will not be able to use group mode to manage any of the products that you install later using this Installation Manager.
- Make sure that you change the installation location from the default location in the current user's home directory to a location that is accessible by all users in the group.
- Set up your groups, permissions, and environment variables as described in the Group mode road maps in the IBM Installation Manager Information Center before installing in group mode.
- For more information on using group mode, read the Group mode road maps in the IBM Installation Manager Information Center.

The installer opens an **Install Packages** window.

c. Make sure that the Installation Manager package is selected, and click **Next**.

d. Accept the terms in the license agreements, and click **Next**.

The program creates the directory for your installation.

e. Click **Next**.

f. Review the summary information, and click **Install**.

- If the installation is successful, the program displays a message indicating that installation is successful.
- If the installation is not successful, click **View Log File** to troubleshoot the problem.

- If you already have a version of Installation Manager installed on your system and you want to use it to install and maintain the product, obtain the necessary product files from the physical media or the web.

  There are three basic options for installing the product.

  - **Access the physical media, and use local installation**

    You can access the product repositories on the product media. Use Installation Manager to install the product from the product repositories on the media.

  - **Download the files from the Passport Advantage site, and use local installation**

    Licensed customers with a Passport Advantage ID and password can download the necessary product repositories from the Passport Advantage site.

    a. Download the product repositories from the Passport Advantage site.

    b. Use Installation Manager to install the product from the downloaded repositories.

  - **Access the live repositories, and use web-based installation**

    If you have a Passport Advantage ID and password, you can use Installation Manager to install the product from the web-based repositories. Use Installation Manager to install the product from the web-based repository located at

```
http://www.ibm.com/software/repositorymanager/com.ibm.websphere.APPCLIENT.v80
```

    Whenever possible, you should use the remote web-based repositories so that you are accessing the most up-to-date installation files.

  **Notes:**

  - If you do not have a Passport Advantage ID and password, you must install the product from the product repositories on the media or local repositories.
  - With the Packaging Utility, you can create and manage packages for installation repositories. You can copy multiple packages into one repository or copy multiple disks for one product into a repository. You can copy packages from Passport Advantage into a repository for example. For more information on the Packaging Utility, go to the IBM Installation Manager Information Center.

2. Add the product repository to your Installation Manager preferences.

   a. Start Installation Manager.

   b. In the top menu, click **File > Preferences**.

   c. Select **Repositories**.

   d. Perform the following actions:

      1) Click **Add Repository**.

      2) Enter the path to the `repository.config` file in the location containing the repository files.

         For example:

         - Windows `C:\repositories\`*`product_name`*`\local-repositories`
         - AIX HP-UX Linux Solaris `/var/repositories/`*`product_name`*`/local-repositories`

         or

```
http://www.ibm.com/software/repositorymanager/com.ibm.websphere.APPCLIENT.v80
```

      3) Click **OK**.

e. Deselect any locations listed in the Repositories window that you will not be using.
f. Click **Apply**.
g. Click **OK**.
h. Click **File > Exit** to close Installation Manager.

### About this task

Perform this procedure to use the Installation Manager GUI to install the Application Client.

### Procedure

1. Start Installation Manager.

   **Tip:** AIX HP-UX Linux Solaris If you installed Installation Manager using group mode, you can start it in group mode with the ./IBMIM command.
   - Group mode allows users to share packages in a common location and manage them with the same instance of Installation Manager.
   - For more information on using group mode, read the Group mode road maps in the IBM Installation Manager Information Center.

2. Click **Install**.

   **Note:** If you are prompted to authenticate, use the IBM ID and password that you registered with on the program website.

   Installation Manager searches its defined repositories for available packages.

3. Perform the following actions.
   a. Select **Application Client for IBM WebSphere Application Server** and the appropriate version.

      **Note:** If you are installing the ILAN version of this product, select **Application Client for IBM WebSphere Application Server (ILAN)**.

      If you already have the Application Client installed on your system, a message displays indicating that the Application Client is already installed. For a given Installation Manager, you can install only one Application Client.

      **Tip:** If the **Search service repositories during installation and updates** option is selected on the Installation Manager Repository preference page and you are connected to the Internet, you can click **Check for Other Versions and Extensions** to search for updates in the default update repositories for the selected packages. In this case, you do not need to add the specific service-repository URL to the Installation Manager Repository preference page.

   b. Select the fixes to install.

      Any recommended fixes are selected by default.

      If there are recommended fixes, you can select the option to show only recommended fixes and hide non-recommended fixes.

   c. Click **Next**.

   **Note:** If you try to install a newer level of the Application Client with a previous version of Installation Manager, Installation Manager might prompt you to update to the latest level of Installation Manager when it connects to the repository. Update to the newer version before you continue if you are prompted to do so. Read the IBM Installation Manager Information Center for information about automatic updates.

4. Accept the terms in the license agreements, and click **Next**.
5. Specify the installation root directory for the product binaries, which are also referred to as the core product files or system files.

The panel also displays the shared resources directory and disk-space information.

**Restrictions:**

- Deleting the default target location and leaving an installation-directory field empty prevents you from continuing.
- Do not use symbolic links as the destination directory.

  Symbolic links are not supported.
- Do not use a semicolon in the directory name.

  The Application Client cannot install properly if the target directory includes a semicolon.

  Windows A semicolon is the character used to construct the class path on Windows systems.
- Windows The maximum path length on the Windows Server 2008, Windows Vista, and Windows 7 operating systems is 60 characters.

6. Click **Next**.
7. Select any features that you want to install.

   Choose from the following optional features:

   - IBM Developer Kit, Java 2 Technology Edition

     This option installs the IBM Developer Kit, Java 2 Technology Edition.

     This feature includes a development kit and a runtime-environment package. The runtime-environment package is always installed with the Java EE and Java thin application client feature even if this feature is not installed.

     – Java 2 Runtime Environment

       This option installs the Java 2 runtime environment.

       This feature includes the Java 2 runtime environment of IBM Developer Kit, Java 2 Technology Edition.

     – Developer Kit

       This option installs the developer kit.

       This feature includes the developer kit of IBM Developer Kit, Java 2 Technology Edition.
   - Samples

     This option installs executable and source-code examples of programming in both Java EE and non-Java EE client environments.
   - Standalone Thin Clients, Resource Adapters, and Embeddable Containers

     IBM thin clients and resource adapters provide a set of clients and resource adapters for a variety of technologies, such as JAX-WS, JAX-RPC, JAX-RS, XML, EJB, JPA, JMS, and more. An embeddable container runs in a standalone Java Platform, Standard Edition environment. For example, you can use the embeddable EJB container to run enterprise beans outside the application server.

     – Standalone thin clients and resource adapters

       This option installs the runtime for standalone thin clients.

     – Embeddable EJB container

       This option installs the embeddable EJB container.

       The embeddable EJB container is a Java Archive (JAR) file that you can use to run enterprise beans in a standalone Java Platform, Standard Edition environment. You can run enterprise beans using this embeddable container outside the application server. The embeddable EJB container is a part of the EJB 3.1 specification and is primarily used for unit testing enterprise beans business logic.

**Tip:** You can run the Installation Manager later to modify this installation and add or remove features.

8. Click **Next**.
9. Enter the host name and port number of the Websphere Application Server to which you want to connect.
10. Click **Next**.
11. Review the summary information, and click **Install**.
    - If the installation is successful, the program displays a message indicating that installation is successful.

      **Note:** The program might also display important post-installation instructions as well.
    - If the installation is not successful, click **View Log File** to troubleshoot the problem.
12. Click **Finish**.
13. Click **File > Exit** to close Installation Manager.

## Installing the Application Client silently

You can use Installation Manager to install the Application Client silently.

### Before you begin

**Install Installation Manager** on each of the systems onto which you want to install the product.

1. Perform one of the following procedures:
   - If you want to use the Installation Manager that is included with this product, perform the following actions:
     a. Obtain the necessary files from the physical media or the web.

        There are three basic options for obtaining and installing the product.
        - **Access the physical media, and use local installation**

          You can access the product repositories on the product media.
          1) Install Installation Manager on your system.

             You can install Installation Manager using the product media, using a file obtained from the Passport Advantage site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager website.
          2) Use Installation Manager to install the product from the product repositories on the media.
        - **Download the files from the Passport Advantage site, and use local installation**

          Licensed customers with a Passport Advantage ID and password can download the necessary product repositories from the Passport Advantage site.
          1) Download the files from the Passport Advantage site.
          2) Install Installation Manager on your system.

             You can install Installation Manager using the product media, using a file obtained from the Passport Advantage site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager website.
          3) Use Installation Manager to install the product from the downloaded repositories.
        - **Access the live repositories, and use web-based installation**

          If you have a Passport Advantage ID and password, you can install the product from the web-based repositories.
          1) Install Installation Manager on your system.

             You can install Installation Manager using the product media, using a file obtained from the Passport Advantage site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager website.
          2) Use Installation Manager to install the product from the web-based repository located at

http://www.ibm.com/software/repositorymanager/com.ibm.websphere.APPCLIENT.v80

Whenever possible, you should use the remote web-based repositories so that you are accessing the most up-to-date installation files.

**Notes:**

- If you do not have a Passport Advantage ID and password, you must install the product from the product repositories on the media or local repositories.
- With the Packaging Utility, you can create and manage packages for installation repositories. You can copy multiple packages into one repository or copy multiple disks for one product into a repository. You can copy packages from Passport Advantage into a repository for example. For more information on the Packaging Utility, go to the IBM Installation Manager Information Center.

b. Change to the location containing the Installation Manager installation files, and run one of the following commands to install Installation Manager silently:

**Administrative installation:**

- Windows `installc.exe -acceptLicense -log` *`log_file_path_and_name`*
- AIX HP-UX Linux Solaris `./installc -acceptLicense -log` *`log_file_path_and_name`*

**Non-administrative installation:**

- Windows `userinstc.exe -acceptLicense -log` *`log_file_path_and_name`*
- AIX HP-UX Linux Solaris `./userinstc -acceptLicense -log` *`log_file_path_and_name`*

**Group-mode installation:**

AIX HP-UX Linux Solaris `./groupinstc -acceptLicense -dataLocation` *`application_data_location`* `-log` *`log_file_path_and_name`*

**Notes on group mode:**

- Group mode allows multiple users to use single instance of IBM Installation Manager to manage software packages.
- Windows Group mode is not available on Windows operating systems.
- If you do not install Installation Manager using group mode, you will not be able to use group mode to manage any of the products that you install later using this Installation Manager.
- Make sure that you change the installation location from the default location in the current user's home directory to a location that is accessible by all users in the group.
- Set up your groups, permissions, and environment variables as described in the Group mode road maps in the IBM Installation Manager Information Center before installing in group mode.
- For more information on using group mode, read the Group mode road maps in the IBM Installation Manager Information Center.

- If you already have a version of Installation Manager installed on your system and you want to use it to install and maintain the product, obtain the necessary product files from the physical media or the web.

  There are three basic options for installing the product.

  - **Access the physical media, and use local installation**

You can access the product repositories on the product media. Use Installation Manager to install the product from the product repositories on the media.

– **Download the files from the Passport Advantage site, and use local installation**

  Licensed customers with a Passport Advantage ID and password can download the necessary product repositories from the Passport Advantage site.

  a. Download the product repositories from the Passport Advantage site.

  b. Use Installation Manager to install the product from the downloaded repositories.

– **Access the live repositories, and use web-based installation**

  If you have a Passport Advantage ID and password, you can use Installation Manager to install the product from the web-based repositories. Use Installation Manager to install the product from the web-based repository located at

http://www.ibm.com/software/repositorymanager/com.ibm.websphere.APPCLIENT.v80

  Whenever possible, you should use the remote web-based repositories so that you are accessing the most up-to-date installation files.

**Notes:**

– If you do not have a Passport Advantage ID and password, you must install the product from the product repositories on the media or local repositories.

– With the Packaging Utility, you can create and manage packages for installation repositories. You can copy multiple packages into one repository or copy multiple disks for one product into a repository. You can copy packages from Passport Advantage into a repository for example. For more information on the Packaging Utility, go to the IBM Installation Manager Information Center.

2. Add the product repository to your Installation Manager preferences.
   a. Start Installation Manager.
   b. In the top menu, click **File > Preferences**.
   c. Select **Repositories**.
   d. Perform the following actions:
      1) Click **Add Repository**.
      2) Enter the path to the `repository.config` file in the location containing the repository files.

         For example:

         • Windows `C:\repositories\`*`product_name`*`\local-repositories`

         • AIX HP-UX Linux Solaris `/var/repositories/`*`product_name`*`/local-repositories`

         or

http://www.ibm.com/software/repositorymanager/com.ibm.websphere.APPCLIENT.v80

      3) Click **OK**.
   e. Deselect any locations listed in the Repositories window that you will not be using.
   f. Click **Apply**.
   g. Click **OK**.
   h. Click **File > Exit** to close Installation Manager.

## About this task

Using Installation Manager, you can work with response files to install the Application Client silently in a variety of ways. You can record a response file using the GUI as described in the following procedure, or you can generate a new response file by hand or by taking an example and modifying it.

## Procedure

1. Optional: **Record a response file to install the Application Client:** On one of your systems, perform the following actions to record a response file that will install the Application Client.
   a. From a command line, change to the eclipse subdirectory in the directory where you installed Installation Manager.
   b. Start Installation Manager from the command line using the -record option.

      For example:

      - Windows **Administrator or non-administrator:**

```
IBMIM.exe -skipInstall "C:\temp\imRegistry"
  -record C:\temp\install_response_file.xml
```

      - AIX HP-UX Linux Solaris **Administrator:**

```
./IBMIM -skipInstall /var/temp/imRegistry
  -record /var/temp/install_response_file.xml
```

      - AIX HP-UX Linux Solaris **Non-administrator:**

```
./IBMIM -skipInstall user_home/var/temp/imRegistry
  -record user_home/var/temp/install_response_file.xml
```

      **Tip:** When you record a new response file, you can specify the -skipInstall parameter. Using this parameter has the following benefits:
      - No files are actually installed, and this speeds up the recording.
      - If you use a temporary data location with the -skipInstall parameter, Installation Manager writes the installation registry to the specified data location while recording. When you start Installation Manager again without the -skipInstall parameter, you then can use your response file to install against the real installation registry.

        The -skipInstall operation should not be used on the actual agent data location used by Installation Manager. This is unsupported. Use a clean writable location, and re-use that location for future recording sessions.

      For more information, read the IBM Installation Manager Information Center.
   c. Add the appropriate repositories to your Installation Manager preferences.
      1) In the top menu, click **File > Preferences**.
      2) Select **Repositories**.
      3) Perform the following actions for each repository:
         a) Click **Add Repository**.
         b) Enter the path to the `repository.config` file in the remote web-based repository or the local directory into which you unpacked the repository files.

            For example:

            - Remote repositories:

```
https://downloads.mycorp.com:8080/WAS_80_repository
```

              or

```
http://www.ibm.com/software/repositorymanager/com.ibm.websphere.APPCLIENT.v80
```

            - Local repositories:
              – Windows `C:\repositories\appclient\local-repositories`
              – AIX HP-UX Linux Solaris `/var/repositories/appclient/local-repositories`
         c) Click **OK**.
      4) Click **Apply**.
      5) Click **OK**.
   d. Click **Install**.

**Note:** If you are prompted to authenticate, use the IBM ID and password that you registered with on the program website.

Installation Manager searches its defined repositories for available packages.

e. Perform the following actions.

1) Select **Application Client for IBM WebSphere Application Server** and the appropriate version.

**Note:** If you are installing the ILAN version of this product, select **Application Client for IBM WebSphere Application Server (ILAN)**.

If you already have the Application Client installed on your system, a message displays indicating that the Application Client is already installed. For a given Installation Manager, you can install only one Application Client.

2) Click **Next**.

f. Accept the terms in the license agreements, and click **Next**.

g. Specify the installation root directory for the Application Client binaries, which are also referred to as the core product files or system files.

The panel also displays the shared resources directory and disk-space information.

**Restrictions:**

- Deleting the default target location and leaving an installation-directory field empty prevents you from continuing.
- Do not use symbolic links as the destination directory.

  Symbolic links are not supported.
- Do not use a semicolon in the directory name.

  The Application Client cannot install properly if the target directory includes a semicolon.

  Windows A semicolon is the character used to construct the class path on Windows systems.
- Windows The maximum path length on the Windows Server 2008, Windows Vista, and Windows 7 operating systems is 60 characters.

h. Click **Next**.

i. Select any features that you want to install.

Choose from the following optional features:

- IBM Developer Kit, Java 2 Technology Edition

  This option installs the IBM Developer Kit, Java 2 Technology Edition.

  This feature includes a development kit and a runtime-environment package. The runtime-environment package is always installed with the Java EE and Java thin application client feature even if this feature is not installed.

  – Java 2 Runtime Environment

    This option installs the Java 2 runtime environment.

    This feature includes the Java 2 runtime environment of IBM Developer Kit, Java 2 Technology Edition.

  – Developer Kit

    This option installs the developer kit.

    This feature includes the developer kit of IBM Developer Kit, Java 2 Technology Edition.
- Samples

  This option installs executable and source-code examples of programming in both Java EE and non-Java EE client environments.

- Standalone Thin Clients, Resource Adapters, and Embeddable Containers

  IBM thin clients and resource adapters provide a set of clients and resource adapters for a variety of technologies, such as JAX-WS, JAX-RPC, JAX-RS, XML, EJB, JPA, JMS, and more. An embeddable container runs in a standalone Java Platform, Standard Edition environment. For example, you can use the embeddable EJB container to run enterprise beans outside the application server.

  – Standalone thin clients and resource adapters

    This option installs the runtime for standalone thin clients.

  – Embeddable EJB container

    This option installs the embeddable EJB container.

    The embeddable EJB container is a Java Archive (JAR) file that you can use to run enterprise beans in a standalone Java Platform, Standard Edition environment. You can run enterprise beans using this embeddable container outside the application server. The embeddable EJB container is a part of the EJB 3.1 specification and is primarily used for unit testing enterprise beans business logic.

**Tip:** You can run the Installation Manager later to modify this installation and add or remove features.

j. Click **Next**.

k. Enter the host name and port number of the Websphere Application Server to which you want to connect.

l. Click **Next**.

m. Review the summary information, and click **Install**.

- If the installation is successful, the program displays a message indicating that installation is successful.

  **Note:** The program might also display important post-installation instructions as well.

- If the installation is not successful, click **View Log File** to troubleshoot the problem.

n. Click **Finish**.

o. Click **File > Exit** to close Installation Manager.

p. Optional: If you are using an authenticated remote repository, create a keyring file for silent installation.

1) From a command line, change to the eclipse subdirectory in the directory where you installed Installation Manager.

2) Start Installation Manager from the command line using the -record option.

   For example:

   - Windows **Administrator or non-administrator:**

```
IBMIM.exe -skipInstall "C:\temp\imRegistry"
  -keyring C:\IM\im.keyring
  -record C:\temp\keyring_response_file.xml
```

   - AIX HP-UX Linux Solaris **Administrator:**

```
./IBMIM -skipInstall /var/temp/imRegistry
  -keyring /var/IM/im.keyring
  -record /var/temp/keyring_response_file.xml
```

   - AIX HP-UX Linux Solaris **Non-administrator:**

```
./IBMIM -skipInstall user_home/var/temp/imRegistry
  -keyring user_home/var/IM/im.keyring
  -record user_home/var/temp/keyring_response_file.xml
```

3) When a window opens that requests your credentials for the authenticated remote repository, enter the correct credentials and **save** them.

4) Click **File > Exit** to close Installation Manager.

   For more information, read the IBM Installation Manager Information Center.

2. **Use the response files to install the Application Client silently:**
   a. Optional: **Use the response file to install the keyring silently:** Go to a command line on each of the systems on which you want to install the product, change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager, and install the keyring silently.

      For example:

      - Windows **Administrator or non-administrator:**

```
imcl.exe -acceptLicense
  input C:\temp\keyring_response_file.xml
  -log C:\temp\keyring_log.xml
```

      - AIX HP-UX Linux Solaris **Administrator:**

```
./imcl -acceptLicense
  input /var/temp/keyring_response_file.xml
  -log /var/temp/keyring_log.xml
```

      - AIX HP-UX Linux Solaris **Non-administrator:**

```
./imcl -acceptLicense
  input user_home/var/temp/keyring_response_file.xml
  -log user_home/var/temp/keyring_log.xml
```

   b. **Use the response file to install the product silently:** Go to a command line on each of the systems on which you want to install the product, change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager, and install the product silently.

      For example:

      - Windows **Administrator or non-administrator:**

```
imcl.exe -acceptLicense
  input C:\temp\install_response_file.xml
  -log C:\temp\install_log.xml
  -keyring C:\IM\im.keyring
```

      - AIX HP-UX Linux Solaris **Administrator:**

```
./imcl -acceptLicense
  input /var/temp/install_response_file.xml
  -log /var/temp/install_log.xml
  -keyring /var/IM/im.keyring
```

      - AIX HP-UX Linux Solaris **Non-administrator:**

```
./imcl -acceptLicense
  input user_home/var/temp/install_response_file.xml
  -log user_home/var/temp/install_log.xml
  -keyring user_home/var/IM/im.keyring
```

      **Notes:**

      - The relevant terms and conditions, notices, and other information are provided in the license-agreement files in the `lafiles` or *product_name*`/lafiles` subdirectory of the installation image or repository for this product.
      - The program might write important post-installation instructions to standard output.

      Read the IBM Installation Manager Information Center for more information.

Windows

## Example

The following is an example of a response file for silently installing the Application Client.

```
<?xml version="1.0" encoding="UTF-8"?>

<!-- ##### Copyright #####################################################
# Licensed Materials - Property of IBM (c) Copyright IBM Corp. 2011.
# All Rights Reserved. US Government Users Restricted Rights-Use, duplication
# or disclosure restricted by GSA ADP Schedule Contract with IBM Corp.

<!-- ##### Frequently Asked Questions ###################################
# The latest information about using Installation Manager is
# located in the online Information Center. There you can find
# information about the commands and attributes used in
# silent installation response files.
#
#     Installation Manager Information Center can be found at:
#     http://publib.boulder.ibm.com/infocenter/install/v1r4/index.jsp
#
```

```
# Question 1. How do I record a response file using Installation Manager?
# Answer 1. Start Installation Manager from the command line under the
# eclipse subdirectory with the record parameter and it will generate a
# response file containing actions it performed, repositories it used, and
# its preferences settings. Optionally use the -skipInstall parameter if
# you do not want the product to be installed to the machine. Specify a
# new agentDataLocation location value when doing a new installation. Do
# not use an existing agentDataLocation for an installation because it might
# damage the installation data and prevent you from modifying, updating,
# rolling back, or uninstalling the installed packages.
#
# Windows: IBMIM -record <responseFile> -skipInstall <agentDataLocation>
# Linux or UNIX: ./IBMIM -record <responseFile> -skipInstall <agentDataLocation>
#
# For example:
#   Windows = IBMIM.exe -record c:\temp\responsefiles\WASv8.install.Win32.xml
#     -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#   Linux or UNIX = ./IBMIM -record /home/user/responsefiles/WASv8.install.RHEL64.xml
#     -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#
# Question 2. How do I run Installation Manager silently using response file?
# Answer 2. Create a silent installation response file and run the following command
# from the eclipse\tools subdirectory in the directory where you installed
# Installation Manager:
#
#   Windows = imcl.exe -acceptLicense -showProgress
#     input <response_file_path_and_name> -log <log_file_path_and_name>
#   Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#     input <response_file_path_and_name> -log <log_file_path_and_name>
#
# For example:
#   Windows = imcl.exe -acceptLicense -showProgress
#     input c:\temp\responsefile\WASv8.install.Win32.xml
#   Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#     input /home/user/responsefile/WASv8.install.RHEL64.xml
#
# The -acceptLicense command must be included to indicate acceptance of all
#     license agreements of all offerings being installed, updated or modified.
# The -showProgress command shows progress when running in silent mode.
# Additional commands can be displayed by requesting help:  IBMIM -help
#
# Question 3. How do I store and pass credentials to repositories that
# require authentication?
# Answer 3. Installation Manager uses a key ring file to store encrypted
# credentials for authenticating with repositories. Follow this two-step
# process for creating and using a key ring file with Installation Manager.
#
# First, create a key ring file with your credentials by starting
# Installation Manager from the command line under eclipse subdirectory
# with the keyring parameter.
# Use the optional password parameter to password protect your file.
#
#   Windows = IBMIM.exe -keyring <path and file name> -password <password>
#   Linux, UNIX, IBM i and z/OS = ./IBMIM -keyring <path and file name>
#                                 -password <password>
#
# Installation Manager will start in graphical mode. Verify that the
# repositories to which you need to authenticate are included in the
# preferences, File / Preferences / Repositories. If they are not
# listed, then click Add Repositories to add the URL or UNC path.
# Installation Manager will prompt for your credentials. If the repository
# is already in the list, then any attempt to access the repository location,
# such as clicking the Test Connections button, will also prompt for your
# credentials. Enter the correct credential and check the Save password
# checkbox. The credentials are saved to the key ring file you specified.
#
# Second, when you start a silent installation, run imcl under eclipse/tools
# subdirectory, and provide Installation Manager with the location of the key
# ring file and the password if the file is protected. For example:
#
#   Windows = imcl.exe -acceptLicense -showProgress
#     input <path and file name of response file>
#     -keyring <path and name of key ring file> -password <password>
#   Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#     input <path and file name of response file>
#     -keyring <path and name of key ring file> -password <password>
#
################################################################## -->

<!-- ##### Agent Input ############################################
#
# Note that the "acceptLicense" attribute has been deprecated.
# Use "-acceptLicense" command line option to accept license agreements.
#
# The clean and temporary attributes specify the repositories and other
# preferences Installation Manager uses and whether those settings
# should persist after the silent installation finishes.
#
# Valid values for clean:
#      true = only use the repositories and other preferences that are
```

```
#           specified in the response file.
#      false = use the repositories and other preferences that are
#           specified in the response file and Installation Manager.
#
# Valid values for temporary:
#      true = repositories and other preferences specified in the
#           response file do not persist in Installation Manager.
#      false = repositories and other preferences specified in the
#           response file persist in Installation Manager.

    <!-- <repository location='insert the full directory path inside single quotes'/> -->
</server>

<!-- ##### Installation Packages ######################################
#
# Install Command
#
# Use the install command to inform Installation Manager of the
# installation packages to install.
#
# The modify attribute is optional and can be paired with an install
# command to add features or paired with an uninstall command to
# remove commands. If omitted, the default value is set to false.
#    false = indicates not to modify an existing install by adding
#            or removing features.
#    true = indicates to modify an existing install by adding or
#           removing features.
#
# The offering ID attribute is required because it specifies the
# offering to be installed. The offering listed must be present in
# at least one of the repositories listed earlier. The example
# command below contains the offering ID for the Application Client
# for IBM WebSphere Application Server.
#
# The version attribute is optional. If a version number is provided,
# then the offering will be installed at the version level specified
# as long as it is available in the repositories. If the version
# attribute is not provided, then the default behavior is to install
# the latest version available in the repositories. The version number
# can be found in the repository.xml file in the repositories.
# For example, <offering ..... version='8.0.0.20110221_2221' ......>.
#
```

```
# The profile attribute is required and typically is unique to the
# offering. If modifying or updating an existing installation, the
# profile attribute must match the profile ID of the targeted installation
# of Application Client.
#
# The features attribute is optional. Offerings always have at least
# one feature; a required core feature which is installed regardless
# of whether it is explicitly specified. If other feature names
# are provided, then only those features will be installed.
# Features must be comma delimited without spaces.
#
# The feature values for Application Client include:
#  javaruntime,developerkit,embeddablecontainer,
#  samples,standalonethinclient.resourceadapter.runtime
#
# The installFixes attribute indicates whether fixes available in
# repositories are installed with the product. By default, all
# available fixes will be installed with the offering.
#
# Valid values for installFixes:
#      none = do not install available fixes with the offering.
#      recommended = installs all available recommended fixes with the offering.
#      all = installs all available fixes with the offering.
#
# Interim fixes for offerings also can be installed while they
# are being installed by including the offering ID for the interim
# fix and specifying the profile ID. A commented out example is
# provided in the install command below.
#
# Installation Manager supports installing multiple offerings at once.
# Additional offerings can be included in the install command,
# with each offering requiring its own offering ID, version, profile value,
# and feature values.
#
# Profile Command
#
# A separate profile command must be included for each offering listed
# in the install command. The profile command informs Installation
# Manager about offering specific properties or configuration values.
#
# The installLocation specifies where the offering will be installed.
# If the response file is used to modify or update an existing
# installation, then ensure the installLocation points to the
# location where the offering was installed previously.
#
# The eclipseLocation data key should use the same directory path to
# Application Client as the installationLocation attribute.
#
# Include data keys for product specific profile properties.
#

<!-- ##### Shared Data Location ########################################
# Uncomment the preference for eclipseCache to set the shared data
# location the first time you use Installation Manager to do an
# installation.
#
# Eclipse cache location can be obtained from the installed.xml file found in
# Linux/Unix: /var/ibm/InstallationManager
# Windows: C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager
# from the following property:
# <property name='cacheLocation' value='C:\Program Files\IBM\IMShared'/>
#
# Open the installed.xml file in a text editor because the style sheet
# might hide this value if opened in a web browser.
# For further information on how to edit preferences, refer to the public library at:
# http://publib.boulder.ibm.com/infocenter/install/v1r4/index.jsp?topic=/com.ibm.silentinstall12.doc/topics/r_silent_prefs.html
#
# After the shared data location is set, it cannot be changed
# using a response file or the graphical wizard.
#
# Ensure that the shared data location is a location that can be written
# to by all user accounts that are expected to use Installation Manager.
```

```
#
# By default, Installation Manager saves downloaded artifacts to
# the shared data location. This serves two purposes.
#
# First, if the same product is installed a more than once to the machine,
# then the files in the shared data location will be used rather than
# downloading them again.
#
# Second, during the rollback process, the saved artifacts are used.
# Otherwise, if the artifacts are not saved or are removed, then
# Installation Manager must have to access the repositories used to
# install the previous versions.
#
# Valid values for preserveDownloadedArtifacts:
#     true = store downloaded artifacts in the shared data location
#     false = remove downloaded artifacts from the shared data location
#

</agent-input>
```

**Note:** In the following list, the optional feature offering names are enclosed in parentheses:

- IBM Developer Kit, Java 2 Technology Edition
  - Java 2 Runtime Environment (`javaruntime`)
  - Developer Kit (`developerkit`)
- Samples (`samples`)
- Standalone Thin Clients, Resource Adapters, and Embeddable Containers
  - Standalone Thin Clients Runtime (`standalonethinclient.resourceadapter.runtime`)
  - Standalone Thin Clients Samples (`standalonethinclient.resourceadapter.samples`)
  - Embeddable EJB Container (`embeddablecontainer`)

## Installing and removing features in the Application Client

You can use Installation Manager to install or remove a feature in the Application Client for IBM WebSphere Application Server.

## Before you begin

Make sure that your Installation Manager preferences are pointing to the appropriate web-based or local repositories containing the Application Client for IBM WebSphere Application Server.

## About this task

Perform this procedure to use the Installation Manager GUI to install or remove a feature in the Application Client for IBM WebSphere Application Server.

**Note:** Like other Installation Manager operations, you can also invoke a modification using one of the following procedures:

- Using a silent response file

  You can record this response file using the GUI and Installation Manager's record mode, or you can manually create or modify a response file to suit your needs.
- Using the imcl command-line tool

  Go to the Installation Manager Information Center for more information.

  **Restriction:** The imcl command-line tool in Installation Manager Version 1.4.x and earlier cannot update the product and remove features at the same time You should update the package with the same features using the `imcl` command and then remove unwanted features using the `imcl` command.

## Procedure

1. Stop all servers and applications on the Application Client installation that is being modified.
2. Start Installation Manager.
3. Click **Modify**.
4. Select the package group to modify.
5. Click **Next**.

   **Note:** If you are prompted to authenticate, use the IBM ID and password that you registered with on the program website.
6. Expand **Application Client for IBM WebSphere Application Server**.
7. Check the appropriate checkbox to install a feature, or clear the appropriate checkbox to remove a feature if you already have it installed.
   - IBM Developer Kit, Java 2 Technology Edition

     This option installs the IBM Developer Kit, Java 2 Technology Edition.

     This feature includes a development kit and a runtime-environment package. The runtime-environment package is always installed with the Java EE and Java thin application client feature even if this feature is not installed.
     - Java 2 Runtime Environment

       This option installs the Java 2 runtime environment.

       This feature includes the Java 2 runtime environment of IBM Developer Kit, Java 2 Technology Edition.
     - Developer Kit

       This option installs the developer kit.

       This feature includes the developer kit of IBM Developer Kit, Java 2 Technology Edition.
   - Samples

     This option installs executable and source-code examples of programming in both Java EE and non-Java EE client environments.

- Standalone Thin Clients, Resource Adapters, and Embeddable Containers

  IBM thin clients and resource adapters provide a set of clients and resource adapters for a variety of technologies, such as JAX-WS, JAX-RPC, JAX-RS, XML, EJB, JPA, JMS, and more. An embeddable container runs in a standalone Java Platform, Standard Edition environment. For example, you can use the embeddable EJB container to run enterprise beans outside the application server.

  – Standalone thin clients and resource adapters

    This option installs the runtime for standalone thin clients.

  – Embeddable EJB container

    This option installs the embeddable EJB container.

    The embeddable EJB container is a Java Archive (JAR) file that you can use to run enterprise beans in a standalone Java Platform, Standard Edition environment. You can run enterprise beans using this embeddable container outside the application server. The embeddable EJB container is a part of the EJB 3.1 specification and is primarily used for unit testing enterprise beans business logic.

8. Click **Next**.
9. Review the summary information, and click **Modify**.
   - If the modification is successful, the program displays a message indicating that installation is successful.
   - If the modification is not successful, click **View Log File** to troubleshoot the problem.
10. Click **Finish**.
11. Click **File > Exit** to close Installation Manager.

## Example

In the following list, the optional feature offering names are enclosed in parentheses:

- IBM Developer Kit, Java 2 Technology Edition
  – Java 2 Runtime Environment (`javaruntime`)
  – Developer Kit (`developerkit`)
- Samples (`samples`)
- Standalone Thin Clients, Resource Adapters, and Embeddable Containers
  – Standalone Thin Clients Runtime (`standalonethinclient.resourceadapter.runtime`)
  – Standalone Thin Clients Samples (`standalonethinclient.resourceadapter.samples`)
  – Embeddable EJB container (`embeddablecontainer`)

Windows Here is a response file that modifies an existing Application Client for IBM WebSphere Application Server installation:

```
<?xml version="1.0" encoding="UTF-8"?>

<!-- ##### Frequently Asked Questions ##################################
# The latest information about using Installation Manager is
# located in the online Information Center. There you can find
# information about the commands and attributes used in
# silent installation response files.
#
#     Installation Manager Information Center can be found at:
#     http://publib.boulder.ibm.com/infocenter/install/v1r4/index.jsp
#
# Question 1. How do I record a response file using Installation Manager?
# Answer 1. Start Installation Manager from the command line under the
# eclipse subdirectory with the record parameter and it will generate a
# response file containing actions it performed, repositories it used, and
# its preferences settings. Optionally use the -skipInstall parameter if
```

```
# you do not want the product to be installed to the machine. Specify a
# new agentDataLocation location value when doing a new installation. Do
# not use an existing agentDataLocation for an installation because it might
# damage the installation data and prevent you from modifying, updating,
# rolling back, or uninstalling the installed packages.
#
# Windows: IBMIM -record <responseFile> -skipInstall <agentDataLocation>
# Linux or UNIX: ./IBMIM -record <responseFile> -skipInstall <agentDataLocation>
#
# For example:
#   Windows = IBMIM.exe -record c:\temp\responsefiles\WASv8.install.Win32.xml
#     -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#   Linux or UNIX = ./IBMIM -record /home/user/responsefiles/WASv8.install.RHEL64.xml
#     -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#
# Question 2. How do I run Installation Manager silently using response file?
# Answer 2. Create a silent installation response file and run the following command
# from the eclipse\tools subdirectory in the directory where you installed
# Installation Manager:
#
#   Windows = imcl.exe -acceptLicense -showProgress
#     input <response_file_path_and_name> -log <log_file_path_and_name>
#   Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#     input <response_file_path_and_name> -log <log_file_path_and_name>
#
# For example:
#   Windows = imcl.exe -acceptLicense -showProgress
#     input c:\temp\responsefile\WASv8.install.Win32.xml
#   Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#     input /home/user/responsefile/WASv8.install.RHEL64.xml
#
# The -acceptLicense command must be included to indicate acceptance of all
#     license agreements of all offerings being installed, updated or modified.
# The -showProgress command shows progress when running in silent mode.
# Additional commands can be displayed by requesting help:  IBMIM -help
#
# Question 3. How do I store and pass credentials to repositories that
# require authentication?
# Answer 3. Installation Manager uses a key ring file to store encrypted
# credentials for authenticating with repositories. Follow this two-step
# process for creating and using a key ring file with Installation Manager.
#
# First, create a key ring file with your credentials by starting
# Installation Manager from the command line under eclipse subdirectory
# with the keyring parameter.
# Use the optional password parameter to password protect your file.
#
#   Windows = IBMIM.exe -keyring <path and file name> -password <password>
#   Linux, UNIX, IBM i and z/OS = ./IBMIM -keyring <path and file name>
#                                 -password <password>
#
# Installation Manager will start in graphical mode. Verify that the
# repositories to which you need to authenticate are included in the
# preferences, File / Preferences / Repositories. If they are not
# listed, then click Add Repositories to add the URL or UNC path.
# Installation Manager will prompt for your credentials. If the repository
# is already in the list, then any attempt to access the repository location,
# such as clicking the Test Connections button, will also prompt for your
# credentials. Enter the correct credential and check the Save password
# checkbox. The credentials are saved to the key ring file you specified.
#
# Second, when you start a silent installation, run imcl under eclipse/tools
# subdirectory, and provide Installation Manager with the location of the key
# ring file and the password if the file is protected. For example:
#
#   Windows = imcl.exe -acceptLicense -showProgress
#     input <path and file name of response file>
#     -keyring <path and name of key ring file> -password <password>
#   Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#     input <path and file name of response file>
#     -keyring <path and name of key ring file> -password <password>
#
################################################################################ -->

<!-- ##### Agent Input ############################################
#
# The clean and temporary attributes specify the repositories and other
# preferences Installation Manager uses and whether those settings
# should persist after the installation finishes.
#
# Valid values for clean:
#      true = only use the repositories and other preferences that are
#           specified in the response file.
#      false = use the repositories and other preferences that are
#           specified in the response file and Installation Manager.
#
# Valid values for temporary:
#      true = repositories and other preferences specified in the
#           response file do not persist in Installation Manager.
#      false = repositories and other preferences specified in the
```

```
#           response file persist in Installation Manager.
#
################################################################# -->

<!-- ##### Modify Packages ##########################################
#
# Install and Uninstall Commands
#
# Use the install and uninstall commands to inform Installation Manager
# of the installation packages to install or uninstall.
#
# The modify attribute is optional and can be paired with an install
# command to add features or paired with an uninstall command to
# remove commands. If omitted, the default value is set to false.
#    false = indicates not to modify an existing install by adding
#            or removing features.
#    true = indicates to modify an existing install by adding or
#           removing features.
#
# The offering ID attribute is required because it specifies the
# offering to be installed. The offering listed must be present in
# at least one of the repositories listed earlier. The example
# command below contains the offering ID for Application Client.
#
# The version attribute is optional. If a version number is provided,
# then the offering will be installed or uninstalled at the version level
# specified as long as it is available in the repositories. If the version
# attribute is not provided, then the default behavior is to install or
# uninstall the latest version available in the repositories. The version
# number can be found in the repository.xml file in the repositories.
# For example, <offering ... version='8.0.0.20110617_2222'>.
#
# The profile attribute is required and typically is unique to the
# offering. If modifying or updating an existing installation, the
# profile attribute must match the profile ID of the targeted installation
# of Application Client.
#
# The features attribute is optional. Offerings always have at least
# one feature; a required core feature which is installed regardless
# of whether it is explicitly specified. If other feature names
# are provided, then only those features will be installed.
```

```
# Features must be comma delimited without spaces.
#
# The feature values for Application Client include:
#    developerkit,embeddablecontainer,samples,
#    standalonethinclient.resourceadapter.runtime
#
# In the example that follows, the samples and standalonethinclient.re-
# -sourceadapter.runtime features are being added and the embeddablecontainer
# and developerkit features are being removed from the specified offering.
#
# The core.feature cannot be removed because they are required features.
#
# The installFixes attribute indicates whether fixes available in
# repositories are installed with the product. By default, all
# available fixes will be installed with the offering.
#
# Valid values for installFixes:
#      none = do not install available fixes with the offering.
#      recommended = installs all available recommended fixes with the offering.
#      all = installs all available fixes with the offering.
#
# Installation Manager supports modifying multiple offerings at once.
# Additional offerings can be included in the install and uninstall commands,
# with each offering requiring its own offering ID, version, profile value,
# and feature values.
#
# Profile Command
#
# A separate profile command must be included for each offering listed
# in the install command. The profile command informs Installation
# Manager about offering specific properties or configuration values.
#
# The installLocation specifies where the offering will be installed.
# If the response file is used to modify or update an existing
# installation, then ensure the installLocation points to the
# location where the offering was installed previously.
#
# The eclipseLocation data key should use the same directory path to
# Application Client as the installationLocation attribute.
#
# Include data keys for product specific profile properties.

## Installing fix packs on the Application Client

You can use Installation Manager to update the Application Client to a later version.

### Before you begin

Make sure that the web-based or local service repository location is listed and checked or that the **Search service repositories during installation and updates** option is selected on the Repositories panel in your Installation Manager preferences. For more information on using service repositories with Installation Manager, read the Installation Manager Information Center.

### About this task

Perform this procedure to use Installation Manager to update the Application Client.

### Procedure

1. Start Installation Manager.
2. Click **Update**.

   **Note:** If you are prompted to authenticate, use the IBM ID and password that you use to access protected IBM software websites.
3. Select the package group to update.

4. Click **Next**.
5. Select the version to which you want to update under **Application Client for IBM WebSphere Application Server**.
6. Click **Next**.
7. Accept the terms in the license agreements, and click **Next**.
8. Select the optional features that you want in your updated installation.
9. Review the summary information, and click **Update**.
   - If the installation is successful, the program displays a message indicating that installation is successful.
   - If the installation is not successful, click **View Log File** to troubleshoot the problem.
10. Click **Finish**.
11. Click **File > Exit** to close Installation Manager.

## Uninstalling fix packs from the Application Client using the Installation Manager GUI

You can use Installation Manager to roll back the Application Client to an earlier version.

### Before you begin

During the rollback process, Installation Manager must access files from the earlier version of the package. By default, these files are stored on your computer when you install a package. If you change the default setting or delete the files using the **Remove Saved Files** option, Installation Manager requires access to the repository that was used to install the earlier version.

### About this task

Perform this procedure to use Installation Manager to roll back the Application Client to an earlier version.

### Procedure

1. Start Installation Manager.
2. Click **Roll Back**.

   **Note:** If you are prompted to authenticate, use the IBM ID and password that you use to access protected IBM software websites.
3. Select the package group to roll back.
4. Click **Next**.
5. Select the version to which you want to roll back under **Application Client for IBM WebSphere Application Server**.
6. Click **Next**.
7. Review the summary information, and click **Roll Back**.
   - If the rollback is successful, the program displays a message indicating that the rollback is successful.
   - If the rollback is not successful, click **View Log File** to troubleshoot the problem.
8. Click **Finish**.
9. Click **File > Exit** to close Installation Manager.

## Uninstalling the Application Client using the GUI

Use the Installation Manager GUI to uninstall the Application Client.

### Procedure

1. Uninstall the Application Client.
   a. Stop all servers and applications on the Application Client installation that contains the product.
   b. Start Installation Manager.
   c. Click **Uninstall**.
   d. In the **Uninstall Packages** window, perform the following actions.
      1) Select **Application Client for IBM WebSphere Application Server** and the appropriate version.

         **Note:** If you are uninstalling the ILAN version of this product, select **Application Client for IBM WebSphere Application Server (ILAN)**.
      2) Click **Next**.
   e. Review the summary information.
   f. Click **Uninstall**.
      - If the uninstallation is successful, the program displays a message that indicates success.
      - If the uninstallation is not successful, click **View log** to troubleshoot the problem.
   g. Click **Finish**.
   h. Click **File > Exit** to close Installation Manager.
2. Optional: Uninstall IBM Installation Manager.

   **Important:** Before you can uninstall IBM Installation Manager, you must uninstall all of the packages that were installed by Installation Manager.

   Read Uninstalling Installation Manager in the Installation Manager information center for information about performing this procedure.

## Uninstalling the Application Client silently

You can use Installation Manager to uninstall the Application Client silently.

### Before you begin

**Optional:** Perform or record the installation of Installation Manager and installation of the Application Client to a temporary installation registry on one of your systems so that you can use this temporary registry to record the uninstallation without using the standard registry where Installation Manager is installed.

Read the following for more information:

- “Installing the Application Client using the GUI” on page 182
- “Installing the Application Client silently” on page 187

### About this task

Using Installation Manager, you can work with response files to uninstall the Application Client silently in a variety of ways. You can record a response file using the GUI as described in the following procedure, or you can generate a new response file by hand or by taking an example and modifying it.

### Procedure

1. Stop all servers and applications on the Application Client installation that contains the product.
2. Optional: **Record a response file to uninstall the Application Client:** On one of your systems, perform the following actions to record a response file that will uninstall the Application Client:
   a. From a command line, change to the eclipse subdirectory in the directory where you installed Installation Manager.

b. Start Installation Manager from the command line using the -record option.

For example:

- Windows **Administrator or non-administrator:**

```
IBMIM.exe -skipInstall "C:\temp\imRegistry"
  -record C:\temp\uninstall_response_file.xml
```

- AIX HP-UX Linux Solaris **Administrator:**

```
./IBMIM -skipInstall /var/temp/imRegistry
  -record /var/temp/uninstall_response_file.xml
```

- AIX HP-UX Linux Solaris **Non-administrator:**

```
./IBMIM -skipInstall user_home/var/temp/imRegistry
  -record user_home/var/temp/uninstall_response_file.xml
```

**Tip:** If you choose to use the -skipInstall parameter with a temporary installation registry created as described in "Before you begin," Installation Manager uses the temporary installation registry while recording the response file. It is important to note that when the -skipInstall parameter is specified, no packages are installed or uninstalled. All of the actions that you perform in Installation Manager simply update the installation data that is stored in the specified temporary registry. After the response file is generated, it can be used to uninstall the Application Client, removing the Application Client files and updating the standard installation registry.

The -skipInstall operation should not be used on the actual agent data location used by Installation Manager. This is unsupported. Use a clean writable location, and re-use that location for future recording sessions.

For more information, read the IBM Installation Manager Information Center.

c. Click **Uninstall**.

d. In the **Uninstall Packages** window, perform the following actions.

1) Select **Application Client for IBM WebSphere Application Server** and the appropriate version.

**Note:** If you are uninstalling the ILAN version of this product, select **Application Client for IBM WebSphere Application Server (ILAN)**.

2) Click **Next**.

e. Review the summary information.

f. Click **Uninstall**.

- If the uninstallation is successful, the program displays a message that indicates success.
- If the uninstallation is not successful, click **View log** to troubleshoot the problem.

g. Click **Finish**.

h. Click **File > Exit** to close Installation Manager.

3. **Use the response file to uninstall the Application Client silently:** From a command line on each of the systems from which you want to uninstall the Application Client, change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager and use the response file that you created to silently uninstall the Application Client.

For example:

- Windows **Administrator or non-administrator:**

```
imcl.exe
  input C:\temp\uninstall_response_file.xml
  -log C:\temp\uninstall_log.xml
```

- AIX HP-UX Linux Solaris **Administrator:**

```
./imcl
  input /var/temp/uninstall_response_file.xml
  -log /var/temp/uninstall_log.xml
```

- AIX HP-UX Linux Solaris **Non-administrator:**

```
./imcl
  input user_home/var/temp/uninstall_response_file.xml
  -log user_home/var/temp/uninstall_log.xml
```

Go to the IBM Installation Manager Information Center for more information.

4. Optional: Uninstall IBM Installation Manager.

   **Important:** Before you can uninstall IBM Installation Manager, you must uninstall all of the packages that were installed by Installation Manager.

   Read the IBM Installation Manager Information Center for information about using the uninstall script to perform this procedure.

Windows

## Example

The following is an example of a response file for silently uninstalling the Application Client:

```
<?xml version="1.0" encoding="UTF-8"?>

<!-- ##### Copyright #####################################################
# Licensed Materials - Property of IBM (c) Copyright IBM Corp. 2011.

<!-- ##### Frequently Asked Questions ###################################
# The latest information about using Installation Manager is
# located in the online Information Center. There you can find
# information about the commands and attributes used in
# silent installation response files.
#
#     Installation Manager Information Center can be found at:
#     http://publib.boulder.ibm.com/infocenter/install/v1r4/index.jsp
#
# Question 1. How do I record a response file using Installation Manager?
# Answer 1. Start Installation Manager from the command line under the
# eclipse subdirectory with the record parameter and it will generate a
# response file containing actions it performed, repositories it used, and
# its preferences settings. Optionally use the -skipInstall parameter if
# you do not want the product to be installed to the machine. Specify a
# new agentDataLocation location value when doing a new installation. Do
# not use an existing agentDataLocation for an installation because it might
# damage the installation data and prevent you from modifying, updating,
# rolling back, or uninstalling the installed packages.
#
# Windows: IBMIM -record <responseFile> -skipInstall <agentDataLocation>
# Linux or UNIX: ./IBMIM -record <responseFile> -skipInstall <agentDataLocation>
#
# For example:
#   Windows = IBMIM.exe -record c:\temp\responsefiles\WASv8.install.Win32.xml
#     -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#   Linux or UNIX = ./IBMIM -record /home/user/responsefiles/WASv8.install.RHEL64.xml
#     -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#
# Question 2. How do I run Installation Manager silently using response file?
# Answer 2. Create a silent installation response file and run the following command
# from the eclipse\tools subdirectory in the directory where you installed
# Installation Manager:
#
#   Windows = imcl.exe -acceptLicense -showProgress
#     input <response_file_path_and_name> -log <log_file_path_and_name>
#   Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#     input <response_file_path_and_name> -log <log_file_path_and_name>
#
# For example:
#   Windows = imcl.exe -acceptLicense -showProgress
#     input c:\temp\responsefile\WASv8.install.Win32.xml
#   Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#     input /home/user/responsefile/WASv8.install.RHEL64.xml
#
# The -acceptLicense command must be included to indicate acceptance of all
#     license agreements of all offerings being installed, updated or modified.
# The -showProgress command shows progress when running in silent mode.
# Additional commands can be displayed by requesting help:  IBMIM -help
#
################################################################### -->

<!-- ##### Agent Input ##########################################
# The clean and temporary attributes specify the repositories and other
# preferences Installation Manager uses and whether those settings
# should persist after the uninstall finishes.
#
# Valid values for clean:
```

```
#      true = only use the repositories and other preferences that are
#           specified in the response file.
#      false = use the repositories and other preferences that are
#           specified in the response file and Installation Manager.
#
# Valid values for temporary:
#      true = repositories and other preferences specified in the
#           response file do not persist in Installation Manager.
#      false = repositories and other preferences specified in the
#           response file persist in Installation Manager.
#
################################################################## -->

<agent-input clean='true' temporary='true'>

<!-- ##### Repositories ################################################
# Repositories are locations that Installation Manager queries for
# installable packages. Repositories can be local (on the machine
# with Installation Manager) or remote (on a corporate intranet or
# hosted elsewhere on the internet).
#
# If the machine using this response file has access to the internet,
# then include the IBM WebSphere Live Update Repositories in the list
# of repository locations.
#
# If the machine using this response file cannot access the internet,
# then comment out the IBM WebSphere Live Update Repositories and
# specify the URL or UNC path to custom intranet repositories and
# directory paths to local repositories to use.
#
################################################################## -->

<server>
    <!-- ##### IBM WebSphere Live Update Repositories ###################
     # These repositories contain Application Client offerings,
     # and updates for those offerings
     #
     # To use the secure repository (https), you must have an IBM ID,
     # which can be obtained by registering at: http://www.ibm.com/account
     # or your Passport Advantage account.
     #
     # And, you must use a key ring file with your response file.
     ############################################################## -->
    <repository location="http://www.ibm.com/software/repositorymanager/com.ibm.websphere.APPCLIENT.v80" />
    <!-- <repository location="https://www.ibm.com/software/rational/repositorymanager/repositories/websphere" /> -->

    <!-- ##### Custom Repositories ######################################
     # Uncomment and update the repository location key below
     # to specify URLs or UNC paths to any intranet repositories
     # and directory paths to local repositories to use.
     ############################################################## -->
    <!-- <repository location='https:\\w3.mycompany.com\repositories\'/> -->
    <!-- <repository location='/home/user/repositories/websphere/'/> -->

    <!-- ##### Local Repositories #######################################
     # Uncomment and update the following line when using a local
     # repository located on your own machine to install a
     # Application Client offering.
     ########################################################## -->
    <!-- <repository location='insert the full directory path inside single quotes'/> -->
</server>

<!-- ##### Uninstall Packages ########################################
#
# Uninstall Command
#
# Use the uninstall command to inform Installation Manager of the
# installation packages to uninstall.
#
# The modify attribute is optional and can be paired with an install
# command to add features or paired with an uninstall command to
# remove commands. If omitted, the default value is set to false.
#    false = indicates not to modify an existing install by adding
#            or removing features.
#    true = indicates to modify an existing install by adding or
#           removing features.
#
# The offering ID attribute is required because it specifies the
# offering to be uninstalled. The example command below contains the
# offering ID for Application Client.
#
# The version attribute is optional. If a version number is provided,
# then the offering will be uninstalled at the version level specified
# If the version attribute is not provided, then the default behavior is
# to uninstall the latest version. The version number can be found in
# the repository.xml file in the repositories.
# For example, <offering ... version='8.0.0.20110617_2222'>.
#
# The profile attribute is required and must match the package group
# name for the offering to be uninstalled.
```

```
#
# The features attribute is optional. If there is no feature attribute,
# then all features are uninstalled. If features are specified, then
# only those features will be uninstalled.
# Features must be comma delimited without spaces.
#
# The feature values for Application Client include:
#  javaruntime,developerkit,samples,
#  standalonethinclient.resourceadapter.runtime,embeddablecontainer
#
# Installation Manager supports uninstalling multiple offerings at once.
# Additional offerings can be included in the uninstall command,
# with each offering requiring its own offering ID, version, profile value,
# and feature values.
#
# Profile Command
#
# A separate profile command must be included for each offering listed
# in the install command. The profile command informs Installation
# Manager about offering specific properties or configuration values.
#
# The installLocation specifies where the offering will be installed.
# If the response file is used to modify or update an existing
# installation, then ensure the installLocation points to the
# location where the offering was installed previously.
#
# The eclipseLocation data key should use the same directory path to
# Application Client as the installationLocation attribute.
#
# Include data keys for product specific profile properties.
#
################################################################## -->

<uninstall modify='false'>
<offering id='com.ibm.websphere.APPCLIENT.v80'
 profile='Application Client for IBM WebSphere Application Server V8.0'
 features='javaee.thinclient.core.feature,javaruntime,developerkit,samples,standalonethinclient.resourceadapter.runtime,embeddablecontainer'/>
</uninstall>

<profile id='Application Client for IBM WebSphere Application Server V8.0'
 installLocation='C:\Program Files\IBM\WebSphere\AppClient'>
<data key='eclipseLocation' value='C:\Program Files\IBM\WebSphere\AppClient'/>
<data key='user.import.profile' value='false'/>
<data key='user.select.64bit.image,com.ibm.websphere.APPCLIENT.v80' value='false'/>
<data key='user.appclient.serverHostname' value='localhost'/>
<data key='user.appclient.serverPort' value='2809'/>
<data key='cic.selector.nl' value='en'/>
</profile>

<!-- ##### Shared Data Location ########################################
# Uncomment the preference for eclipseCache to set the shared data
# location the first time you use Installation Manager to do an
# installation.
#
# Eclipse cache location can be obtained from the installed.xml file found in
# Linux/Unix: /var/ibm/InstallationManager
# Windows: C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager
# from the following property:
# <property name='cacheLocation' value='C:\Program Files\IBM\IMShared'/>
#
# Open the installed.xml file in a text editor because the style sheet
# might hide this value if opened in a web browser.
# For further information on how to edit preferences, refer to the public library at:
# http://publib.boulder.ibm.com/infocenter/install/v1r4/index.jsp?topic=/com.ibm.silentinstall12.doc/topics/r_silent_prefs.html
#
# After the shared data location is set, it cannot be changed
# using a response file or the graphical wizard.
#
# Ensure that the shared data location is a location that can be written
# to by all user accounts that are expected to use Installation Manager.
#
# By default, Installation Manager saves downloaded artifacts to
# the shared data location. This serves two purposes.
#
# First, if the same product is installed a more than once to the machine,
# then the files in the shared data location will be used rather than
# downloading them again.
#
# Second, during the rollback process, the saved artifacts are used.
# Otherwise, if the artifacts are not saved or are removed, then
# Installation Manager must have to access the repositories used to
# install the previous versions.
#
# Valid values for preserveDownloadedArtifacts:
#     true = store downloaded artifacts in the shared data location
#     false = remove downloaded artifacts from the shared data location
#
################################################################## -->

<!--
```

```
<preference name='com.ibm.cic.common.core.preferences.eclipseCache' value='C:\Program Files\IBM\IMShared'/>
<preference name='com.ibm.cic.common.core.preferences.preserveDownloadedArtifacts' value='true'/>
-->

<!-- ##### Preferences Settings ######################################
# Additional preferences for Installation Manager can be specified.
# These preference correspond to those that are located in the graphical
# interface under File / Preferences.
#
# If a preference command is omitted from or commented out of the response
# file, then Installation Manager uses the preference value that was
# previously set or the default value for the preference.
#
# Preference settings might be added or deprecated in new versions of
# Installation Manager. Consult the online Installation Manager
# Information Center for the latest set of preferences and
# descriptions about how to use them.
#
# http://publib.boulder.ibm.com/infocenter/install/v1r4/index.jsp
#

```

# Developing stand-alone thin client applications

Develop the application code, then assemble the code into a client application that you can deploy on a client machine.

## About this task

## Procedure

- Getting server objects and resources.

  A stand-alone client application can get suitable server objects and resources (like connection factories, JMS queues, and data sources) programmatically without using JNDI. Alternatively, a client application can use full JNDI support provided by the Thin Client for EJB.
- Compiling stand-alone thin client applications. To compile your client application, include the JAR files needed in the CLASSPATH setting for the javac command; for example, any extra JAR files for the client application's own classes, JAR files for IBM Thin clients used, and JAR files for JDBC provider classes.

  For the stand-alone thin clients, the following JAR files are provided in the `/runtimes/` directory of either an Application Client installation or Application Server installation:

*Table 38. JAR files for stand-alone thin clients. The product provides JAR files for stand-alone thin clients descriptions.*

| JAR file | Description |
|---|---|
| com.ibm.jaxws.thinclient_8.0.0.jar | IBM Thin Client for Java API for XML-based Web Services (JAX-WS). This file enables a Java SE client application to use the JAX-WS programming model to invoke web services that are hosted by the application server. You must use the endorsed APIs JAR file when starting Java because the Thin Client for JAX-WS requires APIs that are more current than what is available in JDKs to support JAX-WS 2.2 and JAXB 2.2 implementations. |
| com.ibm.ws.ejb.thinclient_8.0.0.jar | Thin Client for Enterprise Java Beans (EJB) . This file enables a Java SE client application to access remote Enterprise Java Beans on a server through Java Naming and Directory Interface (JNDI) look up. If this file is running with a non-IBM product JRE on a non-IBM product platform, the IBM ORB implementation library, com.ibm.ws.orb_8.0.0.jar, is also needed. |

*Table 38. JAR files for stand-alone thin clients (continued). The product provides JAR files for stand-alone thin clients descriptions.*

| JAR file | Description |
|---|---|
| com.ibm.ws.jpa.thinclient_8.0.0.jar | IBM Thin Client for Java Persistence API (JPA). This file allows a Java SE client application to use the Java Persistence API (JPA) to store and retrieve persistent data without the use of an application server. |
| com.ibm.ws.messagingClient.jar | With the com.ibm.ws.ejb.thinclient_8.0.0.jar file, this file enables a Java SE client application to use WebSphere MQ messaging provider JMS resources from the WebSphere Application Server JNDI namespace. WebSphere MQ client jar files are also needed, and must be obtained from the WebSphere MQ product. |
| com.ibm.ws.orb_8.0.0.jar | The IBM ORB implementation library. This file is needed if the IBM Thin Client for EJB is running with a non-IBM product JRE on a non-IBM product platform. |
| com.ibm.ws.sib.client.thin.jms_8.0.0.jar | IBM Thin Client for Java Messaging Service (JMS). This file enables a Java SE client application to use JMS resources of the default messaging provider. For languages other than US English, you also need the additional language files from sibc.nls.zip, which provides language-specific resource bundles. |
| com.ibm.ws.sib.client_ExpeditorDRE_8.0.0.jar | The JMS Client packaged for Lotus® Expeditor. |
| com.ibm.ws.webservices.thinclient_8.0.0.jar | IBM Thin Client for Java API for XML-based RPC (JAX-RPC). This file enable a Java SE client application to use the JAX-RPC programming model to invoke web services that are hosted by the application server. |

If you are running two or more of these stand-alone thin clients together, you must obtain all the clients that you are using from the same installation of Application Client for WebSphere Application Server, the same installation of the WebSphere Application Server product, or the same service refresh.

### What to do next

After developing and compiling a stand-alone thin client application, you can deploy and run the client application.

### Using JMS resources

If you are using JMS resources with the Thin Client for JMS with WebSphere Application Server, you can choose either to obtain these resources programmatically or using the Java Naming and Directory Interface (JNDI). Stand-alone Java SE JMS thin client applications that connect to an external WebSphere MQ queue manager can get administratively-created WebSphere MQ messaging provider JMS resources from the WebSphere Application Server Java Naming and Directory Interface (JNDI) namespace.

#### About this task

If you are using the Thin Client for JMS with WebSphere Application Server, you can obtain suitable JMS connection factories and references to JMS queues or topics programmatically without using JNDI. Alternatively, full JNDI support might be obtained from the Thin Client for EJB with WebSphere Application Server. For further information, refer to the Using JMS resources with the Thin Client for JMS with WebSphere Application Server topic.

If you are using a stand-alone Java SE JMS thin client application that connects to an external WebSphere MQ queue manager and want to obtain administratively-created WebSphere MQ messaging provider JMS resources from the WebSphere Application Server JNDI namespace, refer to the Obtaining WebSphere MQ JMS resources in the thin client environment topic.

## Developing a Java EE client application

This topic provides the steps that are required to develop code for a Java Platform, Enterprise Edition (Java EE) client application.

## About this task

## Procedure

1. Write the client application program. Write the Java EE client application on any development machine. At this stage, you do not require access to the WebSphere Application Server.
2. Assemble the client application JAR file using an assembly tool.

   The JNDI namespace knows what to return on a lookup because of the information assembled by the assembly tool.

   Assemble the client application on any development machine with the assembly tool installed.

   When you assemble your client application, provide the required information to initialize the runtime environment for your client application. For information about how to provide the required information, see the documentation for the assembly tool.

   When you configure resources for use by your client application, consider the following items:
   - Resource environment references are different than resource references. Resource environment references enables your client application to use a logical name to look up a resource bound into the server JNDI namespace. A resource reference enables your application to use a logical name to look up a local Java EE resource. The Java EE specification does not specify a particular implementation of a resource. The following table contains supported resource types and identifies the resources to which the WebSphere Application Server provides a client implementation.

*Table 39. Supported resource types and resource identifiers. Supported resource types*

| Resource Type | Client Configuration Notes® | Client implementation provided by WebSphere Application Server |
|---|---|---|
| javax.sql.DataSource | Supports specification of any data source implementation class | No |
| java.net.URL | Supports specification of custom protocol handlers | Provided by Java Runtime Environment files |
| javax.mail.Session | Supports custom protocol configuration | Yes - POP3/POP3S, SMTP/SMTPS, IMAP/IMAPS |
| javax.jms.QueueConnectionFactory, javax.jms.TopicConnectionFactory, javax.jms.Queue, javax.jms.Topic | Supports configuration of WebSphere embedded messaging, IBM MQ Series and other JMS providers | Yes - WebSphere embedded messaging |

3. Assemble the Enterprise Archive (EAR) file.

   The application is contained in an enterprise archive (EAR file). The EAR file is composed of:
   - Enterprise bean, application client, and user-defined modules or JAR files
   - Web applications or WAR files
   - Metadata describing the applications or application XML files

## What to do next

After developing the Java EE client application code, deploy the application onto the client machines where the client application is to run.

## Java EE client application class loading

When you run your Java Platform, Enterprise Edition (Java EE) application client, a hierarchy of class loaders is created to load classes used by your application.

The following list describes the hierarchy of class loaders:

- The Application Client for WebSphere Application Server (Application Client) run time sets this value to the `WAS_LOGGING` environment variable.

- The extensions class loader class loader is a child to the bootstrap class loader. This class loader contains JAR files in the `java/jre/lib/ext` directory or those JAR files defined by the `-Djava.ext.dirs` parameter on the Java command. The Application Client client run time does not set `-Djava.ext.dirs` parameters. So it uses the JAR files in the `java/jre/lib/ext` directory.
- The *system class loader* class loader contains JAR files and classes that are defined by the `-classpath` parameter on the Java command. The Application Client run time sets this parameter to the `WAS_CLASSPATH` environment variable.
- The *WebSphere class loader* class loader loads the Application Client run time and any classes placed in the Application Client user directories. The directories used by this class loader are defined by the `WAS_EXT_DIRS` environment variable. The `WAS_BOOTCLASSPATH`, `WAS_CLASSPATH`, and the `WAS_EXT_DIRS` environment variables are set in the *app_server_root*`/bin/setupCmdLine` script for WebSphere Application Server installations, or in the *app_server_root*`/bin/setupClient` script for client installations.

As the Java EE application client run time initializes, additional class loaders are created as children of the WebSphere class loader. If your client application uses resources such as Java DataBase Connectivity (JDBC) API, Java Message Service (JMS) API, or Uniform Resource Locator (URL), a different class loader is created to load each of those resources. Finally, the Application Client run time sets the WebSphere class loader to load classes within the EAR file by processing the client JAR manifest repeatedly. The system class path, defined by the CLASSPATH environment variable is never used and is not part of the hierarchy of class loaders.

To package your client application correctly, you must understand which class loader loads your classes. When the Java code loads a class, the class loader used to load that class is assigned to it. Any classes subsequently loaded by that class will use that class loader or any of its parents, but it will not use children class loaders.

In some cases the Application Client run time can detect when your client application class is loaded by a different class loader from the one created for it by the Application Client run time. When this detection occurs, you see the following message:

```
WSCL0205W: The incorrect class loader was used to load [0]
```

This message occurs when your client application class is loaded by one of the parent class loaders in the hierarchy. This situation is typically caused by having the same classes in the EAR file and on the hard drive. If one of the parent class loaders locates a class, that class loader loads it before the Application Client run time class loader. In some cases, your client application still functions correctly. In most cases, however, you receive "class not found" exceptions.

### Configuring the classpath fields

When packaging your Java EE client application, you must configure various class path fields. Ideally, you should package everything required by your application into your EAR file. This is the easiest way to distribute your Java EE client application to your clients. However, you should not package such resources as JDBC APIs, JMS APIs, or URLs. In the case of these resources, use class path references to access those classes on the hard drive. You might also have other classes installed on your client machines that you do not need to redistribute. In this case, you also want to use classpath references to access the classes on the hard drive, as described below.

### Referencing classes within the EAR file

WebSphere product Java EE applications do not use the system class path. Use the MANIFEST Class path entry to refer to other JAR files within the EAR file. Configure these values using an assembly tool. For example, if your client application needs to access the path of the EJB JAR file, add the deployed enterprise bean module name to your application client class path. The format of the Class path field for each of the different modules (Application Client, EJB, Web) is the same:
- The values must refer to JAR and class files that are contained within the EAR file.
- The values must be relative to the root of the EAR file.

- The values cannot refer to absolute paths in the file systems.
- Multiple values must be separated by spaces, not colons or semicolons.

**Attention:** This is the Java method for allowing applications to function platform independent.

Typically, you add modules (JAR files) to the root of the EAR file. In this case, you only need to specify the name of the module (JAR file) in the Class path field. If you choose to add a module with a path, you need to specify the path relative to the root of the EAR file.

For referencing class files, you must specify the directory relative to the root of the EAR file. With an assembly tool, you can add individual class files to the EAR file. It is recommended that these additional class files are packaged in a JAR file. Add this JAR file to the module Class path fields. If you add class files to the root of the EAR file, add **./** to the module Class path fields.

Consider the following example directory structure in which the file myapp.ear contains an application client JAR file named `myclient.jar` and a `mybeans.jar` EJB module. Additional classes reside in class1.jar and utility/class2.zip files. A class file named `xyz.class` is not packaged in a JAR file but is in the root of the EAR file. Specify `./ mybeans.jar utility/class2.zip class1.jar` as the value of the Classpath property. The search order is: `myapp.ear/myclient.jar myapp.ear/xyz.class myapp.ear/mybeans.jar myapp.ear/utility/class2.zip myapp.ear/class1.jar`

### Referencing classes that are not in the EAR file

Use the launchClient `-CCclasspath` parameter. This parameter is specified at run time and takes platform-specific class path values, which means multiple values are separated by semi-colons or colons. The client and the server are similar in this respect.

### Resource class paths

When you configure resources used by your client application using the Application Client Resource Configuration Tool, you can specify class paths that are required by the resource. For example, if your application is using a JDBC to a DB2® database, add `db2java.zip` to the class path field of the database provider. These class path values are platform-specific and require semi-colons or colons to separate multiple values.

On WebSphere Application Server for i5/OS®, if you use the IBM Developer Kit for Java JDBC provider to access DB2/400, you do not have to add the `db2_classes.jar` file to the class path. However, if you use the IBM Toolbox for Java JDBC provider, specify the location of the `jt400.jar` file.

### Using the launchClient API

If you use the launchClient command, the WebSphere class loader hierarchy is created for you. However, if you use the launchClient API, you must perform this setup yourself. Copy the `launchClient` shell command in defining the Java system properties.

## Assembling Java EE client applications

Application client projects contain programs that run on networked client systems. An application client project is deployed as a Java archive (JAR) file.

### About this task

Assemble a client module to contain client application code. Group enterprise beans, web components, and resource adapter code in separate modules.

Use an assembly tool to assemble an application client module in any of the following ways:
- Import an existing application client JAR file.

- Create a new application client module.

### Procedure

1. Start an assembly tool.
2. If you have not done so already, configure the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules. Ensure that Java EE capability is enabled.
3. Migrate application client JAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an assembly tool. To migrate files, import your application client JAR files to the assembly tool.
4. Create a new client application.
5. Verify the contents of the new client application in either of the following ways:
   - In the Project Explorer view, expand **Application Client Projects** and view the new module.
   - Click **Window > Show View > Navigator** to see the associated files for the application client module in a Navigator view.

### What to do next

After you finish assembling all of your application's modules, you are ready to deploy your application.

## Developing a Java thin client application

Develop the application code, then assemble the code into a client application that you can deploy on a client machine.

### About this task

To develop a Java thin client application, you developing the application code, generate the client bindings needed for the enterprise bean and CORBA objects, and package these pieces together to install on the client machine.

With the Java thin client, the client application must code explicitly the fully-qualified location for each resource that it uses. For example, a Java thin client application that looks up an enterprise bean Home contains the following code:

```
java.lang.Object ejbHome =
  initialContext.lookup("the/fully/qualified/path/to/actual/home/in/namespace/MyEJBHome");
MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,  MyEJBHome.class);
```

The Java thin client application must know the fully-qualified physical location of the enterprise bean Home in the namespace. If this location changes, the thin client application must also change the value placed on the lookup() statement.

To compile a Java thin client application, include the client jars file needed by the application in the CLASSPATH setting for the javac command.

## Developing ActiveX client application code

This topic provides an outline for developing an ActiveX Windows program, such as Visual Basic, VBScript, and Active Server Pages, to use the WebSphere ActiveX to EJB bridge to access enterprise beans.

## Before you begin

**Important:** This topic assumes that you are familiar with ActiveX programming and developing on the Windows platform. For information about the programming concepts of ActiveX application clients and the ActiveX to EJB bridge, refer to the ActiveX to Enterprise JavaBeans™ (EJB) Bridge topic, and related topics.

Consider the information given in ActiveX to EJB bridge as good programming guidelines.

## About this task

To use the ActiveX to EJB bridge to access a Java class, develop your ActiveX program to complete the following steps:

## Procedure

1. Create an instance of the XJB.JClassFactory object.
2. Create Java virtual machine (JVM) code within the ActiveX program process, by calling the XJBInit() method of the XJB.JClassFactory object. After the ActiveX program has created an XJB.JClassFactory object and called the XJBInit() method, the JVM code is initialized and ready for use.
3. Create a proxy object for the Java class, by using the XJB.JClassFactory FindClass() and NewInstance() methods. The ActiveX program can use the proxy object to access the Java class, object fields, and methods.
4. Call methods on the Java class, using the Java method invocation syntax, and access Java fields as required.
5. Use the helper functions to do the conversion in cases where automatic conversion is not possible. You can convert between the following data types:
   - Java Byte and Visual Basic Byte
   - Visual Basic Currency types and Java 64-bit
6. Implement methods to handle any errors returned from the Java class. In Visual Basic or VBScript, use the Err.Number and Err.Description fields to determine the actual Java error.

## Example

- Viewing a System.out message
- ActiveX client application using helper methods for data type conversion

Viewing a System.out message: The ActiveX to Enterprise JavaBeans (EJB) bridge does not have a console available to view Java System.out messages. To view these messages when running a stand-alone client program (such as Visual Basic), redirect the output to a file.

The following example illustrates how to redirect output to a file:

```
launchClientXJB.bat MyProgram.exe > output.txt
```

- To view the System.out messages when running a Service program such as Active Server Pages, override the Java System.out OutputStream object to FileOutputStream. For example, in VBScript:

```
'Redirect system.out to a file
' Assume that oXJB is an initialized XJB.JClassFactory object
 Dim clsSystem
 Dim oOS
 Dim oPS
 Dim oArgs

' Get the System class
  Set clsSystem = oXJB.FindClass("java.lang.System")

' Create a FileOutputStream object
' Create a PrintStream object and assign to it our FileOutputStream
  Set oArgs = oXJB.GetArgsContainer  oArgs.AddObject "java.io.OutputStream", oOS
```

```
  Set oPS = oXJB.NewInstance(oXJB.FindClass("java.io.PrintStream"), oArgs)

' Set our System OutputStream to our file
  clsSystem.setOut oPS
```

**ActiveX client application using helper methods for data type conversion.** Generally, data type conversion between ActiveX (Visual Basic and VBScript) and Java methods occurs automatically, as described in ActiveX to EJB bridge, converting data types. However, the byte helper function and currency helper function are provided for cases where automatic conversion is not possible.

- Byte helper function

  Because the Java Byte data type is signed (-127 through 128) and the Visual Basic Byte data type is unsigned (0 through 255), convert unsigned Bytes to a Visual Basic Integers, which look like the Java signed byte. To make this conversion, you can use the following helper function:

```
Private Function GetIntFromJavaByte(Byte jByte) as Integer
      GetIntFromJavaByte = (CInt(jByte) + 128) Mod 256 - 128
End Function
```

- Currency helper function

  Visual Basic 6.0 cannot properly handle 64-bit integers like Java methods can (as the Long data type). Therefore, Visual Basic uses the Currency type, which is intrinsically a 64-bit data type. The only side effect of using the Currency type (the Variant type VT_CY) is that a decimal point is inserted into the type. To extract and manipulate the 64-bit Long value in Visual Basic, use code like the following example. For more details on this technique for converting Currency data types, see Q189862, "HOWTO: Do 64-bit Arithmetic in VBA", on the Microsoft Knowledge Base.

```
' Currency Helper Types
Private Type MungeCurr
    Value As Currency
End Type
Private Type Munge2Long
    LoValue As Long
    HiValue As Long
End Type

' Currency Helper Functions
Private Function CurrToText(ByVal Value As Currency) As String
    Dim Temp As String, L As Long
    Temp = Format$(Value, "#.0000")
    L = Len(Temp)
    Temp = Left$(Temp, L - 5) & Right$(Temp, 4)
    Do While Len(Temp) > 1 And Left$(Temp, 1) = "0"
        Temp = Mid$(Temp, 2)
    Loop
    Do While Len(Temp) > 2 And Left$(Temp, 2) = "-0"
        Temp = "-" & Mid$(Temp, 3)
    Loop
    CurrToText = Temp
End Function

Private Function TextToCurr(ByVal Value As String) As Currency
    Dim L As Long, Negative As Boolean
    Value = Trim$(Value)
    If Left$(Value, 1) = "-" Then
        Negative = True
        Value = Mid$(Value, 2)
    End If
    L = Len(Value)
    If L < 4 Then
        TextToCurr = CCur(IIf(Negative, "-0.", "0.") & _
                          Right$("0000" & Value, 4))
    Else
        TextToCurr = CCur(IIf(Negative, "-", "") & _
                          Left$(Value, L - 4) & "." & Right$(Value, 4))
```

```
    End If
End Function

' Java Long as Currency Usage Example
Dim LC As MungeCurr
Dim L2 As Munge2Long

' Assign a Currency Value (really a Java Long)
' to the MungeCurr type variable
LC.Value = cyTestIn

' Coerce the value to the Munge2Long type variable
LSet L2 = LC

' Perform some operation on the value, now that we
' have it available in two 32-bit chunks
L2.LoValue = L2.LoValue + 1

' Coerce the Munge value back into a currency value
LSet LC = L2
cyTestIn = LC.Value
```

## What to do next

After you develop the ActiveX client application code, deploy and run the ActiveX application.

## Example: Using an ActiveX client application to access a Java class or object

This reference topic provides an example of using Java proxy objects with the ActiveX to Enterprise JavaBeans (EJB) bridge.

To use Java proxy objects with the ActiveX to Enterprise JavaBeans (EJB) bridge:

- After an ActiveX client program (Visual Basic, VBScript, or Active Server Pages (ASP)) has initialized the XJB.JClassFactory object and thereby, the Java virtual machine (JVM), the client program can access Java classes and initialize Java objects. To complete this action, the client program uses the XJB.JClassFactory FindClass() and NewInstance() methods.
- In Java programming, two ways exists to access Java classes: direct invocation through the Java compiler and through the Java Reflection interface. Because the ActiveX to Java bridge needs no compilation and is a complete run-time interface to the Java code, the bridge depends on the latter Reflection interface to access its classes, objects, methods and fields. The XJB.JClassFactory FindClass() and NewInstance() methods behave very similarly to the Java Class.forName() and the Method.invoke() and Field.invoke() methods.
- XJB.JClassFactory.FindClass() takes the fully qualified class name as its only parameter and returns a Proxy Object (JClassProxy). You can use the returned Proxy object like a normal Java Class object and call static methods and access static fields. You can also create a Class Instance (or object), as described below. For example, the following Visual Basic code extract returns a Proxy object for the java.lang.Integer Java class:

  ```
  ...
  Dim clsMyString as Object
  Set clsMyString = oXJB.FindClass("java.lang.Integer")
  ```

- After the proxy is created, you can access its static information directly. For example, you can use the following code extract to convert a decimal integer to its hexadecimal representation:

  ```
  ...
  Dim strHexValue as String
  strHexValue = clsMyString.toHexString(CLng(255))
  ```

- The equivalent Java syntax is: `static String toHexString(int i)`. Because ints units in Java programming are really 32-bit (which translates to Long in Visual Basic), the CLng() function converts the value from the default int to a long. Also, even though the toHexString() function returns a

java.lang.String, the code extract does not return an Object proxy. Instead, the returned java.lang.String is automatically converted to a native Visual Basic string.

To create an object from a class, you use the JClassFactory.NewInstance() method. This method creates an Object instance and takes whatever parameters your class constructor needs. Once the object is created, you have access to all of its public instance methods and fields. For example, you can use the following Visual Basic code extract to create an instance of the java.lang.Integer string:

```
...
Dim oMyInteger as Object
set oMyInteger = oXJB.NewInstance(CLng(255))

Dim strMyInteger as String
strMyInteger = oMyInteger.toString
```

## Example: ActiveX client application calling Java methods

In the ActiveX to Enterprise Java Beans (EJB) bridge, methods are called using the native language method invocation syntax.

The following differences between Java invocation and ActiveX Automation invocation exist:

- Unlike Java methods, ActiveX does not support method (and constructor) polymorphism; that is, you cannot have two methods in the same class with the same name.
- Java methods are case-sensitive, but ActiveX Automation is not case-sensitive.
- To compensate for Java polymorphic behavior, give the exact parameter types to the method call. The parameter types determine the correct method to invoke. For a listing of correct types to use, see ActiveX to EJB bridge, converting data types.
- For example, the following Visual Basic code fails if the CLng() method was not present or the toHexString syntax was incorrectly typed as ToHexString:

  ```
  ...
  Dim strHexValue as String
  strHexValue = clsMyString.toHexString(CLng(255))
  ```
- Sometimes it is difficult to force some development environments to leave the case of your method calls unchanged. For example, in Visual Basic if you want to call a method `close()` (lowercase), the Visual Basic code capitalizes it `"Close()"`. In Visual Basic, the only way to effectively work around this behavior is to use the CallByName() method. For example:

  ```
  o.Close(123)                                'Incorrect...
  CallByName(o, "close", vbMethod, 123)       'Correct...
  ```

  or in VBScript, use the `Eval` function:

  ```
  o.Close(123)                                 'Incorrect...
  Eval("o.Close(123)")                         'Correct...
  ```
- The return value of a function is always converted dynamically to the correct type. However, you must take care to use the set keyword in Visual Basic. If you expect a non-primitive data type to return, you must use set. (If you expect a primitive data type to return, you do not need to use set.) See the following example for more explanation:

  ```
  Set oMyObject = o.getObject
  iMyInt = o.getInt
  ```
- In some cases, you might not know the type of object returning from a method call, because wrapper classes are converted automatically to primitives (for example, java.lang.Integer returns an ActiveX Automation Long). In such cases, you might need to use your language built-in exception handling techniques to try to coerce the returned type (for example, On Error and Err.Number in Visual Basic).
- Methods with character arguments

  Because ActiveX Automation does not natively support character types supported by Java methods, the ActiveX to EJB bridge uses strings (byte or VT_I1 do not work because characters have multiple bytes in Java code). If you try to call a method that takes a char or java.lang.Character type you must use the JMethodArgs argument container to pass character values to methods or constructors. For more information about how this argument container is used, see Methods with "Object" Type as Argument and Abstract Arguments.

- Methods with "Object" Type as Argument and Abstract Arguments

  Because of the polymorphic nature of Java programming, the ActiveX to Java bridge uses direct argument type mapping to find a method. This method works well in most cases, but sometimes methods are declared with a Parent or Abstract class as an argument type (for example, java.lang.Object). You need the ability to send an object of arbitrary type to a method. To acquire this ability, you must use the XJB.JMethodArgs object to coerce your parameters to match the parameters on your method. You can get a JMethodArgs instance by using the JClassFactory.GetArgsContainer() method.

  The JMethodArgs object is a container for method parameters or arguments. This container enables you to add parameters to it one-by-one and then you can send the JMethodArgs object to your method call. The JClassProxy and JObjectProxy objects recognize the JMethodArgs object and attempt to find the correct method and let the Java language coerce your parameters appropriately.

  For example, to add an element to a Hashtable object the method syntax is `Object put(Object key, Object value)`. In Visual Basic, the method usage looks like the following example code:

```
Dim oMyHashtable as Object
Set oMyHashtable = _
    oXJB.NewInstance(oXJB.FindClass("java.utility.Hashtable"))

' This line will not work. The ActiveX to EJB bridge cannot find a method
' called "put" that has a short and String as a parameter:
oMyHashtable.put 100, "Dogs"
oMyHashtable.put 200, "Cats"

' You must use a XJB.JMethodArgs object instead:
Dim oMyHashtableArgs as Object
Set oMyHashtableArgs = oXJB.GetArgsContainer
oMyHashtableArgs.AddObject("java.lang.Object", 100)
oMyHashtableArgs.AddObject("java.lang.Object", "Dogs")

oMyHashtable.put oMyHashTableArgs
' Reuse the same JMethodArgs object by clearing it.
oMyHashtableArgs.Clear
oMyHashtableArgs.AddObject("java.lang.Object", 200)
oMyHashtableArgs.AddObject("java.lang.Object", "Cats")

oMyHashtable.put oMyHashTableArgs
```

## ActiveX client programming best practices

The best way to access Java components is to use the Java language. It is recommended that you do as much programming as possible in the Java language and use a small simple interface between your COM Automation container (for example, Visual Basic) and the Java code. This interface avoids any overhead and performance problems that can occur when moving across the interface.

**best-practices:** The following topics are covered:

- Visual Basic guidelines
- CScript and Windows Scripting Host
- Active Server Pages guidelines
- J2EE guidelines

### Visual Basic guidelines

The following guidelines are intended to help optimize your use of the ActiveX to EJB bridge with Visual Basic:

- Launch the Visual Basic replication through the `launchClientXJB.bat` file. If you want to run your Visual Basic application through the Visual Basic debugger, run the Visual Basic integrated development environment (IDE) within the ActiveX to EJB bridge environment. After you create your Visual Basic project, you can launch it from a command line; for example, `launchClientXJB MyApplication.vbp`. You

can also launch the Visual Basic application alone in the ActiveX to EJB environment, by changing the Visual Basic shortcut on the Windows Start menu so that the `launchClientXJB.bat` file precedes the call to the `VB6.EXE` file.

- Exit the Visual Basic IDE before debugging programs.

  Because the Java virtual machine (JVM) code attaches to the running process, you must exit the Visual Basic editor before debugging your program. If you run the process, then exit your program within the Visual Basic IDE, the JVM code continues to run and you reattach the same JVM code when XJBInit() is called by the debugger. This causes problems if you try to update XJBInit() arguments (for example, classpath) because the changes are not be applied until you restart the Visual Basic program.
- Store the XJB.JClassFactory object globally.

  Because you cannot unload or reinitialize the JVM code, cache the resulting XJB.JClassFactory object as a global variable. The overhead of treating this object as a global variable or passing a single reference around is much less than recreating a new XJB.JClassFactory object and calling the XJBInit() argument more than once.

### CScript and Windows Scripting Host

The following guidelines intend to help optimize your use of the ActiveX to EJB bridge with CScript and Windows Scripting Host (WSH):

- Launch in ActiveX to EJB environment.

  Launch the VBScript files in the ActiveX to EJB bridge environment, to run VBScript files in `.vbs` files. Two common ways exist to launch your script:
  - `launchClientXJB MyScript.vbs`
  - `launchClientXJB cscript MyScript.vbs`

### Active Server Pages guidelines

The following guidelines intend to help optimize your use of the ActiveX to EJB bridge with Active Server Pages software:

- Use the ActiveX to EJB Helper functions from the Active Server Pages Application.

  Because Active Server Pages (ASP) code typically use VBScript, you can use the included helper functions in any VBScript environment with minor changes. For more information about these helper functions, see Helper functions for data type conversion. To run outside of the ASP environment, remove or change all references to the Server, Request, Response, Application and Session objects; for example, change `Server.CreateObject` to `CreateObject`.
- Set JRE path globally in system.

  The XJB.JClassFactory object must be able to find the Java run time dynamic link library (DLL) when initializing. In Internet Information Server, you cannot specify a path for its processes independently; you must set the process paths in the system PATH variable. You can only have a single JVM version available on a machine using the ASP application. Also, remember that after you change the system PATH variable you must reboot the Internet Information Server machine so that the Internet Information Server can see the change.
- Set the system TEMP environment variable.

  If the system TEMP environment variable is not set, Internet Information Server stores all temporary files in the `WINNT` directory, which is usually not desired.
- Use high isolation or an isolated process.

  When using the ActiveX to Java bridge with Active Server Pages software, creating your web application in its own process is recommended. You can only load one JVM instruction in a single process and if you want to have more than one application running with different JVM environment options (for example, different classpaths), then you need to have separate processes.
- Use the Application Unload option.

  When debugging your application, use **Unload** when viewing your ASP application properties in the Internet Information Server administration console to unload the process from memory and thereby unload the JVM code.

- Run one process per application.

  Use only one ASP application per J2EE application or JVM environment, in your ASP environment. If you need separate class paths or JVM settings, you need separate ASP applications (virtual directories with high isolation or an isolated process).
- Store the XJB.JClassFactory object in application scope.

  Because of the one-to-one relationship required between a JVM instruction and a process, and because the JVM code can never detach or shut down from a process independently, cache the XJB.JClassFactory object at application scope and call the XJBInit() method only once.

  Because the ActiveX to EJB bridge employs a free-threaded marshaler, take advantage of the multi-threaded nature of Internet Information Server and the ASP environment. If you choose to reinitialize the XJB.JClassFactory object at Page scope (local variables), then the XJBInit() method can only initialize your local XJB.JClassFactory variable. It is more efficient to use the XJBInit() method once.
- Use VBScript conversion functions.

  Because VBScript code only supports variant data types, use the CStr(), CByte(), CBool(), CCur(), CInt(), Clng(), CSng() and CDbl() functions to tell the activeX to EJB bridge which data type you are using; for example `oMyObject.Foo(CDbl(1.234))`.

### J2EE guidelines

The following guidelines are intended to help optimize your use of the ActiveX to EJB bridge with the J2EE environment;

- Store client container objects globally.

  Because you can only have one JVM instruction per process, and a single J2EE client container (com.ibm.websphere.client.applicationclient.launchClient) per JVM instruction, initialize your J2EE client container only once and reuse it. For ASP applications, store the J2EE client container in an application level variable and initialize it only once (either on the Application_OnStart() event in the `global.asa` file or by checking to see if it IsEmpty()).

  A side effect to storing the client container object globally is that you cannot change the client container parameters without destroying the object and creating a new one. These parameters include the EAR file, BootstrapHost, class path, and so on. If you run a Visual Basic application and want to change the client container parameters, you must end the application and restart it. If you run an Active Server Pages application, you must first unload the application from Internet Information Server (see "Use the Application Unload Button" under Active Server Pages guidelines). Then load the Active Server Pages application with the different client container parameters. The parameters set the first time the Active Server Pages application loads. Since the client container is stored on the Internet Information Server, all the browser clients share the parameters using the Active Server Pages application. This behavior is normal for Active Server Pages code, but can be confusing when you try to run to different WebSphere Application Servers using the same Active Server Pages application, which is not supported.
- Reuse custom temporary directory for EAR file extraction.

  By default, the client container launches and extracts the application `.ear` file to your `temp` directory and then sets up the thread class loader to use the extracted EAR file directory and the JAR files included in the client JAR manifest. This process is time consuming and because of some limitations with JVM shutdown through Java Native Interface (JNI) and file locking, these files are never cleaned up.

  Specifically, each time the client container launch() method is called, it extracts the EAR file to a random directory name in your temporary directory on your hard drive. The current Java thread class loader is then changed to point to this extracted directory which in turn locks the files within. In a normal J2EE Java client, these files automatically clean up after the application exits. This cleanup occurs when the client container shutdown hook is called (which never happens in the ActiveX to EJB bridge), which leaves the temporary directory there.

  To avoid these problems, you can specify a directory to extract the EAR file by setting the com.ibm.websphere.client.applicationclient.archivedir Java system property before calling the client container launch() method. If the directory does not exist or is empty, you extract the EAR file normally.

If the EAR file was previously extracted, the directory is reused. This feature is particularly important for server processes (for example, ASP), which can stop and restart, potentially calling the launchClient() method several times.

If you need to update your EAR file, delete the temporary directory first. The next time you create the client container object, it extracts the new EAR file to the temporary directory. If you do not delete the temporary directory or change the system property value to point to a different temporary directory, the client container reuses the currently extracted EAR file, and does not use your changed EAR file.

**Note:** When specifying the com.ibm.websphere.client.applicationclient.archivedir property, ensure that the directory you specify *is unique* for each EAR file you use. For example, do not point `MyEar1.ear` and `MyEar2.ear` files to the same directory.

If you choose not to use this system property, go regularly to your Windows `temp` directory and delete the WSTMP* subdirectories. Over a relatively short period of time, these subdirectories can waste a significant amount of space on the hard drive.

## ActiveX client programming, tips for passing arrays

Arrays are very similar between Java and Automation containers like Visual Basic and `VBScript`. This topic provides some important points to consider when passing arrays back and forth between these containers.

Here are some important points to consider when passing arrays back and forth between these containers:

- Java arrays cannot mix types. All Java arrays contain a single type, so when passing arrays of variants to a Java array, you must make sure that all of the elements in the variant array are of the same base type. For example, in Visual Basic code:

```
...
Dim VariantArray(1) as Variant
VariantArray(0) = CLng(123)
VariantArray(1) = CDbl(123.4)
oMyJavaObject.foo(VariantArray) '     Illegal!

VariantArray(0) = CLng(123)
VariantArray(1) = CLng(1234)
oMyJavaObject.foo(VariantArray) '     This works
```

- Arrays of primitive types are converted using the rules defined in primitive data type conversion.
- Arrays of Java objects are handled through arrays of JObjectProxy objects.
- Arrays of JObjectProxy objects must be fully initialized and of the correct associated Java type. When initializing an array in Visual Basic (for example, Dim oJavaObjects(1) as Object), you must set each object to a JObjectProxy object before you send the array to a Java object. The bridge is unable to determine the type of null or empty object values.
- When receiving an array from a Java method, the lower-bound is always zero. Java methods only support zero-based arrays.
- Nested or multidimensional arrays are treated as zero-based multidimensional arrays in Visual Basic and VBScript containers.
- Uninitialized arrays or Array Types are unsupported. When calling a Java method that takes an array of objects as a parameter, you must fully initialize the array of JObjectProxy objects.

## ActiveX client programming, Java field programming tips

Using the ActiveX to Enterprise JavaBeans (EJB) bridge to access Java fields has the same case sensitivity issue that it has when invoking methods. Field names must use the same case as the Java field syntax.

Visual Basic code has the same problem with unsolicited case changing on fields as it does with methods. (For more information about this problem, see ActiveX to EJB bridge, calling Java methods). You might use the CallByName() function to set a field in the same way that you call a method in some cases. For fields, use VBLet for primitive types and VBSet for objects. For example:

```
o.MyField = 123                         'Incorrect...
CallByName(o, "MyField", vbLet, 123)    'Correct...
```

or in VBScript:

```
o.MyField = 123                         'Incorrect...
Eval("o.myField = 123")                 'Correct...
```

## ActiveX client programming, JClassProxy and JObjectProxy classes

The majority of tasks for accessing your Java classes and objects are handled with the JClassProxy and JObjectProxy objects. This topic provides reference information about the object classes of the ActiveX to Enterprise Java Beans (EJB) bridge.

JClassFactory is the object used to access the majority of Java Virtual Machine (JVM) features. This object handles JVM initialization, accesses classes and creates class instances (objects). Use the JClassProxy and JObjectProxy objects to access the majority of your Java classes and objects:

- XJBInit(String astrJavaParameterArray())

  Initializes the JVM environment using an array of strings that represent the command line parameters you normally send to the `java.exe` file.

  If you have invalid parameters in the XJBInit() string array, the following error is displayed:

  ```
  Error: 0x6002 "XJBJNI::Init() Failed to create VM" when calling XJBInit()
  ```

  If you have C++ logging enabled, the activity log displays the invalid parameter.
- JClassProxy FindClass(String strClassName)

  Uses the current thread class loader to load the specified fully qualified class name and returns a JClassProxy object representing the Java Class object.
- JObjectProxy NewInstance()

  Creates a Class instance for the specified JClassProxy object using the parameters supplied to call the Class constructor. For more information about using the JMethodArgs method, see ActiveX to EJB bridge, calling Java methods.

```
JObjectProxy NewInstance(JClassFactory obj, Variant vArg1, Variant vArg2, Variant vArg3, ...)
JObjectProxy NewInstance(JClassFactory obj, JMethodArgs args)
```

- JMethodArgs GetArgsContainer()

  Returns a JMethodArgs object (Class instance).

  You can create a JClassProxy object from the JClassFactory.FindClass() method and from any Java method call that normally return a Java Class object. You can use this object as if you had direct access to the Java Class object. All of the class static methods and fields are accessible as are the java.lang.Class methods. In case of a clash between static method names of the reflected user class and those of the java.lang.Class (for example, getName()), the reflected static methods would execute first.

  For example, the following is a static method called getName(). The java.lang.Class object also has a method called getName():

  – In Java:

  ```
  class foo{
   foo(){};
   public static String getName(){return "abcdef";}
   public static String getName2(){return "ghijkl";}
   public String toString2(){return "xyz";}
  }
  ```

  – In Visual Basic:

  ```
  ...
  Dim clsFoo as Object
  set clsFoo = oXJB.FindClass("foo")
  clsFoo.getName()  ' Returns "abcdef" from the static foo class
  clsFoo.getName2() ' Returns "ghijkl" from the static foo class
  clsFoo.toString() ' Returns "class foo" from the java.lang.Class object.
  oFoo = oXJB.NewInstance(clsFoo)
  oFoo.toString() ' Returns some text from the java.lang.Object's
                  ' toString() method which foo inherits from.
  oFoo.toString2() ' Returns "xyz" from the foo class instance
  ```

You can create a JObjectProxy object from the JClassFactory.NewInstance() method, and can be created from any Java method call that normally returns a Class instance object. You can use this object as if you had direct access to the Java object and can access all the static methods and fields of the object. All of object instance methods and fields are accessible (including those accessible through inheritance).

The JMethodArgs object is created from the JClassFactory.GetArgsContainer() method. Use this object as a container for method and constructor arguments. You must use this object when overriding the object type when calling a method (for example, when sending a java.lang.String JProxyObject type to a constructor that normally takes a java.lang.Object type).

You can use two groups of methods to add arguments to the collection: Add and Set. You can use Add to add arguments in the order that they are declared. Alternatively, you can use Set to set an argument based on its position in the argument list (where the first argument is in position 1).

For example, if you had a Java Object Foo that took a constructor of Foo (int, String, Object), you could use a JMethodArgs object as shown in the following code extract:

```
...
Dim oArgs as Object
set oArgs = oXJB.GetArgsContainer()

oArgs.AddInt(CLng(12345))
oArgs.AddString("Apples")
oArgs.AddObject("java.lang.Object", oSomeJObjectProxy)

Dim clsFoo as Object
Dim oFoo as Object
set clsFoo = oXJB.FindClass("com.mypackage.foo")
set oFoo = oXJB.NewInstance(clsFoo, oArgs)

' To reuse the oArgs object, just clear it and use the add method
' again, or alternatively, use the Set method to reset the parameters
' Here, we will use Set
oArgs.SetInt(1, CLng(22222))
oArgs.SetString(2, "Bananas")
oArgs.SetObject(3, "java.lang.Object", oSomeOtherJObjectProxy)

Dim oFoo2 as Object
set oFoo2 = oXJB.NewInstance(clsFoo, oArgs)
```

- AddObject (String strObjectTypeName, Object oArg)

  Adds an arbitrary object to the argument container in the next available position, casting the object to the class name specified in the first parameter. Arrays are specified using the traditional [] syntax; for example:

  ```
  AddObject("java.lang.Object[][]", oMy2DArrayOfFooObjects)
  ```

  or

  ```
  AddObject("int[]", oMyArrayOfInts)
  ```

- AddByte (Byte byteArg)

  Adds a primitive byte value to the argument container in the next available position.

- AddBoolean (Boolean bArg)

  Adds a primitive boolean value to the argument container in the next available position.

- AddShort (Integer iArg)

  Adds a primitive short value to the argument container in the next available position.

- AddInt (Long lArg)

  Adds a primitive int value to the argument container in the next available position.

- AddLong (Currency cyArg)

  Adds a primitive long value to the argument container in the next available position.

- AddFloat (Single fArg)

  Adds a primitive float value to the argument container in the next available position.

- AddDouble (Double dArg)

  Adds a primitive double value to the argument container in the next available position.
- AddChar (String strArg)

  Adds a primitive char value to the argument container in the next available position.
- AddString (String strArg)

  Adds the argument in string form to the argument container in the next available position.
- SetObject (Integer iArgPosition, String strObjectTypeName, Object oArg)

  Adds an arbitrary object to the argument container in the specified position casting it to the class name or primitive type name specified in the second parameter. Arrays are specified using the traditional [] syntax; for example:

  ```
  SetObject(1, "java.lang.Object[][]", oMy2DArrayOfFooObjects)
  ```

  or

  ```
  SetObject(2, "int[]", MyArrayOfInts)
  ```
- SetByte (Integer iArgPosition, Byte byteArg)

  Sets a primitive byte value to the argument container in the position specified.
- SetBoolean (Integer iArgPosition, Boolean bArg)

  Sets a primitive boolean value to the argument container in the position specified.
- SetShort (Integer iArgPosition, Integer iArg)

  Sets a primitive short value to the argument container in the position specified.
- SetInt (Integer iArgPosition, Long lArg)

  Sets a primitive int value to the argument container in the position specified.
- SetLong (Integer iArgPosition, Currency cyArg)

  Sets a primitive long value to the argument container in the position specified.
- SetFloat (Integer iArgPosition, Single fArg)

  Sets a primitive float value to the argument container in the position specified.
- SetDouble (Integer iArgPosition, Double dArg)

  Sets a primitive double value to the argument container in the position specified.
- SetChar (Integer iArgPosition, String strArg)

  Sets a primitive char value to the argument container in the position specified.
- SetString (Integer iArgPosition, String strArg)

  Sets a java.lang.String value to the argument container in the position specified.
- Object Item(Integer iArgPosition)

  Returns the value of an argument at a specific argument position.
- Clear()

  Removes all arguments from the container and resets the next available position to one.
- Long Count()

  Returns the number of arguments in the container.

## ActiveX client programming, Java virtual machine initialization tips

Initialize the Java virtual machine (JVM) code with the ActiveX to Enterprise Java Beans (EJB) bridge. For an ActiveX client program (Visual Basic, VBScript, or ASP) to access Java classes or objects, the first step that the program must do is to create Java virtual machine (JVM) code within its process.

To create JVM code, the ActiveX program calls the XJBInit() method of the XJB.JClassFactory object. When an XJB.JClassFactory object is created and the XJBInit() method called, the JVM is initialized and ready to use.

- To enable the XJB.JClassFactory to find the Java run-time description definition language (DLL) when initializing, the Java Runtime Environment (JRE) bin and `bin\classic` directories must exist in the system path environment variable.
- The XJBInit() method accepts only one parameter: an array of strings. Each string in the array represents a command line argument that for a Java program you would normally specify on the

`Java.exe` command line. This string interface is used to set the class path, stack size, heap size and debug settings. You can get a listing of these parameters by typing `java -?` from the command line.
- If you set a parameter incorrectly, you receive a `0x6002 "Failed to initialize VM"` error message.
- Due to the current limitations of Java Native Interface (JNI), you cannot unload or reinitialize the JVM code after it has loaded. Therefore, after the XJBInit() method has been called once, subsequent calls have no effect other than to create a duplicate JClassFactory object for you to access. It is best to store your XJB.JClassFactory object globally and continue to reuse that object.
- The following Visual Basic extract shows an example of initializing JVM code:

```
Dim oXJB as Object
set oXJB = CreateObject("XJB.JClassFactory")
Dim astrJavaInitProps(0) as String
astrJavaInitProps(0) = _
     "-Djava.class.path=.;c:\myjavaclasses;c:\myjars\myjar.jar"
oXJB.XJBInit(astrJavaInitProps)
```

## ActiveX to Java primitive data type conversion values

All primitive Java data types are automatically converted to native ActiveX Automation types. However, not all Automation data types are converted to Java types (for example, VT_DATE). Variant data types are used for data conversion.

Variant data types are a requirement of any Automation interface, and are used automatically by Visual Basic and VBScript. The tables below provide details about how primitive data types are converted between Automation types and Java types.

*Table 40. ActiveX to Java primitive data type conversion. Conversion details for primitive data types*

| Visual Basic Type | Variant Type | Java Type | Notes |
|---|---|---|---|
| Byte | VT_I1 | byte | Byte in Visual Basic is unsigned, but is signed in Java data type. |
| Boolean | VT_BOOL | boolean | |
| Integer | VT_I2 | short | |
| Long | VT_I4 | int | |
| Currency | VT_CY | long | |
| Single | VT_R4 | float | |
| Double | VT_R8 | double | |
| String | VT_BSTR | java.lang.String | |
| String | VT_BSTR | char | |
| Date | VT_DATE | n/a | |

***Example: ActiveX client application using helper methods for data type conversion:***

Generally, data type conversion between ActiveX (Visual Basic and VBScript) and Java methods occurs automatically, as described in ActiveX to EJB bridge, converting data types. However, the byte helper function and currency helper function are provided for cases where automatic conversion is not possible:
- Byte helper function

  Because the Java Byte data type is signed (-127 through 128) and the Visual Basic Byte data type is unsigned (0 through 255), convert unsigned Bytes to a Visual Basic Integers, which look like the Java signed byte. To make this conversion, you can use the following helper function:

```
Private Function GetIntFromJavaByte(Byte jByte) as Integer
      GetIntFromJavaByte = (CInt(jByte) + 128) Mod 256 - 128
End Function
```
- Currency helper function

Visual Basic 6.0 cannot properly handle 64-bit integers like Java methods can (as the Long data type). Therefore, Visual Basic uses the Currency type, which is intrinsically a 64-bit data type. The only side effect of using the Currency type (the Variant type VT_CY) is that a decimal point is inserted into the type. To extract and manipulate the 64-bit Long value in Visual Basic, use code like the following example. For more details on this technique for converting Currency data types, see Q189862, "HOWTO: Do 64-bit Arithmetic in VBA", on the Microsoft Knowledge Base.

```
' Currency Helper Types
Private Type MungeCurr
    Value As Currency
End Type
Private Type Munge2Long
    LoValue As Long
    HiValue As Long
End Type

' Currency Helper Functions
Private Function CurrToText(ByVal Value As Currency) As String
    Dim Temp As String, L As Long
    Temp = Format$(Value, "#.0000")
    L = Len(Temp)
    Temp = Left$(Temp, L - 5) & Right$(Temp, 4)
    Do While Len(Temp) > 1 And Left$(Temp, 1) = "0"
        Temp = Mid$(Temp, 2)
    Loop
    Do While Len(Temp) > 2 And Left$(Temp, 2) = "-0"
        Temp = "-" & Mid$(Temp, 3)
    Loop
    CurrToText = Temp
End Function

Private Function TextToCurr(ByVal Value As String) As Currency
    Dim L As Long, Negative As Boolean
    Value = Trim$(Value)
    If Left$(Value, 1) = "-" Then
        Negative = True
        Value = Mid$(Value, 2)
    End If
    L = Len(Value)
    If L < 4 Then
        TextToCurr = CCur(IIf(Negative, "-0.", "0.") & _
                          Right$("0000" & Value, 4))
    Else
        TextToCurr = CCur(IIf(Negative, "-", "") & _
                          Left$(Value, L - 4) & "." & Right$(Value, 4))
    End If
End Function

' Java Long as Currency Usage Example
Dim LC As MungeCurr
Dim L2 As Munge2Long

' Assign a Currency Value (really a Java Long)
' to the MungeCurr type variable
LC.Value = cyTestIn

' Coerce the value to the Munge2Long type variable
LSet L2 = LC

' Perform some operation on the value, now that we
' have it available in two 32-bit chunks
L2.LoValue = L2.LoValue + 1
```

```
' Coerce the Munge value back into a currency value
LSet LC = L2
cyTestIn = LC.Value
```

## ActiveX client programming, handling error codes

All exceptions thrown in Java code are encapsulated and thrown again as a COM error through the ISupportErrorInfo interface and the EXCEPINFO structure of IDispatch::Invoke(), the Err object in Visual Basic and VBScript. Because there are no error numbers associated with Java exceptions, whenever a Java exception is thrown, the entire stack trace is stored in the error description text and the error number assigned is 0x6003.

In Visual Basic or VBScript, you need to use the **Err.Number** and **Err.Description** fields to determine the actual Java error. Non-Java errors are thrown as you would expect via the IDispatch interface; for example, if a method cannot be found, then error 438 "Object doesn't support this property or method" is thrown.

*Table 41. Error numbers and descriptions.. Error numbers and descriptions in VBScript*

| Error number | Description |
|---|---|
| 0x6001 | Java Native Interface (JNI) error |
| 0x6002 | Initialization error |
| 0x6003 | Java exception. Error description is the Java Stack Trace. |
| 0x6FFF | General Internal Failure |

## ActiveX client programming, threading tips

The ActiveX to Enterprise JavaBeans (EJB) bridge supports both free-threaded and apartment-threaded access and implements the Free Threaded Marshaler to work in a hybrid environment such as Active Server Pages (ASP). Each thread created in the ActiveX process is mirrored in the Java environment when the thread communicates through the ActiveX to EJB bridge.

When all references to Java objects (there are no JObjectProxy or JClassProxy objects) are loaded in an ActiveX thread, the ActiveX to EJB bridge detaches the thread from the Java virtual machine (JVM) code. Therefore, you must be careful that any Java code that you access from a multithreaded Windows application is thread safe. Visual Basic code and VBScript applications are both essentially single threaded. Therefore, Visual Basic and VBScript applications do not have threading issues in the Java programs they access. Active Server Pages and multithreaded C and C++ programs can have issues.

Consider the following scenario:

1. A multithreaded Windows Automation Container (our ActiveX Process) starts. It exists on Thread A.
2. The ActiveX Process initializes the ActiveX to EJB bridge, which starts the JVM code. The JVM attaches to the same thread and internally calls it Thread 1.
3. The ActiveX Process starts two threads: B and C.
4. Thread B in the ActiveX Process uses the ActiveX to EJB bridge to access an object that was created in Thread A. The JVM attaches to thread B and calls it Thread 2.
5. Thread C in the ActiveX Process never talks to the JVM code, so the JVM never needs to attach to it. This is a case where the JVM code does not have a one-to-one relationship between ActiveX threads and Java threads.
6. Thread B later releases all of the JObjectProxy and JClassProxy objects that it used. The Java Thread 2 is detached.
7. Thread B again uses the ActiveX to EJB bridge to access an object that was created in Thread A. The JVM code attaches again to the thread and calls it Thread 3.

*Table 42. Thread scenario.. Thread scenario*

| ActiveX process | JVM access by ActiveX process |
|---|---|
| Thread A - Created in 1 | Thread 1 - Attached in 2 |
| Thread B - Created in 4 | Thread 2 - Attached in 4, detached in 6 Thread 3 - Attached in 7 |
| Thread C - Created in 4 | |

### Threads and Active Server Pages

Active Server Pages (ASP) in Microsoft Internet Information Server is a multithreaded environment. When you create the XJB.JClassFactory object, you can store it in the Application collection as an Application-global object. All threads within your ASP environment can now access the same ActiveX to EJB bridge object. Active Server Pages by default creates 10 Apartment Threads per ASP process per CPU. This means that when your ActiveX to EJB bridge object is initialized any of the 10 threads can call this object, not just the thread that created it.

If you need to simulate single-apartment behavior, you can create a Single-Apartment Threaded ActiveX dynamic link library (DLL) in Visual Basic code and encapsulate the ActiveX to the EJB bridge object. This encapsulation guarantees that all access to the JVM object is on the same thread. You need to use the <OBJECT> tag to assign the XJB.JClassFactory to an Application object and must be aware of the consequences of introducing single-threaded behavior to a web application.

The Microsoft KnowlegeBase has several articles about ASP and threads, including:
- Q243543 INFO: Do Not Store STA Objects in Session or Application
- Q243544 INFO: Component Threading Model Summary Under Active Server Pages
- Q243548 INFO: Design Guidelines for VB Components Under ASP

## Example: Enabling logging and tracing for activeX client applications

The ActiveX to EJB bridge provides two logging and tracing formats: Windows Application Event Log and Java Trace Log.

- Windows Event Log

  The Windows Application Event Log shows JNI errors, Java console error messages, and XJB initialization messages. This log is most useful for determining XJBInit() errors and any unusual exceptions that do not come from the Java environment. By default, critical error logging will be enabled and debug and event logging is disabled.

  To enable or disable logging of certain event types to the Windows Event Log, specify one or more parameters to XJBInit(). If more than one parameter is set, they will be processed in the order in which they appear in the input string array to the XJBInit() method. Once the XJBInit() method is initialized, these parameters can no longer be set/reset for the life of the process. Using Java java.lang.System.setProperty() to set these values also has no effect.
  - -Dcom.ibm.ws.client.xjb.native.logging.debug=enabled|disabled

    Enables or disables debug level messages from displaying in the Windows operating system event log. This level of logging is most useful and shows most internal errors, user programming issues or configuration problems.
  - -Dcom.ibm.ws.client.xjb.native.logging.event=enabled|disabled

    Enables or disables event level messages from appearing in the Windows operating system event log.
  - -Dcom.ibm.ws.client.xjb.native.logging.*=enabled|disabled

    Enables or disables both event and debug level messages from appearing in the Windows operating system event log. It is not possible to disable some critical error messages from being displayed in the error log. Only debug and event level messages can be disabled.

  To view the Windows application event log with the Event Viewer, complete the following steps:

1. Click **Start** > **Control Panel**.
2. Double-click **Administrative Tools**.
3. Double-click **Event Viewer**.

All ActiveX to EJB bridge events display the text `WebSphere XJB` in the source column and in the application log.

When using the Event Viewer, you can get help information by clicking the menu choice **Action** > **Help**.

- Java trace log

  The Java trace log displays information that you can use to debug method calls, class lookups, and argument coercion problems. Because the Java portion of the bridge mirrors the function of the COM IDispatch interface, the information in the trace log is similar to what you have come to expect from an IDispatch interface. To understand the trace log, you need a fundamental understanding of IDispatch.

  To enable user-logging, add the following parameters to the XJBInit() input string array:

```
"-DtraceString=com.ibm.ws.client.xjb.*=event=enabled"
"-DtraceFile=C:\MyTrace.txt"
```

### Example: Viewing a System.out message

The ActiveX to Enterprise JavaBeans (EJB) bridge does not have a console available to view Java System.out messages. To view these messages when running a stand-alone client program (such as Visual Basic), redirect the output to a file.

This example redirects output to a file:

```
launchClientXJB.bat MyProgram.exe > output.txt
```

- To view the System.out messages when running a Service program such as Active Server Pages, you need to override the Java System.out OutputStream object to FileOutputStream. For example, in VBScript:

```
'Redirect system.out to a file
' Assume that oXJB is an initialized XJB.JClassFactory object
 Dim clsSystem
 Dim oOS
 Dim oPS
 Dim oArgs

' Get the System class
  Set clsSystem = oXJB.FindClass("java.lang.System")

' Create a FileOutputStream object
' Create a PrintStream object and assign to it our FileOutputStream
  Set oArgs = oXJB.GetArgsContainer  oArgs.AddObject "java.io.OutputStream", oOS
  Set oPS = oXJB.NewInstance(oXJB.FindClass("java.io.PrintStream"), oArgs)

' Set our System OutputStream to our file
  clsSystem.setOut oPS
```

## Developing applet client code

Applet clients are capable of communicating over the HTTP protocol and the RMI-IIOP protocol.

### About this task

Unlike typical applets that reside on either web servers or WebSphere Application Servers and can only communicate using the HTTP protocol, applet clients are capable of communicating over the HTTP protocol and the RMI-IIOP protocol. This additional capability gives the applet direct access to enterprise beans.

Standard applets require the HTML `<APPLET>` tag to identify the applet to the browser. If you replace the `<OBJECT>` and `<EMBED>` tags, make sure that you specify appropriate values for `<OBJECT>` and `<EMBED>` tags, especially the `<OBJECT classid` and `<EMBED type` values.

In the code for your applet client, when you initialize an instance of the InitialContext class, you must set properties to specify the computer name, domain, and port, and to identify this program (the client) as an applet.

## Example

- Applet client tag requirements
- Applet client code requirements

Applet client tag requirements: Standard applets require the HTML <APPLET> tag to identify the applet to the browser. The <APPLET> tag invokes the Java virtual machine (JVM) of the browser. It can also be replaced by <OBJECT> and <EMBED> tags. The following code example illustrates the applet code using the <APPLET> tag:

```
<APPLET code="MyAppletClass.class" archive="Applet.jar, EJB.jar" width="600" height="500" >
</APPLET>
```

The following code example illustrates the applet code using the <OBJECT> and <EMBED> tags.

```
<OBJECT classid="clsid: 8AD9C840-044E-11D1-B3E9-00805F499D93"
width="600" height="500">
<PARAM NAME=CODE VALUE=MyAppletClass.class>
<PARAM NAME="archive" VALUE='Applet.jar, EJB.jar'>
<PARAM TYPE="application/x-java-applet;version=1.5.0">
<PARAM NAME="scriptable" VALUE="false">
<PARAM NAME="cache-option" VALUE="Plugin">
<PARAM NAME="cache-archive" VALUE="Applet.jar, EJB.jar">
<COMMENT>
<EMBED type="application/x-java-applet;version=1.5.0" CODE=MyAppletClass.class
ARCHIVE="Applet.jar, EJB.jar" WIDTH="600" HEIGHT="500"
scriptable="false">
<NOEMBED>
</COMMENT>
</NOEMBED>WebSphere Java Application/Applet Thin Client for
Windows is required.
</EMBED>
</OBJECT>
```

**Attention:** To successfully invoke the applet client in WebSphere Application Server version 6.1 or later, the <OBJECT classid and <EMBED type values need to be those shown in the preceding example.

For more information about the <APPLET> tag, see the Sun Microsystems article, Using applet, object and embed Tags.

Applet client code requirements: The code used by an applet to talk to an enterprise bean is the same as that used by a stand-alone Java program or a servlet, except for one additional property called java.naming.applet. This property informs the InitialContext and the Object Request Broker (ORB) that this client is an applet rather than a stand-alone Java application or servlet. The following code example illustrates the applet code using the <APPLET> tag:

When you initialize an instance of the InitialContext class, the first two lines in this code snippet illustrate what both a stand-alone Java program and a servlet issue to specify the computer name, domain, and port. In this example, <yourserver.yourdomain.com> is the computer name and domain where WebSphere Application Server resides, and 900 is the configured port. After the bootstrap values (<yourserver.yourdomain.com>:900) are defined, the client to server communications occur within the underlying infrastructure. In addition to the first two lines for applets, you must add the third line to your code, which identifies this program as an applet, for example:

```
prop.put(Context.INITIAL_CONTEXT_FACTORY, "com.ibm.websphere.naming.WsnInitialContextFactory");
prop.put(Context.PROVIDER_URL, "iiop://<yourserver.yourdomain.com>:900)
prop.put(Context.APPLET, this);
```

### Example: Applet client tag requirements

Standard applets require the HTML <APPLET> tag to identify the applet to the browser. The <APPLET> tag invokes the Java virtual machine (JVM) of the browser. It can also be replaced by <OBJECT> and <EMBED> tags.

The following code example illustrates the applet code using the <APPLET> tag.

```
<APPLET code="MyAppletClass.class" archive="Applet.jar, EJB.jar" width="600" height="500" >
</APPLET>
```

The following code example illustrates the applet code using the <OBJECT> and <EMBED> tags.

```
<OBJECT classid="clsid: 8AD9C840-044E-11D1-B3E9-00805F499D93"
width="600" height="500">
<PARAM NAME=CODE VALUE=MyAppletClass.class>
<PARAM NAME="archive" VALUE='Applet.jar, EJB.jar'>
<PARAM TYPE="application/x-java-applet;version=1.5.0">
<PARAM NAME="scriptable" VALUE="false">
<PARAM NAME="cache-option" VALUE="Plugin">
<PARAM NAME="cache-archive" VALUE="Applet.jar, EJB.jar">
<COMMENT>
<EMBED type="application/x-java-applet;version=1.5.0" CODE=MyAppletClass.class
ARCHIVE="Applet.jar, EJB.jar" WIDTH="600" HEIGHT="500"
scriptable="false">
<NOEMBED>
</COMMENT>
</NOEMBED>WebSphere Java Application/Applet Thin Client for
Windows is required.
</EMBED>
</OBJECT>
```

**Attention:** To successfully invoke the applet client in WebSphere Application Server version 6.1 or later, the <OBJECT classid and <EMBED type values need to be those shown in the preceding example.

For more information about the <APPLET> tag, see the Sun Microsystems article, Using applet, object and embed Tags.

### Example: Applet client code requirements

The code used by an applet to talk to an enterprise bean is the same as that used by a stand-alone Java program or a servlet, except for one additional property called java.naming.applet. This property informs the InitialContext and the Object Request Broker (ORB) that this client is an applet rather than a stand-alone Java application or servlet.

When you initialize an instance of the InitialContext class, the first two lines in this code snippet illustrate what both a stand-alone Java program and a servlet issue to specify the computer name, domain, and port. In this example, <yourserver.yourdomain.com> is the computer name and domain where WebSphere Application Server resides, and 900 is the configured port. After the bootstrap values (<yourserver.yourdomain.com>:900) are defined, the client to server communications occur within the underlying infrastructure. In addition to the first two lines for applets, you must add the third line to your code, which identifies this program as an applet, for example:

```
prop.put(Context.INITIAL_CONTEXT_FACTORY, "com.ibm.websphere.naming.WsnInitialContextFactory");
prop.put(Context.PROVIDER_URL, "iiop://<yourserver.yourdomain.com>:900)
prop.put(Context.APPLET, this);
```

## Running the Pluggable Application Client code

This topic provides steps for installing and using the Pluggable Application Client.

### Before you begin

**Remember:** The Pluggable Application Client is available only on Windows systems.

Both Java Platform, Enterprise Edition (Java EE) application clients and Thin application clients can access JMS resources provided by the default messaging provider.

**Important:** The Pluggable Application Client is deprecated. It is replaced by the stand-alone thin client, IBM Thin Client for EJB.

## Procedure

1. Install the Pluggable Application Client.

   Read “Installing and uninstalling the Pluggable Application Client for WebSphere Application Server” for more information,
2. Set the Java application pluggable client environment by using the setupClient command.
3. Add your specific Java client application JAR files to the CLASSPATH and start your Java client application from this environment, after setting the environment variables.
4. Run a Java command to invoke your client application.

```
"%JAVA_HOME%\bin\java" %WAS_LOGGING% -Djava.security.auth.login.config=
"%app_client_root%\properties\wsjaas_client.conf"
-classpath "%WAS_CLASSPATH%;<list_of_your_application_jars_and_classes>
-Djava.ext.dirs="%JAVA_JRE%\lib\ext;%WAS_EXT_DIRS%;%WAS_HOME%\plugins;%WAS_HOME%\lib\WMQ\java\lib"
-Djava.naming.provider.url=iiop://<your_application_client_machine_name>
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
-Djava.endorsed.dirs="%WAS_ENDORSED_DIRS%"
%CLIENT_ROOT% %CLIENTSAS% %CLIENTSSL% <fully_qualified_class_name_to_run>
```

## Installing and uninstalling the Pluggable Application Client for WebSphere Application Server

IBM Installation Manager is a common installer for many IBM software products that you use to install and uninstall the Pluggable Application Client for WebSphere Application Server.

### Before you begin

**Note:** The Pluggable Application Client for WebSphere Application Server is now installed by Installation Manager rather than by the programs based on InstallShield MultiPlatform (ISMP) that are used to install and uninstall previous versions.

**Important:** The Pluggable Application Client is deprecated. It is replaced by the standalone thin client, IBM Thin Client for EJB.

The Pluggable Application Client runs only on the Windows platform and requires that you have previously installed the Sun Java Runtime Environment (JRE) Version 1.6.0 or later. In all other aspects, the Pluggable Application Client and the IBM Thin Client for EJB are similar.

### About this task

Perform one of these procedures to install or uninstall the Pluggable Application Client for IBM WebSphere Application Server.

### Procedure

- “Installing the Pluggable Application Client using the GUI”
- “Installing the Pluggable Application Client silently” on page 238
- “Uninstalling the Pluggable Application Client using the GUI” on page 247
- “Uninstalling the Pluggable Application Client silently” on page 247

#### *Installing the Pluggable Application Client using the GUI:*

You can use the Installation Manager GUI to install the Pluggable Application Client.

**Before you begin**

**Install Installation Manager:**

1. Perform one of the following procedures:
   - If you want to use the Installation Manager that is included with this product, perform the following actions:
     a. Obtain the necessary files from the physical media or the web.

        There are three basic options for obtaining and installing the product.

        – **Access the physical media, and use local installation**

          You can access the product repositories on the product media.

          1) Install Installation Manager on your system.

             You can install Installation Manager using the product media, using a file obtained from the Passport Advantage site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager website.

          2) Use Installation Manager to install the product from the product repositories on the media.

        – **Download the files from the Passport Advantage site, and use local installation**

          Licensed customers with a Passport Advantage ID and password can download the necessary product repositories from the Passport Advantage site.

          1) Download the files from the Passport Advantage site.
          2) Install Installation Manager on your system.

             You can install Installation Manager using the product media, using a file obtained from the Passport Advantage site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager website.

          3) Use Installation Manager to install the product from the downloaded repositories.

        – **Access the live repositories, and use web-based installation**

          If you have a Passport Advantage ID and password, you can install the product from the web-based repositories.

          1) Install Installation Manager on your system.

             You can install Installation Manager using the product media, using a file obtained from the Passport Advantage site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager website.

          2) Use Installation Manager to install the product from the web-based repository located at

`http://www.ibm.com/software/repositorymanager/com.ibm.websphere.PLUGCLIENT.v80`

             Whenever possible, you should use the remote web-based repositories so that you are accessing the most up-to-date installation files.

        **Notes:**

        – If you do not have a Passport Advantage ID and password, you must install the product from the product repositories on the media or local repositories.
        – With the Packaging Utility, you can create and manage packages for installation repositories. You can copy multiple packages into one repository or copy multiple disks for one product into a repository. You can copy packages from Passport Advantage into a repository for example. For more information on the Packaging Utility, go to the IBM Installation Manager Information Center.

     b. Change to the location containing the Installation Manager installation files, and as an administrator, run the following command:

        – Windows `install.exe`

        – AIX HP-UX Linux Solaris `./install`

        The installer opens an **Install Packages** window.

c. Make sure that the Installation Manager package is selected, and click **Next**.
d. Accept the terms in the license agreements, and click **Next**.
The program creates the directory for your installation.
e. Click **Next**.
f. Review the summary information, and click **Install**.
– If the installation is successful, the program displays a message indicating that installation is successful.
– If the installation is not successful, click **View Log File** to troubleshoot the problem.

- If you already have a version of Installation Manager installed on your system and you want to use it to install and maintain the product, obtain the necessary product files from the physical media or the web.

  There are three basic options for installing the product.

  – **Access the physical media, and use local installation**

    You can access the product repositories on the product media. Use Installation Manager to install the product from the product repositories on the media.

  – **Download the files from the Passport Advantage site, and use local installation**

    Licensed customers with a Passport Advantage ID and password can download the necessary product repositories from the Passport Advantage site.

    a. Download the product repositories from the Passport Advantage site.
    b. Use Installation Manager to install the product from the downloaded repositories.

  – **Access the live repositories, and use web-based installation**

    If you have a Passport Advantage ID and password, you can use Installation Manager to install the product from the web-based repositories. Use Installation Manager to install the product from the web-based repository located at

`http://www.ibm.com/software/repositorymanager/com.ibm.websphere.PLUGCLIENT.v80`

    Whenever possible, you should use the remote web-based repositories so that you are accessing the most up-to-date installation files.

  **Notes:**

  – If you do not have a Passport Advantage ID and password, you must install the product from the product repositories on the media or local repositories.
  – With the Packaging Utility, you can create and manage packages for installation repositories. You can copy multiple packages into one repository or copy multiple disks for one product into a repository. You can copy packages from Passport Advantage into a repository for example. For more information on the Packaging Utility, go to the IBM Installation Manager Information Center.

2. Add the product repository to your Installation Manager preferences.
   a. Start Installation Manager.
   b. In the top menu, click **File > Preferences**.
   c. Select **Repositories**.
   d. Perform the following actions:
      1) Click **Add Repository**.
      2) Enter the path to the `repository.config` file in the location containing the repository files.
         For example:
         - Windows `C:\repositories\`*`product_name`*`\local-repositories`
         - AIX HP-UX Linux Solaris `/var/repositories/`*`product_name`*`/local-repositories`

         or

http://www.ibm.com/software/repositorymanager/com.ibm.websphere.PLUGCLIENT.v80

3) Click **OK**.

e. Deselect any locations listed in the Repositories window that you will not be using.

f. Click **Apply**.

g. Click **OK**.

h. Click **File > Exit** to close Installation Manager.

### About this task

Perform this procedure to use the Installation Manager GUI to install the Pluggable Application Client.

### Procedure

1. Start Installation Manager.
2. Click **Install**.

   **Note:** If you are prompted to authenticate, use the IBM ID and password that you registered with on the program website.

   Installation Manager searches its defined repositories for available packages.
3. Perform the following actions.
   a. Select **Pluggable Application Client for IBM WebSphere Application Server** and the appropriate version.

   **Attention:** Pluggable Application Client has limitations when running on Windows Server 2008 as a non-administrator user. Specifically, the versioninfo.bat and historyinfo.bat files that are located in the `..\PlugClient\bin` directory return invalid path errors. The errors occur because of the inability of non-administrator users to access Oracle JRE components due to user permissions.

   **Note:** If you are installing the ILAN version of this product, select **Pluggable Application Client for IBM WebSphere Application Server (ILAN)**.

   If you already have the Pluggable Application Client installed on your system, a message displays indicating that the Pluggable Application Client is already installed. For a given Installation Manager, you can install only one Pluggable Application Client.

   **Tip:** If the **Search service repositories during installation and updates** option is selected on the Installation Manager Repository preference page and you are connected to the Internet, you can click **Check for Other Versions and Extensions** to search for updates in the default update repositories for the selected packages. In this case, you do not need to add the specific service-repository URL to the Installation Manager Repository preference page.

   b. Select the fixes to install.

   Any recommended fixes are selected by default.

   If there are recommended fixes, you can select the option to show only recommended fixes and hide non-recommended fixes.

   c. Click **Next**.

   **Note:** If you try to install a newer level of the Pluggable Application Client with a previous version of Installation Manager, Installation Manager might prompt you to update to the latest level of Installation Manager when it connects to the repository. Update to the newer version before you continue if you are prompted to do so. Read the IBM Installation Manager Information Center for information about automatic updates.
4. Accept the terms in the license agreements, and click **Next**.
5. Specify the installation root directory for the product binaries, which are also referred to as the core product files or system files.

The panel also displays the shared resources directory and disk-space information.

**Restrictions:**

- Deleting the default target location and leaving an installation-directory field empty prevents you from continuing.
- Do not use a semicolon in the directory name.

  The Pluggable Application Client cannot install properly if the target directory includes a semicolon.

  A semicolon is the character used to construct the class path on Windows systems.

6. Click **Next**.
7. Optional: Select **Pluggable Application Client Samples** if you want to install the samples.

   **Tip:** You can run the Installation Manager later to modify this installation and add or remove the feature.
8. Click **Next**.
9. Enter the host name and port number of the Websphere Application Server to which you want to connect, and click **Next**.
10. Enter the location of the SUN JRE to use with the clients.
11. Optional: Enter the location of the SUN SDK to use when compiling the sample clients.
12. Click **Next**.
13. Review the summary information, and click **Install**.
    - If the installation is successful, the program displays a message indicating that installation is successful.

      **Note:** The program might also display important post-installation instructions as well.
    - If the installation is not successful, click **View Log File** to troubleshoot the problem.
14. Click **Finish**.
15. Click **File > Exit** to close Installation Manager.

***Installing the Pluggable Application Client silently:***

You can use Installation Manager to install the Pluggable Application Client silently.

**Before you begin**

**Install Installation Manager** on each of the systems onto which you want to install the product.

1. Perform one of the following procedures:
   - If you want to use the Installation Manager that is included with this product, perform the following actions:
     a. Obtain the necessary files from the physical media or the web.

        There are three basic options for obtaining and installing the product.
        - **Access the physical media, and use local installation**

          You can access the product repositories on the product media.

          1) Install Installation Manager on your system.

             You can install Installation Manager using the product media, using a file obtained from the Passport Advantage site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager website.

          2) Use Installation Manager to install the product from the product repositories on the media.
        - **Download the files from the Passport Advantage site, and use local installation**

Licensed customers with a Passport Advantage ID and password can download the necessary product repositories from the Passport Advantage site.

1) Download the files from the Passport Advantage site.
2) Install Installation Manager on your system.

   You can install Installation Manager using the product media, using a file obtained from the Passport Advantage site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager website.
3) Use Installation Manager to install the product from the downloaded repositories.

– **Access the live repositories, and use web-based installation**

  If you have a Passport Advantage ID and password, you can install the product from the web-based repositories.

1) Install Installation Manager on your system.

   You can install Installation Manager using the product media, using a file obtained from the Passport Advantage site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager website.
2) Use Installation Manager to install the product from the web-based repository located at

`http://www.ibm.com/software/repositorymanager/com.ibm.websphere.PLUGCLIENT.v80`

Whenever possible, you should use the remote web-based repositories so that you are accessing the most up-to-date installation files.

**Notes:**

– If you do not have a Passport Advantage ID and password, you must install the product from the product repositories on the media or local repositories.
– With the Packaging Utility, you can create and manage packages for installation repositories. You can copy multiple packages into one repository or copy multiple disks for one product into a repository. You can copy packages from Passport Advantage into a repository for example. For more information on the Packaging Utility, go to the IBM Installation Manager Information Center.

b. Change to the location containing the Installation Manager installation files, and run one of the following commands to install Installation Manager silently:

**Administrative installation:**

```
installc.exe -acceptLicense -log log_file_path_and_name
```

**Non-administrative installation:**

```
userinstc.exe -acceptLicense -log log_file_path_and_name
```

- If you already have a version of Installation Manager installed on your system and you want to use it to install and maintain the product, obtain the necessary product files from the physical media or the web.

  There are three basic options for installing the product.

  – **Access the physical media, and use local installation**

    You can access the product repositories on the product media. Use Installation Manager to install the product from the product repositories on the media.

  – **Download the files from the Passport Advantage site, and use local installation**

    Licensed customers with a Passport Advantage ID and password can download the necessary product repositories from the Passport Advantage site.

    a. Download the product repositories from the Passport Advantage site.
    b. Use Installation Manager to install the product from the downloaded repositories.

  – **Access the live repositories, and use web-based installation**

If you have a Passport Advantage ID and password, you can use Installation Manager to install the product from the web-based repositories. Use Installation Manager to install the product from the web-based repository located at

```
http://www.ibm.com/software/repositorymanager/com.ibm.websphere.PLUGCLIENT.v80
```

Whenever possible, you should use the remote web-based repositories so that you are accessing the most up-to-date installation files.

**Notes:**

- If you do not have a Passport Advantage ID and password, you must install the product from the product repositories on the media or local repositories.
- With the Packaging Utility, you can create and manage packages for installation repositories. You can copy multiple packages into one repository or copy multiple disks for one product into a repository. You can copy packages from Passport Advantage into a repository for example. For more information on the Packaging Utility, go to the IBM Installation Manager Information Center.

2. Add the product repository to your Installation Manager preferences.
   a. Start Installation Manager.
   b. In the top menu, click **File > Preferences**.
   c. Select **Repositories**.
   d. Perform the following actions:
      1) Click **Add Repository**.
      2) Enter the path to the `repository.config` file in the location containing the repository files.
         For example:

```
C:\repositories\product_name\local-repositories
```

         or

```
http://www.ibm.com/software/repositorymanager/com.ibm.websphere.PLUGCLIENT.v80
```

      3) Click **OK**.
   e. Deselect any locations listed in the Repositories window that you will not be using.
   f. Click **Apply**.
   g. Click **OK**.
   h. Click **File > Exit** to close Installation Manager.

### About this task

Using Installation Manager, you can work with response files to install the Pluggable Application Client silently in a variety of ways. You can record a response file using the GUI as described in the following procedure, or you can generate a new response file by hand or by taking an example and modifying it.

### Procedure

1. Optional: **Record a response file to install the Pluggable Application Client:** On one of your systems, perform the following actions to record a response file that will install the Pluggable Application Client.
   a. From a command line, change to the eclipse subdirectory in the directory where you installed Installation Manager.
   b. Start Installation Manager from the command line using the -record option.
      For example:

```
IBMIM.exe -skipInstall "C:\temp\imRegistry" -record C:\temp\install_response_file.xml
```

      **Tip:** When you record a new response file, you can specify the -skipInstall parameter. Using this parameter has the following benefits:

- No files are actually installed, and this speeds up the recording.
- If you use a temporary data location with the -skipInstall parameter, Installation Manager writes the installation registry to the specified data location while recording. When you start Installation Manager again without the -skipInstall parameter, you then can use your response file to install against the real installation registry.

  The -skipInstall operation should not be used on the actual agent data location used by Installation Manager. This is unsupported. Use a clean writable location, and re-use that location for future recording sessions.

For more information, read the IBM Installation Manager Information Center.

c. Add the appropriate repositories to your Installation Manager preferences.
   1) In the top menu, click **File > Preferences**.
   2) Select **Repositories**.
   3) Perform the following actions for each repository:
      a) Click **Add Repository**.
      b) Enter the path to the `repository.config` file in the remote web-based repository or the local directory into which you unpacked the repository files.

         For example:

         - Remote repositories:

```
https://downloads.mycorp.com:8080/WAS_80_repository
```

or

```
http://www.ibm.com/software/repositorymanager/com.ibm.websphere.PLUGCLIENT.v80
```

         - Local repositories:

```
C:\repositories\plugclient\local-repositories
```

      c) Click **OK**.
   4) Click **Apply**.
   5) Click **OK**.

d. Click **Install**.

   **Note:** If you are prompted to authenticate, use the IBM ID and password that you registered with on the program website.

   Installation Manager searches its defined repositories for available packages.

e. Perform the following actions.
   1) Select **Pluggable Application Client for IBM WebSphere Application Server** and the appropriate version.

      **Note:** If you are installing the ILAN version of this product, select **Pluggable Application Client for IBM WebSphere Application Server (ILAN)**.

      If you already have the Pluggable Application Client installed on your system, a message displays indicating that the Pluggable Application Client is already installed. For a given Installation Manager, you can install only one Pluggable Application Client.
   2) Click **Next**.

f. Accept the terms in the license agreements, and click **Next**.

g. Specify the installation root directory for the Pluggable Application Client binaries, which are also referred to as the core product files or system files.

   The panel also displays the shared resources directory and disk-space information.

   **Restrictions:**

   - Deleting the default target location and leaving an installation-directory field empty prevents you from continuing.

- Do not use a semicolon in the directory name.

  The Pluggable Application Client cannot install properly if the target directory includes a semicolon.

  A semicolon is the character used to construct the class path on Windows systems.

h. Click **Next**.

i. Optional: Select **Pluggable Application Client Samples** if you want to install the samples.

**Tip:** You can run the Installation Manager later to modify this installation and add or remove the feature.

j. Click **Next**.

k. Enter the host name and port number of the Websphere Application Server to which you want to connect, and click **Next**.

l. Enter the location of the SUN JRE to use with the clients.

m. Optional: Enter the location of the SUN SDK to use when compiling the sample clients.

n. Click **Next**.

o. Review the summary information, and click **Install**.

- If the installation is successful, the program displays a message indicating that installation is successful.

  **Note:** The program might also display important post-installation instructions as well.
- If the installation is not successful, click **View Log File** to troubleshoot the problem.

p. Click **Finish**.

q. Click **File > Exit** to close Installation Manager.

r. Optional: If you are using an authenticated remote repository, create a keyring file for silent installation.

1) From a command line, change to the eclipse subdirectory in the directory where you installed Installation Manager.

2) Start Installation Manager from the command line using the -record option.

   For example:

```
IBMIM.exe -skipInstall "C:\temp\imRegistry"
  -keyring C:\IM\im.keyring
  -record C:\temp\keyring_response_file.xml
```

3) When a window opens that requests your credentials for the authenticated remote repository, enter the correct credentials and **save** them.

4) Click **File > Exit** to close Installation Manager.

   For more information, read the IBM Installation Manager Information Center.

2. **Use the response files to install the Pluggable Application Client silently:**

a. Optional: **Use the response file to install the keyring silently:** Go to a command line on each of the systems on which you want to install the Pluggable Application Client, change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager, and install the keyring silently.

   For example:

```
imcl.exe -acceptLicense
  input C:\temp\keyring_response_file.xml
  -log C:\temp\keyring_log.xml
```

b. **Use the response file to install the Pluggable Application Client silently:** Go to a command line on each of the systems on which you want to install the Pluggable Application Client, change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager, and install the Pluggable Application Client silently.

   For example:

```
imcl.exe -acceptLicense
  input C:\temp\install_response_file.xml
  -log C:\temp\install_log.xml
  -keyring C:\IM\im.keyring
```

**Notes:**

- The relevant terms and conditions, notices, and other information are provided in the license-agreement files in the `lafiles` or *product_name*`/lafiles` subdirectory of the installation image or repository for this product.
- The program might write important post-installation instructions to standard output.

Read the IBM Installation Manager Information Center for more information.

Windows

## Example

The following is an example of a response file for silently installing the Pluggable Application Client.

```
<?xml version="1.0" encoding="UTF-8"?>

<!-- ##### Copyright #####################################################
# Licensed Materials - Property of IBM (c) Copyright IBM Corp. 2011.
# All Rights Reserved. US Government Users Restricted Rights-Use, duplication
# or disclosure restricted by GSA ADP Schedule Contract with IBM Corp.
###################################################################### -->

<!-- ##### Frequently Asked Questions ###################################
# The latest information about using Installation Manager is
# located in the online Information Center. There you can find
# information about the commands and attributes used in
# silent installation response files.
#
#     Installation Manager Information Center can be found at:
#     http://publib.boulder.ibm.com/infocenter/install/v1r4/index.jsp
#
# Question 1. How do I record a response file using Installation Manager?
# Answer 1. Start Installation Manager from the command line under the
# eclipse subdirectory with the record parameter and it will generate a
# response file containing actions it performed, repositories it used, and
# its preferences settings. Optionally use the -skipInstall parameter if
# you do not want the product to be installed to the machine. Specify a
# new agentDataLocation location value when doing a new installation. Do
# not use an existing agentDataLocation for an installation because it might
# damage the installation data and prevent you from modifying, updating,
# rolling back, or uninstalling the installed packages.
#
# Windows: IBMIM -record <responseFile> -skipInstall <agentDataLocation>
# Linux or UNIX: ./IBMIM -record <responseFile> -skipInstall <agentDataLocation>
#
# For example:
#   Windows = IBMIM.exe -record c:\temp\responsefiles\WASv8.install.Win32.xml
#     -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#   Linux or UNIX = ./IBMIM -record /home/user/responsefiles/WASv8.install.RHEL64.xml
#     -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#
# Question 2. How do I run Installation Manager silently using response file?
# Answer 2. Create a silent installation response file and run the following command
# from the eclipse\tools subdirectory in the directory where you installed
# Installation Manager:
#
#   Windows = imcl.exe -acceptLicense -showProgress
#     input <response_file_path_and_name> -log <log_file_path_and_name>
#   Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#     input <response_file_path_and_name> -log <log_file_path_and_name>
#
# For example:
#   Windows = imcl.exe -acceptLicense -showProgress
#     input c:\temp\responsefile\WASv8.install.Win32.xml
#   Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#     input /home/user/responsefile/WASv8.install.RHEL64.xml
#
# The -acceptLicense command must be included to indicate acceptance of all
#     license agreements of all offerings being installed, updated or modified.
# The -showProgress command shows progress when running in silent mode.
# Additional commands can be displayed by requesting help:  IBMIM -help
#
# Question 3. How do I store and pass credentials to repositories that
# require authentication?
# Answer 3. Installation Manager uses a key ring file to store encrypted
# credentials for authenticating with repositories. Follow this two-step
# process for creating and using a key ring file with Installation Manager.
#
# First, create a key ring file with your credentials by starting
```

```
# Installation Manager from the command line under eclipse subdirectory
# with the keyring parameter.
# Use the optional password parameter to password protect your file.
#
#   Windows = IBMIM.exe -keyring <path and file name> -password <password>
#   Linux, UNIX, IBM i and z/OS = ./IBMIM -keyring <path and file name>
#                                 -password <password>
#
# Installation Manager will start in graphical mode. Verify that the
# repositories to which you need to authenticate are included in the
# preferences, File / Preferences / Repositories. If they are not
# listed, then click Add Repositories to add the URL or UNC path.
# Installation Manager will prompt for your credentials. If the repository
# is already in the list, then any attempt to access the repository location,
# such as clicking the Test Connections button, will also prompt for your
# credentials. Enter the correct credential and check the Save password
# checkbox. The credentials are saved to the key ring file you specified.
#
# Second, when you start a silent installation, run imcl under eclipse/tools
# subdirectory, and provide Installation Manager with the location of the key
# ring file and the password if the file is protected. For example:
#
#   Windows = imcl.exe -acceptLicense -showProgress
#     input <path and file name of response file>
#     -keyring <path and name of key ring file> -password <password>
#   Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#     input <path and file name of response file>
#     -keyring <path and name of key ring file> -password <password>
#
################################################################## -->

     # repository located on your own machine to install a
     # Pluggable Application Client offering.
     ############################################################ -->
    <!-- <repository location='insert the full directory path inside single quotes'/> -->
</server>

<!-- ##### Install Packages ######################################
#
# Install Command
#
# Use the install command to inform Installation Manager of the
# installation packages to install.
#
# The modify attribute is optional and can be paired with an install
# command to add features or paired with an uninstall command to
# remove commands. If omitted, the default value is set to false.
#    false = indicates not to modify an existing install by adding
#            or removing features.
#    true = indicates to modify an existing install by adding or
#           removing features.
#
# The offering ID attribute is required because it specifies the
# offering to be installed. The offering listed must be present in
# at least one of the repositories listed earlier. The example
# command below contains the offering ID for the Pluggable Application
# Client.
#
# The version attribute is optional. If a version number is provided,
# then the offering will be installed at the version level specified
# as long as it is available in the repositories. If the version
# attribute is not provided, then the default behavior is to install
# the latest version available in the repositories. The version number
# can be found in the repository.xml file in the repositories.
# For example, <offering ... version='8.0.0.20110617_2222'>.
#
# The profile attribute is required and typically is unique to the
# offering. If modifying or updating an existing installation, the
# profile attribute must match the profile ID of the targeted installation
# of Pluggable Application Client.
#
# The features attribute is optional. Offerings always have at least
# one feature; a required core feature which is installed regardless
# of whether it is explicitly specified. If other feature names
# are provided, then only those features will be installed.
# Features must be comma delimited without spaces.
#
# The feature values for Pluggable Application Client include:
#  pluggableclient.samples
#
# The installFixes attribute indicates whether fixes available in
# repositories are installed with the product. By default, all
# available fixes will be installed with the offering.
#
# Valid values for installFixes:
#      none = do not install available fixes with the offering.
#      recommended = installs all available recommended fixes with the offering.
#      all = installs all available fixes with the offering.
#
# Interim fixes for offerings also can be installed while they
# are being installed by including the offering ID for the interim
# fix and specifying the profile ID. A commented out example is
# provided in the install command below.
#
# Installation Manager supports installing multiple offerings at once.
# Additional offerings can be included in the install command,
# with each offering requiring its own offering ID, version, profile value,
# and feature values.
#
# Profile Command
#
# A separate profile command must be included for each offering listed
# in the install command. The profile command informs Installation
# Manager about offering specific properties or configuration values.
#
# The installLocation specifies where the offering will be installed.
# If the response file is used to modify or update an existing
# installation, then ensure the installLocation points to the
# location where the offering was installed previously.
#
# The eclipseLocation data key should use the same directory path to
# Pluggable Application Client as the installationLocation attribute.
#
# Include data keys for product specific profile properties.
#
```

```

<!-- ##### Shared Data Location ########################################
# Uncomment the preference for eclipseCache to set the shared data
# location the first time you use Installation Manager to do an
# installation.
#
# Eclipse cache location can be obtained from the installed.xml file found in
# C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager
# from the following property:
# <property name='cacheLocation' value='C:\Program Files\IBM\IMShared'/>
#
# Open the installed.xml file in a text editor because the style sheet
# might hide this value if opened in a web browser.
# For further information on how to edit preferences, refer to the public library at:
# http://publib.boulder.ibm.com/infocenter/install/v1r4/index.jsp?topic=/com.ibm.silentinstall12.doc/topics/r_silent_prefs.html
#
# After the shared data location is set, it cannot be changed
# using a response file or the graphical wizard.
#
# Ensure that the shared data location is a location that can be written
# to by all user accounts that are expected to use Installation Manager.
#
# By default, Installation Manager saves downloaded artifacts to
# the shared data location. This serves two purposes.
#
# First, if the same product is installed a more than once to the machine,
# then the files in the shared data location will be used rather than
# downloading them again.
#
# Second, during the rollback process, the saved artifacts are used.
# Otherwise, if the artifacts are not saved or are removed, then
# Installation Manager must have to access the repositories used to
# install the previous versions.
#
# Valid values for preserveDownloadedArtifacts:
#     true = store downloaded artifacts in the shared data location
#     false = remove downloaded artifacts from the shared data location
#

### *Uninstalling the Pluggable Application Client using the GUI:*

Use the Installation Manager GUI to uninstall the Pluggable Application Client.

**Procedure**

1. Uninstall the Pluggable Application Client.
   a. Stop all servers and applications on the Pluggable Application Client installation.
   b. Start Installation Manager.
   c. Click **Uninstall**.
   d. In the **Uninstall Packages** window, perform the following actions.
      1) Select **Pluggable Application Client for IBM WebSphere Application Server** and the appropriate version.

         **Note:** If you are uninstalling the ILAN version of this product, select **Pluggable Application Client for IBM WebSphere Application Server (ILAN)**.
      2) Click **Next**.
   e. Review the summary information.
   f. Click **Uninstall**.
      - If the uninstallation is successful, the program displays a message that indicates success.
      - If the uninstallation is not successful, click **View log** to troubleshoot the problem.
   g. Click **Finish**.
   h. Click **File > Exit** to close Installation Manager.
2. Optional: Uninstall IBM Installation Manager.

   **Important:** Before you can uninstall IBM Installation Manager, you must uninstall all of the packages that were installed by Installation Manager.

   Read Uninstalling Installation Manager in the Installation Manager information center for information about performing this procedure.

### *Uninstalling the Pluggable Application Client silently:*

You can use Installation Manager to uninstall the Pluggable Application Client silently.

**Before you begin**

**Optional:** Perform or record the installation of Installation Manager and installation of the Pluggable Application Client to a temporary installation registry on one of your systems so that you can use this temporary registry to record the uninstallation without using the standard registry where Installation Manager is installed.

Read the following for more information:

- “Installing the Pluggable Application Client using the GUI” on page 234
- “Installing the Pluggable Application Client silently” on page 238

### About this task

Using Installation Manager, you can work with response files to uninstall the Pluggable Application Client silently in a variety of ways. You can record a response file using the GUI as described in the following procedure, or you can generate a new response file by hand or by taking an example and modifying it.

### Procedure

1. Stop all servers and applications on the Pluggable Application Client installation that contains the product.
2. Optional: **Record a response file to uninstall the Pluggable Application Client:** On one of your systems, perform the following actions to record a response file that will uninstall the Pluggable Application Client:
   a. From a command line, change to the eclipse subdirectory in the directory where you installed Installation Manager.
   b. Start Installation Manager from the command line using the -record option.

      For example:

```
IBMIM.exe -skipInstall "C:\temp\imRegistry"
  -record C:\temp\uninstall_response_file.xml
```

      **Tip:** If you choose to use the -skipInstall parameter with a temporary installation registry created as described in "Before you begin," Installation Manager uses the temporary installation registry while recording the response file. It is important to note that when the -skipInstall parameter is specified, no packages are installed or uninstalled. All of the actions that you perform in Installation Manager simply update the installation data that is stored in the specified temporary registry. After the response file is generated, it can be used to uninstall the Pluggable Application Client, removing the Pluggable Application Client files and updating the standard installation registry.

      The -skipInstall operation should not be used on the actual agent data location used by Installation Manager. This is unsupported. Use a clean writable location, and re-use that location for future recording sessions.

      For more information, read the IBM Installation Manager Information Center.
   c. Click **Uninstall**.
   d. In the **Uninstall Packages** window, perform the following actions.
      1) Select **Pluggable Application Client for IBM WebSphere Application Server** and the appropriate version.

         **Note:** If you are uninstalling the ILAN version of this product, select **Pluggable Application Client for IBM WebSphere Application Server (ILAN)**.
      2) Click **Next**.
   e. Review the summary information.
   f. Click **Uninstall**.
      - If the uninstallation is successful, the program displays a message that indicates success.
      - If the uninstallation is not successful, click **View log** to troubleshoot the problem.
   g. Click **Finish**.
   h. Click **File > Exit** to close Installation Manager.
3. **Use the response file to uninstall the Pluggable Application Client silently:** From a command line on each of the systems from which you want to uninstall the Pluggable Application Client, change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager and use the response file that you created to silently uninstall the Pluggable Application Client.

   For example:

```
imcl.exe
  input C:\temp\uninstall_response_file.xml
  -log C:\temp\uninstall_log.xml
```

Go to the IBM Installation Manager Information Center for more information.

4. Optional: Uninstall IBM Installation Manager.

   **Important:** Before you can uninstall IBM Installation Manager, you must uninstall all of the packages that were installed by Installation Manager.

   Read the IBM Installation Manager Information Center for information about using the uninstall script to perform this procedure.

Windows

## Example

The following is an example of a response file for silently uninstalling the Pluggable Application Client.

```
<?xml version="1.0" encoding="UTF-8"?>

<!-- ##### Frequently Asked Questions ###################################
# The latest information about using Installation Manager is
# located in the online Information Center. There you can find
# information about the commands and attributes used in
# silent installation response files.
#
#     Installation Manager Information Center can be found at:
#     http://publib.boulder.ibm.com/infocenter/install/v1r4/index.jsp
#
# Question 1. How do I record a response file using Installation Manager?
# Answer 1. Start Installation Manager from the command line under the
# eclipse subdirectory with the record parameter and it will generate a
# response file containing actions it performed, repositories it used, and
# its preferences settings. Optionally use the -skipInstall parameter if
# you do not want the product to be installed to the machine. Specify a
# new agentDataLocation location value when doing a new installation. Do
# not use an existing agentDataLocation for an installation because it might
# damage the installation data and prevent you from modifying, updating,
# rolling back, or uninstalling the installed packages.
#
# Windows: IBMIM -record <responseFile> -skipInstall <agentDataLocation>
# Linux or UNIX: ./IBMIM -record <responseFile> -skipInstall <agentDataLocation>
#
# For example:
#   Windows = IBMIM.exe -record c:\temp\responsefiles\WASv8.install.Win32.xml
#     -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#   Linux or UNIX = ./IBMIM -record /home/user/responsefiles/WASv8.install.RHEL64.xml
#     -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#
# Question 2. How do I run Installation Manager silently using response file?
# Answer 2. Create a silent installation response file and run the following command
# from the eclipse\tools subdirectory in the directory where you installed
# Installation Manager:
#
#   Windows = imcl.exe -acceptLicense -showProgress
#     input <response_file_path_and_name> -log <log_file_path_and_name>
#   Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#     input <response_file_path_and_name> -log <log_file_path_and_name>
#
# For example:
#   Windows = imcl.exe -acceptLicense -showProgress
#     input c:\temp\responsefile\WASv8.install.Win32.xml
#   Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#     input /home/user/responsefile/WASv8.install.RHEL64.xml
#
# The -acceptLicense command must be included to indicate acceptance of all
#     license agreements of all offerings being installed, updated or modified.
# The -showProgress command shows progress when running in silent mode.
# Additional commands can be displayed by requesting help:  IBMIM -help
#
################################################################### -->

<!-- ##### Agent Input ##########################################

## Example: Enabling logging and tracing for application clients

The ActiveX to EJB bridge provides two logging and tracing formats: Windows Application Event Log and Java Trace Log.

- Windows Event Log

  The Windows Application Event Log shows JNI errors, Java console error messages, and XJB initialization messages. This log is most useful for determining `XJBInit()` errors and any unusual exceptions that do not come from the Java environment. By default, critical error logging will be enabled and debug and event logging is disabled.

  To enable or disable logging of certain event types to the Windows Event Log, specify one or more parameters to `XJBInit()`. If more than one parameter is set, they will be processed in the order in which they appear in the input string array to the `XJBInit()` method. Once the `XJBInit()` method is initialized, these parameters can no longer be set/reset for the life of the process. Using Java `java.lang.System.setProperty()` to set these values also has no effect.

  – `-Dcom.ibm.ws.client.xjb.native.logging.debug=enabled|disabled`

    Enables or disables debug level messages from displaying in the Windows operating system event log. This level of logging is most useful and shows most internal errors, user programming issues or configuration problems.

  – `-Dcom.ibm.ws.client.xjb.native.logging.event=enabled|disabled`

    Enables or disables event level messages from appearing in the Windows operating system event log.

  – `-Dcom.ibm.ws.client.xjb.native.logging.*=enabled|disabled`

    Enables or disables both event and debug level messages from appearing in the Windows operating system event log. It is not possible to disable some critical error messages from being displayed in the error log. Only debug and event level messages can be disabled.

  Viewing the Windows application event log with the event viewer:

To open the event viewer in the Windows operating system:

1. Click **Start** > **Settings** > **Control Panel**.
2. Double-click **Administrative Tools**.
3. Double-click **Event Viewer**.

All ActiveX to EJB bridge events display the text `WebSphere XJB` in the source column and in the application log. For information about using Event Viewer, click the **Action** menu in Event Viewer, and then click **Help**.

To open the even viewer in the Windows operating system, click **Start** > **Programs** > **Administrative Tools** > **Event Viewer**. All ActiveX to EJB bridge events have the text `WebSphere XJB` in the source column and display in the application log. For information about using Event Viewer, click the **Help** menu in Event Viewer.

- Java trace log

  The Java trace log displays information that you can use to debug method calls, class lookups, and argument coercion problems. Since the Java portion of the bridge mirrors the function of the COM IDispatch interface, the information in the trace log is similar to what you have come to expect from an IDispatch interface. To understand the trace log, you need a fundamental understanding of IDispatch.

  To enable user-logging, add the following parameters to the XJBInit() input string array:

```
"-DtraceString=com.ibm.ws.client.xjb.*=event=enabled"
"-DtraceFile=C:\MyTrace.txt"
```

# Chapter 7. Deploying client applications

Deploying a client application depends on installing appropriate supporting files on the client machine, usually some configuring actions, and adding the program files for the client application. When the client application has been deployed, the application can run.

### About this task

The steps required to deploy and run a client application depend on the type of client and the programming model used.

You can install an application client JAR file using the administrative console, wsadmin AdminApp install, or update commands. Install the client module only on a Version 8.0 deployment target (such as server, cluster, and so on).

Complete one or more of the following tasks:

### Procedure

- Deploy the client application
- Run an ActiveX client application
- Deploy and run a Java EE client application
- Run the IBM Thin Client for Enterprise JavaBeans

## Deploying applet client code

Applet clients are capable of communicating over the HTTP protocol and the RMI-IIOP protocol.

### Before you begin

Applet clients have the following setup requirements:
- These clients are available on the Windows platforms. Check the prerequisites page for information on platform support and product prerequisites.
- The browser installation precedes the client code installation.

### About this task

Unlike typical applets that are on web servers or WebSphere Application Servers and can only communicate over the HTTP protocol, applet clients can communicate over the HTTP protocol and the RMI-IIOP protocol. This additional capability gives the applet direct access to enterprise beans.

The applet container is the web browser and the Java plug-in combination. You must first install the Application Client for WebSphere Application Server so that the browser recognizes the IBM product Java plug-in.

### Procedure

1. Install the Application Client for WebSphere Application Server.
2. Configure required Java runtime parameters.
   a. Click **Start** > **Control panel** .
   b. Select the IBM Control Panel for Java
   c. On the Advanced tab, enter the following parameter values in the Java Runtime Parameters field.

© Copyright IBM Corp. 2011

```
-Xmx512M
-Djava.security.policy=<app_client_root>\properties\client.policy
-Dwas.install.root=<app_client_root>
-Djava.ext.dirs=<app_client_root>\java\jre\lib\ext;
<app_client_root>\lib;
<app_client_root>\plugins;
<app_client_root>\lib\ext;
<app_client_root>\installedConnectors\
-Djava.class.path=<app_client_root>\properties
-Dcom.ibm.CORBA.ConfigURL=file:<app_client_root>\properties\sas.client.props
-Dcom.ibm.SSL.ConfigURL=file:<app_client_root>\properties\ssl.client.props
```

**Note:** These parameter entries are automatically placed into the WebSphere Application Server control panel for the Java plug-in user who installed the WebSphere Application Server Application Client provided you are using a Java SE Development Kit (JDK) prior to JDK 1.5. If the applet is being run by a user other than the person who installed the client, then that user must enter the parameter entries.

For JDK 1.5 and later, this automatic parameter feature is removed.

- The Java Runtime Parameters field is similar to the command prompt when using command line options. Therefore, you can enter most options available from the command prompt (for example, -cp, classpath, and others) in this field as well.

3. Configure use of secure sockets layer (SSL) for secure access to resources. By default, the applet client is configured to have security enabled. If you have administrative security turned on at the server from which you are accessing resources, then you can use SSL when needed. If you decide that the security requirements for applet client applications differ from other types of client applications, then you can create special copies of client property files for applets to use.

## Running an ActiveX client application

To run an ActiveX client application that is to use the ActiveX to Enterprise Java Beans (EJB) bridge, you must perform some initial configuration to set appropriate environment variables and to enable the ActiveX to EJB bridge to find its `XJB.JAR` file and the Java run time. This initial configuration sets up the environment within which the ActiveX client application can run.

### About this task

To perform the required configuration, complete one or more of the following tasks:

### Procedure

1. Start an ActiveX application and configure service programs.
2. Start an ActiveX application and configuring non-service programs

## Starting an ActiveX application and configuring service programs

To run an ActiveX service program such as Active Server Page (ASP) that is to use the ActiveX to the Enterprise Java Bean (EJB) bridge, some initial configuration (to set appropriate environment variables and to enable the ActiveX to EJB bridge to find its `XJB.JAR` file and the Java run time) is necessary. This configuration sets up the environment within which the ActiveX service program can run.

### Before you begin

The XJB.JClassFactory must find the Java run time dynamic link library (DLL) when initializing. In a service program such as Internet Information Server you cannot specify a path for its processes independently; you must set the process paths in the system PATH variable. This limitation means that you can only have a single Java virtual machine (JVM) version available on a machine using ASP.

### About this task

To add the Java Runtime Environment (JRE) directories to your system path, complete one of the following task.

### Procedure

On Windows XP systems, complete the following steps:
1. Open the Control Panel, then double-click the **System** icon.
2. Click the **Advanced** tab on the System Properties window.
3. Click **Environment Variables**.
4. Edit the Path variable in the System Variables window.
5. Add the following information to the beginning of the path that is displayed in the Variable Value field:

   `C:\WebSphere\AppClient\Java\jre\bin;C:\WebSphere\AppClient\Java\jre\bin\classic;`

   where `C:\WebSphere\AppClient` is the directory in which you installed the Java client in the WebSphere product.
6. Click **OK** in the Edit System Variable window to apply the changes.
7. Click **OK** in the Environment Variables window.
8. Click **OK** in the System Properties window.
9. Restart Windows XP.

### What to do next

After you change the system PATH variable you must reboot the Internet Information Server machine so that Internet Information Server can see the change.

## Starting an ActiveX application and configuring non-service programs

To run an ActiveX program initiated from an icon or command line (a non-service program) that is to use the ActiveX to the Enterprise Java Beans (EJB) bridge, you must perform some initial configuration to set appropriate environment variables and to enable the ActiveX to EJB bridge to find its `XJB.JAR` file and the Java run-time environment. This uses a batch file to set up the environment within which the ActiveX program can run.

### About this task

To perform the required configuration, complete the following steps:

### Procedure

1. Edit the `setupCmdLineXJB.bat` file to specify appropriate values for the environment variables required by the ActiveX to EJB bridge. For more information about these environment variables, see ActiveX to EJB bridge, environment and configuration. For more information about creating a JVM for an ActiveX program, see ActiveX to EJB bridge, initializing the Java virtual machine (JVM). After the ActiveX program has created an XJB.JClassFactory object and called the XJBInit() method, the JVM is initialized and ready for use.
2. Start the ActiveX client application by using one of the following methods:
   - Use the `launchClientXJB.bat` file to start the application. For example:

     `launchClientXJB MyApplication.exe` *`parm1 parm2`*

     or

     `launchClientXJB MyApplication.vbp`
   - Use the `setupCmdLineXJB.bat` file to create an environment in which to run the application, then start the application from within that environment.

# setupCmdLineXJB.bat, launchClientXJB.bat and other ActiveX batch files

This topic provides reference information about the aids that client applications and client services can use to access the ActiveX to EJB bridge. These enable the ActiveX to Enterprise JavaBeans (EJB) bridge to find its XJB.JAR file and the Java run-time environment.

## Location

The include file is located in the *was_client_home*\aspIncludes directory. You can include the file into your Active Server Pages (ASP) application with the following syntax in your ASP page:

```
<--  #include virtual ="/WSASPIncludes/setupASPXJB.inc" -->
```

This syntax assumes that you have created a virtual directory in Internet Information Server called WSASPIncludes that points to the *was_client_home*\aspIncludes directory.

## Usage notes

The following batch files are provided for client applications to use the ActiveX to EJB bridge:

- **setupCmdLineXJB.bat**

  Sets the client environment variables.
- **launchClientXJB.bat**

  Calls the setupCmdLineXJB.bat file and launches the application you specify as its arguments; for example:

  ```
  launchClientXJB.bat myapp.exe parm1 parm2
  ```

  or

  ```
  launchClientXJB MyApplication.vbp
  ```
- **Active Server Pages (ASP) include file**

  An include file is provided for ASP users to automatically set the following page-level (local) environment variables:
  - **com_ibm_websphere_javahome**. Path to the Java run-time directory installed with the WebSphere advanced server client.
  - **com_ibm_websphere_washome**. Path to the WebSphere advanced server client directory.
  - **com_ibm_websphere_namingfactory**. Sets the Java java.naming.factory.initial system property.
  - **com_ibm_websphere_computername**. (Optional) Name of the computer where the WebSphere Advanced Server Client is installed. If you intend to talk to a single specific computer, you are recommended to change this value to become the server name that you intend to access.
- **System settings**

  To enable the ActiveX to EJB bridge to access the Java run-time dynamic link library (DLL), the following directories must exist in the system PATH environment variable:

  ```
  was_client_home\java\jre\bin;was_client_home\java\jre\bin\classic
  ```

  Where *was_client_home* is the name of the directory where you installed the WebSphere Application Server client (for example, C:\WebSphere\AppClient).

  **Note:** This technique enables only one Java run time to activate on a machine, therefore all client services on that machine must use the same Java run time. Client applications do not have this limitation because they each have their own private, non-system scope.

# Deploying and running a Java EE client application

You can use the launchClient command to run a Java Enterprise Edition (EE) client application in an Application Client installation or in a WebSphere Application Server node. Alternatively, you can use Java Web Start on a remote client machine to download and run a Java EE client application, including Thin client application, with a single click from a web browser on that machine.

## Procedure

1. Deploy and run a Java EE client application for use with the launchClient command.

   After deploying a Java EE client application onto a machine with an Application Client installation or in a WebSphere Application Server node, you can start the application by using the launchClient command on that machine.

   a. Deploy the Java EE client application

   b. Start the Java EE client application

2. Deploy and run a Java EE client application by using Java Web Start.

   a. Prepare the Java EE client application ready to be deployed by remote action.

   b. Use Java Web Start on a remote client machine to download and run the Java EE client application.

# Deploying a Java EE client application

Deploying a Java EE client application onto the client machines where it is to run includes distributing the EAR file for the client application and configuring resource references for use by the client application.

## Before you begin

To run a deployed Java EE client application, the application needs access to a Application Client installation or a WebSphere Application Server installation.

For information about installing the Application Client on a client machine, refer to the Installing Application Client for WebSphere Application Server topic.

**Attention:** Application Client for WebSphere Application Server ships only with the 32-bit WebSphere Application Server.

## About this task

Use this topic only if you later want to use the want to launchClient command to run the Java client application on an Application Client installation or in a WebSphere Application Server node.

If you want to download and run a Java EE client application remotely, you can use the Java Web Start to deploy the application onto the remote client machine with a single click from a Web browser on the client machine. For information about using Java Web Start to deploy Java EE client applications, see “Downloading and running a Java EE client application by using Java Web Start”.

## Procedure

1. Distribute the EAR file.

   The client machines configured to run a client application must have access to the EAR file.

   - If all the machines in your environment share the same image and platform, run the Application Client Resource Configuration Tool (ACRCT) on one machine to configure the external resources, then distribute the configured EAR file to the other machines.
   - If your environment is set up with a variety of client installations and platforms, run the ACRCT for each unique configuration.

- You can either distribute an EAR file to the correct client machines, or make it available on a network drive.
- Distributing EAR files is the responsibility of the system and network administrator.

2. Configure the resources for the application client. This generally involves using the Application Client Resource Configuration Tool (ACRCT) to configure references for the resources that the application is to use, including resource adapters, resource providers, data sources, and Java Message Service resources. These configurations are stored in the client JAR file within the application EAR file. The client runtime uses these configurations to resolve and create an instance of the resources for the client application.

   For some types of resources, other actions are needed; for example, to install a resource adapter and define environment variable needed to start the client application. More information about the actions for different types of resources is given in other configuring resources topics.

   If you plan to deploy the client application on z/OS, run the ACRCT on Windows. You can also run the ACRCT for distributed platforms locally.

   If the client application defines the local resources, but the resources are installed in a different location, run the ACRCT (clientConfig command) on the local machine to change the configuration in the EAR file. For example, the EAR file can contain a DB2 resource, configured as `C:\DB2`. If, however, you installed DB2 in the `D:\Program Files\DB2` directory, use the ACRCT to create a local version of the EAR file.

## What to do next

After deploying the Java EE client application, use the launchClient command to run the client application.

## Starting the Application Client Resource Configuration Tool and opening an EAR file

You can perform many tasks by starting the Application Client Resource Configuration Tool (ACRCT). Many of these tasks also involve then opening an EAR file.

### Before you begin

**Attention:** This task only applies to Java Platform, Enterprise Edition (Java EE) application clients.

### About this task

Use these steps to start the Application Client Resource Configuration Tool. When you start the tool, one of the most common tasks that you perform is opening and modifying the components of EAR files.

### Procedure

1. Open a command prompt and change to the *app_server_root*`\bin` directory.
2. Run the `clientConfig.bat` file.

   **Note:** Vista Windows 7 When running the `clientConfig.bat` file, run the script using the administrator account that was created when you installed the operating system.

3. Open an EAR file within the Application Client Resource Configuration Tool (ACRCT):
   a. Click **File** > **Open**.
   b. Select the file then click **Open**.
4. Save your changes to the file and close the tool:
   a. Click **File** > **Save**.
   b. Click **File** > **Exit**.

## Deploying a resource adapter for a Java EE client application

A Java EE client application can use a resource adapter to connect to an enterprise information system (EIS). To use a resource adapter, you need to install it, configure it, and configure related resources.

## About this task

The resource adapter support provided for Java EE client applications is a subset of the support provided for application servers. A client resource adapter is used in a non-managed environment and must conform to the J2EE Connector Architecture Specification Version 1.5 or higher. Only outbound connections to the EIS are supported through the ManagedConnectionFactory interfaces. The inbound messaging support (from the EIS), life cycle management, and work management aspects of the specification are not supported on the client.

When running Java EE application clients, the launchClient script specifies a system property called **com.ibm.ws.client.installedConnector**, which is set to the same value as the *CLIENT_CONNECTOR_INSTALL_ROOT* variable. This is the default location for installed resource adapters and can be overridden for each launchClient call by specifying the **-CCD** parameter. When the client container is activated, all resource adapter subdirectories under the specified default location for the resource adapters directory are added to the classpath. This action allows the client application to use the resource adapters without using the ACRCT to specify any of the client resources.

## Procedure

1. Install the resource adapter archive (RAR) file

   For a client application to use a resource adapter, the RAR file must be installed in the directory specified by the environment variable, CLIENT_CONNECTOR_INSTALL_ROOT, defined when the setupCmdLine script runs. The launchClient tool, Application Client Resource Configuration Tool (ACRCT) and clientRAR tool all use this variable to find the default location of all installed resource adapters.

   To install a RAR file for a client application, use the clientRAR tool.
2. Configure the resource adapter and its resources for the client application Use the Application Client Resource Configuration Tool (ACRCT) to define the resource adapter, connection factories, and administered objects in the EAR file for the client application. The client application uses this configuration to resolve and create an instance of the resource adapter and the other resources.
   a. Configure the resource adapter
   b. Configure a connection factory
   c. Configure administered objects

### *clientRAR tool:*

This topic describes the command line syntax for the client resource adapter installation tool.

If this tool is used to add or delete resource adapters on the server, then only the client can use the resource adapter. If the resource adapter is installed on the server using the wsadmin tool or the administrative console, then do not use the clientRAR tool remove it. Only resource adapters that are installed using the clientRAR tool should be removed using the clientRAR tool.

The command line invocation syntax for the `clientRAR` tool follows:

```
clientRAR [-help | -?] [-CRDcom.ibm.ws.client.installedConnectors=<dir>] <task> <archive>

where
-help, -?
Print the usage information.
-CRDcom.ibm.ws.client.installedConnectors
The directory where resource adapters are installed.
This will override the system property of the same name
(com.ibm.ws.client.installedConnectors).

<task>
The task to perform: add - install, delete - uninstall.
```

```
<archive>
if task=add then this is the fully qualified name of the resource adapter archive file.
If task=delete then this is the filename of the resource adapter archive to be uninstalled.
```

The following examples demonstrate correct syntax.

Windows On Windows operating systems:

- clientRAR add c:\rars\myrar.rar
- clientRAR delete myrar.rar

AIX Linux HP-UX Solaris On UNIX and Linux operating systems:

- ./clientRAR add /usr/rars/myrar.rar
- ./clientRAR delete myrar.rar

***Configuring resource adapters for the client:***

Use the Application Client Resource Configuration Tool (ACRCT) to configure resource adapters for the client.

**Procedure**

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new resource adapters. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new resource adapters from the tree.
4. Expand the JAR file to view its contents.
5. Right-click the Resource Adapters folder, and click **New**.
6. Configure the resource adapter settings in the resulting property dialog.
7. Click **OK**.
8. Click **File > Save** on the menu bar to save your changes.

*Resource adapters for the client:*

A resource adapter is a system-level software driver that a Java application uses to connect to an enterprise information system (EIS). A resource adapter plugs into an application client and provides connectivity between the EIS and the enterprise application.

**Important:** This topic is not relevant to the WebSphere MQ resource adapter. WebSphere MQ classes are picked up automatically by the client container (for both stand alone and with a WebSphere Application Server installation).

The resource adapter support for the Java EE client applications is a subset of the support for the server. For any resource adapter installed using the clientRAR tool, the client resource adapter is used in a non-managed environment and must conform to the Java EE Connector Architecture Specification Version 1.5 or higher. Only outbound connections to the EIS are supported through the ManagedConnectionFactory interfaces. The inbound messaging support (from the EIS), life cycle management, and work management aspects of the specification are not supported on the client.

For a client application to use a resource adapter, it must be installed in the directory specified by the environment variable, CLIENT_CONNECTOR_INSTALL_ROOT, defined when the setupCmdLine script runs. The launchClient tool, Application Client Resource Configuration Tool (ACRCT) and clientRAR tool all use this variable to find the default location of all installed resource adapters. To install a resource adapter in the client, use the clientRAR tool. Once the resource adapter is installed, it must be configured using

the ACRCT. The client configuration tool adds the resource adapter configuration to the EAR file. Then, connection factories and administered objects are defined.

When running Java EE application clients, the `launchClient` script specifies a system property called `com.ibm.ws.client.installedConnector`, which is set to the same value as the `CLIENT_CONNECTOR_INSTALL_ROOT` variable. This is the default location for installed resource adapters and can be overridden for each `launchClient` call by specifying the `-CCD` parameter. When the client container is activated, all resource adapter subdirectories under the specified default location for the resource adapters directory are added to the classpath. This action allows the client application to use the resource adapters without using the ACRCT to specify any of the client resources.

Using resource adapters is a new mechanism for easily extending client applications.

*Resource adapter settings:*

Use this panel to view or change the configuration properties of the resource adapter. These configuration properties control how resource adapters are created.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapter**. Right-click **Resource Adapter** and click **New**. The following fields appear on the **General** tab.

*Name:*

The name by which this Resource Adapter is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the Resource Adapters across the product administrative domain.

**Data type** String

*Description:*

A description of this resource adapter for administrative purposes within IBM WebSphere Application Server.

**Data type** String

*Class Path:*

Any additional class path. The path to the resource adapter directory is automatically added.

**Data type** String
**Default** The path to your Resource Adapter directory.

*Native Path:*

The native path where the Resource Adapter is located. Enter any additional native class path here.

**Data type** String

*Resource Adapter Name:*

A mandatory field that points to an installed resource adapter subdirectory. The entry does not represent the full directory name for the resource adapter. The full directory name is the installed resource adapter path, plus the resource adapter name.

**Data type** String

*Installed Resource Adapter Path:*

The directory where resource adapters are installed. If you do not complete this field, then the default takes effect.

If you specify the value, `${CONNECTOR_INSTALL_ROOT}`, then this value replaces the value of the `CLIENT_CONNECTOR_INSTALL_ROOT` variable on the machine on which the client application runs. This action allows the application to run easily on different machines, where the client installation might be in different locations.

**Data type** String
**Default** ${CONNECTOR_INSTALL_ROOT}

### *Configuring new connection factories for resource adapters for the client:*

Use the Application Client Resource Configuration Tool (ACRCT) to configure new connection factories for resource adapters for the client.

#### About this task

Complete this task to configure new connection factories for resource adapters.

#### Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new connection factories. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new connection factories from the tree.
4. Expand the JAR file to view its contents.
5. Click the Resource Adapters folder.
6. Expand the resource adapter for which you want to create connection factories.
7. Right-click the Connection Factories folder and click **New**.
8. Configure the connection factory properties in the resulting property dialog.
9. Click **OK**.
10. Click **File > Save** on the menu bar to save your changes.

*Resource adapter connection factory settings:*

Use this panel to view or change the configuration properties of the selected resource adapter connection factory.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapters**. Right-click the **Connection Factories** folder, and click **New**. The following fields appear on the **General** tab.

*Name:*

The name by which this connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the resource adapter connection factories across the product administrative domain.

**Data type** String

*Description:*

An optional description of this connection factory for administrative purposes within IBM WebSphere Application Server.

**Data type** String

*JNDI Name:*

The JNDI name that is used to match this resource adapter connection factory definition to the deployment descriptor. This entry should be a `resource-ref` name.

**Data type** String

*User Name:*

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly when getting a connection. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly when getting a connection.

**Data type** String

*Password:*

Specifies an encrypted password. If you complete this field, then the **Password** field in the Properties box is ignored.

If you specify a value for the **UserName** property, you must also specify a value for the **Password** property.

**Data type** String

*Re-Enter Password:*

Confirms the password.

*Type:*

A drop-down list of all the `connectionFactoryInterfaces` as defined for the factories in the Resource Adapter Archive.

For each **Type**, there is a set of properties specified in the Properties box. This set of properties is constructed by retrieving the properties from each connection definition object. For any existing connection factories that are displayed for updating, this list of properties is overlaid with the properties specified for the objects. When the **Type** field is changed, the properties also change to reflect the correct properties for that type.

**Data type** String

***Configuring administered objects for resource adapters for the client:***

This section helps you configure new administered objects for the client.

**Before you begin**

Before you configure new administered objects, you must complete the following prerequisites:

1. Install the Resource Adapter Archive file (RAR) using the clientRAR tool.
2. Configure the resource adapter for the `.ear` file, using the Application Client Resource Configuration Tool (ACRCT) tool.

**About this task**

Complete this task to configure new administered objects for installed resource adapters.

**Procedure**

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new administered objects. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new administered objects from the tree.
4. Expand the JAR file to view its contents.
5. Click the **Resource Adapters** folder.
6. Expand the resource adapter for which you want to create administered objects.
7. Right-click the **Administered Objects** folder and click **New**.
8. Configure the administered object properties in the resulting property dialog.
9. Click **OK**.
10. Click **File > Save** on the menu bar to save your changes.

*Administered objects settings:*

Use this panel to view or change the configuration properties of the selected administered objects.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapters** > *resource_adapter_instance*. Right-click **Administered Objects** and click **New**. The following fields appear on the **General** tab.

The settings for administered objects are handled similarly to connection factories. When updating administered objects, use the same panels that you used to create administered objects.

*Name:*

The name by which this administered object is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the resource adapter administered objects across the product administrative domain.

**Data type** String

*Description:*

An optional description of this connection factory for administrative purposes within IBM WebSphere Application Server.

**Data type** String

*JNDI Name:*

This entry is a `resource-env-ref` name, a `message-destination-ref` name (if the `message-destination-ref` has no link), or a `message-destination` link.

**Data type** String

*Type:*

A drop-down list of all the administered object class-interface pairs as defined for the admin objects in the Resource Adapter Archive (RAR) file.

For each **Type**, there is a set of properties specified in the Properties box. This set of properties is constructed by retrieving the properties from each administered object definition. For any existing administered objects that are displayed for updating, this list of properties is overlaid with the properties specified for the objects. When the **Type** field is changed, the properties also change to reflect the correct properties for that type.

**Data type** String

## Enabling client use of data sources

If a Java EE client application accesses a database directly, you must provide the database drivers on the client machine, and configure the data source provider (JDBC provider) and data sources. Instead of accessing the database directly, it is recommended that your client application access the database through an enterprise bean.

### About this task

WebSphere Application Server and the Application Client for WebSphere Application Server do not provide client database drivers to be used directly from a Java EE client application. You can contact your database vendor to get client database driver code and licenses.

Data sources configured on the server and looked up on the client do not participate in global transactions.

Instead of accessing the database directly, it is recommended that your client application access the database through an enterprise bean. This technique eliminates the need to have database drivers on the client machine, because the database access is handled by the enterprise bean running on WebSphere Application Server. It also enables the client application to take advantage of the pooling and additional database functions provided by the server.

For a current list of data source providers that are supported on WebSphere Application Server, see the WebSphere Application Server prerequisite website.

## Procedure

1. For direct access from a client to the database, install the client database drivers on the client machine. For information about installing database drivers, see the documentation provided by your database vendor.
2. Configure a data source provider and a data source for the client application Use the Application Client Resource Configuration Tool (ACRCT) to define the data source provider and a data source in the EAR file for the client application. The client application uses this configuration to resolve and create an instance of the data source provider and data source.
   a. Configure a new data source provider. This provider describes the JDBC database implementation for your client application.
   b. Configuring a new data source This describes the client properties of the database your client application uses.

### *Configuring new data source providers (JDBC providers) for application clients:*

You can create new data source providers, also known as JDBC providers, for your application client using the Application Client Resource Configuration Tool (ACRCT).

#### Before you begin

During this task, you create new data source providers, also known as JDBC providers, for your application client. In a separate administrative task, install the Java code for the required data source provider on the client machine on which the application client resides.

#### About this task

Use this task to connect application clients to relational databases.

#### Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the EAR file for which you want to configure the new data source provider. The EAR file contents display in a tree view.
2. Select the JAR file in which you want to configure the new data source provider from the tree.
3. Expand the JAR file to view its contents.
4. Click the Data Source Providers folder. Do one of the following:
   - Right-click the folder and click **New Provider**.
   - Click **Edit > New** on the menu bar.
5. Configure the data source provider properties in the resulting property dialog.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

#### Example

You can configure data source provider and data source settings.

- Configuring data source provider and data source settings

The following code examples illustrates how to use configure data source provider and data source settings:

```
<resources.jdbc:JDBCProvider xmi:id="JDBCProvider_1" name="jdbcProvider:name"
description="jdbcProvider:description" implementationClassName="jdbcProvider:
ImplementationClass">
<classpath>jdbcProvider:classPath</classpath>
<factories xmi:type="resources.jdbc:WAS40DataSource" xmi:id="WAS40DataSource_1"
name="jdbcFactory:name" jndiName="jdbcFactory:jndiName"
description="jdbcFactory:description" databaseName="jdbcFactory:databasename">
```

```
<propertySet xmi:id="J2EEResourcePropertySet_13">
<resourceProperties xmi:id="J2EEResourceProperty_13" name="jdbcFactory:customName"
value="jdbcFactory:customValue"/>
<resourceProperties xmi:id="J2EEResourceProperty_14" name="user"
value="jdbcFactory:user"/>
<resourceProperties xmi:id="J2EEResourceProperty_15" name="password"
value="{xor}NTs9PBk+PCswLSZlMT4yOg==/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_14">
<resourceProperties xmi:id="J2EEResourceProperty_16" name="jdbcProvider:customName"
value="jdbcProvider:customeValue"/>
</propertySet>
</resources.jdbc:JDBCProvider>
```

- Required fields:
  - Data Source Provider Properties page: name
  - Data Source Properties page: name, jndiName
- Special cases:
  - The user name and password fields have no equivalent XMI tags. You must specify these fields in the custom properties.
  - The password is encrypted when you use the Application Client Resource Configuration Tool (ACRCT). If you do not use the ACRCT the field cannot be encrypted.

*Example: Configuring data source provider and data source settings:*

You can configure data source provider and data source settings.

The purpose of this article is to help you to configure data source provider and data source settings.

- Required fields:
  - Data Source Provider Properties page: name
  - Data Source Properties page: name, jndiName
- Special cases:
  - The user name and password fields have no equivalent XMI tags. You must specify these fields in the custom properties.
  - The password is encrypted when you use the Application Client Resource Configuration Tool (ACRCT). If you do not use the ACRCT the field cannot be encrypted.
- Example:

```
<resources.jdbc:JDBCProvider xmi:id="JDBCProvider_1" name="jdbcProvider:name"
description="jdbcProvider:description" implementationClassName="jdbcProvider:
ImplementationClass">
<classpath>jdbcProvider:classPath</classpath>
<factories xmi:type="resources.jdbc:WAS40DataSource" xmi:id="WAS40DataSource_1"
name="jdbcFactory:name" jndiName="jdbcFactory:jndiName"
description="jdbcFactory:description" databaseName="jdbcFactory:databasename">
<propertySet xmi:id="J2EEResourcePropertySet_13">
<resourceProperties xmi:id="J2EEResourceProperty_13" name="jdbcFactory:customName"
value="jdbcFactory:customValue"/>
<resourceProperties xmi:id="J2EEResourceProperty_14" name="user"
value="jdbcFactory:user"/>
<resourceProperties xmi:id="J2EEResourceProperty_15" name="password"
value="{xor}NTs9PBk+PCswLSZlMT4yOg==/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_14">
<resourceProperties xmi:id="J2EEResourceProperty_16" name="jdbcProvider:customName"
value="jdbcProvider:customeValue"/>
</propertySet>
</resources.jdbc:JDBCProvider>
```

*Data source provider settings for application clients:*

Use this page to create a data source under a JDBC provider which provides the specific JDBC driver implementation class.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Data Source Providers** > and click **New**. The following fields appear on the **General** tab:

*Name:*

Specifies the display name for the data source.

For example you can set this field to *Test Data Source*.

**Data type** String

*Description:*

Specifies a text description for the resource.

**Data type** String

*Class Path:*

A list of paths or `.jar` file names which together form the location for the resource provider classes.

*Implementation class:*

Use this setting to perform database specific functions.

**Data type** String
**Default** Dependent on JDBC driver implementation class

*Custom Properties:*

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

***Configuring new data sources for application clients:***

Learn how to create date sources for application clients.

**About this task**

During this task, you create new data sources for your application client.

**Procedure**

1. Click the data source provider for which you want to create a data source in the tree. Take one of the following actions as needed:
   - Configure a new data source provider.
   - Click an existing data source provider.

2. Expand the data source provider to view its Data Sources folder.
3. Click the data source folder. Take one of the following actions as needed:
   - Right click the data source folder and click **New Factory**.
   - Click **Edit > New** on the menu bar.
4. Configure the data source properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

*Data source properties for application clients:*

Use this page to create or modify the data sources.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Data Source Providers** > *Data source provider instance*. Right-click **Data Sources** and click **New**. The following fields are displayed on the **General** tab:

*Name:*

Specifies the display name of this data source.

**Data type** String

*Description:*

Specifies a text description of the data source.

**Data type** String

*JNDI Name:*

The application client run time uses this field to retrieve configuration information.

*Database Name:*

The name of the database to which you want to connect.

*User:*

Use the user ID with the Password property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the User ID property, then you must also specify a value for the Password property. The connection factory User ID and Password properties are used if the calling application does not provide a user ID and password explicitly.

*Password:*

Use the password with the User ID property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the Password property, then you must also specify a value for the User ID property.

*Re-Enter Password:*

Confirms the password.

*Custom Properties:*

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

## Configuring mail providers and sessions for application clients

You can edit the configurations of mail sessions and providers for your application clients using the Application Client Resource Configuration Tool (ACRCT).

### About this task

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of mail sessions and providers for your application clients to use.

### Procedure

1. Start the ACRCT.
2. Open an EAR file.
3. Locate the mail objects in the tree that is displayed for the EAR file. For example, if your file contains mail sessions, expand **Resources** > ***application*.jar** > **Mail Providers** > ***java_mail_provider_instance*** > **Mail Sessions**.

   In this example, ***java_mail_provider_instance*** is a particular mail provider.

### Results

The mail session instances are located in the JavaMail Sessions folder.

### Example

You can configure mail provider and mail session settings.

- Configuring mail provider and mail session settings for application clients

The following code examples illustrates how to configure mail provider and mail session settings for application clients:

```
<resources.mail:MailProvider xmi:id="builtin_mailprovider" name="Built-in Mail Provider" description="The built-in mail provider">
  <factories xmi:type="resources.mail:MailSession"
             xmi:id="MailSession_1207766754834" name="MailSession"
             jndiName="mail/session" description="Sample mail session" category="Sample"
             mailTransportHost="smtp.coldmail.com" mailTransportUser="transportUser"
             mailTransportPassword="{xor}Lz4sLChvLTs="
             mailFrom="smith@coldmail.com" mailStoreHost="imap.coldmail.com" mailStoreUser="storeUser"
             mailStorePassword="{xor}Lz4sLChvLTs="
             debug="true" strict="true"
             mailTransportProtocol="builtin_smtp" mailStoreProtocol="builtin_imap">
    <propertySet xmi:id="J2EEResourcePropertySet_1207766778585">
      <resourceProperties xmi:id="J2EEResourceProperty_1207766778585" name="key" type="java.lang.String" value="value" required="false"/>
    </propertySet>
  </factories>
  <protocolProviders xmi:id="builtin_smtp" protocol="smtp" classname="com.sun.mail.smtp.SMTPTransport" type="TRANSPORT"/>
  <protocolProviders xmi:id="builtin_pop3" protocol="pop3" classname="com.sun.mail.pop3.POP3Store" type="STORE"/>
  <protocolProviders xmi:id="builtin_imap" protocol="imap" classname="com.sun.mail.imap.IMAPStore" type="STORE"/>
  <protocolProviders xmi:id="builtin_smtps" protocol="smtps" classname="com.sun.mail.smtp.SMTPSSLTransport" type="TRANSPORT"/>
  <protocolProviders xmi:id="builtin_pop3s" protocol="pop3s" classname="com.sun.mail.pop3.POP3SSLStore" type="STORE"/>
  <protocolProviders xmi:id="builtin_imaps" protocol="imaps" classname="com.sun.mail.imap.IMAPSSLStore" type="STORE"/>
</resources.mail:MailProvider>
```

- Required fields:
  - Mail Provider Properties page: name, and at least one protocol provider
  - Mail Session Properties page: name, jndiName, outgoing server and protocol, and/or incoming server and protocol
- Special cases:
  - If you use the ACRCT tool, the password field will be encrypted. You cannot encrypt the password field if you do not use the ACRCT tool.

***Mail provider settings for application clients:***

Use this page to implement the JavaMail API and create mail sessions.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Mail Providers** > and click **New**. The following fields appear on the **General** tab:

*Name:*

The name of the JavaMail resource provider.

*Description:*

An optional description for the resource provider.

*Class Path:*

Specifies a list of paths or JAR file names which together form the location for the resource provider classes.

*Protocol:*

Specifies the name of the protocol.

*Classname:*

Specifies the name of the class implementing the protocol. Leave this field blank if you want to use the default implementation.

*Type:*

This menu contains the following two values: `TRANSPORT` or `STORE`.

*Custom Properties:*

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

***Mail session settings for application clients:***

Use this page to configure mail session properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Mail Providers** > *mail provider instance*. Right-click **Mail Sessions** and click **New**. The following fields appear on the **General** tab:

*Name:*

Represents the administrative name of the JavaMail session object.

*Description:*

Provides an optional description for your administrative records.

*JNDI Name:*

The application client run time uses this field to retrieve configuration information.

*Mail Transport Host:*

Specifies the server to connect to when sending mail.

*Mail Transport Protocol:*

Specifies the transport protocol to use when sending mail.

*Mail Transport User:*

Specifies the user ID to use when the mail transport host requires authentication.

*Mail Transport Password:*

Specifies the password to use when the mail transport host requires authentication.

*Enable strict Internet address parsing:*

Specifies whether the recipient addresses must be parsed strictly in compliance with RFC 822, which is a specifications document issued by the Internet Architecture Board.

This setting is not generally used for most mail applications. RFC 822 syntax for parsing addresses effectively enforces a strict definition of a valid email address. If you select this setting, JavaMail will adhere to RFC 822 syntax and reject recipient addresses that do not parse into valid email addresses (as defined by the specification). If you do not select this setting, JavaMail will not adhere to RFC 822 syntax and will accept recipient addresses that do not comply with the specification. By default, this setting is deselected. You can view the RFC 822 specification at the following URL for the World Wide Web Consortium (W3C): http://www.w3.org/Protocols/rfc822/.

*Re-Enter Password:*

Confirms the password.

*Mail From:*

Specifies the mail originator.

*Mail Store Host:*

Specifies the mail account host (or "domain") name.

*Mail Store User:*

Specifies the user ID of the mail account.

*Mail Store Password:*

Specifies the password of the mail account.

*Re-Enter Password:*

Confirms the password.

*Mail Store Protocol:*

Specifies the protocol to be used when receiving mail.

*Mail Debug:*

When `true`, JavaMail interaction with mail servers, along with these mail session properties are printed to the `stdout` file.

*Custom Properties:*

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

***Example: Configuring mail provider and mail session settings for application clients:***

You can configure mail provider and mail session settings. This topic provides the required fields, special cases, and an example.

The purpose of this topic is to help you configure mail provider and mail session settings.

- Required fields:
  - Mail Provider Properties page: name, and at least one protocol provider
  - Mail Session Properties page: name, jndiName, outgoing server and protocol, and/or incoming server and protocol
- Special cases:
  - If you use the ACRCT tool, the password field will be encrypted. You cannot encrypt the password field if you do not use the ACRCT tool.
- Example:

```
<resources.mail:MailProvider xmi:id="builtin_mailprovider" name="Built-in Mail Provider" description="The built-in mail provider">
  <factories xmi:type="resources.mail:MailSession"
             xmi:id="MailSession_1207766754834" name="MailSession"
             jndiName="mail/session" description="Sample mail session" category="Sample"
             mailTransportHost="smtp.coldmail.com" mailTransportUser="transportUser"
             mailTransportPassword="{xor}Lz4sLChvLTs="
             mailFrom="smith@coldmail.com" mailStoreHost="imap.coldmail.com" mailStoreUser="storeUser"
             mailStorePassword="{xor}Lz4sLChvLTs="
             debug="true" strict="true"
             mailTransportProtocol="builtin_smtp" mailStoreProtocol="builtin_imap">
    <propertySet xmi:id="J2EEResourcePropertySet_1207766778585">
      <resourceProperties xmi:id="J2EEResourceProperty_1207766778585" name="key" type="java.lang.String" value="value" required="false"/>
    </propertySet>
  </factories>
  <protocolProviders xmi:id="builtin_smtp" protocol="smtp" classname="com.sun.mail.smtp.SMTPTransport" type="TRANSPORT"/>
  <protocolProviders xmi:id="builtin_pop3" protocol="pop3" classname="com.sun.mail.pop3.POP3Store" type="STORE"/>
  <protocolProviders xmi:id="builtin_imap" protocol="imap" classname="com.sun.mail.imap.IMAPStore" type="STORE"/>
```

```
  <protocolProviders xmi:id="builtin_smtps" protocol="smtps" classname="com.sun.mail.smtp.SMTPSSLTransport" type="TRANSPORT"/>
  <protocolProviders xmi:id="builtin_pop3s" protocol="pop3s" classname="com.sun.mail.pop3.POP3SSLStore" type="STORE"/>
  <protocolProviders xmi:id="builtin_imaps" protocol="imaps" classname="com.sun.mail.imap.IMAPSSLStore" type="STORE"/>
</resources.mail:MailProvider>
```

## Configuring new mail sessions for application clients

You can use the Application Client Resource Configuration Tool (ACRCT) to configure new mail sessions for your application client.

### Before you begin

During this task, you configure new mail sessions for your application client. The mail sessions are associated with the pre-configured default mail provider supplied by the product.

### Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the EAR file. The EAR file contents are displayed in a tree view.
2. Select the JAR file in which you want to configure the new JavaMail session.
3. Expand the JAR file to view its contents.
4. Click **Mail Providers > Mail Provider > Mail Sessions**. Complete one of the following actions:
   - Right click the Mail Sessions folder and select **New Factory**.
   - Click **Edit > New** on the menu bar.
5. Configure the Mail Session properties in the displayed fields.
6. Click **OK**.
7. Click **File > Save** on the menu bar to save your changes.

## Configuring new URL providers for application clients

You can create URL providers and URLs for your client application using the Application Client Resource Configuration Tool (ACRCT).

### Before you begin

During this task, you create URL providers and URLs for your client application. In a separate administrative task, you must install the Java code for the required URL provider on the client machine on which the client application resides.

### About this task

### Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new URL provider. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new URL provider from the tree.
4. Expand the JAR file to view the contents.
5. Click the folder called URL Providers. Complete one of the following actions:
   - Right click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
6. Configure the URL provider properties in the resulting property dialog.
7. Click **OK**.
8. Click **File > Save** on the menu bar to save your changes.

## Example

- Configuring URL and URL provider settings for application clients

This code example illustrates how to configure URL and URL provider settings for application clients:

```
<resources.url:URLProvider xmi:id="URLProvider_1" name="urlProvider:name"
description="urlProvider:description"
streamHandlerClassName="urlProvider:streamHandlerClass"
protocol="urlProvider:protocol">
<classpath>urlProvider:classpath</classpath>
<factories xmi:type="resources.url:URL" xmi:id="URL_1" name="urlFactory:name"
jndiName="urlFactory:jndiName" description="urlFactory:description"
spec="urlFactory:url">
<propertySet xmi:id="J2EEResourcePropertySet_18">
<resourceProperties xmi:id="J2EEResourceProperty_20" name="urlFactory:customName"
value="urlFactory:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_19">
<resourceProperties xmi:id="J2EEResourceProperty_21" name="urlProvider:customName"
value="urlProvider:customValue"/>
</propertySet>
</resources.url:URLProvider>
```

- Required fields:
  - URL Properties page: name, jndiName, url
  - URL Provider Properties page: name

***URLs for application clients:***

A *Uniform Resource Locator* (URL) is an identifier that points to an electronically accessible resource, such as a directory file on a machine in a network, or a document stored in a database.

URLs appear in the format *scheme*:*scheme_information*.

You can represent a *scheme* as `http`, `ftp`, `file`, or another term that identifies the type of resource and the mechanism by which you can access the resource.

In a web browser location or address box, a URL for a file available using HyperText Transfer Protocol (HTTP) starts with `http:`. An example is `http://www.ibm.com`. Files available using File Transfer Protocol (FTP) start with `ftp:`. Files available locally start with `file:`.

The *scheme_information* commonly identifies the Internet machine making a resource available, the path to that resource, and the resource name. The scheme_information for HTTP, FTP and File generally starts with two slashes (//), then provides the Internet address separated from the resource path name with one slash (/). For example,

`http://www.ibm.com/software/webservers/appserv/library.html`.

For HTTP and FTP, the path name ends in a slash when the URL points to a directory. In such cases, the server generally returns the default index for the directory.

***URL providers for the Application Client Resource Configuration Tool:***

A URL provider implements the function for a particular URL protocol, such as HyperText Transfer Protocol (HTTP). This provider, comprised of a pair of classes, extends the java.net.URLStreamHandler and java.net.URLConnection classes.

***Configuring URL providers and sessions using the Application Client Resource Configuration Tool:***

You can edit the configurations of URL providers and URLs to be used by your application clients using the Application Client Resource Configuration Tool (ACRCT).

**Before you begin**

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of URL providers and URLs to be used by your application clients.

**About this task**

**Procedure**

1. Start the ACRCT.
2. Open an EAR file.
3. Locate the URL objects in the tree that displays. For example, if your file contains URL providers and URLs, expand **Resources > *application* > .jar > URL Providers > *url_provider_instance***
   where *url_provider_instance* is a particular URL provider.
4. If you expand the tree further, you will also see the URLs folders containing the URL instances for each URL provider instance.

*URL settings for application clients:*

Use this page to implement the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP).

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **URL Providers** > *URL provider instance*. Right-click **URLs** and click **New**. The following fields appear on the **General** tab.

This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

*Name:*

The administrative name for the URL.

*Description:*

This is an optional description of the URL for your administrative records.

*JNDI Name:*

The application client run time uses this field to retrieve configuration information.

*URL:*

A Uniform Resource Locator (URL) name that points to an Internet or intranet resource. For example: `http://www.ibm.com`.

*Custom Properties:*

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

*URL provider settings for application clients:*

Use this page create new URL providers.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **URL Providers**, and click **New**. The following fields appear on the **General** tab.

A URL provider implements the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP). This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

*Name:*

Administrative name for the URL.

*Description:*

Optional description of the URL, for your administrative records.

*Class Path:*

A list of paths or JAR file names which together form the location for the resource provider classes.

*Protocol:*

Protocol supported by this stream handler. For example, `nntp`, `smtp`, `ftp`, and so on.

To use the default protocol, leave this field blank.

*Stream handler class:*

Fully qualified name of a User-defined Java class that extends the `java.net.URLStreamHandler` for a particular URL protocol, such as FTP.

To use the default stream handler, leave this field blank.

*Custom Properties:*

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

***Example: Configuring URL and URL provider settings for application clients:***

You can configure URL and URL provider settings. This topic provides the required fields and an example.

The purpose of this article is to help you to configure URL and URL provider settings.

- Required fields:
  - URL Properties page: name, jndiName, url

  – URL Provider Properties page: name
- Example:

```
<resources.url:URLProvider xmi:id="URLProvider_1" name="urlProvider:name"
description="urlProvider:description"
streamHandlerClassName="urlProvider:streamHandlerClass"
protocol="urlProvider:protocol">
<classpath>urlProvider:classpath</classpath>
<factories xmi:type="resources.url:URL" xmi:id="URL_1" name="urlFactory:name"
jndiName="urlFactory:jndiName" description="urlFactory:description"
spec="urlFactory:url">
<propertySet xmi:id="J2EEResourcePropertySet_18">
<resourceProperties xmi:id="J2EEResourceProperty_20" name="urlFactory:customName"
value="urlFactory:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_19">
<resourceProperties xmi:id="J2EEResourceProperty_21" name="urlProvider:customName"
value="urlProvider:customValue"/>
</propertySet>
</resources.url:URLProvider>
```

## Configuring new URLs with the Application Client Resource Configuration Tool

You can use URLs for your client application using the Application Client Resource Configuration Tool (ACRCT).

### Before you begin

During this task, you create URLs for your client application.

### About this task

### Procedure

1. Click the URL provider for which you want to create a URL in the tree. Complete one of the following:
   - Configure a new URL provider.
   - Click an existing URL provider.
2. Expand the URL provider to view the URLs folder.
3. Click the URL folder. Complete one of the following actions:
   - Right click the folder and click **New**.
   - Click **Edit -> New** on the menu bar.
4. Configure the URL properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** in the menu bar to save your changes.

## Configuring Java messaging client resources

To configure Java messaging client resources, you create new JMS provider configurations for your application client. The application client can use a messaging service through the Java Message Service APIs. A JMS provider provides two kinds of J2EE factories. One is a *JMS connection factory*, and the other is a *JMS destination factory*.

### Before you begin

In a separate administrative task, install the Java Message Service (JMS) client on the client machine where the application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

**Attention:** When completing this task, you can either create a new messaging provider, or you can use an existing one.

## Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new JMS provider. The EAR file contents are in the displayed tree view.
3. Select the JAR file in which you want to configure the new JMS provider from the tree.
4. Expand the JAR file to view its contents.
5. Optionally right-click **Messaging Providers** and select **New**, if you want to create and use a new messaging provider.
6. Configure the JMS provider properties in the resulting property dialog.
7. Click **OK**.
8. Click **File > Save**.

***Asynchronous messaging in WebSphere Application Server using JMS:***

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface. The JMS interface provides a common way for Java programs (clients and Java Platform, Enterprise Edition (Java EE) applications) to create, send, receive, and read asynchronous requests as JMS messages.

This topic provides a generic overview of asynchronous messaging using the JMS support provided by WebSphere Application Server.

The base support for asynchronous messaging using the JMS API provides the common set of JMS interfaces and associated semantics that define how a JMS client can access the facilities of a JMS provider. This support enables WebSphere product Java EE applications, as JMS clients, to exchange messages asynchronously with other JMS clients, by using JMS destinations (queues or topics). A Java EE application can use JMS queue destinations for point-to-point messaging and JMS topic destinations for publish and subscribe messaging. A Java EE application can explicitly poll for messages on a destination, and then retrieve messages for processing by business logic beans (enterprise beans).

With the base JMS and XA support, the Java EE application uses standard JMS calls to process messages, including any responses or outbound messaging. An enterprise bean can handle responses acting as a sender bean, or within the enterprise bean that receives the incoming messages. Optionally, this process can use two-phase commit within the scope of a transaction. This level of function for asynchronous messaging is called *bean-managed messaging*, and gives an enterprise bean complete control over the messaging infrastructure, for example, connection and session pool management. The common container has no role in bean-managed messaging.

WebSphere Application Server also supports automatic asynchronous messaging using message-driven beans (a type of enterprise bean defined in the Enterprise JavaBeans (EJB) 2.0 specification) and JMS listeners (part of the JMS application server facilities). Messages are automatically retrieved from JMS destinations, optionally within a transaction, then sent to the message-driven bean in a Java EE application, without the application having to explicitly poll JMS destinations.

***Java Message Service providers for clients:***

Client applications can use messaging resources from three main types of Java Message Service (JMS) providers in WebSphere Application Server: The WebSphere Application Server default messaging provider (which uses service integration as the provider), the WebSphere MQ messaging provider (which uses your WebSphere MQ system as the provider) and third-party messaging providers (which use another company's product as the provider).

IBM WebSphere Application Server supports asynchronous messaging through the use of a JMS provider and its related messaging system. JMS providers must conform to the JMS specification version 1.1. To

use message-driven beans the JMS provider must support the optional Application Server Facility (ASF) function defined within that specification, or support an inbound resource adapter as defined in the JCA specification version 1.5.

**Default messaging provider**
If you mainly want to use messaging between applications in WebSphere Application Server, perhaps with some interaction with a WebSphere MQ system, the default messaging provider is the natural choice. This provider is based on service integration technologies and is fully integrated with the WebSphere Application Server runtime environment.

**WebSphere MQ messaging provider**
If your business also uses WebSphere MQ, and you want to integrate WebSphere Application Server messaging applications into a predominately WebSphere MQ network, choose the WebSphere MQ messaging provider, which allows you to define resources for connecting to any queue manager on the WebSphere MQ network.

**Third-party messaging provider**
You can configure any third-party messaging provider that supports the JMS Version 1.1 unified connection factory. You might want to do this, for example, because of existing investments.

**Note:** In WebSphere Application Server 7.0, the Version 5 default messaging provider is deprecated.

**Note:** For backwards compatibility with earlier releases, WebSphere Application Server Version 7 supports the (deprecated) Version 5 default messaging provider and the Version 6 WebSphere MQ messaging provider. This support enables your applications that still use these resources to communicate with Version 5 and Version 6 nodes in Version 7 mixed cells.

WebSphere applications can use messaging resources provided by any of these JMS providers. However the choice of provider is most often dictated by requirements to use or integrate with an existing messaging system. For example, you may already have a messaging infrastructure based on WebSphere MQ. In this case you may either connect directly using the included support for WebSphere MQ as a JMS provider, or configure a service integration bus with links to a WebSphere MQ network and then access the bus through the default messaging provider.

***Configuring new JMS providers with the Application Client Resource Configuration Tool:***

You can create new Java Message Service (JMS) provider configurations for the Application Client. The Application Client makes use of a messaging service through the JMS interfaces.

**About this task**

During this task, you create new Java Message Service (JMS) provider configurations for the Application Client. The Application Client makes use of a messaging service through the JMS interfaces. A JMS provider provides two kinds of Java Platform, Enterprise Edition (Java EE) resources. One is a JMS connection factory, and the other is a JMS destination.

In a separate administrative task, you must install the JMS client on the client machine where your particular application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

**Procedure**

1. Start the Application Client Resource Configuration Tool and open the EAR file for which you want to configure the new JMS provider. The EAR file contents are displayed in a tree view.
2. From the tree, select the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Right-click **Messaging Providers**. Complete one of the following actions:
   - Right click the folder and select **New**.

- On the menu bar, click **Edit > New**.

5. In the resulting property dialog, configure the JMS provider properties.
6. Click **OK** when finished.
7. Click **File > Save** on the menu bar to save your changes.

**Example**

The following code example illustrates how to configure JMS Provider, JMS Connection Factory and JMS Destination settings for application clients.

```
<resources.jms:JMSProvider xmi:id="JMSProvider_3" name="genericJMSProvider:name"
description="genericJMSProvider:description"
externalInitialContextFactory="genericJMSProvider:contextFactoryClass"
externalProviderURL="genericJMSProvider:providerUrl">
<classpath>genericJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms:GenericJMSDestination"
xmi:id="GenericJMSDestination_1" name="jmsDestination:name"
jndiName="jmsDestination:jndiName" description="jmsDestination:description"
externalJNDIName="jmsDestination:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_15">
<resourceProperties xmi:id="J2EEResourceProperty_17" name="jmsDestination:customName"
value="jmsDestination:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms:GenericJMSConnectionFactory"
xmi:id="GenericJMSConnectionFactory_1" name="jmsCF:name" jndiName="jmsCF:jndiName"
description="jmsCF:description" userID="jmsCF:user" password="{xor}NTIsHBllMT4yOg=="
externalJNDIName="jmsCF:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_16">
<resourceProperties xmi:id="J2EEResourceProperty_18" name="jmsCF:customName"
value="jmsCF:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_17">
<resourceProperties xmi:id="J2EEResourceProperty_19"
name="genericJMSProvider:customName" value="genericJMSProvider:customValue"/>
</propertySet>
</resources.jms:JMSProvider>
```

Required fields include:
- JMS Provider Properties page: name, and at least one protocol provider
- JMS Connection Factory Properties page: name, jndiName, destination type
- JMS Destination Properties page: name, jndiName, destination type

Special cases:
- The destination type must be QUEUE, or TOPIC.

***JMS provider settings for application clients:***

Use this page to configure properties of the Java Message Service (JMS) provider, if you want to use a JMS provider other than the default messaging provider or the WebSphere MQ as a JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **Messaging Providers**, and click **New**. The following fields appear on the **General** tab.

*Name:*

The name by which the JMS provider is known for administrative purposes.

**Data type** String

*Description:*

A description of the JMS provider, for administrative purposes.

**Data type** String

*Class Path:*

A list of paths or `.jar` file names which together form the location for the resource provider classes.

*Context factory class:*

The Java class name of the initial context factory for the JMS provider.

For example, for an LDAP service provider the value has the form: `com.sun.jndi.ldap.LdapCtxFactory`.

**Data type** String

*Provider URL:*

The JMS provider URL for external JNDI lookups.

For example, an LDAP URL for a JMS provider has the form: `ldap://hostname.company.com/contextName`.

**Data type** String

*Custom Properties:*

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

***Default Provider connection factory settings:***

Use this panel to view or change the configuration properties of the selected JMS connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display the appropriate value. Any settings that have fixed values have a drop down menu.

*Name:*

The name of the connection factory.

**Data type** String

*Description:*

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

**Data type** String

*JNDI Name:*

The JNDI name that is used to match this Resource Adapter connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

**Data type** String

*User Name:*

The **User Name** used with the **Password** property for connecting to an application.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

**Data type** String

*Password:*

The password used to authenticate connection to an application.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

**Data type** String

*Re-Enter Password:*

Confirms the password.

*Bus Name:*

The name of the bus to which the connection factory connects.

**Data type** String

*Client Identifier:*

The name of the client. Required for durable topic subscriptions.

**Data type** String

*Nonpersistent Messaging Reliability:*

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

**Default** ReliablePersistent

**Range**

**None** There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

**Best effort nonpersistent**
Messages are never written to disk, and are thrown away if memory cache overruns.

**Express nonpersistent**
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

**Reliable nonpersistent**
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

**Reliable persistent**
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

**Assured persistent**
Highest degree of reliability where assured message delivery is supported.

**As Bus destination**
Use the delivery option configured for the bus destination.

*Persistent Message Reliability:*

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

**Default** ReliablePersistent

**Range**

**None** There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

**Best effort nonpersistent**
Messages are never written to disk, and are thrown away if memory cache overruns.

**Express nonpersistent**
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

**Reliable nonpersistent**
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

**Reliable persistent**
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

**Assured persistent**
Highest degree of reliability where assured message delivery is supported.

**As Bus destination**
Use the delivery option configured for the bus destination.

*Durable Subscription Home:*

The name of the durable subscription home.

**Data type** String

*Share durable subscriptions:*

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Normally, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

**Data type** Selection list
**Default** In cluster
**Range**

**In cluster**
Allows sharing of durable subscriptions when connections are made from within a server cluster.

**Always shared**
Durable subscriptions can be shared across connections.

**Never shared**
Durable subscriptions are never shared across connections.

*Read Ahead:*

Controls the read-ahead optimization during message delivery.

| | |
|---|---|
| **Default** | Default |
| **Range** | Default, AlwaysOn and AlwaysOff |

*Target:*

The name of the Workload Manager target group containing the messaging engine.

| | |
|---|---|
| **Data type** | String |

*Target Type:*

The type of Workload Manager target group that contains the messaging engine.

| | |
|---|---|
| **Default** | BusMember |
| **Range** | BusMember, Custom, ME |

*Target Significance:*

The priority of significance for the target specified.

| | |
|---|---|
| **Default** | Preferred |
| **Range** | Preferred, Required |

*Target Inbound Transport Chain:*

The name of the protocol that resolves to a group of messaging engines.

| | |
|---|---|
| **Data type** | String |

*Provider Endpoints:*

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

| | |
|---|---|
| **Example** | `merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging` where<br><br>`BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP). |
| **Default** | • If the host name is not specified, then the default `localhost` is used as a default value.<br>• If the port number is not specified, then `7276` is used as a default value.<br>• If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value. |

*Connection Proximity:*

The proximity that the messaging engine should have to the requester.

**Default** Bus
**Range** Bus, Host, Cluster, Server

*Temporary Queue Name Prefix:*

The prefix to apply to the names of temporary queues. This name is a maximum of 12 characters.

**Data type** String

*Temporary Topic Name Prefix:*

The prefix to apply to the names of temporary topics. This name is a maximum of 12 characters.

**Data type** String

***Default Provider queue connection factory settings:***

Use this panel to view or change the configuration properties of the selected JMS queue connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Queue Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display the appropriate value. Any settings that have fixed values have a drop down menu.

*Name:*

The name of the queue connection factory.

**Data type** String

*Description:*

A description of this queue connection factory for administrative purposes within WebSphere Application Server.

**Data type** String

*JNDI Name:*

The JNDI name that is used to match this queue connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

**Data type** String

*User Name:*

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

**Data type** String

*Password:*

The password used to create an encrypted. If you complete this field, then the Password field in the Properties box is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

**Data type** String

*Re-Enter Password:*

Confirms the password.

*Bus Name:*

The name of the bus to which the queue connection factory connects.

**Data type** String

*Client Identifier:*

The client identifier. Required for durable topic subscriptions.

**Data type** String

*Nonpersistent Messaging Reliability:*

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

**Default** ReliablePersistent

**Range**

**None** There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

**Best effort nonpersistent**
Messages are never written to disk, and are thrown away if memory cache overruns.

**Express nonpersistent**
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

**Reliable nonpersistent**
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

**Reliable persistent**
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

**Assured persistent**
Highest degree of reliability where assured message delivery is supported.

**As Bus destination**
Use the delivery option configured for the bus destination.

*Persistent Message Reliability:*

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

**Default** ReliablePersistent

**Range**

**None** There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

**Best effort nonpersistent**
Messages are never written to disk, and are thrown away if memory cache overruns.

**Express nonpersistent**
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

**Reliable nonpersistent**
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

**Reliable persistent**
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

**Assured persistent**
Highest degree of reliability where assured message delivery is supported.

**As Bus destination**
Use the delivery option configured for the bus destination.

*Read Ahead:*

Controls the read-ahead optimization during message delivery.

**Default** Default
**Range** Default, AlwaysOn and AlwaysOff

*Target:*

The name of the Workload Manager target group containing the messaging engine.

**Data type** String

*Target Type:*

The type of Workload Manager target group that contains the messaging engine.

**Default** BusMember
**Range** BusMember, Custom, Destination, ME

*Target Significance:*

The priority of significance for the target specified.

**Default** Preferred
**Range** Preferred, Required

*Target Inbound Transport Chain:*

The name of the protocol that resolves to a group of messaging engines.

**Data type** String

*Provider Endpoints:*

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

**Example** `localhost:7777:BootstrapBasicMessaging`

where

`BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).

**Default**

- If the host name is not specified, then the default `localhost` is used as a default value.
- If the port number is not specified, then `7276` is used as a default value.
- If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

*Connection Proximity:*

The proximity that the messaging engine should have to the requester.

**Default** Bus, Cluster, Server
**Range** Bus, Host

*Temporary Queue Name Prefix:*

The prefix to apply to the names of temporary queues. This name is a maximum of 12 characters.

**Data type** String

***Default Provider topic connection factory settings:***

Use this panel to view or change the configuration properties of the selected JMS topic connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Topic Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display that appropriate value. Any settings that have fixed values have a drop down menu.

*Name:*

The name of the topic connection factory.

**Data type** String

*Description:*

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

**Data type** String

*JNDI Name:*

The JNDI name that is used to match this topic connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

**Data type** String

*User Name:*

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

**Data type** String

*Password:*

The password used to create an encrypted. If you complete this field, then the Password field in the Properties box is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

**Data type** String

*Re-Enter Password:*

Confirms the password.

*Bus Name:*

The name of the bus to which the topic connection factory connects.

**Data type** String

*Client Identifier:*

The name of the client. This field is required for durable topic subscriptions.

**Data type** String

*Nonpersistent Messaging Reliability:*

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

**Default** ReliablePersistent

**Range**

**None** There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

**Best effort nonpersistent**
Messages are never written to disk, and are thrown away if memory cache overruns.

**Express nonpersistent**
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

**Reliable nonpersistent**
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

**Reliable persistent**
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

**Assured persistent**
Highest degree of reliability where assured message delivery is supported.

**As Bus destination**
Use the delivery option configured for the bus destination.

*Persistent Message Reliability:*

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

**Default** ReliablePersistent

**Range**

**None** There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

**Best effort nonpersistent**
Messages are never written to disk, and are thrown away if memory cache overruns.

**Express nonpersistent**
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

**Reliable nonpersistent**
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

**Reliable persistent**
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

**Assured persistent**
Highest degree of reliability where assured message delivery is supported.

**As Bus destination**
Use the delivery option configured for the bus destination.

*Durable Subscription Home:*

The name of the durable subscription home.

**Data type** String

*Share durable subscriptions:*

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Normally, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

**Data type** Selection list
**Default** In cluster
**Range**

**In cluster**
Allows sharing of durable subscriptions when connections are made from within a server cluster.

**Always shared**
Durable subscriptions can be shared across connections.

**Never shared**
Durable subscriptions are never shared across connections.

*Read Ahead:*

Controls the read-ahead optimization during message delivery.

| | |
|---|---|
| **Default** | Default |
| **Range** | Default, AlwaysOn and AlwaysOff |

*Target:*

The name of the Workload Manager target group containing the messaging engine.

| | |
|---|---|

|---|---|
| **Default** | Preferred |
| **Range** | Preferred, Required |

*Target Inbound Transport Chain:*

The name of the protocol that resolves to a group of messaging engines.

| | |
|---|---|
| **Data type** | String |

*Provider Endpoints:*

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

| | |
|---|---|
| **Example** | `localhost:7777:BootstrapBasicMessaging`<br><br>where<br><br>`BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP). |
| **Default** | • If the host name is not specified, then the default `localhost` is used as a default value.<br>• If the port number is not specified, then `7276` is used as a default value.<br>• If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value. |

*Connection Proximity:*

The proximity that the messaging engine should have to the requester.

| | |
|---|---|
| **Default** | Bus |
| **Range** | Bus, Host, Cluster, Server |

*Temporary Topic Name Prefix:*

The prefix to apply to the names of temporary topics. This name is a maximum of 12 characters.

| | |
|---|---|
| **Data type** | String |

***Default Provider queue destination settings:***

Use this panel to view or change the configuration properties of the selected JMS queue destination for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Queue Destinations**. Click **New**. The following fields appear on the **General** tab.

*Name:*

The name of the queue destination factory. You must complete this field.

| | |
|---|---|
| **Data type** | String |

*Description:*

A description of this queue destination for administrative purposes within WebSphere Application Server.

| | |
|---|---|
| **Data type** | String |

*JNDI Name:*

The JNDI name used to match this definition to a deployment descriptor `resource-env-ref` name.

| | |
|---|---|
| **Data type** | String |

*Queue Name:*

The name of the queue.

| | |
|---|---|
| **Data type** | String |

*Delivery Mode:*

The delivery mode for messages sent to this destination.

| | |
|---|---|
| **Data type** | String |
| **Range** | Application, Persistent or NonPersistent |

**Default** Application

*Time to Live:*

The default length of time from its dispatch time that a message sent to this destination should be retained by the system, where **0** indicates that time to live value does not expire. Value from the producer is used if the Time to Live field is not completed.

**Data type** Integer
**Units** Milliseconds

*Priority:*

The priority for messages sent to this destination. The value from the producer is used if not completed.

**Data type** Integer
**Range** 0 to 9 with **0** as the lowest priority and **9** as the highest priority

*Read Ahead:*

Used to control read-ahead optimization during message delivery.

**Data type** String
**Range** AsConnection, AlwaysOn and AlwaysOff
**Default** AsConnection

***Default Provider topic destination settings:***

Use this panel to view or change the configuration properties of the selected JMS topic destination for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Topic Destinations**, and click **New**. The following fields appear on the **General** tab.

*Name:*

The name of the topic destination entry.

**Data type** String

*Description:*

A description of the entry.

**Data type** String

*JNDI Name:*

The JNDI name used to match this definition to a deployment descriptor `resource-env-ref` name.

| | |
|---|---|
| **Data type** | String |

*Topic Space:*

The name of the topic space. This field is required.

| | |
|---|---|
| **Data type** | String |
| **Default** | DEFAULT_TOPIC_SPACE |

*Topic Name:*

The name of the topic. This field is required.

| | |
|---|---|
| **Data type** | String |

*Delivery Mode:*

The default mode for messages sent to this destination.

| | |
|---|---|
| **Data type** | String |
| **Range** | Application, Persistent or NonPersistent |
| **Default** | Application |

*Time to Live:*

The default length of time from its dispatch time that a message sent to this destination should be retained by the system, where **0** indicates that time to live value does not expire. Value from the producer is used if not completed.

| | |
|---|---|
| **Data type** | Long |
| **Units** | Milliseconds |

*Priority:*

The priority for messages sent to this destination. Value from producer is used if not completed.

| | |
|---|---|
| **Data type** | Integer |
| **Range** | 0 to 9 with **0** as the lowest priority and **9** as the highest priority |

*Read Ahead:*

Used to control read-ahead optimization during message delivery.

| | |
|---|---|
| **Data type** | String |
| **Range** | AsConnection, AlwaysOn and AlwaysOff |
| **Default** | AsConnection |

***V5 default messaging provider queue connection factory settings for application clients:***

Use this panel to browse or change the configuration properties of the selected JMS queue connection factory for point-to-point messaging for use by WebSphere Application Server version 5 applications. These configuration properties control how connections are created between the JMS provider and the default messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Provider** > **Version 5 Default Provider**. Right-click **Queue Connection Factories** and click **New**. The following fields appear on the **General** tab.

A queue connection factory is used to create JMS connections to queue destinations. The queue connection factory is created by the internal WebSphere Application Server product JMS provider. A V5 default messaging provider queue connection factory has the following properties:

*Name:*

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

**Data type** String

*Description:*

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

**Data type** String
**Default** Null

*JNDI Name:*

The application client run time uses this field to retrieve configuration information.

*User ID:*

The User ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a User ID and password explicitly, for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

**Data type** String

*Password:*

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

*Re-Enter Password:*

Confirms the password.

*Node:*

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

**Data type** String

*Application Server:*

Enter the name of the application server. This name is not the host name of the machine, but the name of the configured application server.

*Custom Properties:*

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

***V5 default messaging provider topic connection factory settings for application clients:***

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the internal product Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and the messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Topic Connection Factories** and click **New**. The following fields appear on the **General** tab.

A V5 default messaging provider topic connection factory has the following properties.

*Name:*

The name by which this queue connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere Application Server administrative domain.

**Data type** String

*Description:*

A description of this topic connection factory for administrative purposes within WebSphere Application Server.

**Data type** String

*JNDI Name:*

The application client run time uses this field to retrieve configuration information.

*User ID:*

The user ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly, for example, if the calling application uses the method createTopicConnection(). The JMS client flows the `userid` and `password` to the JMS server.

| | |
|---|---|
| **Data type** | String |

*Password:*

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

| | |
|---|---|
| **Data type** | String |

*Re-Enter Password:*

Confirms the password.

*Node:*

The WebSphere Application Server node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

| | |
|---|---|
| **Data type** | Enum |
| **Range** | Pull-down list of nodes in the WebSphere Application Server administrative domain. |

*Application Server:*

Enter the name of the application server. This name is not the host name of the machine, but the name of the configured application server.

*Port:*

Which of the two ports that connections use to connect to the JMS Server. The QUEUED port is for full-function JMS publish/subscribe support, the DIRECT port is for nonpersistent, nontransactional, nondurable subscriptions only.

**Note:** Message-driven beans cannot use the direct listener port for publish or subscribe support. Therefore, any topic connection factory configured with the Port set to `Direct` cannot be used with message-driven beans.

| | |
|---|---|
| **Data type** | Enum |
| **Default** | QUEUED |

**Range**

**QUEUED**
The listener port used for full-function JMS compliant, publish or subscribe support.

**DIRECT**
The listener port used for direct TCP/IP connection (nontransactional, nonpersistent, and nondurable subscriptions only) for publish or subscribe support.

The TCP/IP port numbers for these ports are defined on the product internal JMS server.

*Client ID:*

The JMS client identifier used for connections to the MQSeries® queue manager.

**Data type** String

*Custom Properties:*

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

***V5 default messaging provider queue destination settings for application clients:***

Use this panel to view or change the configuration properties of the selected queue destination for use with product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Queue Destinations** and click **New**. The following fields are displayed on the **General** tab.

A queue destination is used to configure the properties of a JMS queue. A V5 default messaging provider queue destination has the following properties.

*Name:*

The name by which the queue is known for administrative purposes within WebSphere Application Server.

**Data type** String

*Description:*

A description of the queue, for administrative purposes.

**Data type** String

*JNDI Name:*

The application client run time uses this field to retrieve configuration information.

*Persistence:*

Whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

**Data type** Enum
**Default** APPLICATION_DEFINED
**Range**
**Application defined**
Messages on the destination have their persistence defined by the application that put them onto the queue.
**Queue defined**
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
**Persistent**
Messages on the destination are persistent.
**Nonpersistent**
Messages on the destination are not persistent.

*Priority:*

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

**Data type** Enum
**Default** APPLICATION_DEFINED
**Range**
**Application defined**
The priority of messages on this destination is defined by the application that put them onto the destination.
**Queue defined**
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
**Specified**
The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

*Specified Priority:*

If the **Priority** property is set to `Specified`, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

**Data type** Integer
**Units** Message priority level
**Range** 0 (lowest priority) through 9 (highest priority)

*Expiry:*

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or whether messages on the queue expire (have an unlimited expiry timeout).

**Data type** Enum

**Default** APPLICATION_DEFINED

**Range**

**Application defined**
The expiry timeout for messages in this queue is defined by the application that put them onto the queue.

**Specified**
The expiry timeout for messages in this queue is defined by the **Specified expiry** property.If you select this option, you must define a time out on the **Specified expiry** property.

**Unlimited**
Messages in this queue have no expiry timeout, and those messages never expire.

*Specified Expiry:*

If the **Expiry timeout** property is set to `Specified`, specify the number of milliseconds (greater than 0) after which messages on this queue expire.

**Data type** Integer

**Units** Milliseconds

**Range** Greater than or equal to 0

- 0 indicates that messages never timeout.
- Other values are an integer number of milliseconds.

*Custom Properties:*

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

***V5 default messaging provider topic destination settings for application clients:***

Use this panel to view or change the configuration properties of the selected topic destination for use with the internal product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Topic Destinations** and click **New**. The following fields appear on the **General** tab.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. A V5 default messaging provider topic has the following properties.

*Name:*

The name by which the topic is known for administrative purposes.

**Data type** String

*Description:*

A description of the topic, for administrative purposes within WebSphere Application Server.

**Data type** String

*JNDI Name:*

The application client run-time environment uses this field to retrieve configuration information.

*Topic Name:* The name of the topic as defined to the JMS provider.

**Data type** String

*Persistence:*

Whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

**Data type** Enum
**Default** APPLICATION_DEFINED
**Range**

**Application defined**
Messages on the destination have their persistence defined by the application that put them onto the queue.

**Queue defined**
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

**Persistent**
Messages on the destination are persistent.

**Nonpersistent**
Messages on the destination are not persistent.

*Priority:*

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

**Data type** Enum
**Default** APPLICATION_DEFINED
**Range**

**Application defined**
The priority of messages on this destination is defined by the application that put them onto the destination.

**Queue defined**
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

**Specified**
The priority of messages on this destination is defined by the **Specified priority** property.*If you select this option, you must define a priority on the **Specified priority** property.*

*Specified Priority:*

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

| | |
|---|---|
| **Data type** | Integer |
| **Units** | Message priority level |
| **Range** | 0 (lowest priority) through 9 (highest priority) |

*Expiry:*

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout).

| | |
|---|---|
| **Data type** | Enum |
| **Default** | APPLICATION_DEFINED |
| **Range** | **Application defined**<br>The expiry timeout for messages on this queue is defined by the application that put them onto the queue.<br>**Specified**<br>The expiry timeout for messages on this queue is defined by the **Specified expiry** property. *If you select this option, you must define a timeout on the **Specified expiry** property.*<br>**Unlimited**<br>Messages on this queue have no expiry timeout, so those messages never expire. |

*Specified Expiry:*

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire.

| | |
|---|---|
| **Data type** | Integer |
| **Units** | Milliseconds |
| **Range** | Greater than or equal to 0<br>• 0 indicates that messages never time out.<br>• Other values are an integer number of milliseconds. |

*Custom Properties:*

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

***WebSphere MQ Provider queue connection factory settings for application clients:***

Use this panel to view or change the configuration properties of the selected queue connection factory for use with the WebSphere MQ Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and WebSphere MQ.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file and click **Messaging Providers** > **WebSphere MQ Provider**. Right click **Queue Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

**Note:**

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the *Using Java* section of the WebSphere MQ information center.
- In WebSphere MQ, names can have a maximum of 48 characters, except for channels which have a maximum of 20 characters.

A queue connection factory for the JMS provider has the following properties.

*Name:*

The name by which this queue connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

**Data type** String

*Description:*

A description of this connection factory for administrative purposes within WebSphere Application Server.

**Data type** String
**Default** Null

*JNDI Name:*

The application client run time uses this field to retrieve configuration information.

*User ID:*

The user ID used, with the password property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the user ID property, you must also specify a value for the password property.

The connection factory user ID and password properties are used if the calling application does not provide a user ID and password explicitly; for example, if the calling application uses the method createQueueConnection(). The JMS client flows the user ID and password to the JMS server.

**Data type** String

*Password:*

The password used, with the user ID property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the user ID property, you must also specify a value for the password property.

**Data type** String
**Default** Null

*Re-Enter Password:*

Confirms the password.

*Queue Manager:*

The name of the WebSphere MQ queue manager for this connection factory.

Connections created by this factory connect to that queue manager.

| | |
|---|---|
| **Data type** | String |

*Enter Hostname and Port Information:*

This radio button is selected by default and, if selected, enables the host and port properties and disables the connection name list property.

| | |
|---|---|
| **Data type** | Radio button |
| **Default** | Selected |

*Host:*

The name of the host on which the WebSphere MQ queue manager runs for client connection only.

| | |
|---|---|
| **Data type** | String |
| **Default** | Null |
| **Range** | A valid TCP/IP host name |

*Port:*

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

| | |
|---|---|
| **Data type** | Integer |
| **Default** | Null |
| **Range** | A valid TCP/IP port number, configured on the WebSphere MQ queue manager. |

*Enter Connection Name List Information:*

If selected, this radio button enables the connection name list property and disables the host and port name properties. Select this radio button if you want to connect to a multi-instance queue manager.

| | |
|---|---|
| **Data type** | Radio button |
| **Default** | Cleared |

*Connection Name List:*

A comma-separated list of host and port information which can be used to connect to a multi-instance queue manager.

The format of the list is:
`host[(port)],[host[(port)]]`

where port is optional and defaults to 1414 if it is not set. For example:
`hostname1,hostname2(1415)`

For further information about multi-instance queue managers, see the WebSphere MQ information center.

This property must only be used for connecting to a multi-instance queue manager. It must not be used for connecting to a list of distinct queue managers as that can result in transaction integrity issues.

*Channel:*

The name of the channel used for connection to the WebSphere MQ queue manager, for client connection only.

| | |
|---|---|
| **Data type** | String |
| **Default** | Null |
| **Range** | 1 through 20 ASCII characters |

*Transport type:*

Specifies whether the WebSphere MQ client connection or JNDI bindings are used for connection to the WebSphere MQ queue manager. The external JMS provider controls the communication protocols between JMS clients and JMS servers. Tune the transport type when you are using non-ASF nonpersistent, nondurable, nontransactional messaging or when you want to satisfy security issues and the client is local to the queue manager node.

| | |
|---|---|
| **Data type** | Enum |
| **Units** | Not applicable |
| **Default** | BINDINGS |
| **Range** | **BINDINGS**<br>JNDI bindings are used to connect to the queue manager. BINDINGS is a shared memory protocol and can only be used when the queue manager is on the same node as the JMS client and poses security risks that must be addressed through the use of EJB roles.<br>**CLIENT**<br>WebSphere MQ client connection is used to connect to the queue manager. CLIENT is a typical TCP-based protocol.<br>**DIRECT**<br>For WebSphere MQ Event Broker using DIRECT mode. DIRECT is a lightweight sockets protocol used in nontransactional, nondurable, and nonpersistent Publish/Subscribe messaging. DIRECT only works for clients and message-driven beans using the non-ASF protocol.<br>**QUEUED**<br>QUEUED is a standard TCP protocol. |

**Recommended**

**Queue connection factory transport type**

BINDINGS is faster by 30% or more, but it requires correctly set up EJB roles to guarantee security. If you have security concerns and need to use CLIENT then you should make appropriate use of SSL to secure the connection to the queue manager.

**Topic connection factory transport type**

DIRECT is the fastest type and must be used where possible. Use BINDINGS when you want to satisfy additional security tasks and the queue manager is local to the JMS client. QUEUED is the fallback for all other cases. WebSphere MQ 5.3 before CSD2 with the DIRECT setting can lose messages when used with message-driven beans and under load. This loss also happens with client-side applications unless the broker maxClientQueueSize is set to 0. You can set this value to 0 with the command:

```
#wempschangeproperties WAS_nodeName_server1
 -e default -o DynamicSubscriptionEngine -n
 maxClientQueueSize -v 0 -x executionGroupUUID
```

where executionGroupUUID can be found by starting the broker and looking in the Event Log/Applications for event 2201. This value is usually ffffffff-0000-0000-000000000000.

**Note:** The WebSphere MQ 5.3 JMS cannot be used within WebSphere Application Server Version 6.1 because WebSphere Application Server Version 6.1 has a Java 5 runtime. Therefore, cross-memory connections cannot be established with WebSphere MQ 5.3 queue managers. This can result in a performance degradation if you were previously using WebSphere MQ 5.3 and BINDINGS for your connections and move to CLIENT network connections in migrating to WebSphere Application Server Version 6.1.

*Client ID:*

The JMS client identifier used for connections to the WebSphere MQ queue manager.

**Data type** String

*CCSID:*

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

**Data type** String

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *System Administration* and *Application Programming Reference* sections of the WebSphere MQ information center.

*Message Retention:*

Select this check box to specify that unwanted messages are to be left on the queue. Otherwise, unwanted messages are handled according to their disposition options.

**Data type** Enum
**Units** Not applicable
**Default** Cleared

**Range**

**Selected**
Unwanted messages are left on the queue.
**Cleared**
Unwanted messages are handled according to their disposition options.

*Temporary model:*

The name of the model definition used to create temporary connection factories if a connection factory does not already exist.

**Data type** String
**Range** 1 through 48 ASCII characters

*Temporary queue prefix:*

The prefix used for dynamic queue naming.

**Data type** String

*Fail if quiesce:*

Specifies whether applications return from a method call if the queue manager has entered a controlled failure.

**Data type** Check box
**Default** Selected

*Local Server Address:*

Specifies the local server address.

**Data type** String

*Polling Interval:*

Specifies the interval, in milliseconds, between scans of all receivers during asynchronous message delivery

**Data type** Integer
**Units** Milliseconds
**Default** 5000

*Rescan interval:*

Specifies the interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

This interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

**Data type** Integer
**Units** Milliseconds

**Default** 5000

*SSL cipher suite:*

Specifies the cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider. The value must match the CipherSpec specified on the SVRCONN channel as the **Channel** property.

You must set this property, if you set the **SSL Peer Name** property.

*SSL certificate store:*

Specifies a list of zero or more Certificate Revocation List (CRL) servers used to check for SSL certificate revocation. If you specify a value for this property, you must use WebSphere MQ JVM at Java 2 version 1.4.

The value is a space-delimited list of entries of the form:
`ldap://hostname:[port]`

A single slash (/) follows this value. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the information about “Working with Certificate Revocation Lists” in the *Security* section of the WebSphere MQ information center.

*SSL peer name:*

For SSL, a *distinguished name* skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connection time.

If this property is not set, such certificate checking is performed.

The SSL peer name property is ignored if **SSL Cipher Suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:
`CN=QMGR.*, OU=IBM, OU=WEBSPHERE`

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the information about “Distinguished Names” in the WebSphere MQ information center.

*Connection pool:*

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This connection pooling is independent from any WebSphere MQ connection pooling. You must configure the connection and session pool properties appropriately for your applications, otherwise you might not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

**Data type** Check box
**Default** Selected

*Client reconnect options:*

Specifies whether a client mode connection reconnects automatically, or not, in the event of a communications or queue manager failure. This property is ignored unless the connection factory is being used in a thin or managed client environment.

**Data type** Drop-down list
**Default** DISABLED
**Range**

**DISABLED**
The client reconnection does not automatically occur.

**ASDEF** The value from the DefRecon attribute from the channels stanza of the client configuration file is used. If there is no DefRecon value specified then this setting has the same effect as a value of DISABLED.

**RECONNECT**
Reconnection occurs to any queue manager consistent with the value of the queue manager attribute, which might be a different queue manager from that to which the connection was originally connected.

**QMGR** Reconnection only occurs to the queue manager to which the connection was originally connected.

For more information about automatic client reconnection, see the WebSphere MQ information center.

*Client reconnect timeout:*

The maximum number of seconds that a client mode connection spends attempting to automatically reconnect to a queue manager after a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment. Whether this parameter is used or not depends on the value of the client reconnect options parameter.

**Data type** Integer
**Units** Seconds
**Default** 1800
**Range** A value greater than zero and up to 2147483647

For more information about automatic client reconnection, see the WebSphere MQ information center.

***WebSphere MQ Provider topic connection factory settings for application clients:***

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the WebSphere MQ Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and WebSphere MQ.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right-click **Topic Connection Factories** and click **New**.

**Note:**

- The property values that you specify must match the values that you specified when configuring WebSphere MQ product JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *Using Java* section of the WebSphere MQ information center.
- In WebSphere MQ, names can have a maximum of 48 characters, except for channels which have a maximum of 20 characters.

**MA0C broker:** When creating a WebSphere Application Server Version 6 topic connection factory for the MA0C broker, consider the following attribute values:

**BrokerControlQueue**
This value is fixed at SYSTEM.BROKER.CONTROL.QUEUE for the MA0C broker and is the queue the broker reads from.

**BrokerVersion**
Set this value to BASIC for the MA0C broker.

**ClientID**
Set this value to whatever you like for the MA0C broker (the value is string and is merely an identifier for your client application).

**XA Enabled**
Set this value to TRUE or FALSE for the MA0C broker (the setting you use is a performance enhancement flag - you probably want to set this value to 'true' most of the time).

**BrokerMessage Selection**
This value is fixed at CLIENT for the MA0C broker because the broker relies on client side message selection.

**Direct Broker Authorization Type**
This value is not required by the MA0C broker.

A topic connection factory for the WebSphere MQ JMS provider has the following properties.

*Name:*

The name by which this topic connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the JMS provider.

**Data type** String

*Description:*

A description of this topic connection factory for administrative purposes within WebSphere Application Server.

**Data type** String

*JNDI Name:*

The Java Naming and Directory Interface (JNDI) name that is used to bind the topic connection factory into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

| | |
|---|---|
| **Data type** | String |
| **Units** | En_US ASCII characters |
| **Range** | 1 through 45 ASCII characters |

*User ID:*

The user ID used, with the password property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the user ID property, you must also specify a value for the password property.

The connection factory user ID and password properties are used if the calling application does not provide a user ID and password explicitly, for example, if the calling application uses the method createTopicConnection(). The JMS client flows the user ID and password to the JMS server.

| | |
|---|---|
| **Data type** | String |

*Password:*

The password used, with the user ID property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the user ID property, you must also specify a value for the password property.

| | |
|---|---|
| **Data type** | String |

*Re-Enter Password:*

Confirms the password.

*Queue Manager:*

The name of the WebSphere MQ queue manager for this connection factory. Connections created by this connection factory connect to this queue manager.

| | |
|---|---|
| **Data type** | String |

*Enter Hostname and Port Information:*

This radio button is selected by default and, if selected, enables the host and port properties and disables the connection name list property.

| | |
|---|---|
| **Data type** | Radio button |
| **Default** | Selected |

*Host:*

The name of the host on which the WebSphere MQ queue manager runs for client connections only.

| | |
|---|---|
| **Data type** | String |
| **Range** | A valid TCP/IP host name |

*Port:*

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

| | |
|---|---|
| **Data type** | Integer |
| **Range** | A valid TCP/IP port number, configured on the WebSphere MQ queue manager. |

*Enter Connection Name List Information:*

If selected, this radio button enables the connection name list property and disables the host and port name properties. Select this radio button if you want to connect to a multi-instance queue manager.

| | |
|---|---|
| **Data type** | Radio button |
| **Default** | Cleared |

*Connection Name List:*

A comma-separated list of host and port information which can be used to connect to a multi-instance queue manager.

The format of the list is:

```
host[(port)],[host[(port)]]
```

where port is optional and defaults to 1414 if it is not set. For example:

```
hostname1,hostname2(1415)
```

For further information about multi-instance queue managers, see the WebSphere MQ information center.

This property must only be used for connecting to a multi-instance queue manager. It must not be used for connecting to a list of distinct queue managers as that can result in transaction integrity issues.

*Channel:*

The name of the channel used for client connections to the WebSphere MQ queue manager, for client connection only.

| | |
|---|---|
| **Data type** | String |
| **Range** | 1 through 20 ASCII characters |

*Transport Type:*

Whether WebSphere MQ client connection or JNDI bindings are used for connection to the WebSphere MQ queue manager.

**Data type** Enum
**Default** BINDINGS
**Range**
**CLIENT**
WebSphere MQ client connection is used to connect to the WebSphere MQ queue manager.
**BINDINGS**
JNDI bindings are used to connect to the WebSphere MQ queue manager.

*Client ID:*

The JMS client identifier used for connections to the WebSphere MQ queue manager.

**Data type** String

*CCSID:*

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs that WebSphere MQ supports. See the properties for the topic destination for more details.

**Data type** String
**Units** Integer
**Range** 1 through 65535

*Broker Control Queue:*

The name of the broker control queue to which all command messages (except publications and requests to delete publications) are sent.

**Data type** String
**Units** En_US ASCII characters
**Range** 1 through 48 ASCII characters

*Broker Queue Manager:*

The name of the WebSphere MQ queue manager that provides the Publisher and Subscriber message broker.

**Data type** String
**Units** En_US ASCII characters
**Range** 1 through 48 ASCII characters

*Broker Publish Queue:*

The name of the broker input queue that receives all publication messages for the default stream.

The name of the broker's input queue (stream queue) that receives all publication messages for the default stream. Applications can also send requests to delete publications on the default stream to this queue.

**Data type** String
**Units** En_US ASCII characters
**Range** 1 through 48 ASCII characters

*Broker Subscribe Queue:*

The name of the broker queue from which nondurable subscription messages are retrieved.

The name of the broker queue from which nondurable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a subscription.

**Data type** String
**Units** En_US ASCII characters
**Range** 1 through 48 ASCII characters

*Broker CCSubQ:*

The name of the broker queue from which nondurable subscription messages are retrieved for a ConnectionConsumer request. This property applies only for use of the web container.

**Data type** String
**Units** En_US ASCII characters
**Range** 1 through 48 ASCII characters

*Broker Version:*

Whether the message broker is provided by the WebSphere MQ MA0C SupportPac or newer versions of WebSphere family message broker products.

**Data type** Enum
**Default** Advanced
**Range**

**Advanced**
The message broker is provided by newer versions of WebSphere family message broker products (WebSphere MQ Integrator and WebSphere MQ Publish and Subscribe).

**Basic**
The message broker is provided by the WebSphere MQ MA0C SupportPac (WebSphere MQ - Publish and Subscribe).

*Cleanup level:*

The level of cleanup provided by the publish or subscribe cleanup utility.

**Data type** Enum
**Default** SAFE
**Range**

**ASPROP**

**NONE**

**STRONG**

*Cleanup interval:*

The interval, in milliseconds, between background executions of the publish/subscribe cleanup utility.

**Data type** Integer
**Units** Milliseconds
**Default** 6000

*Message selection:*

Where broker message selection is performed.

**Data type** Enum
**Default** BROKER
**Range**

**BROKER**
Message selection is performed at the broker location.

**Message CLIENT**
Message selection is performed at the client location.

*Publish acknowledge interval:*

The interval, in number of messages, between publish requests that require acknowledgment from the broker.

**Data type** Integer
**Default** 25

*Sparse subscriptions:*

Enables sparse subscriptions.

**Data type** Check box
**Default** Cleared

*Status refresh interval:*

The interval, in milliseconds, between transactions to refresh the publish or subscribe status.

**Data type** Integer
**Default** 6000

*Subscription store:*

Where WebSphere MQ stores data relating to active JMS subscriptions.

**Data type** Enum
**Default** MIGRATE
**Range**

**MIGRATE**

**QUEUE**

**BROKER**

*Multicast:*

Whether this connection factory uses multicast transport.

**Data type** Enum
**Default** NOT USED
**Range**

**NOT USED**
This connection factory does not use multicast transport.

**ENABLED**
This connection factory always uses multicast transport.

**ENABLED_IF_AVAILABLE**
This connection factory uses multicast transport.

**ENABLED_RELIABLE**
This connection factory uses reliable multicast transport.

**ENABLED_RELIABLE_IF_AVAILABLE**
This connection factory uses reliable multicast transport if available.

*Direct authentication:*

Whether to use direct broker authorization.

**Data type** Enum
**Default** NONE
**Range**

**NONE** Direct broker authorization is not used.

**PASSWORD**
Direct broker authorization is authenticated with a password.

**CERTIFICATE**
Direct broker authorization is authenticated with a certificate.

*Proxy Host Name:*

The host name of a proxy to be used for communication with WebSphere MQ.

**Data type** String

*Proxy Port:*

The port number of a proxy to be used for communication with WebSphere MQ.

**Data type** Integer
**Default** 0

*Fail if quiesce:*

Whether applications return from a method call if the queue manager has entered a controlled failure.

| | |
|---|---|
| **Data type** | Check box |
| **Default** | Selected |

*Local Server Address:*

The local server address.

| | |
|---|---|
| **Data type** | String |

*Polling Interval:*

The interval, in milliseconds, between scans of all receivers during asynchronous message delivery.

| | |
|---|---|
| **Data type** | Integer |
| **Units** | Milliseconds |
| **Default** | 5000 |

*Rescan interval:*

The interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

The rescan interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

| | |
|---|---|
| **Data type** | Integer |
| **Units** | Milliseconds |
| **Default** | 5000 |

*SSL cipher suite:*

The cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider. The value must match the CipherSpec specified on the SVRCONN channel as the **Channel** property.

You must set this property, if you set the **SSL Peer Name** property.

*SSL certificate store:*

A list of zero or more Certificate Revocation List (CRL) servers that are used to check for SSL certificate revocation. If you specify a value for this property, you must use WebSphere MQ JVM at Java 2 version 1.4.

The value is a space-delimited list of entries of the form:
`ldap://hostname:[port]`

A single slash (/) follows this value. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the information about “Working with Certificate Revocation Lists” in the *Security* section of the WebSphere MQ information center.

*SSL peer name:*

For SSL, a *distinguished name* skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connection time.

If this property is not set, such certificate checking is performed.

The SSL peer name property is ignored if **SSL Cipher Suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:

```
CN=QMGR.*, OU=IBM, OU=WEBSPHERE
```

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the information about "Distinguished Names" in the Security section of the WebSphere MQ information center.

*Connection pool:*

An optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This connection pooling is independent from any WebSphere MQ connection pooling. You must configure the connection and session pool properties appropriately for your applications, otherwise you might not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

| | |
|---|---|
| **Data type** | Check box |
| **Default** | Selected |

*Client reconnect options:*

Specifies whether a client mode connection reconnects automatically, or not, in the event of a communications or queue manager failure. This property is ignored unless the connection factory is being used in a thin or managed client environment.

| | |
|---|---|
| **Data type** | Drop-down list |
| **Default** | DISABLED |

**Range**

**DISABLED**
The client reconnection does not automatically occur.

**ASDEF** The value from the DefRecon attribute from the channels stanza of the client configuration file is used. If there is no DefRecon value specified then this setting has the same effect as a value of DISABLED.

**RECONNECT**
Reconnection occurs to any queue manager consistent with the value of the queue manager attribute, which might be a different queue manager from that to which the connection was originally connected.

**QMGR** Reconnection only occurs to the queue manager to which the connection was originally connected.

For more information about automatic client reconnection, see the WebSphere MQ information center.

*Client reconnect timeout:*

The maximum number of seconds that a client mode connection spends attempting to automatically reconnect to a queue manager after a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment. Whether this parameter is used or not depends on the value of the client reconnect options parameter.

| | |
|---|---|
| **Data type** | Integer |
| **Units** | Seconds |
| **Default** | 1800 |
| **Range** | A value greater than zero and up to 2147483647 |

For more information about automatic client reconnection, see the WebSphere MQ information center.

***WebSphere MQ Provider queue destination settings for application clients:***

Use this panel to view or change the configuration properties of the selected queue destination for use with the WebSphere MQ product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file and click **Messaging Providers** > **WebSphere MQ Provider**. Right-click **Queue Destinations** and click **New**. The following fields are displayed on the **General** tab.

**Note:**

- The property values that you specify must match the values that you specified when configuring JMS resources for WebSphere MQ. For more information about configuring JMS resources for WebSphere MQ, see *Using Java* in the WebSphere MQ information center.
- In WebSphere MQ, names can have a maximum of 48 characters.

A queue for use with the WebSphere MQ product JMS provider has the following properties.

*Name:*

The name by which the queue is known for administrative purposes within WebSphere Application Server.

**Data type** String

*Description:*

A description of the queue, for administrative purposes within WebSphere Application Server.

**Data type** String

*JNDI Name:*

The application client runtime environment uses this field to retrieve configuration information.

*Persistence:*

Whether all messages sent to the destination are persistent, nonpersistent or have their persistence defined by the application.

**Data type** Enum
**Default** APPLICATION_DEFINED
**Range**
**Application defined**
Messages on the destination have their persistence defined by the application that put them onto the queue.
**Queue defined**
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
**Persistent**
Messages on the destination are persistent.
**Nonpersistent**
Messages on the destination are not persistent.

*Priority:*

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

**Data type** Enum
**Units** Not applicable
**Default** APPLICATION_DEFINED
**Range**
**Application defined**
The priority of messages on this destination is defined by the application that put them onto the destination.
**Queue defined**
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
**Specified**
The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

*Specified Priority:*

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

**Data type** Integer
**Units** Message priority level
**Range** 0 (lowest priority) through 9 (highest priority)

*Expiry:*

Whether the expiry timeout value for this queue is defined by the application or the by **Specified expiry** property or whether messages on the queue never expire (have an unlimited expiry time out).

**Data type** Enum
**Units** Not applicable
**Default** APPLICATION_DEFINED
**Range**
**Application defined**
The expiry timeout for messages on this queue is defined by the application that put them onto the queue.
**Specified**
The expiry timeout for messages on this queue is defined by the **Specified expiry** property. If you select this option, you must define a timeout on the **Specified expiry** property.
**Unlimited**
Messages on this queue have no expiry timeout and those messages never expire.

*Specified Expiry:*

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire.

**Data type** Integer
**Units** Milliseconds
**Range** Greater than or equal to 0
- 0 indicates that messages never time out
- Other values are an integer number of milliseconds

*Base Queue Name:*

The name of the queue to which messages are sent, on the queue manager specified by the **Base queue manager name** property.

**Data type** String

*Base Queue Manager Name:*

The name of the WebSphere MQ queue manager to which messages are sent.

This queue manager provides the queue specified by the **Base queue name** property.

**Data type** String
**Units** En_US ASCII characters
**Range** A valid WebSphere MQ Queue Manager name, as 1 through 48 ASCII characters

*CCSID:*

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ queue manager. See the WebSphere MQ messaging provider queue and topic advanced properties settings for more details.

**Data type** String

*Integer encoding:*

If native encoding is not enabled, select whether integer encoding is normal or reversed.

**Data type** Enum
**Default** NORMAL
**Range**
**NORMAL**
Normal integer encoding is used.
**REVERSED**
Reversed integer encoding is used.

For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

*Decimal encoding:*

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

**Data type** Enum
**Default** NORMAL
**Range**
**NORMAL**
Normal decimal encoding is used.
**REVERSED**
Reversed decimal encoding is used.

For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

*Floating point encoding:*

If native encoding is not enabled, select the type of floating point encoding.

**Data type** Enum
**Default** IEEENORMAL
**Range**
**IEEENORMAL**
IEEE normal floating point encoding is used.
**IEEEREVERSED**
IEEE reversed floating point encoding is used.
**S390** S390 floating point encoding is used.

For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

*Native encoding:*

Indicates that the queue destination uses native encoding (appropriate encoding values for the Java platform) when you select this check box.

**Data type** Enum
**Default** Cleared
**Range**
**Cleared**
Native encoding is not used, so specify the following properties for integer, decimal and floating point encoding.
**Selected**
Native encoding is used (to provide appropriate encoding values for the Java platform).

For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

*Target client:*

Whether the receiving application is JMS compliant or is a traditional WebSphere MQ application.

**Data type** Enum
**Default** WebSphere MQ
**Range**
**WebSphere MQ**
The target is a traditional WebSphere MQ application that does not support JMS.
**JMS** The target application supports JMS.

*Message body:*

Specifies whether an application processes the RFH version 2 header of a WebSphere MQ message as part of the JMS message body.

**Data type** Drop-down list
**Default** UNSPECIFIED
**Range**
**UNSPECIFIED**
When sending messages, the WebSphere MQ messaging provider does or does not generate and include an RFH version 2 header, depending on the value of the Append RFH version 2 headers to messages sent to this destination property. When receiving messages, the WebSphere MQ messaging provider acts as if the value is set to JMS.
**JMS** When sending messages, the WebSphere MQ messaging provider automatically generates an RFH version 2 header and includes it in the WebSphere MQ message. When receiving messages, the WebSphere MQ messaging provider sets the JMS message properties according to values in the RFH version 2 header (if these value are present); it does not present the RFH version 2 header as part of the JMS message body.
**MQ** When sending messages, the WebSphere MQ messaging provider does not generate an RFH version 2 header. When receiving messages, the WebSphere MQ messaging provider presents the RFH version 2 header as part of the JMS message body.

*ReplyTo destination style:*

Specifies the format of the JMSReplyTo field.

**Data type** Drop-down list
**Default** DEFAULT

**Range**

**DEFAULT**
The default value is equivalent to the information in the RFH version 2 header.

**MQMD** Use the value supplied in the MQMD. This populates the reply to queue manager field with the value from the MQMD, equivalent to the default behaviour of WebSphere MQ Version 6.0.2.4 and 6.0.2.5.

**RFH2** Use the value supplied in the RFH version 2 header. If the sending application set a JMSReplyTo value, then that value is used.

*MQMD read enabled:*

Specifies whether an application can read the values of MQMD fields from JMS messages that have been sent or received using the WebSphere MQ messaging provider.

**Data type** Check box

**Default** Cleared

**Range**

**Cleared**
Applications cannot read the values of the MQMD fields.

**Selected**
Applications can read the values of the MQMD fields.

*MQMD write enabled:*

Specifies whether an application can write the values of MQMD fields to JMS messages that will be sent or received using the WebSphere MQ messaging provider.

**Data type** Check box

**Default** Cleared

**Range**

**Cleared**
Applications cannot write the values of the MQMD fields.

**Selected**
Applications can write the values of the MQMD fields.

*MQMD message context:*

Defines the message context options specified when sending messages to a destination.

**Data type** Drop-down list

**Default** DEFAULT

**Range**

**DEFAULT**
The MQOPEN API call and the MQPMO structure specify no explicit message context options.

**SET_IDENTITY_CONTEXT**
The MQOPEN API call specifies the message context option MQOO_SET_IDENTITY_CONTEXT, and the MQPMO structure specifies MQPMO_SET_IDENTITY_CONTEXT.

**SET_ALL_CONTEXT**
The MQOPEN API call specifies the message context option MQOO_SET_ALL_CONTEXT, and the MQPMO structure specifies MQPMO_SET_ALL_CONTEXT.

*Custom Properties:*

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

***WebSphere MQ Provider topic destination settings for application clients:***

Use this panel to view or change the configuration properties of the selected topic destination for use with the WebSphere MQ product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right click **Topic Destinations**, and click **New**. The following fields are displayed on the **General** tab.

**Note:**

- The property values that you specify must match the values that you specified when configuring JMS resources for WebSphere MQ. For more information about configuring JMS resources for WebSphere MQ, see *Using Java* in the WebSphere MQ information center.
- In WebSphere MQ, names can have a maximum of 48 characters.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. A topic for use with the WebSphere MQ product JMS provider has the following properties.

*Name:*

The name by which the topic is known for administrative purposes within WebSphere Application Server.

**Data type** String

*Description:*

A description of the topic for administrative purposes within WebSphere Application Server.

**Data type** String

*JNDI Name:*

The application client runtime environment uses this field to retrieve configuration information.

*Persistence:*

Whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

**Data type** Enum
**Default** APPLICATION_DEFINED
**Range**
**Application defined**
Messages on the destination have their persistence defined by the application that put them in the queue.
**Queue defined**
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
**Persistent**
Messages on the destination are persistent.
**Nonpersistent**
Messages on the destination are not persistent.

*Priority:*

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

**Data type** Enum
**Default** APPLICATION_DEFINED
**Range**
**Application defined**
The priority of messages on this destination is defined by the application that put them in the destination.
**Queue defined**
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
**Specified**
The priority of messages on this destination is defined by the **Specified priority** property. If you select this option, you must define a priority for the **Specified priority** property.

*Specified Priority:*

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

**Data type** Integer
**Units** Message priority level
**Range** 0 (lowest priority) through 9 (highest priority)

*Expiry:*

Whether the expiry timeout for this queue is defined by the application or by the **Specified expiry** property, or whether messages on the queue never expire (have an unlimited expiry timeout).

**Data type** Enum
**Default** APPLICATION_DEFINED
**Range**
**Application defined**
The expiry timeout for messages on this queue is defined by the application that put them in the queue.
**Specified**
The expiry timeout for messages in this queue is defined by the **Specified expiry** property. If you select this option, you must define a timeout value for the **Specified expiry** property.
**Unlimited**
Messages on this queue have no expiry timeout, and these messages never expire.

*Specified Expiry:*

If the **Expiry timeout** property is set to `Specified`, type the number of milliseconds (greater than 0) after which messages on this queue expire.

**Data type** Integer

**Units** Milliseconds
**Range** Greater than or equal to 0
- 0 indicates that messages never time out.
- Other values are an integer number of milliseconds.

*Base Topic Name:*

The name of the topic to which messages are sent.

**Data type** String

*CCSID:*

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs that WebSphere MQ supports.

**Data type** String
**Units** Integer
**Range** 1 through 65535

*Integer encoding:*

If native encoding is not enabled, select whether integer encoding is normal or reversed.

**Data type** Enum
**Default** NORMAL
**Range**
**NORMAL**
Normal integer encoding is used.
**REVERSED**
Reversed integer encoding is used.

For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

*Decimal encoding:*

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

**Data type** Enum
**Default** NORMAL
**Range**
**NORMAL**
Normal decimal encoding is used.
**REVERSED**
Reversed decimal encoding is used.

For more information about encoding properties, see *Using Java* in the information WebSphere MQ center.

*Floating point encoding:*

If native encoding is not enabled, select the type of floating point encoding.

**Data type** Enum

**Default** IEEENORMAL

**Range**

**IEEENORMAL**
IEEE normal floating point encoding is used.

**IEEEREVERSED**
IEEE reversed floating point encoding is used.

**S390** S/390® floating point encoding is used.

For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

*Native encoding:*

Indicates that the queue destination uses native encoding (appropriate encoding values for the Java platform) when you select this check box.

**Data type** Enum

**Default** Cleared

**Range**

**Cleared**
Native encoding is not used, so specify the previous properties for integer, decimal and floating point encoding.

**Selected**
Native encoding is used (to provide appropriate encoding values for the Java platform).

For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

*BrokerDurSubQueue:*

The name of the broker queue from which durable subscription messages are retrieved.

The subscriber specifies the name of the queue when it registers a subscription.

**Data type** String

**Units** En_US ASCII characters

**Range** 1 through 48 ASCII characters

*BrokerCCDurSubQueue:*

The name of the broker queue from which durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the web container.

**Data type** String

**Units** En_US ASCII characters

**Range** 1 through 48 ASCII characters

*Target Client:*

Whether the receiving application is JMS compliant or is a traditional WebSphere MQ application.

**Data type** Enum

**Default** WebSphere MQ

**Range** **WebSphere MQ**
The target is a traditional WebSphere MQ application that does not support JMS.
**JMS** The target application supports JMS.

*Message body:*

Specifies whether an application processes the RFH version 2 header of a WebSphere MQ message as part of the JMS message body.

**Data type** Drop-down list
**Default** UNSPECIFIED
**Range** **UNSPECIFIED**
When sending messages, the WebSphere MQ messaging provider does or does not generate and include an RFH version 2 header, depending on the value of the Append RFH version 2 headers to messages sent to this destination property. When receiving messages, the WebSphere MQ messaging provider acts as if the value is set to JMS.
**JMS** When sending messages, the WebSphere MQ messaging provider automatically generates an RFH version 2 header and includes it in the WebSphere MQ message. When receiving messages, the WebSphere MQ messaging provider sets the JMS message properties according to values in the RFH version 2 header (if these value are present); it does not present the RFH version 2 header as part of the JMS message body.
**MQ** When sending messages, the WebSphere MQ messaging provider does not generate an RFH version 2 header. When receiving messages, the WebSphere MQ messaging provider presents the RFH version 2 header as part of the JMS message body.

*ReplyTo destination style:*

Specifies the format of the JMSReplyTo field.

**Data type** Drop-down list
**Default** DEFAULT
**Range** **DEFAULT**
The default value is equivalent to the information in the RFH version 2 header.
**MQMD** Use the value supplied in the MQMD. This populates the reply to queue manager field with the value from the MQMD, equivalent to the default behaviour of WebSphere MQ Version 6.0.2.4 and 6.0.2.5.
**RFH2** Use the value supplied in the RFH version 2 header. If the sending application set a JMSReplyTo value, then that value is used.

*Multicast:*

Whether this connection factory uses multicast transport.

**Data type** Enum
**Default** AS_CF

**Range**

**AS_CF** This connection factory uses multicast transport.

**DISABLED**
This connection factory does not use multicast transport.

**NOT_RELIABLE**
This connection factory always uses multicast transport.

**RELIABLE**
This connection factory uses multicast transport when the topic destination is not reliable.

**ENABLED**
This connection factory uses reliable multicast transport.

*MQMD read enabled:*

Specifies whether an application can read the values of MQMD fields from JMS messages that have been sent or received using the WebSphere MQ messaging provider.

**Data type** Check box
**Default** Cleared
**Range**

**Cleared**
Applications cannot read the values of the MQMD fields.

**Selected**
Applications can read the values of the MQMD fields.

*MQMD write enabled:*

Specifies whether an application can write the values of MQMD fields to JMS messages that will be sent or received using the WebSphere MQ messaging provider.

**Data type** Check box
**Default** Cleared
**Range**

**Cleared**
Applications cannot write the values of the MQMD fields.

**Selected**
Applications can write the values of the MQMD fields.

*MQMD message context:*

Defines the message context options specified when sending messages to a destination.

**Data type** Drop-down list
**Default** DEFAULT
**Range**

**DEFAULT**
The MQOPEN API call and the MQPMO structure specify no explicit message context options.

**SET_IDENTITY_CONTEXT**
The MQOPEN API call specifies the message context option MQOO_SET_IDENTITY_CONTEXT, and the MQPMO structure specifies MQPMO_SET_IDENTITY_CONTEXT.

**SET_ALL_CONTEXT**
The MQOPEN API call specifies the message context option MQOO_SET_ALL_CONTEXT, and the MQPMO structure specifies MQPMO_SET_ALL_CONTEXT.

***Generic JMS connection factory settings for application clients:***

Use this panel to view or change the configuration properties of the selected Java Message Service (JMS) connection factory for use with the associated JMS provider. These configuration properties control how connections are created between the JMS provider and the messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > *new_JMS_Provider_instance*. Right-click **Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

A Java Message Service (JMS) connection factory creates connections to JMS destinations. The JMS connection factory is created by the associated JMS provider. A JMS connection factory for a generic JMS provider (other than the internal default messaging provider or WebSphere MQ as a JMS provider) has the following properties:

*Name:*

The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the associated JMS provider.

**Data type** String

*Description:*

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

**Data type** String
**Default** Null

*JNDI Name:*

The application client run time uses this field to retrieve configuration information.

*User ID:*

Indicates the user ID used with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a userid and password explicitly; for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

**Data type** String

*Password:*

The password used with the **User ID** property for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

**Data type** String
**Default** Null

*Re-Enter Password:*

Confirms the password entered in the **Password** field.

*External JNDI Name:*

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name, for example, `jms/`*`Name`*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI API by the platform.

**Data type** String

*Connection Type:*

Whether this JMS destination is a queue (for point-to-point) or topic (for publication or subscription).

Select one of the following options:
**Queue**
A JMS queue destination for point-to-point messaging.
**Topic** A JMS topic destination for publish subscribe messaging.

*Custom Properties:*

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

***Generic JMS destination settings for application clients:***

Use this panel to view or change the configuration properties of the selected JMS destination for use with the associated JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > *new JMS Provider instance*. Right-click **Destinations**, and click **New**. The following fields are displayed on the **General** tab.

A JMS destination is used to configure the properties of a JMS destination for the associated generic JMS provider. Connections to the JMS destination are created by the associated JMS connection factory. A JMS destination for use with a generic JMS provider (not the default messaging provider or WebSphere MQ as a JMS provider) has the following properties.

*Name:*

The name by which the queue is known for administrative purposes within WebSphere Application Server.

**Data type** String

*Description:*

A description of the queue, for administrative purposes.

*JNDI Name:*

The JNDI name of the actual (physical) name of the JMS destination bound into JNDI.

*External JNDI Name:*

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

**Data type** String

*Destination Type:*

Whether this JMS destination is a queue (for point-to-point) or topic (for publishing or subscribing).

Select one of the following options:
**Queue**
A JMS queue destination for point-to-point messaging.
**Topic** A JMS topic destination for pub/sub messaging.

*Custom Properties:*

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

***Example: Configuring JMS provider, JMS connection factory and JMS destination settings for application clients:***

You can configure JMS Provider, JMS Connection Factory and JMS Destination settings. This topic provides the required fields, special cases, and an example.

The purpose of this article is to help you to configure JMS Provider, JMS Connection Factory and JMS Destination settings.
- Required fields include:
  - JMS Provider Properties page: name, and at least one protocol provider
  - JMS Connection Factory Properties page: name, jndiName, destination type
  - JMS Destination Properties page: name, jndiName, destination type

- Special cases:
  - The destination type must be `QUEUE`, or `TOPIC`.
- Example:

```
<resources.jms:JMSProvider xmi:id="JMSProvider_3" name="genericJMSProvider:name"
description="genericJMSProvider:description"
externalInitialContextFactory="genericJMSProvider:contextFactoryClass"
externalProviderURL="genericJMSProvider:providerUrl">
<classpath>genericJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms:GenericJMSDestination"
xmi:id="GenericJMSDestination_1" name="jmsDestination:name"
jndiName="jmsDestination:jndiName" description="jmsDestination:description"
externalJNDIName="jmsDestination:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_15">
<resourceProperties xmi:id="J2EEResourceProperty_17" name="jmsDestination:customName"
value="jmsDestination:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms:GenericJMSConnectionFactory"
xmi:id="GenericJMSConnectionFactory_1" name="jmsCF:name" jndiName="jmsCF:jndiName"
description="jmsCF:description" userID="jmsCF:user" password="{xor}NTIsHBllMT4yOg=="
externalJNDIName="jmsCF:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_16">
<resourceProperties xmi:id="J2EEResourceProperty_18" name="jmsCF:customName"
value="jmsCF:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_17">
<resourceProperties xmi:id="J2EEResourceProperty_19"
name="genericJMSProvider:customName" value="genericJMSProvider:customValue"/>
</propertySet>
</resources.jms:JMSProvider>
```

## Configuring new JMS connection factories for application clients

Use this task to create a new Java Message Service (JMS) connection factory configuration for your application client.

### Procedure

1. Click the JMS provider for which you want to create a connection factory in the tree. Complete one of the following actions:
   - Configure a new JMS provider.
   - Click an existing JMS provider.
2. Expand the JMS provider to view its Connection Factories folder.
3. Click the connection factory folder, and complete one of the following actions:
   - Right-click the folder and select**New**.
   - Click **Edit > New** on the menu bar.
4. Configure the JMS connection factory properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

## Configuring new JMS destinations for application clients

Use this task to create a new Java Message Service (JMS) destination configuration for your application client.

### Procedure

1. Click the JMS provider in the tree for which you want to create a destination. Complete one of the following actions:
   - Configure a new JMS provider.
   - Click an existing JMS provider.

2. Expand the JMS provider to view its Destinations folder.
3. Click the provider folder, and complete one of the following actions:
   - Right-click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
4. Configure the JMS destination properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

## Configuring new resource environment providers for application clients

You can create new resource environment provider configurations for your application client using the Application Client Resource Configuration Tool (ACRCT).

### Before you begin

During this task, you create new resource environment provider configurations for your application client.

### About this task

To configure a new resource environment provider, perform the following steps:

### Procedure

1. Start the Application Configuration Resource Tool and open the EAR file for which you want to configure the new Java Message Service (JMS) provider. The EAR file contents display in a tree view.
2. Select from the tree the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Click the **Resource Environment Providers** folder. Take one of the following actions:
   - Right-click the provider folder, and click **New**.
   - Click **Edit > New** on the menu bar.
5. Configure the JMS provider properties in the displayed fields.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

***Resource environment provider settings for application clients:***

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected Java Archive (JAR) file. Right-click **Resource Environment Providers**, and click **New**. The following fields are displayed on the **General** tab:

*Name:*

Specifies the administrative name for the resource environment provider.

*Description:*

Specifies a description of the resource environment provider for your administrative records.

*Class Path:*

Specifies the path to the JAR file that contains the implementation classes for the resource environment provider.

*Custom Properties:*

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

## Configuring new resource environment entries for application clients

You can create new resource environment entries for your client application using the Application Client Resource Configuration Tool (ACRCT).

### Before you begin

During this task, you create new resource environment entries for your client application.

### About this task

### Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new resource environment entry. The EAR file contents are in the displayed tree view.
3. Click the desired resource environment provider, and complete the following action to configure new providers:
   - Configure a new resource environment provider.
4. Expand the resource environment provider to view the Resource Environment Entries folder.
5. Click the resource environment entries folder, and complete one of the following actions:
   - Right-click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
6. Configure the resource environment entry properties in the displayed fields.
7. Click **OK**.
8. Click **File > Save** on the menu bar to save your changes.

***Resource environment entry settings for application clients:***

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Environment Providers** > *resource environment instance*. Right-click **Resource Environment Entries**, and click **New**. The following fields appear on the **General** tab:

*Name:*

Specifies the administrative name for the resource environment entry.

*Description:*

Specifies a description of the URL for your administrative records.

*JNDI Name:*

Specifies the Java Naming and Directory Interface (JNDI) name for the resource, including any naming subcontexts.

Use this name to link to the binding information of the platform. The binding associates the resources defined in the deployment descriptor of the module to the actual (or physical) resources bound into JNDI by the platform.

*Custom Properties:*

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

***Example: Configuring Resource Environment settings:***

You can configure Resource Environment settings. This topic provides the required fields and an example.

The purpose of this topic is to help you configure Resource Environment settings.
- Required fields:
  - Resource Environment Provider page: **Name**
  - Resource Environment Entry page: **Name, JNDI Name**
- Example:

```
<resources.env:ResourceEnvironmentProvider xmi:id="ResourceEnvironmentProvider_1"
name="resourceEnvProvider:name" description="resourceEnvProvider:description">
<classpath>resourceEnvProvider:classpath</classpath>
<factories xmi:type="resources.env:ResourceEnvEntry" xmi:id="ResourceEnvEntry_1"
name="resourceEnvEntry:name" jndiName="resourceEnvEntry:jndiName"
description="resourceEnvEntry:description">
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_21">
<resourceProperties xmi:id="J2EEResourceProperty_23"
name="resourceEnvProvider:customName" value="resourceEnvProvider:customValue"/>
</propertySet>
</resources.env:ResourceEnvironmentProvider>
```

***Example: Configuring resource environment custom settings for application clients:***

You can configure resource environment custom settings.

The purpose of this topic is to help you configure resource environment custom settings.
- The custom page applies to every resource type. You can specify as many custom names and values as you need.
- Example:

```
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
```

## Running a Java EE client application with launchClient

After deploying a Java EE client application onto a machine with an Application Client installation or in a WebSphere Application Server node, you can start the application by using the launchClient command on that machine.

## Before you begin

Before you can use the launchclient command to run a Java EE client application, you must have deployed the application.

This task only applies to Java EE client applications.

## About this task

The Java Platform, Enterprise Edition (Java EE) specification requires support for a client container that runs Java applications (known as Java EE client applications) and provides Java EE services to the applications. Java EE services include naming, security, and resource connections.

## Procedure

1. Enter the following command to launch Java EE application clients:
   *app_client_root*/bin/launchClient
2. Pass parameters to the launchClient command or to your application client program as well. The launchClient command allows you to do both. The launchClient command requires that the first parameter is either:
   - An EAR file specifying the application client to launch.
   - A request for launchClient usage information.

   The following example illustrates the command line invocation syntax for the launchClient tool:

   launchClient [-profileName pName | -JVMOptions options | -help | -?] *userapp* [-CC*name=value*] [app args]

   where
   - *userapp* is the path and the name of the EAR file that contains the application client.
   - *-CCname=value* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.
   - *app args* are arguments that pass to the application client.
   - *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation.

     AIX Linux HP-UX Solaris Windows The default is default_profile.
   - *-JVMOptions* is a valid Java standard or non-standard option string. Insert quotation marks around the string.
   - *-help, -?* prints the usage information.

   All other parameters intended for the launchClient command must begin with the -CC prefix.

   Parameters that are not EAR files, or usage requests, or that do not begin with the -CC prefix, are ignored by the application client run time, and are passed directly to the application client program.

   The launchClient command retrieves parameters from three places:
   - The command line
   - A properties file
   - System properties

   The parameters are resolved in the order listed above, with command line values having the highest priority and system properties the lowest. Using this prioritization you can set and override default values.
3. Specify the server name.

   AIX Linux HP-UX Solaris Windows By default, the launchClient command uses the localhost for the BootstrapHost property value.

   This setting is effective for testing your application client when it is installed on the same computer as the server. However, in other cases override this value with the name of your server. You can override the BootstrapHost value by invoking launchClient command with the following parameters:

```
launchClient myapp.ear -CCBootstrapHost=abc.midwest.mycompany.com
```

You can also override the default by specifying the value in a properties file and passing the file name to the launchClient shell.

Security is controlled by the server. You do not need to configure security on the client because the client assumes that security is enabled. If server security is not enabled, then the server ignores the security request, and the application client functions as expected.

## Example

You can store launchClient values in a properties file, which is a good method for distributing default values. You can then override one or more values on the command line. The format of the file is one `launchClient -CC` parameter per line without the `-CC` prefix. For example:

Windows

```
 verbose=true classpath=c:\mydir\util.jar;c:\mydir\harness.jar;c:\production\G19
\global.jar BootstrapHost=abc.westcoast.mycompany.com tracefile=c:\WebSphere\mylog.txt
```

AIX HP-UX Linux Solaris

```
 verbose=true classpath=/usr/lpp/mydir/util.jar;/usr/lpp/mydir/harness.jar;/usr/lpp
/production/G19/global.jar BootstrapHost=abc.westcoast.mycompany.com tracefile=/usr
/lpp/WebSphere/mylog.txt
```

## launchClient tool

This topic describes the Java Platform, Enterprise Edition (Java EE) command line syntax for the launchClient tool for WebSphere Application Server.

**Important:** All users who run commands from a specific profile must have authority to modify files that are created by other users that use the same profile. Otherwise, you might see a permission denied error in the log files. To avoid this issue, consider one of the following policies:

- Use specific profiles for distinct user authorities
- Always use the same user for all of the commands that are run in a given profile
- Ensure that all users of a specific profile belong to the same group. In addition, ensure that each user of a group has the read and write authority to the files that are created by other members in the same profile.

The following example illustrates the command line invocation syntax for the launchClient tool:

`launchClient [-profileName pName | -JVMOptions options | -help | -?] userapp [-CCname=value] [app args]`

where

- *userapp* is the path and the name of the EAR file that contains the application client.
- *-CCname=value* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.
- *app args* are arguments that pass to the application client.
- *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation.

  The default is `default_profile`.
- *-JVMOptions* is a valid Java standard or nonstandard option string, except `-cp` or `-classpath`. Insert quotation marks around the string.
- *-help, -?* prints the usage information.

The first parameter must be `-help`, `-?` or contain no parameter at all. The `-profileName pName` and `-JVMOptions` options are optional parameters. If used, they must appear before the *<userapp>* parameter.

All other parameters are optional and can appear in any order after the *userapp* parameter. The Java EE Application client run time ignores any optional parameters that do not begin with a `-CC` prefix and passes those parameters to the application client.

### Client container parameters

Supported arguments include:

**-CCadminConnectorHost**
Specifies the host name of the server from which configuration information is retrieved.

The default is the value of the `-CCBootstrapHost` parameter or the value, `localhost`, if the `-CCBootstrapHost` parameter is not specified.

**-CCadminConnectorPort**
Indicates the port number for the administrative client function to use. The default value is `8880` for SOAP connections and `2809` for Remote Method Invocation (RMI) connections.

**-CCadminConnectorType**
Specifies how the administrative client connects to the server. Specify `RMI` to use the RMI connection type, or specify `SOAP` to use the SOAP connection type. The default value is `SOAP`.

**-CCadminConnectorUser**
Administrative clients use this user name when a server requires authentication. If the connection type is SOAP, and security is enabled on the server, this parameter is required.

**-CCadminConnectorPassword**
The password for the user name that the `-CCadminConnectorUser` parameter specifies.

**-CCaltDD**
The name of an alternate deployment descriptor file. This parameter is used with the `-CCjar` parameter to specify the deployment descriptor to use. Use this argument when a client JAR file is configured with more than one deployment descriptor. Set the value to `null` to use the client JAR file standard deployment descriptor.

**-CCBootstrapHost**
The name of the host server you want to connect to initially. The format is:
*your_server_of_choice.com*

**-CCBootstrapPort**
The server port number. If you do not specify this argument, the WebSphere Application Server default value is `used`.

**-CCclassLoaderMode**
Specifies the class loader mode. If PARENT_LAST is specified, the class loader loads classes from the local class path before delegating the class loading to its parent. The classes loaded for the following are affected:

- Classes defined for the Java EE application client
- Resources defined in the Java EE application
- Classes specified on the manifest of the Java EE client JAR file
- Classes specified using the -CCclasspath option

If PARENT_LAST is not specified, then the default mode, PARENT_FIRST, causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path.

**-CCclasspath**
A class path value. When you launch an application, the system class path is used. If you want to access classes that are not in the EAR file or part of the system class paths, specify the appropriate class path here. Multiple paths can be concatenated.

**-CCD**
Use this option to have the WebSphere Application Server set the specified system property during initialization. Do not use the equals (=) character after the -CCD. For example: -CCDcom.ibm.test.property=testvalue. You can specify multiple -CCD parameters. The general format of this parameter is -CCD<property key>=<property value>. For example, -CCDI18NService.enable=true.

**-CCdumpJavaNameSpace**
Controls generation of a dump of the java: name space for the application that is launched, which can be used for debugging purposes. A value of **true** generates a dump in short format, and includes the name and object type for each binding. A value of **long** generates a dump in long format, and includes additional information for each binding over short format, such as the local object type and string representation of the local object. The default value is **false**, and does not generate a dump.

**-CCexitVM**
Use this option to have the WebSphere Application Server call the System.exit() method after the client application completes. The default is false.

**-CCinitonly**
Use this option to initialize application client run time for ActiveX application clients without launching the client application. The default is false.

**-CCjar**
The name of the client Java Archive (JAR) file that resides within the EAR file for the application you wish to launch. Use this argument when you have multiple client JAR files in the EAR file.

**-CCpropfile**
Indicates the name of a properties file that contains launchClient properties. Specify the properties without the -CC prefix in the file, with the exception of the securityManager, securityMgrClass and securityMgrPolicy properties. See the following example: verbose=true.

**-CCproviderURL**
Provides bootstrap server information that the initial context factory can use to obtain an initial context. WebSphere Application Server initial context factory can use either a Common Object Request Broker Architecture (CORBA) object URL or an Internet Inter-ORB Protocol (IIOP) URL. CORBA object URLs are more flexible than IIOP URLs and are the recommended URL format to use. This value can contain more than one bootstrap server address. This feature can be used when attempting to obtain an initial context from a server cluster. You can specify bootstrap server addresses, for all servers in the cluster, in the URL. The operation will succeed if at least one of the servers is running, eliminating a single point of failure. The address list does not process in a particular order. For naming operations, this value overrides the -CCBootstrapHost and -CCBootstrapPort parameters. A CORBA object URL specifying multiple systems is illustrated in the following example:

```
-CCproviderURL=corbaloc:iiop:myserver.mycompany.com:9810,:mybackupserver.mycompany.com:2809
```

This value is mapped to the java.naming.provider.url system property.

**-CCsecurityManager**
Enables and runs the WebSphere Application Server with a security manager. The default is disable.

**-CCsecurityMgrClass**
Indicates the fully qualified name of a class that implements a security manager. Only use this argument if the -CCsecurityManager parameter is set to enable. The default is java.lang.SecurityManager.

**-CCsecurityMgrPolicy**
Indicates the name of a security manager policy file. Only use this argument if the -CCsecurityManager parameter is set to enable. When you enable this parameter, the java.security.policy system property is set. The default is *app_server_root*/properties/client.policy.

**-CCsoapConnectorPort**
The Simple Object Access Protocol (SOAP) connector port. If you do not specify this argument, the WebSphere Application Server default value is used.

**-CCtrace**
Use this option to obtain debug trace information. You might need this information when reporting a problem to IBM customer support. The default is `false`. For more information, read the Enabling trace topic.

**-CCtracefile**
Indicates the name of the file to which trace information is written. The default is to write output to the console.

**-CCtraceMode**
Specifies the trace format to use for tracing. If the valid value, `basic`, is not specified the default is advanced. Basic tracing format is a more compact form of tracing.

For more information on basic and advanced trace formatting, refer to the Interpreting trace output topic.

**-CCverbose**
This option displays additional information messages. The default is `false`.

If you are using an EJB client application with security enabled, edit the `sas.client.props` file, which is located in the *profile_root*`/properties` directory. Within the file, change the `com.ibm.CORBA.loginSource` value to *none*.

For more information on the `sas.client.props` utility, refer to the Manually encoding passwords in properties files and the PropFilePasswordEncoder command reference topics.

**RMI connection with security. Used with the EJB and administrative client application.**

Using Jacl:

```
wsadmin -conntype RMI -port  rmiportnumber -user userid
-password password
```

Using Jython:

```
wsadmin -lang jython -conntype RMI -port  rmiportnumber -user userid
-password password
```

*rmiportnumber* for your connection displays in the administrative console as BOOTSTRAP_ADDRESS.

**Attention:** On the AIX®, HP-UX, Linux, IBM i, Solaris, and z/OS operating systems, the use of -password option may result in security exposure as the password information becomes visible to the system status program, such as ps command, which can be invoked by other users to display all of the running processes. Do not use this option if security exposure is a concern. Instead, specify user and password information in the `soap.client.props` file for SOAP connector or `sas.client.props` file for RMI connector. The `soap.client.props` and `sas.client.props` files are located in the properties directory of your WebSphere Application Server profile.

If Kerberos (KRB5) is enabled for administrative authentication, the authentication target supports BasicAuth and KRB5. To use KRB5, update the `sas.client.props`, `soap.client.props`, and `ipc.client.props` files, according to the connector type.

**Attention:** When using Kerberos authentication, the user password does not flow across the wire. A one-way hash of password is used to identify the client.

The following examples demonstrate correct syntax.

Windows

```
launchClient c:\earfiles\myapp.ear -CCBootstrapHost=myWASServer -CCverbose=true app_parm1 app_parm2
```

AIX HP-UX Solaris

```
./launchClient.sh /usr/earfiles/myapp.ear -CCBootstrapHost=myWASServer -CCverbose=true app_parm1 app_parm2
```

### Specifying the directory for an expanded EAR file

You can archive the `Manifest.mf` client Java Archive (JAR) files instead of automatically cleaning them up after the application exits.

#### Before you begin

Each time the launchClient tool is called, it extracts the Enterprise Archive (EAR) file to a random directory name in the temporary directory on your hard drive. Then the tool sets up the thread ClassLoader to use the extracted EAR file directory and JAR files included in the `Manifest.mf` client Java Archive (JAR) file. In a normal J2EE Java client, these files are automatically cleaned up after the application exits. This cleanup occurs when the client container shutdown hook is called. To avoid extracting the EAR file (and removing the temporary directory) each time the launchClient tool is called, complete the following steps:

#### Procedure

1. Specify a directory to extract the EAR file by setting the `com.ibm.websphere.client.applicationclient.archivedir` Java system property. If the directory does not exist or is empty, the EAR file is extracted normally. If the EAR file was previously extracted, the launchClient tool reuses the directory.
2. Delete the directory before running the launchClient tool again, if you need to update your EAR file. When you call the `launchClient` command, it extracts the new EAR file to the directory. If you do not delete the directory or change the system property value to point to a different directory, the launchClient tool reuses the currently extracted EAR file and does not use your changed EAR file. When specifying the `com.ibm.websphere.client.applicationclient.archivedir` property, make sure that the directory you specify is unique for each EAR file you use. For example, do not point the `MyEar1.ear` and the `MyEar2.ear` files to the same directory.

## Downloading and running a Java EE client application using Java Web Start

Learn about the Java Web Start technology that is provided by the Java Standard Edition runtime environment to deploy Java Enterprise Edition application clients, including Thin application clients, on the remote client machine with a single click from a web browser on the client machine.

### Before you begin

The supported client platforms for deploying application clients using the Java Web Start are the same as the IBM Application Client for WebSphere Application Server supported platforms, except Linux on Power® and OS/400® operating systems.

Before you begin this task, see the following topics to understand Java Web Start technology and its components:

- “Java Web Start architecture for deploying application clients” on page 351
- “Client application Java Network Launcher Protocol deployment descriptor file” on page 352
- “ClientLauncher class” on page 356

**Note:** The Sun Java Web Start, which is available from Sun Microsystems, is not compatible with the IBM Runtime Environment, Java 2 Technology Edition, which is provided by WebSphere Application Server and the IBM Application Client. The IBM Runtime Environment contains some additional

functionality that is not supported in the Sun Java Web Start. Also, the IBM Runtime Environment uses a different packaging structure than the Sun Java Web Start. Use the IBM Runtime Environment.

## About this task

To deploy application clients using Java Web Start, the client machine must have at least a Java SE runtime environment installed. The Java SE runtime environment includes the Java Web Start, which implements the JSR 56: Java Network Launching Protocol and API. The application clients Enterprise Archive (EAR) file is a Java archive (JAR) resource in a JNLP descriptor file that resides on a central server. The JNLP descriptor file also specifies the runtime environment requirement for running the application.

WebSphere Application Server provides a launcher class to launch the Java EE application client in the application client container inside of Java Web Start. The client machine might not have the IBM Application Client for WebSphere Application Server installed. If this is the case, create and install an application client container and runtime package as a runtime environment through Java Web Start. The JNLP descriptor file specifies this runtime environment as the required runtime environment for running the Java EE application client.

WebSphere Application Server also provides command-line utility programs to create this application client container and runtime package from an existing IBM Application Client for WebSphere Application Server installation, as well as an installer class to install this package as a runtime environment for the application client container and also the Java Runtime Environment (JRE) in the IBM Application Client for WebSphere Application Server installation. To run the Java EE application client, the EAR file is deployed as a JAR resource that is described in the JNLP descriptor file.

## Procedure

1. Identify the client machine operating system, and install the corresponding IBM Application Client for WebSphere Application Server on a development machine. For example, if the Java EE application clients are targeted to run on Windows operating systems, install the IBM Application Client for WebSphere Application Server for Windows.
2. Run the utility programs to create the application client container and runtime package.
   a. Use the “buildClientRuntime tool” on page 360 utility to create the package.
   b. Use the “buildClientLibJars tool” on page 352 utility to create the JAR files containing the launcher and the installer class. This utility also zips up the properties files in the <app_client_root>/properties directory.
3. Create the runtime installer JNLP descriptor file. The JNLP response must be included in the JNLP version ID to indicate the current runtime version in the response header, for example, `x-java-jnlp-version-id=1.6.0`. Using a servlet of a JavaServer Pages (JSP) file to provide a dynamic JNLP response.
4. Create the Java EE application client launch JNLP descriptor file.
5. Package the application client container runtime environments and the Java EE application in an Enterprise Archive (EAR) file. Depending on your preferred deployment strategy, the files can be in two separate Web modules, or combined into one.
6. All JAR resources must be Java signed, including the Java EE application client EAR file.
7. Deploy the Enterprise Archive file on an application server, and start the application. The Java EE application client is ready to be deployed.

## Example

A Java Web Start deployment Sample is included in the client samples. This Sample demonstrates the steps to deploy a Java EE application client with an automated ANT script. The Sample has a servlet to generate the runtime installer JNLP response with JNLP version ID, for example, `x-java-jnlp-version-id`.

**Important:** When the application client initially launches using Java Web Start from Sun Microsystems Java SE Runtime Environment 6.0, it installs the Application Client runtime, which includes the IBM JRE. An null pointer exception (NPE) is thrown from the `com.sun.deploy.services.WPlatformService.getSecureRandom()` method. This is a known bug in Sun Java SE 6 (http://bugs.sun.com/bugdatabase/view_bug.do?bug_id=6505528). If you experience this exception, relaunch the application. The NPE only occurs on the first launch of the application client.

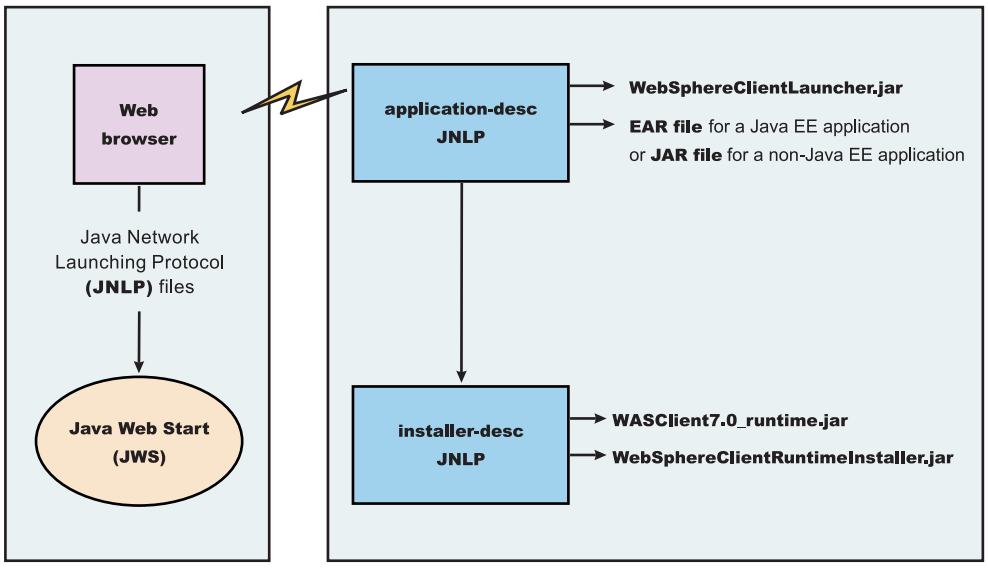
## Java Web Start architecture for deploying application clients

Java Web Start is an application-deployment technology that includes the portability of applets, the maintainability of servlets and JavaServer Pages (JSP) file technology, and the simplicity of mark-up languages such as XML and HTML. It is a Java application that allows full-featured Java EE client applications to be launched, deployed and updated from a standard Web server. The Java Web Start client is used with platforms that support a web browser.

Upon launching Java Web Start for the first time, you might download new client applications from the Web. Each time you launch JWS thereafter, you can initiate applications either through a link on a web page or (in Windows) from desktop icons or the Start menu. You can deploy applications quickly using Java Web Start, cache applications on the client machine, and launch applications remotely offline. Additionally, because Java Web Start is built from the Java Platform, Enterprise Edition (Java EE) infrastructure, the technology inherits the complete security architecture of the Java EE platform.

The technology underlying Java Web Start is the Java Network Launching Protocol & API (JNLP). Java Web Start is a JNLP client and it reads and parses a JNLP descriptor file (JNLP file). Based on the JNLP descriptor, it downloads appropriate pieces of a client application and any of its dependencies. If any of the pieces of the application are already cached on the client machine, then those components are not downloaded again, unless they have been updated on the server machine. After you download and cache the client application, JWS launches it natively on the client machine.

The following diagram shows an overview of launching a client application, include the Application Client for WebSphere Application Server as a dependent resource, using Java Web Start.



The web browser running on a client machine connects to a web application located on a server machine. The client application JNLP descriptor file is downloaded and processed by Java Web Start on the client machine.

In this diagram, there are two JNLP descriptor files:

- Client application JNLP descriptor (application-desc in the diagram)
- Application Clients run-time installer JNLP descriptor (installer-desc in the diagram)

Each of these JNLP descriptor files, the client application (JAR or EAR) and the dependent resource JAR files are packaged as web applications in an EAR file. This EAR file is deployed to an Application server. The client machine with JWS installed uses a web browser to connect to the URL of the client application JNLP descriptor file to download and run the client application.

Using Java Web Start from Java SE Runtime Environment 6.0 or later is highly recommended. All the platforms supported by the application client for WebSphere Application Server are supported with the exception Linux on Power and OS/400 platforms.

You can use the following:

- Java Web Start on the Java Standard Edition Developer Kits that IBM provides, packaged in Application Client for WebSphere Application Server
- Java Web Start on Sun Microsystems Java SE 6 Development Kit or Java SE Runtime Environment 6.0, which you can download from the Sun Microsystems website for Windows, Linux and Solaris operating systems
- Java Web Start on HP-UX JDK or JRE for Java Platform, Standard Edition, Version 6, which you can download from the HP website

***buildClientLibJars tool:***

For a Java Platform, Enterprise Edition (Java EE) application client application and or Thin application client application to be launched using Java Web Start (JWS), the properties files bundled in Application Client for WebSphere Application Server must be installed in the Java Web Start. Use this tool to create those property JAR files. The Java Web Start client is used with platforms that support a web browser.

The buildClientLibJars tool copies the JAR files from the Application Client for WebSphere Application Server installation and creates a `properties.jar` file, which contains the properties files from the Application Clients installation properties directory to a specified location. When this property is created, the tool uses the value of `keystore`, `storepass`, `alias` and `storetype` to sign all of the JAR files in the specified location.

```
Windows usage: buildClientLibJars.bat  [-help] [-verbose] destdir keystore storepass alias storetype

Unix usage:    buildClientLibJars.sh  [-help] [-verbose] destdir keystore storepass alias storetype
```

where:

- `-help` will display the message
- `-verbose` will turn on verbose message
- `destdir` will output the destination directory name
- `keystore` is the key store file
- `storepass` is the key store password
- `alias` key is the alias name
- `storetype` is the key store type

## Client application Java Network Launcher Protocol deployment descriptor file

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application.

## Location

The client application has an Application Clients runtime dependency that provides the following:

- Java SE Runtime Environment from IBM
- Application Clients run-time properties
- SSL KeyStore and TrustStore file
- Application Clients run-time library JAR files (optional for Thin Application client applications)

If the Application Clients run-time dependency is not met, it is downloaded and installed in Java Web Start (JWS), as described by the Application Clients run-time installer JNLP descriptor file. For example:

```
<j2se version="1.6" href="http://your_server.com/jws/wasappclient/download.jnlp"/>
```

## Usage notes

The client application must also include the `WebSphereClientLauncher.jar` file, which contains the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, that completes one of the following actions:

- If it is a Java Platform, Enterprise Edition (Java EE) Application client application (that is the resources for the application contain an EAR file with a client application), the EAR file must be specified as a JAR resource so that it can be downloaded to JWS and specified in the system property, `com.ibm.websphere.client.launcher.ear`. See "JNLP descriptor file for a Java EE Application client application" on page 354 for an example.
- If it is a Thin Application client application, the Thin Application client application JAR file must be specified as a JAR resource so that it can be downloaded to JWS and the name of the class containing main method entry point is specified in the system property, `com.ibm.websphere.launcher.main`. See "JNLP descriptor file for a Thin Application client application" on page 354 for an example.

The JNLP specification requires all the resource (JAR or EAR) files used in a JNLP file to be signed.

You can specify the –CC arguments defined in the launchClient tool for a J2EE Application client application in application arguments section of the JNLP descriptor files. However, only –CCD is supported for a Thin Application client application to define system properties and the JNLP <property> tag can also be used to define system properties. See the following example for details:

```
<property name="java.naming.provider.url" value="corbaloc:iiop:myserver.com:9089"/>
```

For a J2EE Application client application, specify the following application arguments as defined in the JNLP.

1. Specify your target server provider URL, as shown in the following example:

   ```
   <argument> >-CCDjava.naming.provider.url =corbaloc:iiop:myserver.mydomain.com:9080 </argument>
   ```

2. Specify the SSL Key File and SSL Trust File location. These files are expected to be available in the client machine. To use the ones in the Application Clients run-time dependency installed in JWS cache, specify these application arguments:

   ```
   <argument> -CCDcom.ibm.ssl.keyStore=${WAS_ROOT}/etc/key.p12 </argument>
   <argument> -CCDcom.ibm.ssl.trustStore=${WAS_ROOT}/etc/trust.p12 </argument>
   ```

3. Specify the initial naming context factor, as shown in the following example:

   ```
   <argument>-CCDjava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory </argument>
   ```

   For a Thin Application client application, you also need to specify the actual location of the `sas.client.props` and `ssl.client.props` files located in the Application Clients runtime dependency that is installed in the JWS cache.

   ```
   <argument>-CCDcom.ibm.CORBA.ConfigURL=file:${WAS_ROOT}/properties/sas.client.props </argument>
   <argument>-CCDcom.ibm.SSL.ConfigURL=file:${WAS_ROOT}/properties/ssl.client.props </argument>
   ```

   If any of the default settings in the `sas.client.props` and `sas.client.props` file need modifying, use the –CCD to change the settings through the system properties, as shown in the following example:

   ```
   <argument>-CCDjavacom.ibm.CORBA.securityEnabled=false </argument>
   ```

**Important:** The ${WAS_ROOT} token used in the JNLP file is replaced by the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, to the actual location of the Application Clients run-time dependency installation in the JWS cache. If you are using JSP to dynamically create this JNLP description file, you must escape this token because it has a different meaning in JSP 2.0. See the following example for details:

```
<argument>-CCDcom.ibm.ssl.keyStore=\${WAS_ROOT}/etc/key.p12 </argument>
<argument>-CCDcom.ibm.ssl.trustStore=\${WAS_ROOT}/etc/trust.p12 </argument>
```

***JNLP descriptor file for a Java EE Application client application:***

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application.

Here is an example of the client application JNLP descriptor file for a Java EE Application client application:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
This sample program is provided AS IS and may be used, executed, copied and modified
without royalty payment by customer (a) for its own instruction and study, (b) in order
to develop applications designed to run with an IBM WebSphere product, either for customer's
own internal use or for redistribution by customer, as part of such an application, in
customer's own products.

***ClientLauncher class:***

The class, com.ibm.websphere.client.installer.ClientLauncher, contains a main() method that is called by Java Web Start (JWS) to launch the client application. The Java Web Start client is used with platforms that support a web browser.

This client is packaged in the `WebSphereClientLauncher.jar` file that is located in the Application Client for WebSphere Application Server installation under the <*app_client_root*>/ lib/webstart directory.

The launcher class requires that the following properties are defined. These properties are not defined in a separate properties file. Instead, the properties are defined as part of the Java Network Launching Protocol (JNLP) files.

**com.ibm.websphere.client.launcher.main**
: If the client application is a Thin Application client, then this property should be specified. It specifies the class where the main entry point of the client application resides.

**com.ibm.websphere.client.launcher.ear**
: If the client application is a Java Platform, Enterprise Edition (Java EE) Application client, then this property should be specified. It specifies the name of the EAR file to be executed. This property takes precedence over com.ibm.websphere.client.launcher.main. However, only one of the two properties should be specified.

***Application client launcher for Java Web Start:***

The application client launcher for Java Web Start is a Java class, com.ibm.websphere.client.installer.ClientLauncher, which has a main() method that Java Web Start calls to start the application client container and to invoke the application client's main() method. It provides similar functions as the **lauchClient** command line tool to start application clients from the command line.

The com.ibm.websphere.client.launcher.ClientLauncher class is packaged in the WebSphereClientLauncher.jar file under the <app_client_root>/lib/webstart directory.

The launcher tool requires that the following properties are defined.

**com.ibm.websphere.client.launcher.main**
: If the client that is to be run is a thin client, then this property should be specified. It specifies the class where the main entry point of the application resides. It is the main class name for a Thin application client. If it is set, the launcher will not start the client container, it will rather invoke the main method for the application directly. However, if `com.ibm.websphere.client.launcher.ear` is also set, it will be ignored.

**com.ibm.websphere.client.launcher.ear**
: If the client that is to run is the Java Platform, Enterprise Edition (Java EE) client, then this property should be specified. It specifies the name of the ear file to be executed. This property takes precedence over `com.ibm.websphere.client.launcher.main` although only one of the two properties should be specified.

These properties are not defined in a separate properties file. Instead, they are defined as part of the Java Network Launching Protocol files.

When `com.ibm.websphere.client.launcher.ear` is set, the application client launcher for JWS supports almost all of the –CC arguments as the **lauchClient** command line tool supports. However, if only

com.ibm.websphere.client.launcher.main is set, the launcher will only support the –CCD argument. The following table shows the comparison of the supported –CC arguments for the **launchClient** command line tool and the application client launcher for JWS:

*Table 43. Comparison of the supported –CC arguments for the* **launchClient** *command line tool and the application client launcher for JWS. Comparison of the supported –CC arguments*

| -CC argument | launchClient | Application client launcher for JWS |
|---|---|---|
| -CCverbose | Yes | Yes |
| -CCjar | Yes | Yes |
| -CCclasspath | Yes | N/A |
| -CCadminConnectorHost | Yes | Yes |
| -CCadminConnectorPort | Yes | Yes |
| -CCadminConnectorType | Yes | Yes |
| -CCadminConnectorUser | Yes | Yes |
| -CCaltDD | Yes | Yes |
| -CCBootstrapHost | Yes | Yes |
| -CCBootstrapPort | Yes | Yes |
| -CCproviderURL | Yes | Yes |
| -CCinitonly | Yes | N/A |
| -CCtrace | Yes | Yes |
| -CCtracefile | Yes | Yes |
| -CCsecurityManager | Yes | N/A |
| -CCsecurityMgrClass | Yes | N/A |
| -CCsecurityMgrPolicy | Yes | N/A |
| -CCD | Yes | Yes |
| -CCexitVM | Yes | Yes |
| -CCdumpJavaNameSpace | Yes | Yes |
| -CCsoapConnectorPort | Yes | Yes |
| -CCtraceMode | Yes | Yes |
| -CCclassLoaderMode | Yes | Yes |

Macro expansion is supported for the –CCD argument by the application client launcher for JWS. The launcher will automatically substitute certain macro keys (enclosed with ${...}) with the calculated value at runtime. For example, if a macro key is used in the –CCD argument in the application client JNLP manifest file,

```
<argument>-CCDcom.ibm.ssl.keyStore= ${WAS_ROOT}/etc/key.p12</argument>
```

it will be expanded to the JWS cache installation root location and the argument will become:

```
-CCDcom.ibm.ssl.keyStore=/home/tiu/.java/deployment/cache/javaws/ext/E1134532441112/etc/key12.p12
```

The following table shows the three macro keys that are currently supported and will be substituted by the launcher:

*Table 44. Currently supported macro keys. Supported macro keys*

| Macro key | Value |
|---|---|
| ${WAS_ROOT} | Installation root location within the JWS cache that is used by the application client container and runtime installer for JWS. |
| ${JAVA_HOME} | Location of Java home. The return value of System.getProperty("java.home"). |
| ${USER_HOME} | Location of user home. The return value of System.getProperty("user.home"). |

## Preparing the application client run time dependency component for Java Web Start

To launch a Java Platform, Enterprise Edition (Java EE) application client application, a Thin application client application, or both using Java Web Start (JWS), a Java Runtime Environment implementation Java archive (JAR) that IBM provides, the library JAR files and properties files bundled in Application Client for WebSphere Application Server must be installed in the JWS. Learn the steps to build the application client run time dependency component from an application client installation. It is packaged as a web application archive (WAR) file that can be installed in an application Server.

### Before you begin

Install the Application Client for WebSphere Application Server for the operating system to which the client application deploys. If there is a requirement to deploy the client application to multiple operating systems, the application client run time dependency component must be built separately for each operating system that client application supports.

Windows Linux For example, if the client application deploys to both the Windows operating system and Linux operating system, follows the steps for this task to build the application client run time dependency component for Windows operating systems, with the Application Client for WebSphere Application Server for Windows installed. Then, repeat the steps for this task to build the application client run time dependency component for Linux, on a Linux operating system, with the Application Client for WebSphere Application Server for Linux installed.

### Procedure

1. Install the Application Client for WebSphere Application Server for the client application supported operating systems.

   Windows Install the application client in the C:\Program Files\IBM\WebSphere\AppClient directory.
2. Change the directory to the installation bin directory.

   Windows On Windows operating systems, the directory is as follows:

   ```
   CD C:\Program files\IBM\WebSphere\AppClient\bin
   ```
3. Run the "buildClientRuntime tool" on page 360 to generate the application client run time JAR file, which contains the Java Standard Edition Runtime Environment, the run time library JAR files, properties files, and the SSL KeyStore and TrustStore files from the application client installation.

   Windows For example, if you are using Version 7.0 and using the test certificate that is included in the application client installation:

   ```
   buildClientRuntime C:\WebApp1\runtime\WASClient7.0_windows.jar ..\etc\DummyClientKeyFilejar WebAS
   "websphere dummy client" JKS
   ```
4. Run the buildClientLibJars tools to package up the properties files in the properties directory of the application client installation into a properties.jar file in the specified location. The buildClientLibJars tools will also copy the `WebSphereClientLauncher.jar` file and `WebSphereClientRuntimeInstaller.jar` file from the application client installation to the specified location. All jar files in the specified location will be signed by the provided certificate.

For example, if you are using Version 7.0 and using the test certificate that is included in the application client installation:

```
buildClientLibJars C:\Temp\webstart ..\etc\DummyClientKeyFilejar WebAS "websphere dummy client" JKS
```

5. Create a JavaServer Pages (JSP) file or use a servlet to generate the application client run time installer Java Network Launching Protocol (JNLP) descriptor to respond to Java Web Start request. See the Java Web Start deployment sample in the application client installation.
6. Package the two signed JAR files, `WASClient7.0_windows.jar` and `WebSphereClientRuntimeInstaller.jar`, and the JSP file or servlet for generating the Application Client run time installer JNLP descriptor into a web application archive (WAR) file. This WAR file is packaged into an EAR file that can be deployed to an application server. See the Java Web Start deployment sample in the application client installation.

## Results

Your web application is ready to serve the application client run time and the JRE environment.

## Example

```
<!-- This sample program applies to WebSphere Application Server, Version 6.1.
It is provided AS IS and may be used, executed, copied and modified
without royalty payment by customer (a) for its own instruction and study, (b) in order
to develop applications designed to run with an IBM WebSphere product, either for customer's
own internal use or for redistribution by customer, as part of such an application, in
customer's own products.

```

1. Specifies that the file is a JNLP mime type so that the browser can process the JNLP file.
2. Specifies the exact version of this Application Client run time dependency component in the response by setting the HTTP header field: `x-java-jnlp-version-id`.
3. Specifies the required JRE version to run the installer program.
4. Specifies the installer `WebSphereClientRuntimeInstaller.jar` file, which contains the ClientRuntimeInstaller class.
5. Specifies a system property that defines the version of Application Client run time dependency component. This version is registered to the JNLP client.
6. Specifies resources for a particular platform. Each supported client application platform needs its own separate JAR file.
7. Specifies the Application Client run time dependency component JAR file.
8. Specifies the program to call that starts a JVM for the client application.

***buildClientRuntime tool:***

For a Java Platform, Enterprise Edition (Java EE) application client application and or Thin application client application to be launched using Java Web Start (JWS), the library JAR files bundled in Application Client for WebSphere Application Server must be installed in the Java Web Start. Use this tool to build those JAR files. The Java Web Start client is used with platforms that support a web browser.

The buildClientRuntime tool builds the required components from the WebSphere Application Server clients installation into the JAR file specified on the command. This JAR file contains:

- License files
- Java SE Runtime Environment 6 (JRE 6) that IBM provides
- Application Clients runtime properties and configuration
- SSL KeyStore and TrustStore files
- Runtime library JAR files

In the case of building an Application Clients runtime JAR file only for serving Thin Application client applications and not for Java EE Application client applications, the runtime library JAR files and the Application Clients runtime properties files are not included, except the configuration files, `sas.client.props`, `ssl.client.props` and `soap.client.props`, located in the `WAS_ROOT/properties` directory. The Java Web Start client is used with platforms that support a web browser.

The command-line invocation syntax for the buildClientRuntime tool is shown in the following example:

```
Windows Usage:    buildClientRuntime.bat  [-help] [-verbose] outfile keystore storepass alias storetype

Unix Usage:         buildClientRuntime.sh    [-help] [-verbose] outfile keystore storepass alias storetype
```

where:

- -help will display the message
- -verbose will turn on verbose message
- outfile is the output file name
- keystore is the key store file
- storepass is the key store password
- alias is the key alias name
- storetype is the key store type

***ClientRuntimeInstaller class:***

This section provides information on the ClientRuntimeInstaller class.

This class, com.ibm.websphere.client.installer.ClientRuntimeInstaller, contains a main() method that Java Web Start (JWS) calls to install the Application Client for WebSphere Application Server run-time dependency component in JWS cache. It is packaged in `WebSphereClientRuntimeInstaller.jar` file located in the Application Client for WebSphere Application Server installation in the *<app_server_root>*/`JWS` directory.

Specify the `WebSphereClientRuntimeInstaller.jar` file and the Application Client run-time dependency component JAR file as JAR resources in the Application Client run-time installer Java Network Launcher Protocol (JNLP) descriptor file. See the following example for details:

```
<jar href="Launcher/WebSphereClientRuntimeInstall.jar" main="true"/>
<jar href="Launcher/WASClient6.1_windows.jarRuntimeInstall.jar" main="true"/>
```

The ClientRuntimeInstaller class main method requires the following properties to be set in the JNLP file:

**com.ibm.websphere.client.jre.version**
: Specifies a Java Runtime Environment (JRE) version name that is to be used when referring to the Application Client run-time dependency component.

**com.ibm.websphere.client.jre.launch.java**
Specifies the relative location of the javaw.exe program in the Application Client run-time dependency component JAR file.

The previously mentioned properties, JRE version name and the location of the javaw.exe program are registered to the Java Web Start Application Manager, as shown in the following example:

```
<property name="com.ibm.websphere.client.jre.version" value="WASclient6.1"/>
<property name="com.ibm.websphere.client.jre.launch.java" value="java\jre\bin\javaw.exe"/>
```

## Using the Java Web Start sample

The EAR file, `WasAppClientRuntime.ear`, is provided in the *app_client_root*`/samples/bin/WasAppClientRuntime` directory of the Client Application for WebSphere Application Server installation. This EAR file provides a sample Application Clients run-time installer JNLP descriptor file and a sample Application Clients run-time library component JNLP descriptor file. Follow the steps in this task to build the Application Clients run-time dependency component and the Application Clients run-time library component. Add these components to the `WebSphereClientRuntime.ear` file, and then install the EAR file in an Application Server to be used by the client application.

### About this task

There is a new Java Web Start sample available in the client sample gallery for WebSphere Application Server V7.0. Refer to the client sample gallery in the Application Client for WebSphere Application Server product. The name of the new sample is "Java Web Start Deployment Sample".

## Installing Java Web Start

Learn about the steps that are necessary to install Java Web Start (JWS).. Java Web Start technology is provided by the Java SE runtime environment to deploy Java EE application clients (including Thin application clients) on the remote client machine with a single click from a web browser on the client machine.

### Before you begin

Before you begin this task, see the “Preparing the application client run time dependency component for Java Web Start” on page 358 topic to understand Java Web Start (JWS) technology and components.

**Note:** The Sun Java Web Start, which is available from Sun Microsystems, is not compatible with the IBM Runtime Environment, Java 2 Technology Edition, which is provided by WebSphere Application Server and the IBM Application Client. The IBM Runtime Environment contains some additional functionality that is not supported in the Sun Java Web Start. Also, the IBM Runtime Environment uses a different packaging structure than the Sun Java Web Start. Use the IBM Runtime Environment.

**Note:** AIX The Java Web Start can load native shared libraries with the .so file extension only. Rename any native shared libraries so that they have the .so file extension before packaging them in a Java archive (JAR) file for Java Web Start deployment.

### About this task

Complete the following steps to install JWS:

### Procedure

1. Install IBM Application Client for WebSphere Application Server.
2. Change your directory to the `javaws` path.
   - AIX HP-UX Linux Solaris *client_install_root*`\java\jre\lib\javaws`
   - Windows *client_install_root*`/java/jre/lib/javaws`

3. Run the update settings script from the path mentioned in the previous step.
   - AIX HP-UX Linux Solaris Run the `updateSetting.sh` script
   - Windows Run the `updateSetting` script
4. Change your path to the JWS installed path. For example, enter:
   - AIX HP-UX Linux Solaris *client_install_root*\java\jre\javaws
   - Windows *client_install_root*/java/jre/javaws
5. Run `javaws` from the path mentioned in the previous step.
   - AIX HP-UX Linux Solaris Run `./javaws` command.
   - Windows Run `javaws` command.

### Using a static JNLP file with Java Web Start for Application clients

Do not use JSP to dynamically generate a JNLP file, otherwise the JNLP jsp page cannot be opened in some IE browsers.

#### About this task

To use a static JNLP file, you will need to add the following mime type mapping in the web.xml file:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_ID" version="2.4" xmlns="http://java.sun.com/xml/ns/j2ee"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee
http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd">
       <display-name>
       WAS Client runtime for Java Web Start</display-name>
       <welcome-file-list>
              <welcome-file>index.html</welcome-file>
              <welcome-file>index.htm</welcome-file>
              <welcome-file>index.jsp</welcome-file>
              <welcome-file>default.html</welcome-file>
              <welcome-file>default.htm</welcome-file>
              <welcome-file>default.jsp</welcome-file>
       </welcome-file-list>
       <mime-mapping>
       <extension>jnlp</extension>
       <mime-type>application/x-java-jnlp-file</mime-type>
       </mime-mapping>
</web-app>
```

## Running the IBM Thin Client for Enterprise JavaBeans (EJB)

An EJB Client is a Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) Java Platform, Standard Edition (Java SE) application that accesses remote Enterprise Java Beans from a server through Java Naming and Directory Interface (JNDI) look up. IBM Thin Client for EJB offers a smaller footprint and is easy to deploy to a Java SE environment and an Eclipse Rich Client Platform (RCP) environment. You can bundle the IBM Thin Client for EJB library using the WebSphere Application Server installation or the Application Client for WebSphere Application Server installation with your application. The IBM Thin Client for EJB also extends the choice of Java SE runtime. It can be run in the Java Runtime Environment (JRE) that is packaged with the WebSphere Application Server product, the Sun Microsystems JRE that is downloaded from the Sun Microsystems website, or the JRE that is downloaded from the HP website.

### Before you begin

The IBM ORB implementation library is required if the IBM Thin Client for EJB is running with a non-IBM product JRE on a non-IBM product platform. For example, running the IBM Thin Client for EJB with Sun Microsystems JRE on Windows, Linux, or Solaris, and with the HP JRE on HP-UX. The IBM-provided Solaris hybrid and HP hybrid JRE are not considered non-IBM product JRE environments.

The IBM Thin Client for EJB can access version 2.x and version 3.x EJB on the WebSphere Application Server using the JNDI lookup, but it cannot access version 3.x EJB through resource injection. Resource injection is supported if the client application is a Java Platform, Enterprise Edition (Java EE) Application Client running within the Java Platform, Enterprise Edition (Java EE) Application Client Container.

Before you set up an EJB Thin Client environment, obtain the Java archive (JAR) file for the EJB Thin Client for WebSphere Application Server. To obtain the EJB Thin Client for WebSphere Application Server, install WebSphere Application Server or Application Client. The EJB Thin Client for WebSphere Application Server file, `com.ibm.ws.ejb.thinclient_8.0.0.jar`, is located in the *app_server_root*`\runtimes` directory.

Copy the Java archive (JAR) file for the IBM Thin Client for EJB with WebSphere Application Server product, `com.ibm.ws.ejb.thinclient_8.0.0.jar` and the `endorsed_apis_8.0.0.jar` files, to other machines to create a lightweight client environment that enables communications with the products. Copies of the IBM Thin Client for EJB are subject to the same terms and conditions of the license agreement for the WebSphere product where you obtained the Thin Client for EJB. Refer to the license agreements for correct usage and other limitations.

Copy the *app_server_root*`\runtimes\endorsed\endorsed_apis_8.0.0.jar` file into the default directory, `JAVA_JRE\lib\endorsed`. Alternatively, you can use the java.endorsed.dirs property to specify a directory of your choice. If you choose to use an alternative directory, it is a best practice to only include the endorsed_apis JAR file.

The IBM Thin Client for EJB with WebSphere Application Server runs on distributed operating systems with JDK support, including both Version 5 and Version 6. When using the IBM Thin Client for EJB as a standalone Java SE application with a non-IBM product JRE, you must override the default ORB implementation for the JRE through one of following methods:

- Include the com.ibm.ws.orb_8.0.0.jar file in the Java system classpath.
- Override the default ORB implementation in the JRE, using Java Endorsed Standards Override Mechanism.
- Set the java.endorsed.dirs path to a directory that contains the com.ibm.ws.orb_8.0.0.jar file.

When running the IBM Thin Client for EJB as an Eclipse RCP application, it is recommended to use method two, to override the default JRE ORB implementation.

**Important:** The Pluggable Application Client is deprecated. It is replaced by the IBM Thin Client for EJB.

**Attention:** When running the IBM Thin Client for EJB, and the `-Djava.util.logging.manager=com.ibm.ws.bootstrap.WsLogManager` command line option is used, a ClassDefNotFoundError error is thrown. The use of WsLogManager is not supported in the IBM Thin Client for EJB, but you can use another Java logging manager.

## About this task

Run the IBM Thin Client for EJB, by completing the following steps.

## Procedure

1. Invoke the client application. Run the following Java command:

   Windows

   ```
   <java_install_root>\bin\java
   -classpath com.ibm.ws.ejb.thinclient_8.0.0.jar;<list_of_your_application_jars_and_classes>
   -Djava.naming.provider.url=iiop://<your_application_server_machine_name>
   <fully_qualified_class_name_to_run>
   ```

   Add the following system properties to the Java command if you want authentication and SSL enabled:

   AIX HP-UX Solaris Linux

```
<java_install_root>/bin/java
-classpath com.ibm.ws.ejb.thinclient_8.0.0.jar:<list_of_your_application_jars_and_classes>
-Djava.naming.provider.url=iiop://<your_application_server_machine_name>
-Dcom.ibm.SSL.ConfigURL=file:///home/user1/ssl.client.props
-Dcom.ibm.CORBA.ConfigURL=file:///home/user1/sas.client.props
<fully_qualified_class_name_to_run>
```

2. Provide IIOP authentication configuration and Client SSL Configuration. Add the following system properties to the Java command:

   ```
   -Dcom.ibm.SSL.ConfigURL=file:///home/user1/ssl.client.props
   -Dcom.ibm.CORBA.ConfigURL=file:///home/user1/sas.client.props
   ```

   You can obtain the `ssl.client.props` file and `sas.client.props` file from the WebSphere Application Server installation and modify the file to suit your environment. You must, at a minimum, update the location of the key files in the `ssl.client.props` file to the match location of your target environment. For example,

   ```
   -Dcom.ibm.ssl.keyStore=/home/user1/etc/key.p12
   -Dcom.ibm.ssl.trustStore=/home/user1/etc/trust.p12
   ```

   Recommended SSL configuration settings when running the application with a non-IBM product JRE:

   ```
   com.ibm.ssl.protocol=SSL
   com.ibm.ssl.trustManager=SunX509
   com.ibm.ssl.keyManager=SunX509
   com.ibm.ssl.contextProvider=SunJSSE

   com.ibm.ssl.keyStoreType=JKS
   com.ibm.ssl.keyStoreProvider=SUN
   com.ibm.ssl.keyStore=/home/user1/etc/key.jks

   com.ibm.ssl.trustStoreType=JKS
   com.ibm.ssl.trustStoreProvider=SUN
   com.ibm.ssl.trustStore=/home/user1/etc/trust.jks
   ```

   The key store file and trust store file must be created using the Java keytool utility before the application runs. The automatic key file generation is not supported with a non-IBM product JRE.

   You must override the default ORB implementation of the non-IBM product JRE with the `com.ibm.ws.orb_8.0.0.jar` file, or add it to the classpath.

3. Run your client application:

   - Enter the following command if you have copied the endorsed_apis_8.0.0.jar file into the `JAVA_JRE\lib\endorsed` default directory; for example:

     **Windows**

     ```
     %JAVA_HOME%\bin\java -Dcom.ibm.SSL.ConfigURL=file:\\\home\sample\ssl.client.props <your_client_application>
     ```

     **AIX** **HP-UX** **Solaris** **Linux**

     ```
     $JAVA_HOME/bin/java -Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props <your_client_application>
     ```

   - Enter the following command if you have copied the endorsed_apis_8.0.0.jar file into a directory other than the default `JAVA_JRE\lib\endorsed` directory; for example:

     **Windows**

     ```
     %JAVA_HOME%\bin\java
     -Djava.endorsed.dirs=<directory_that_includes_endorsed_apis_8.0.0.jar>
     -Dcom.ibm.SSL.ConfigURL=file:\\\home\sample\ssl.client.props <your_client_application>
     ```

     **AIX** **HP-UX** **Solaris** **Linux**

     ```
     $JAVA_HOME/bin/java
     -Djava.endorsed.dirs=<directory_that_includes_endorsed_apis_8.0.0.jar>
     -Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props <your_client_application>
     ```

## What to do next

Enable trace for the IBM Thin Client for EJB by adding the following to the Java command.

```
-Dcom.ibm.ejs.ras.lite.traceSpecification=*=all
```

# Running Java thin client applications

You can run Java thin client applications on machines installed with either a WebSphere Application Client installation or a WebSphere Application Server installation.

## About this task

**Important:** Java thin clients are not packaged with JDBC provider classes. For example, the WebSphere Application Server Version 7.0 Java thin client is not packaged with Apache Derby 10.2 classes. Likewise, the version 6.1 Java thin client is not packaged with Cloudscape Version 5.1, Cloudscape Version 10.0, or Cloudscape version 10.1 classes. Therefore, to utilize the JDBC provider classes (such as Apache Derby, Oracle, DB2, Informix®, or Sybase) on a Java thin client, you must:

1. Add the classes to your Java thin client application environment.
2. Make the classes visible to the Java thin client application. To do this, add the path to the classes in the client classpath within the script that launched the client program.

Otherwise, any attempt to load a database class (such as through the JNDI lookup of a datasource) results in a ClassNotFoundException.

The Java invocation to run a Java thin client application varies between a client and a server. If your Java thin client application needs to run on both a client installation and a server installation, follow the steps in the Running a Java thin client application on a server machine topic.

## Procedure

- “Running a Java thin client application on a client machine” on page 368
- “Running a Java thin client application on a server machine” on page 368

## Example

Your Java thin application client no longer needs additional code to set security providers if you have enabled security for your WebSphere Application Server instance. This code found in IBM i Java thin or pluggable application clients should be removed to prevent migration and compatibility problems. The java.security file from your WebSphere instance in the properties directory is now used to configure the security providers.

- Running the thin or pluggable application client with security enabled

**Running the thin or pluggable application client with security enabled.** The following code examples illustrates how security providers were set programmatically in the main() method and occurred prior to any code that accessed enterprise beans:

```
import java.security.*;
  ...
  if (System.getProperty("os.name").equals("OS/400")) {

    // Set the default provider list first.
    Provider jceProv = null;
    Provider jsseProv = null;
    Provider sunProv = null;

    // Allow for when the Provider is not needed, when
    // it is not in the client application's classpath.
    try {
      jceProv = new com.ibm.crypto.provider.IBMJCE();
    }
    catch (Exception ex) {
 ex.printStackTrace();
    throw new Exception("Unable to acquire provider.");
 }
```

```
   try {
     jsseProv = new com.ibm.jsse.JSSEProvider();
   }
   catch (Exception ex) {
ex.printStackTrace();
   throw new Exception("Unable to acquire provider.");
}

   try {
     sunProv = new sun.security.provider.Sun();
   }
   catch (Exception ex) {
ex.printStackTrace();
   throw new Exception("Unable to acquire provider.");
}

   // Enable providers early and ahead of other providers
   // for consistent performance and function.
   if ( (null != sunProv) && (1 != Security.insertProviderAt(sunProv, 1)) ) {
     Security.removeProvider(sunProv.getName());
     Security.insertProviderAt(sunProv, 1);
   }
   if ( (null != jceProv) && (2 != Security.insertProviderAt(jceProv, 2)) ) {
     Security.removeProvider(jceProv.getName());
     Security.insertProviderAt(jceProv, 2);
   }
   if ( (null != jsseProv) && (3 != Security.insertProviderAt(jsseProv, 3)) ) {
     Security.removeProvider(jsseProv.getName());
     Security.insertProviderAt(jsseProv, 3);
   }

   // Adjust default ordering based on admin/startstd properties file.
   // Maximum allowed in property file is 20.
   String provName;
   Class  provClass;
   Object provObj =  null;

   for (int i = 0; i < 21; i++) {
     provName = System.getProperty("os400.security.provider."+ i);

     if (null != provName) {

       try {
         provClass = Class.forName(provName);
         provObj = provClass.newInstance();
       }
       catch (Exception ex) {
         // provider not found
         continue;
       }

       if (i != Security.insertProviderAt((Provider) provObj, i)) {

         // index 0 adds to end of existing list
         if (i != 0) {
           Security.removeProvider(((Provider) provObj).getName());
           Security.insertProviderAt((Provider) provObj, i);
         }
       }
     } // end if (null != provName)
   } // end for (int i = 0; i < 21; i++)
 } // end if ("os.name").equals("OS/400")
```

For examples of Java thin client applications, refer to the Samples section of the information center.

# Running a Java thin client application on a client machine

To run a Java thin client application on a machine with Application Client for WebSphere Application Server installed, use the setup Client command then start the application.

## Before you begin

Before performing this task, you must install the Java thin application client from the Application Client for WebSphere Application Server installation.

## Procedure

1. Set up the client application environment. Run the setupClient command.

   Windows

   *app_client_root*\AppClient\bin\setupClient.bat

   AIX Linux HP-UX Solaris

   *app_client_root*/AppClient/bin/setupClient.sh

2. Run a Java command to invoke your client application.

   Windows

   ```
   "%JAVA_HOME%\bin\java" %WAS_LOGGING% -Djava.security.auth.login.config="%WAS_HOME%\properties\wsjaas_client.conf"
   -classpath "%WAS_CLASSPATH%;<list_of_your_application_jars_and_classes>"
   -Djava.ext.dirs="%JAVA_JRE%\lib\ext;%WAS_EXT_DIRS%;%WAS_HOME%\plugins;%WAS_HOME%\lib\WMQ\java\lib"
   -Djava.naming.provider.url=iiop://<your_application_server_machine_name>
   -Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
   "%SERVER_ROOT%" "%CLIENTSAS%" "%CLIENTSSL%" <fully_qualified_class_name_to_run>
   ```

   For information about IIOP and corbaloc URLs, see Developing applications that use JNDI.

   AIX Linux HP-UX Solaris

   ```
   $JAVA_HOME/bin/java $WAS_LOGGING
   -classpath "$WAS_CLASSPATH: <list_of_your_application_jars_and_classes>"
   -Djava.ext.dirs=$JAVA_JRE/lib/ext:$WAS_EXT_DIRS:$WAS_HOME/plugins:$WAS_HOME/lib/WMQ/java/lib"
   -Djava.naming.provider.url=iiop://<your_application_server_machine_name>
   -Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
   $SERVER_ROOT $CLIENTSAS $CLIENTSSL <fully_qualified_class_name_to_run>
   ```

# Running a Java thin client application on a server machine

To run a Java thin client application on a machine with WebSphere Application Server installed, use the setupClient command then start the application.

## Before you begin

You must install WebSphere Application Server before performing this task.

## Procedure

1. Set up the Thin application client environment.

   Windows Use the setupCmdLine shell.

   *app_server_root*\bin\setupCmdLine.bat

   AIX Linux HP-UX Solaris Use the setupCmdLine shell.

   *app_server_root*/bin/setupCmdLine.sh

2. Run the application client.

   Windows Perform one of the following methods:

   - Run a Java command to call your main class directly.

```
"%JAVA_HOME%\bin\java" %WAS_LOGGING%"
-Djava.security.auth.login.config="%USER_INSTALL_ROOT%\properties\wsjaas_client.conf"
-Djava.ext.dirs="%JAVA_HOME%\jre\lib\ext;%WAS_EXT_DIRS%;%WAS_HOME%\plugins;%WAS_HOME%\lib\WMQ\java\lib"
-Djava.naming.provider.url=<an_IIOP_URL_or_a_corbaloc_URL_to_your
```

```
application_server_machine_name>
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
-Dserver.root="%WAS_HOME%" "%CLIENTSAS%" "$CLIENTSSL" %USER_INSTALL_PROP%
-classpath "%WAS_CLASSPATH%;<list_of_your_application_jars_and_classes>"
<fully_qualified_class_name_to_run> <your_application_parameters>
```

- Enter a command to use the WebSphere Application Server launcher.

```
"%JAVA_HOME%\bin\java" %WAS_LOGGING%
-Djava.security.auth.login.config="%USER_INSTALL_ROOT%\properties\wsjaas_client.conf"
-classpath "%WAS_CLASSPATH%;<list_of_your_application_jars_and_classes>
-Djava.ext.dirs="%WAS_EXT_DIRS%;%WAS_HOME%\plugins"
-Djava.endorsed.dirs="%WAS_ENDORSED_DIRS%
-Djava.naming.provider.url=iiop://<your_application_server_machine_name>
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
%SERVER_ROOT% %CLIENTSAS% %CLISENTSSL% <fully_qualified_class_name_to_run>
```

AIX Linux HP-UX Solaris Perform one of the following methods:

- Run a Java command to call your main class directly.

```
"$JAVA_HOME/bin/java" $WAS_LOGGING
-Djava.security.auth.login.config="$USER_INSTALL_ROOT/properties/wsjaas_client.conf"
-Djava.ext.dirs="$JAVA_HOME/jre/lib/ext:$WAS_EXT_DIRS:$WAS_HOME/plugins: $WAS_HOME/lib/WMQ/java/lib"
-Djava.naming.provider.url=<an_IIOP_URL_or_a_corbaloc_URL_to_your
application_server_machine_name>
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
-Dserver.root="$WAS_HOME" $USER_INSTALL_PROP "$CLIENTSAS" "$CLIENTSSL"
-classpath "$WAS_CLASSPATH:<list_of_your_application_jars_and_classes>"
<fully_qualified_class_name_to_run> <your_application_parameters>
```

For more information on IIOP and corbaloc URLs, see Developing applications that use JNDI.

- Enter a command to use the WebSphere Application Server launcher.

```
"$JAVA_HOME/bin/java" $WAS_LOGGING
-Djava.security.auth.login.config="$USER_INSTALL_ROOT/properties/wsjaas_client.conf"
 "-Dws.ext.dirs=<list_of_your_application_jars_and_classes>
$WAS_EXT_DIRS:$WAS_USER_DIRS"
-Djava.naming.provider.url=<an_IIOP_URL_or_a_corbaloc_URL_to_your
application_server_machine_name>
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
"-Dserver.root=$WAS_HOME"
"$CLIENTSAS" "$CLIENTSSL" $USER_INSTALL_PROP -classpath "$WAS_CLASSPATH"
com.ibm.ws.bootstrap.WSLauncher
<fully_qualified_class_name_to_run> <your_application_parameters>
```

# Chapter 8. Developing Communications Enabled Applications

Communications Enabled Applications (CEA) is a functionality that provides the ability to add dynamic web communications to any application or business process. The product provides a suite of integrated telephony and collaborative web services that extends the interactivity of enterprise and web commerce applications. With the CEA capability, enterprise solution architects and developers can use a single core application to enable multiple modes of communication. Enterprise developers do not need to have extensive knowledge of telephony or Session Initiation Protocol (SIP) to implement CEA. The CEA capability delivers call control, notifications, and interactivity and provides the platform for more complex communications.

## Developing communications enabled applications

## Developing SIP communications applications

### Before you begin

### Procedure

- Use the Session Initiation Protocol (SIP) application router to select the order in which SIP applications are triggered.

  When configuring a SIP application router, you can either use the default application router or create a custom application router.
- Use the Asynchronous Invocation API to transfer events that require processing in the context of a Session Initiation Protocol (SIP) application session to any server in a cluster based on the related application session ID.

  The Asynchronous Invocation API transfers the event task to the correct server.
- Use the Domain Resolver API to perform DNS lookups of SIP URIs using the RFC 3263 protocol.

  The Domain Resolver API provides an interface that enables an application to perform DNS queries for SIP URIs.
- Create a SIP servlet request that includes proprietary header fields.

  SIP proprietary header fields enable certain SIP settings to be implemented on a per message basis. SIP settings set at the SIP container level apply to all SIP messages handled by that SIP container.

### Domain Resolver API

Use the Domain Resolver API to perform DNS lookups of SIP URIs using the RFC 3263 protocol. These lookups can be performed synchronously if you want to avoid having to preserve state in order to handle an asynchronous callback. They can also be performed asynchronously if you need a better performing interface.

The Domain Resolver API provides an interface that enables an application to perform DNS queries for SIP URIs. When the Domain Resolver API is used asynchronously, a listener is called after the DNS query completes. You can use one of the following methods in your application code to access the Domain Resolver API:

- Get an attribute from the ServletContext using com.ibm.ws.sip.container.domain.resolver as a key.

  ```
  getServletContext().getAttribute("com.ibm.ws.sip.container.domain.resolver")
  ```
- Use @resource injection.

  ```
  @resource
  DomainResolver resolver
  ```

Use one of the following methods to perform the URI lookup:

- Use the SIPURI method if a synchronous API which will return the result of the URI resolve request response.

© Copyright IBM Corp. 2011

```
DomainResolver
locate(SIPURI)
```

- locate(SIPURI, Listener) – an asynchronous API which will signal the listener once it is finished. When the result is cached the listener will be triggered on the same caller thread.

```
DomainResolver
locate(SIPURI, Listener)
```

For more information about this API, expand the **Reference > Programming interfaces > APIs - Application Programming Interfaces** section in the Feature Pack for Communications Enabled Applications Information Center navigation. Then scroll down to the com.ibm.ws.sip.container.domain.resolver API.

For more information about DNS servers, see the topic *Using DNS procedures to locate SIP servers*

## SIP proprietary header fields

You can create a SIP servlet request that includes proprietary header fields. SIP proprietary header fields enable certain SIP settings to be implemented on a per message basis. SIP settings set at the SIP container level apply to all SIP messages handled by that SIP container.

To include one or more proprietary header fields in a message, set up your SIP servlet request such that it includes one or more SipServletMessage.setHeader(*string_name*, *string value*) methods. When the application calls SipServletRequest.send() to send the request, the message object that is passed to the SIP stack for transmission includes the propriety header information. The SIP stack then creates a client transaction to send out the request, and adjusts the SIP configuration settings for this specific request based on any proprietary header fields that are included in the message object. The stack removes the proprietary header fields before the message is sent out to the network.

### Proprietary header fields used to specify timer values

The following proprietary header fields are available for specifying timer values for a specific message. The application can set multiple timer values in one message instance, but cannot specify multiple values for the same proprietary header field.

**IBM-TransactionTimeout**
: Use this header field to specify, in milliseconds, the length of the client transaction timeout. This header is equivalent to specifying a value for timer B in INVITE client transactions, and timer F in non-INVITE client transactions.

**IBM-RetransmissionInterval**
: Use this header field to specify, in milliseconds, the length of the request retransmission interval. This header is equivalent to specifying a value for timer A in INVITE client transactions, and timer E in non-INVITE client transactions.

**IBM-RetransmissionMaxInterval**
: Use this header field to specify, in milliseconds, the maximum retransmission interval. This header is equivalent to specifying a value for timer T2 in non-INVITE client transactions, and timer B in INVITE client transactions.

# Chapter 9. Developing Data access resources

This page provides a starting point for finding information about data access. Various enterprise information systems (EIS) use different methods for storing data. These backend data stores might be relational databases, procedural transaction programs, or object-oriented databases.

The flexible IBM WebSphere Application Server provides several options for accessing an information system backend data store:

- Programming directly to the database through the JDBC 4.0 API, JDBC 3.0 API, or JDBC 2.0 optional package API.
- Programming to the procedural backend transaction through various J2EE Connector Architecture (JCA) 1.0 or 1.5 compliant connectors.
- Programming in the bean-managed persistence (BMP) bean or servlets indirectly accessing the backend store through either the JDBC API or JCA-compliant connectors.
- Using container-managed persistence (CMP) beans.
- Using the IBM data access beans, which also use the JDBC API, but give you a rich set of features and function that hide much of the complexity associated with accessing relational databases.

Service Data Objects (SDO) simplify the programmer experience with a universal abstraction for messages and data, whether the programmer thinks of data in terms of XML documents or Java objects. For programmers, SDOs eliminate the complexity of the underlying data access technology such as, JDBC, RMI/IIOP, JAX-RPC, and JMS, and message transport technology such as, java.io.Serializable, DOM Objects, SOAP, and JMS.

## Developing data access applications

## Developing data access applications

You can use data access applications to manipulate data from outside sources for use within your application serving environment.

### About this task

You can access data in various ways:

- using standard or extended APIs
- using container-managed persistence beans
- using bean-managed persistence beans, session beans, or web components.
- using Service Data Objects (SDO)

### Procedure

1. Decide how to implement data access.

   The Enterprise JavaBeans (EJB) programming model provides several distinct server-side component types: entity, session, and message-driven beans, and servlets. Of these types, entity beans are typically used to model business components in an application. Entity beans have both *state* and *behavior*.

   The state of entity beans is persistent and is stored in a database. As changes are made to an entity bean, its state is kept in synchronization with the database record representing the bean. There are two types of entity beans provided by the EJB model and these two types differ in the mechanism used to provide persistence. These two types of entity beans are *container-managed persistence* (CMP) beans and *bean-managed persistence* (BMP) beans.

   - With BMP beans, the developer manually produces code to manage the persistent state of the bean.

© Copyright IBM Corp. 2011

- With CMP beans, the EJB container manages the persistent state of the bean. Persistent state management is a complex and difficult task; using CMP beans allows the developer to concentrate on business logic by delegating persistence behavior to the container.

  Typical examples of CMP beans are *Customer*, *Account*, and so on. Because CMP beans are objects, their data (state) is accessed using field accessors. For example, a *Customer* entity bean is likely to have fields such as *name* and *phoneNumber*. These pieces of data are accessed using the accessor methods *getName()/setName()* and *getPhoneNumber()/setPhoneNumber()*. As a developer, you are not concerned with how this data is eventually stored and retrieved from the backend database and can assume that the integrity of the data is maintained by the container.

See the topic, Developing enterprise beans for information on developing entity beans.

**Tips:**

- To maximize the efficiency of application requests to relational databases, consider using Structured Query Language in Java (SQLJ) when developing BMP and CMP beans. This option is available for applications that use the DB2 JDBC Universal Driver to access DB2 databases.
- Also consider using cursor holdability for potential performance gains; see the topic, JDBC application cursor holdability support, for details.

An alternative to developing entity beans is using the Service Data Objects (SDO) framework, which is a unified framework for data application development. With SDO, you do not need to be familiar with a technology-specific API in order to access and utilize data. You need to know only one API, the SDO API, which lets you work with data from multiple sources, including relational databases, entity EJB components, XML pages, web services, the Java Connector Architecture, JavaServer Pages, and more.

2. Look up a data source or connection factory using a resource reference. See the topic, Looking up data sources with resource references for relational access for more information. *Do not perform this step if you work with CMP beans. The EJB container handles this process for CMP beans.*

   To run applications on WebSphere Application Server, your code must use resource references to logically named data sources or connection factories. Mapping the resource references to actual resources is usually done at assembly time. The Application Server administrator configures those resources.

   - For relational database access, administrators configure a JDBC provider and associated data sources, which work with the embedded WebSphere Relational Resource Adapter.
   - For non-relational database access, administrators install a Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) resource adapter onto an application server and configure associated connection factories.

   **Note:** Generic work context implementation provides a mechanism for a resource adapter to control the contexts in which instances of work submitted by the resource adapter to WebSphere Application Server's work manager for execution are executed. By submitting a work instance that implements the WorkContextProvider interface, the resource adapter can propagate various types of context to the WebSphere Application Server. The application server then, if it supports the propagated context type, sets the provided context as the execution context of the work instance during its execution.

3. Get a connection to a data source or a connection factory. See the "Getting connections" section of the topic, Connection life cycle for details.) *Do not perform this step if you work with CMP beans. The EJB container handles this process for CMP beans.*

   The connection management architecture for both relational and procedural access to enterprise information systems (EIS) is based on the Java EE Connector Architecture (JCA) specification. The Connection Manager (CM), which pools and manages connections within an application server, is capable of managing connections obtained through both resource adapters (RAs) defined by the JCA specification, and data sources defined by the JDBC Extensions Specification.

## Using Bean Validation in RAR modules

WebSphere Application Server validates resource archive (RAR) JavaBeans constraints in compliance with the Java Connector Architecture (JCA) version 1.6 specification.

***Bean validation in RAR modules:***

WebSphere Application Server validates resource adapter archive (RAR) JavaBeans constraints in compliance with the Java Connector Architecture (JCA) version 1.6 specification.

Resource adapters can specify the validation requirements of configuration properties to the Application Server through annotations in the source code of the resource adapter, constraint specifications in a resource adapter validation descriptor, or a mixture of both. In specifying these constraints, resource adapters can use the built-in bean validation constraints supplied with the Application Server, custom bean validation constraints supplied either by the application developer or a third party, or a mixture of both. Resource adapter developers can apply constraints to the fields and JavaBeans-compliant properties of the following JCA types:

- ResourceAdapter
- ManagedConnectionFactory
- ActivationSpec
- AdministeredObject

At run time, the application server creates instances of bean types declared by the resource adapter. Each instance is validated immediately upon setting its configuration properties, before placing the instance into service.

When validating a RAR bean, the Application Server creates an instance of a validator factory according to the bean validation deployment descriptor discovered by the Application Server. A validator instance is then obtained from the factory and used to validate the bean instance.

If validation fails, the Application Server throws a constraint violation exception and reports all violations to the system log. The effects of the exception for each RAR bean type and problem determination information are documented in the topic, Troubleshooting bean validation in RAR modules.

**Note:** The Bean Validation specification requires that no more than one `validation.xml` is visible on the class path. This requirement is violated whenever two or more stand-alone RARs provide a validation descriptor. See the section, "RAR bean validation descriptor" in this topic, for more information. When more than one `validation.xml` is visible to the Application Server class loaders, the Application Server or application modules might fail to acquire the default ValidatorFactory and subsequently cannot perform bean validation. For example, the server cannot validate beans of a RAR embedded in an application whenever the embedded RAR lacks a validation configuration, and two or more stand-alone RARs provide configurations. To avoid trouble, install stand-alone RARs that provide a bean validation descriptor as isolated whenever possible.

**Built-in constraint annotations**

**Note:** Use built-in constraint annotations to specify the range and mandatory attributes of configuration properties rather than provide custom annotations for the same purpose. The following constraints are useful, but you can use all bean validation built-in constraints. See the topic Bean validation built-in constraints for a complete list of the constraints.

- @Min

  Specifies the minimum value of the configuration property decorated with this annotation. The value must be greater than or equal to the specified minimum.
- @Max

Specifies the maximum value of the configuration property decorated with this annotation. The value must less than or equal to the specified maximum.

- @Size

  Specifies the range of values of the configuration property decorated with this annotation. The value must be greater than or equal to the specified minimum and be less than or equal to the specified maximum.

- @NotNull

  Specifies the value of the configuration property decorated with this annotation must not be null. That is, the property is required.

The following example is a RAR bean class that is decorated with built-in constraint annotations.

The value of the serverName configuration property must not be null, and the value of the instanceCount property must be at least 1 when the Application Server creates and configures an instance of the MyConnector class. Otherwise, a constraint validation exception occurs and, in the case of ResourceAdapter bean, the resource adapter fails to start. See the topic Troubleshooting bean validation in RAR modules for more information.

```
package com.my.company;

@Connector(...)
public class MyConnector implements ResourceAdapter, Serializable
{
 @ConfigProperty(type=java.lang.String.class,defaultValue="WAS")
 private String serverName;

 @NotNull()
 public String getServerName() {return serverName;}

 private Integer instanceCount = 0;

 @Min(value=1)
 public Integer getInstanceCount() {return instanceCount;}
 ...
```

### RAR bean validation descriptor

Bean validation constraints can be declared through an XML descriptor supplied by a RAR module. In the simplest case, a RAR validation descriptor consists of the validation configuration declared in the validation.xml file and zero or more XML files that declare RAR bean validation constraints. Files containing constraint declarations are specified in the constraint-mapping elements of the validation configuration (validation.xml).

You must package the validation descriptor in the META-INF directory of a RAR module. Any custom constraint annotation classes that are declared in the validation descriptor must also be packaged in the RAR module.

The following example is a simple RAR validation descriptor that declares constraint metadata like the code shown in the section, "Built-in constraint annotations."

```
<?xml version="1.0" encoding="UTF-8"?>
<validation-config
  xmlns="http://jboss.org/xml/ns/javax/validation/configuration"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://jboss.org/xml/ns/javax/validation/configuration validation-configuration-1.0.xsd">
<constraint-mapping>META-INF/constraints.xml</constraint-mapping>
</validation-config>
```

The constraints XML file is also located in the META-INF directory and looks like the following:

```
<constraint-mappings
 xmlns="http://jboss.org/xml/ns/javax/validation/mapping"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://jboss.org/xml/ns/javax/validation/mapping validation-mapping-1.0.xsd">
<default-package>com.my.company</default-package>
<bean class="MyConnector" ignore-annotations="true">
 <field name="serverName">
  <valid/>
  <!-- @NotNull() -->
```

```
  <constraint annotation="javax.validation.constraints.NotNull">
   <message>Value is not null</message>
  </constraint>
 </field>
 <field name="instanceCount">
  <valid/>
  <!-- @Min(1) -->
  <constraint annotation="javax.validation.constraints.Min">
    <message>Minimum possible value is 1</message>
    <element name="value">1</element>
   </constraint>
  </field>
 </bean>
<constraint-mapping>
```

The packaged RAR module, `MyResourceAdapter.rar`, looks like the following:

```
my/
  company/
    MyConnector.class
. . .
META-INF
  /validation.xml
  /constraints.xml
```

### Third-party bean validation

WebSphere Application Server supports using different bean validation implementations. If a resource adapter requires a bean validation implementation different from the implementation that is provided by the product, and the RAR provides the bean validation implementation, you must package the JAR file that contains the bean validation implementation in the RAR module root directory.

The RAR module must also contain a single validation configuration descriptor (`validation.xml`), which can be packaged in the META-INF directory of the RAR module, or in the `META-INF/services` directory of the bean validation JAR file, but not both.

### RAR bean validation configuration discovery

When validating RAR beans, the Application Server bootstraps the bean validation configuration, specific to the RAR, according to the bean validation descriptor supplied in the RAR META-INF directory. If the descriptor does not exist, the server bootstraps the configuration using the first validation descriptor discovered in the RAR class loading context, such as that supplied in a third-party bean validation that is packaged in the RAR. Finally, the server uses the default validation configuration provided by the product.

The server then creates a validator factory specific to the discovered bean validation configuration and uses this factory to create validator instances for validating the RAR bean instances. When you deploy a RAR that supplies a bean validation descriptor, you must take additional steps to ensure that the class loader that loads the RAR loads the bean validation descriptor and classes packaged in the RAR.

For an embedded RAR, after you have deployed the application that embeds the RAR, you must set the delegation mode of the application class loader to Parent-Last (Child-First). See the topic Configuring application class loaders for more information.

For a stand-alone RAR, you must install the RAR as an isolated resource provider. See the topic Resource Adapter settings for more information.

#### *Troubleshooting bean validation in RAR modules:*

RAR beans that fail validation are not placed into service. When constraint violations occur, applications encounter resource connectivity issues that are different according to the bean type and how the RAR is deployed. This topic explains how to understand, service, and prevent these known issues.

### RAR bean constraint violations

WebSphere Application Server displays a constraint violation exception and reports all constraint violations to the system log when it validates RAR bean instances that violate one or more constraints. The cause of all constraint violation must be determined and resolved to restore full connectivity to the affected resource.

Problem determination starts with consulting the RAR provider documentation for the valid values of the configuration properties that are indicated in the violations. If the property values are invalid, you must reconfigure them according to the documentation and restart the resource adapter. If the adapter is embedded in an application, then restart the application to restart the adapter; if the adapter is stand-alone, then restart the application server.

If a valid configuration property value is indicated in a violation, then the constraint might be incorrectly specified for the bean, or the bean is incorrectly computing the property value. In these cases, the RAR vendor must correct the problem.

If the problem is caused by a faulty constraint definition (implementation), then the bean validation provider must correct the problem. In these cases, if the RAR is provided by IBM, or the RAR uses the bean validation implementation supplied by the Application Server, then contact IBM support to continue problem determination.

### ResourceAdapter beans

ResourceAdapter beans are validated when the server starts a Java 2 Connector (J2C) resource adapter. When validation fails, the server rejects the ResourceAdapter instance and the resulting constraint violation exception causes the J2C resource adapter to fail. Applications cannot establish outbound connections to the resource, and the resource cannot deliver messages to applications. For an embedded adapter, the application that embeds the adapter fails to start. In-doubt transactions that involve the resource cannot be recovered.

The following example is a ResourceAdapter bean, MyConnector, at heap address 7efa7efa. Two validation constraints are violated. The constraint violation exception causes J2CResourceAdapter_1285109360562 to fail:

```
[9/29/10 10:51:24:125 CDT] 00000000 BeanValidatio E
 J2CA0238E: JavaBean com.my.company.adapter.MyConnector@7efa7efa failed Bean Validation due to one or more invalid
 configuration settings indicated in the following list of constraint violations:

 ConstraintViolationImpl{interpolatedMessage='The minimum size is 2', propertyPath=dataBaseName, rootBeanClass=class
    com.my.company.adapter.MyConnector, messageTemplate='The minimum size is 2'}
 ConstraintViolationImpl{interpolatedMessage='must be greater than or equal to 10', propertyPath=idleTimeout, rootBeanClass=class
    com.my.company.adapter.MyConnector, messageTemplate='{javax.validation.constraints.Min.message}'}
...
[9/29/10 10:51:24:468 CDT] 00000000 RALifeCycleMa E
 J2CA0128E: An Exception occurred while trying to start ResourceAdapter
  cells/IBM-46DF84D297BNode01Cell/nodes/IBM-46DF84D297BNode01/resources.xml#J2CResourceAdapter_1285109360562. The exception is:

 at com.ibm.ejs.j2c.RAWrapperImpl.startRA(
 at com.ibm.ejs.j2c.RALifeCycleManagerImpl.startRA(
 at com.ibm.ejs.j2c.RALifeCycleManagerImpl.resourceProviderEvent(
. . .
```

### ManagedConnectionFactory beans

ManagedConnectionFactory JavaBeans are validated during the initial Java Naming and Directory Interface (JNDI) lookup of a J2C connection factory.

When validation fails, the Application Server rejects the ManagedConnectionFactory instance and displays a naming exception to the application that performs the lookup. This exception indicates the causal constraint violation exception (javax.validation.ConstraintValidationException).

Applications cannot establish outbound connections to the resource. In-doubt transactions started over connections to the resource that were created by the connection factory cannot be recovered.

The following example is a ManagedConnectionFactory bean, MyMcf, at heap address 7dd07dd0, Two validation constraints are violated. The constraint violation exception causes the application to not obtain a connection factory that is required to create a connection to the resource, MyConnector:

```
[9/30/10 7:58:58:734 CDT] 00000023 BeanValidatio E
 J2CA0238E: JavaBean com.my.company.adapter.MyMcf@7dd07dd0 failed Bean Validation due to one or more invalid
  configuration settings indicated in the following list of constraint violations:
 ConstraintViolationImpl{interpolatedMessage='must be less than or equal to 30', propertyPath=mcfProperty2,
    rootBeanClass=class com.my.company.adapter.MyMcf, messageTemplate='{javax.validation.constraints.Max.message}'}
 ConstraintViolationImpl{interpolatedMessage='The value should be greater than 10', propertyPath=mcfProperty4,
    rootBeanClass=class com.my.company.adapter.MyMcf, messageTemplate='The value should be greater than 10'}
....
[9/30/10 7:58:58:765 CDT] 00000023 ConnectionFac E

### ActivationSpec bean violations

ActivationSpec beans are validated when the applications starts. This is when the Application Server initially activates message endpoints bound to J2C activation specifications. These activation specifications name the bean class in their configuration. When validation fails, the endpoint fails to activate and the resulting constraint violation exception causes the application hosting the endpoint to fail.

Because the J2C resource adapter that contains the activation specification is started, applications can still establish connections to the resource. The resource can deliver messages to endpoints that have successfully activated. If the activation specification is defined within an embedded resource adapter, the server stops the adapter in the course of stopping the application. Failed transactional messages delivered by previous instances of the resource adapter that contains the activation specification cannot be recovered.

The following example is an ActivationSpec bean, MyActSpec, at heap address 51625162. Two validation constraints are violated. The log shows the constraint violation exception that causes the application, my_company_app, to fail:

```
[9/29/10 10:52:05:125 CDT] 00000009 BeanValidatio E
 J2CA0238E: JavaBean com.my.company.adapter.MyActSpec@51625162 failed Bean Validation due to one or more invalid
  configuration settings indicated in the following list of constraint violations:

### AdministeredObject beans

AdministeredObject beans are validated when the server starts a J2C resource adapter that contains the administered object in its configuration. When validation fails, the server rejects the AdministeredObject instance and the resulting constraint violation exception causes the resource adapter to fail.

The following example is an AdministeredObject beans, MyAdminObj, at heap address 3a803a80. Two validation constraints are violated. The log shows the constraint violation exception that causes resource adapter to fail:

```
[9/29/10 10:51:25:125 CDT] 00000000 BeanValidatio E

## JCA 1.6 support for annotations in RAR modules

**Note:** The Java Connector Architecture (JCA) Version 1.6 specification adds support for Java annotations in resource archive (RAR) modules. Annotations are a means of specifying metadata, or configuration data, for a RAR module in the class files that make up the module.

Before JCA 1.6, this metadata was specified only in the deployment descriptor, but now you can specify this metadata using either a deployment descriptor or annotations. Metadata that is specified in annotations is merged into the deployment descriptor of a RAR module when it is updated, if the module is not marked metadata-complete in the deployment descriptor and if the module version is 1.6 or later.

The metadata-complete element defines whether the deployment descriptor for the resource adapter module is complete or whether the class files that are available to the module and packaged with the resource adapter should be examined for annotations that specify deployment information. If the metadata-complete is set to *true*, the application server deployment tool must ignore any annotations that specify deployment information, which might be present in the class files of the application. If metadata-complete is not specified, or is set to *false*, the deployment tool must examine the class files of the application for annotations, as specified by the JCA 1.6 Specification. If the deployment descriptor is not included, or is included but not marked metadata-complete, the deployment tool processes annotations.

Application servers must assume that metadata-complete is *true* for resource adapter modules with deployment descriptors that meet the requirements of JCA specification 1.5 and earlier. For a complete list of the supported annotations and their usage, consult the JCA specification.

**Note:** The JCA Version 1.6 specification also adds support for Bean Validation constraint annotations in RAR modules. You can specify Bean Validation constraint metadata for RAR JavaBeans by decorating your classes with Bean Validation constraint annotations or by supplying XML validation descriptors. The Application Server validates the constraints of all JCA 1.6 RAR JavaBeans instances before placing them into service at run time.

## Extensions to data access APIs

If a single data access API does not provide a complete solution for your applications, use WebSphere Application Server extensions to achieve interoperability between both the JCA and JDBC APIs.

Applications that draw from diverse and complex resource management configurations might require use of both the Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) API and the Java Database Connectivity (JDBC) API. However, in some cases the JDBC programming model does not completely integrate with the JCA (even though full integration is a foundation of the JCA specification). These inconsistencies can limit data access options for an application that uses both APIs. WebSphere Application Server provides API extensions to resolve the compatibility issues.

For example:

Without the benefit of an extension, applications using both APIs cannot modify the properties of a shareable connection after making the connection request, if other handles exist for that connection. (If no other handles are associated with the connection, then the connection properties can be altered.) This limitation stems from an incompatibility between the connection-configuration policies of the APIs:

The Connector Architecture (JCA) specification supports relaying to the resource adapter the specific properties settings at the time you request the connection (using the getConnection() method) by passing in a *ConnectionSpec* object. The ConnectionSpec object contains the necessary connection properties used to get a connection. After you obtain a connection from this environment, your application does not need to alter the properties. The JDBC programming model, however, does not have the same interface to specify the connection properties. Instead, it gets the connection first, then sets the properties on the connection.

WebSphere Application Server provides the following extensions to fill in such gaps between the JDBC and JCA specifications:

- WSDataSource interface - this interface extends the *javax.sql.DataSource* class, and enables a component or an application to specify the connection properties through the WebSphere Application Server *JDBCConnectionSpec* class to get a connection.
  - getConnection(JDBCConnectionSpec) - this method returns a connection with the properties specified in the JDBCConnectionSpec class.
  - For more information see the **WSDataSource** API documentation topic (as listed in the API documentation index).
- JDBCConnectionSpec interface - this interface extends the *com.ibm.websphere.rsadapter.WSConnectionSpec* class, which extends the *javax.resources.cci.ConnectionSpec* class. The standard ConnectionSpec interface provides only the interface marker without any get() and set() methods. The WSConnectionSpec and the JDBCConnectionSpec interfaces define a set of get() and set() methods used by the WebSphere Application Server run time. This interface enables the application to specify all the essential connection properties in order to get an appropriate connection. You can create this class from the WebSphere WSRRAFactory class. For more information see the **JDBCConnection** API documentation topic (as listed in the API documentation index).
- WSRRAFactory class - this is a factory class for the WebSphere Relational Resource Adapter, which allows the user to create a JDBCConnectionSpec object or other resource adapter related object. For more information see the **WSRRAFactory** API documentation topic (as listed in the API documentation index).
- WSConnection interface - this is an interface that allows users to call WebSphere proprietary methods on SQL connections; those methods are:
  - setClientInformation(Properties props) - See the topic, Example: Setting the client information with the setClientInformation(Properties) API, for more information and examples of setting client information.
  - Properties getClientInformation() - This method returns the properties object that is set using *setClientInformation(Properties)*. Note that the properties object returned is not affected by implicit settings of client information.
  - WSSystemMonitor getSystemMonitor() - This method returns the SystemMonitor object from the backend database connection if the database supports System Monitors. The backend database will provide some connection statistics in the SystemMonitor object. The SystemMonitor object returned is wrapped in a WebSphere object (*com.ibm.websphere.rsadapter.WSSystemMonitor*) to shield applications from dependency on any database vendor code. See *com.ibm.websphere.rsadapter.WSSystemMonitor* Java documentation for more information. The following code is an example of using the *WSSystemMonitor* class:

```
import com.ibm.websphere.rsadapter.WSConnection;
...
try{
 InitialContext ctx=new InitialContext();
 // Perform a naming service lookup to get the DataSource object.
 DataSource ds=(javax.sql.DataSource]ctx.lookup("java:comp/jdbc/myDS");
} catch (Exception e) {;}
```

```
WSConnection conn=(WSConnection)ds.getConnection();
WSSystemMonitor sysMon=conn.getSystemMonitor();
if (sysMon!=null) // indicates that system monitoring is supported on the current backend database
 {
  sysMon.enable(true);
  sysMon.start(WSSystemMonitor.RESET_TIMES);
  // interact with the database
  sysMon.stop();
  // collect data from the sysMon object
 }
conn.close();
```

The WSConnection interface is part of the *plugins_root*/com.ibm.ws.runtime.jar file.

### Example: Using IBM extended APIs for database connections.

Using the WSDataSource extended API, you can code your JDBC application to define connection properties through an object *before* obtaining a connection. This behavior increases the chances that the application can share a connection with another component, such as a CMP.

If your application runs with a shareable connection that might be shared with other container-managed persistence (CMP) beans within a transaction, it is recommended that you use the WebSphere Application Server extended APIs to get the connection. When you use these APIs, you cannot port your application to other application servers.

You can code with the extended API directly in your JDBC application; instead of using the DataSource interface to get a connection, use the WSDataSource interface. The following code segment illustrates WSDataSource:

```
import com.ibm.websphere.rsadapter.*;

...

// Create a JDBCConnectionSpec and set connection properties. If this connection is shared with
the CMP bean, make sure that the isolation level is the same as the isolation level that is mapped by
 the Access Intent defined on the CMP bean.

JDBCConnectionSpec connSpec = WSRRAFactory.createJDBCConnectionSpec();

connSpec.setTransactionIsolation(CONNECTION.TRANSACTION_REPEATABLE_READ);

connSpec.setCatalog("DEPT407");

//Use WSDataSource to get the connection

Connection conn = ((WSDataSource)datasource).getConnection(connSpec);
```

### Example: Using IBM extended APIs to share connections between CMP beans and BMP beans.

Within an application component that accesses data through JDBC objects (such as a bean-managed persistence (BMP) bean), you can use a WebSphere extended API to define connection properties through an object *before* obtaining a connection. This behavior increases the chances that the BMP bean can share a connection with a container-managed persistence (CMP) bean.

If your BMP bean runs with a shareable connection that might be shared with other container-managed persistence (CMP) beans within a transaction, it is recommended that you use the WebSphere Application Server extended APIs to get the connection. When you use these APIs, you cannot port your application to other application servers.

In this case, use the extended API WSDataSource interface rather than the DataSource interface. To ensure that both the CMP and bean-managed persistence (BMP) beans are sharing the same physical connection, define the same access intent profile on both the CMP and BMP beans. Inside your BMP method, you can get the right isolation level from the relational resource adapter helper class.

```
package fvt.example;

```

## Recreating database tables from the exported table data definition language

When the WebSphere Application Server deployment tooling deploys an EJB jar file containing container-managed persistence (CMP) enterprise beans, it selects the target database and creates a corresponding *Table*.ddl file. This file contains the SQL statement necessary to generate the database table for your CMP beans.

### About this task

The following steps demonstrate the process for creating tables in DB2.

### Procedure

1. Extract the *Table*.ddl file from your CMP enterprise bean JAR file and save it on your database server.
   - Save the file to a working directory, such as *C:\temp*, on your DB2 machine.
2. Run the *Table*.ddl file.
   - Run the command **C:\temp>db2cmd**, replacing *C:\temp* with your chosen directory. A DB2 command window is displayed, in which you enter the following commands (replacing *C:\temp* with your chosen directory):
     a. `C:\temp>db2 connect to your_db_name`
     b. `C:\temp>db2 -tf Table.ddl` //This command runs and creates tables for your CMP enterprise bean.
     c. `C:\temp>db2 disconnect all`

     **Note:** AIX HP-UX Solaris If you run DB2 on supported UNIX systems, use these same commands. Run them from a user with permissions for DB2, rather than from a DB2 command window.

### Results

The database tables are created.

## Container managed persistence bean associated technologies

WebSphere Application Server delivers container-managed persistence (CMP) services beyond the standards set by the Enterprise JavaBeans (EJB) specification.

According to the specification, the EJB container synchronizes the state of CMP beans with the underlying database, and manages the relationships (container-managed relationships, or CMR's) among entity beans. Thus the EJB specification relieves bean developers from writing any database-specific code; instead, they can focus on writing business logic. WebSphere Application Server offers the following additional CMP functions to increase development efficiency even more, as well as optimize the run-time performance of business logic:

**Entity bean inheritance**

Inheritance is a key aspect of object-oriented software development and is a capability currently missing from the EJB specification.

The use of inheritance enables a developer to define fields, relationships, and business logic in a superclass entity bean that are inherited by all subclasses. See the section *EJB inheritance* of the Rational Application Developer documentation for details on using inheritance with WebSphere Application Server and entity beans.

**Access Intent Policies**

Access intent policies provide Java Platform, Enterprise Edition (Java EE) application developers the mechanism by which they can indicate the intent of an application's interaction with the essential state for entity beans in order that the persistence mechanisms can make appropriate optimizations. For example, if it is known that an entity is not updated during the course of a transaction, then the persistence management is able to ease up on the concurrency control and still maintain data integrity by disallowing update operations on that bean for the duration of the transaction.

**Caching data across transactions**

Data caching across transactions is a configurable option set by the bean deployer that can greatly improve performance. Essentially, this is for data that changes infrequently. The option is known as *LifetimeInCache*. The data for an entity configured for lifetime in cache is stored in a

cache until its specified lifetime expires. Requests on the entity during that configured lifetime use the cached data, and do not result in the execution of queries against the underlying data store. Lifetime can be expressed as time elapsed since the data was retrieved from the data store or until a specific time of day or week. The *LifetimeInCache* value can be one of the following:

**Off** The LifetimeInCache setting is ignored. Beans of this type are only cached in a transaction scoped cache. The cached data for this instance is not valid when the transaction is completed.

**ElapsedTime**
The value in the LifetimeInCache setting is added to the current time when the transaction (in which the bean instance is retrieved) is completed. The cached data for this instance is not valid after this time. The value of the LifetimeInCache setting can add up to minutes, hours, days, and so on.

**ClockTime**
The value of LifetimeInCache represents a particular time of day. The value is added to the immediately preceding or following midnight to calculate a future time value, which is then treated as for Elapsed Time. Using this setting enables you to specify that all instances of this bean type have their cached data invalidated at a specific time no matter when the data were retrieved.

The use of preceding or following midnight to calculate a future time value depends on the value of LifetimeInCache. If LifetimeInCache plus preceding midnight is earlier than the current time, then the following midnight is used.

When you use the ClockTime setting, the value of LifetimeInCache must not represent more than 24 hours. If it does, the cache manager subtracts increments of 24 hours from it until a value less than or equal to 24 hours is achieved. To invalidate data at 12 midnight, you set LifetimeInCache to zero (0).

**WeekTime**
This setting is similar to ClockTime, except the value of LifetimeInCache is added to the preceding or following Sunday midnight (actually, 11:59 PM on Saturday plus 1 minute). In this case, the LifetimeInCache value can represent more than 24 hours, but not more than 7 days.

See the *LifetimeInCache* help sections of the assembly tool for more details.

**Note:**

Because the data used by an entity bean can be loaded by previous transactions, if you configure the bean as LifeTimeInCache, the isolation level and update lock (access intent policies) for the bean are lost for the current transaction. This can cause data integrity problems if your application has logic to calculate information from read-only data, and then save the result in another bean. This makes it important to perform read-read consistency checking to ensure the data get locked properly if loading the data from in-memory cache; otherwise, data is updated to the database without knowing the underlining data is changed, causing previous changes to be lost. For more information, see the topic Configuring read-read consistency checking with an assembly tool.

**Read-only entity beans**
Declaring entity beans as read-only potentially increases the performance enhancement offered by caching. Both features operate on the same principle: to minimize the overhead incurred by frequent reloading of entity beans from data in persistent storage. When you designate entity beans as read-only, you can specify the reload requirements and frequency, according to the needs of your application.

To use this function, you declare the bean type as read-only by selecting a particular set of bean caching options, through a selection list within the assembly tooling. See Configuring read-read consistency checking with an assembly tool for details.

***Container-managed persistence restrictions and exceptions:***

Some external software that directly impact your applications can limit container-managed persistence (CMP) features. However, you can work around these limitations.

In each case, only very specific behaviors of the software place restrictions on your CMP beans. The following tips help you prevent these behaviors.

**CMP deployment and Sybase IMAGE type restriction**

When deploying enterprise beans with container managed persistence (CMP) types that are non-primitive and do not have a natural JDBC mapping, the deployment tool maps the CMP type to a binary type in the database, where it is stored as a serialized instance. For Sybase, the tool uses the JDBC type *LONG VARBINARY*. The Sybase driver maps *LONG VARBINARY* to the native type *IMAGE*.

Although the type *VARBINARY* has fewer restrictions than *IMAGE* in Sybase, you cannot use it because it is limited to a size of 255 bytes, which is too small for typical serialized Java objects.

The specific restrictions on the IMAGE type are:

- You cannot use the *IMAGE* type in the *WHERE* clause of an SQL query. You can encounter this restriction whenever an enterprise bean contains an EJB-QL query that has a CMP type in the *WHERE* clause, which maps to the *IMAGE* type in the Sybase relational database.
- You cannot use *IMAGE* type in select queries marked *DISTINCT*. This situation arises in these user scenarios:
  - When the *DISTINCT* key word is specified in an EJB-QL select query having a Java type mapping to IMAGE.
  - When Enterprise beans have finder and ejbSelect() methods returning java.util. Set and have CMP types mapping to *IMAGE*.

To work around this restriction, edit the EJB mappings in the Rational Application Developer toolset and do either of the following:

- If you are **sure** that the serialized instance of the CMP type is **never** larger than 255 bytes, you can change the CMP type mapping from *IMAGE* or *LONG VARBINARY* to *VARBINARY*.
- Map the CMP type to multiple RDB fields through a composer. For example, if the CMP type is a Java object X with an int field and a string field, then map X to two RDB fields *INTEGER* and *VARCHAR*, using a composer. Refer to the Rational Application Developer documentation for more information about using composers.

**A ClassCastException exception occurs when running CMP 1.1 beans**

If you created your Enterprise JavaBeans (EJB) application using Rational Application Developer or WebSphere Studio Application Developer Integration Edition, Version 4.0.x , and the application contains container managed persistence (CMP) 1.1 beans with associations (relationships), you might receive a *java.lang.ClassCastException* exception when you run your application on WebSphere Application Server.

**Note:** Business processes modeled with WebSphere Studio Application Developer Integration Edition Version 5.0 or earlier are deprecated.

The cast operation generated by Rational Application Developer or WebSphere Studio Application Developer Integration Edition, Version 4.0.x, does not use the *javax.rmi.PortableRemoteObject.narrow(...)* object to convert the remote object to the remote interface of CMP beans in the *XToYLink.java* (or *YToXLink.java*) class where X and Y are CMP 1.1 beans.

**Recommended response**

1. Locate the following methods in all link classes, for example, XToYLink.java and YToXLink.java where X and Y are CMP 1.1 beans:

```
public void secondaryAddElementCounterLinkOf(javax.ejb.EJBObject anEJB)
public void secondaryRemoveElementCounterLinkOf(javax.ejb.EJBObject anEJB)
public void secondarySetCounterLinkOf(javax.ejb.EJBObject anEJB)
```

2. Add the javax.rmi.PortableRemoteObject.narrow(...) object to convert the remote object to the remote interface of CMP beans.

For example, change the following original method:

```
public void secondaryAddElementCounterLinkOf(javax.ejb.EJBObject anEJB) throws java.rmi.RemoteException {
        if (anEJB != null)
               ((X) anEJB).secondaryAddY((Y) getEntityContext().getEJBObject());
```

to:

```
public void secondaryAddElementCounterLinkOf(javax.ejb.EJBObject anEJB) throws java.rmi.RemoteException {
        if (anEJB != null)
             ((X) anEJB).secondaryAddY((Y)

```

***Application performance and entity bean behavior:***

WebSphere Application Server allows you to override two behaviors that are required by the Enterprise JavaBeans (EJB) specification, because your application might benefit from handling these aspects of bean data management in a slightly different manner.

**Application-managed persistent store synchronization for findBy methods**

Sections 10.5.3 and 12.1.4.2 of the EJB 2.0 and 2.1 specifications require that prior to running a query as part of any findBy method (except for findByPrimaryKey), the EJB container writes out to persistent storage the state of any entity beans of the type that are enlisted in the current transaction. Stated another way, the container performs the following actions:

1. Creates a list of beans that are both enlisted in the current transaction and are of the same type that the findby method is returning
2. Stores the state of these enterprise beans to persistent storage before running the query

If the state of an EJB instance is not altered in the current transaction, the store operation is skipped for that instance. This practice ensures that the query is performed on the most current state of all the persistent data, reducing the chance of data integrity issues.

However, there are scenarios where it is inefficient and wasteful for the EJB container to automatically perform this action on every findBy method. Examples of this would be where the application itself ensures that the most current data is used on findBy queries, or where the application can tolerate some non-current data as part of the query results.

WebSphere Application Server allows you to initiate the synchronization process under application control, and to disable the container-managed synchronization for specific EJB types within your application. Careful use of these functions can improve the performance of your application without sacrificing data integrity. Refer to the topic Manipulating the synchronization of entity beans and datastores.

**Avoiding ejbStore invocations on non-modified entity bean instances**

The EJB specification requires that the EJB container invoke the user-provided ejbStore method on all entity beans within a transaction when that transaction is committed. For container-managed persistence (CMP) beans (as opposed to bean-managed persistence beans) this operation is usually unnecessary, because this method on CMP beans is often empty. Even in cases where the method is not empty, the application might only require the method to be called if the bean's persistent state is modified during the current transaction.

WebSphere Application Server provides a mechanism for you to indicate if you want this behavior for specific EJB types within the application. See the topic Avoiding ejbStore invocations on non-modified EntityBean instances.

## Manipulating synchronization of entity beans and datastores

You can indicate that a particular Enterprise JavaBeans (EJB) type should not synchronize its state to persistent storage prior to each findBy invocation by using environment variables or a marker interface.

### About this task

There are two options available for indicating that a particular EJB type should not synchronize its state to persistent storage prior to each findBy invocation:

- Set an EJB environment variable within the bean's deployment descriptor
- Have the bean implementation class implement a marker interface. This second technique is especially useful if you have a number of bean implementations that all extend a single root class; in this case you can have the root class implement the marker interface, causing all beans that extend this class to inherit the behavior as well.

### Procedure

- **To use the EJB environment variable technique**, edit the EJB deployment descriptor using any standard Java Platform, Enterprise Edition (Java EE) development tool. For information on your tool options, see the topic, Assembly tools.
  1. Start the tool.
  2. Select the EJB deployment descriptor of the bean with which you want to work.
  3. Create an EJB environment variable with the name **com/ibm/websphere/ejbcontainer/disableFlushBeforeFind**.
  4. Set the type of this variable to **java.lang.Boolean**.
  5. Set the value to True to prevent the pre-find synchronization, or False to enable the default behavior.
  6. Save your changes.
- **To use a marker interface**, code your bean implementation class to implement the **com.ibm.websphere.ejbcontainer.disableFlushBeforeFind** interface. The bean implementation class need not directly implement the interface; any parent class can implement the interface. See the **com.ibm.websphere.ejbcontainer** package in the **Reference** > **Developer** > **API documentation** section of the information center.

  **Ensuring data integrity for queries performed during a transaction**

  If you choose to disable the automatic pre-find synchronization for certain bean types, it is very important that your application use other means to ensure that queries performed during the transaction are not performed on data that might no longer be valid. You can use the flushCache method on the com.ibm.websphere.ejbcontainer.EJBContextExtension class (an extension of javax.ejb.EJBContext) to perform a manual synchronization to persistent storage at times that are defined by the application. For more information on EJBContextExtension and its related classes SessionContextExtension, EntityContextExtension and MessageDrivenContextExtension, see the **com.ibm.websphere.ejbcontainer** package in the **Reference** > **Developer** > **API documentation** section of the information center.

## Avoiding ejbStore invocations on non-modified EntityBean instances

You can configure your EntityBean instances to bypass an invocation of the ejbStore method if they have not been modified during the current transaction.

### About this task

There are two options available for indicating that a particular Enterprise JavaBeans (EJB) type should only have its ejbStore method invoked if the bean has been modified during the current transaction:

- Set an EJB environment variable within the bean's deployment descriptor
- Have the bean implementation class implement a marker interface. This second technique is especially useful if you have a number of bean implementations that all extend a single root class; in this case you may have the root class implement the marker interface, causing all beans that extend this class to inherit the behavior as well.

### Procedure

- **To use the EJB environment variable technique**, edit the EJB deployment descriptor using any standard Java Platform, Enterprise Edition (Java EE) development tool. Use the following steps as a guide. For information on your tool options, see the topic, Assembly tools.
  1. Start the tool.
  2. Select the EJB deployment descriptor of the bean you want to work with.
  3. Create an EJB environment variable with the name **com/ibm/websphere/ejbcontainer/ disableEJBStoreForNonDirtyBeans**.
  4. Set the type of this variable to **java.lang.Boolean.**
  5. Set the value to True to avoid the ejbStore invocation, or False to enable the default behavior.
  6. Save your changes.
- **To use a marker interface**, code your bean implementation class to implement the **com.ibm.websphere.ejbcontainer.DisableEJBStoreForNonDirtyBeans** interface. The bean implementation class need not directly implement the interface; any parent class can implement the interface. See the **com.ibm.websphere.ejbcontainer** package in the **Reference** > **Developer** > **API documentation** section of the information center.

## Resource reference benefits

WebSphere Application Server requires your code to reference application server resources (such as data sources or J2C connection factories) through logical names, rather than access the resources directly in the Java Naming and Directory Interface (JNDI) name space. These logical names are called *resource references*.

Application Server requires use of resource references for the following reasons:

- If application code looks up a data source directly in the JNDI naming space, every connection that is maintained by that data source inherits the properties that are defined in the application. Consequently, you create the potential for numerous exceptions if you configure the data source to maintain shared connections among multiple applications. For example, an application that requires a different connection configuration might attempt to access that particular data source, resulting in application failure.
- It relieves the programmer from having to know the name of the actual data source or connection factory at the target application server.
- You can set the default isolation level for a data source through resource references. With no resource reference you get the default for the JDBC driver you use.

#### Example of using a resource reference

The following code invokes a data source by creating a place holder for it through the lookup method. Using the logical name *jdbc/Section*, the code stores the place holder in the JNDI subcontext *java:comp/env/*; hence *jdbc/Section* becomes a resource reference. (The subcontext *java:comp/env/* is the name space that WebSphere Application Server provides exclusively for object references within application code.)

```
javax.sql.DataSource specificDataSource  =
   (javax.sql.DataSource) (new InitialContext()).lookup("java:comp/env/jdbc/Section");
//The method InitialContext()).lookup creates the logical name, or resource reference, jdbc/Section.
```

Generally, an actual data source is configured later as an administrative task.

The logical name *jdbc/Section* is officially declared as a resource reference in the application deployment descriptor. You can then associate the resource reference with the JNDI name of the actual data source in several ways:

- If you know the data source JNDI name at the point of application assembly, specify the name on the resource references Bindings page.
- Specify the data source JNDI name during application deployment.
- Map the resource reference to the data source JNDI name when you configure the application after deployment.

This act of association is called *binding* the resource reference to the data source.

See the article, Application bindings, for information on all types of required resource bindings.

***Requirements for setting data access isolation levels:***

This article discusses the criteria and effects of setting isolation levels for data access components that comprise Enterprise JavaBeans (EJB) 2.x and later modules.

In an EJB 1.1 module, you can set the isolation level at the method level or bean level. This capability also applies to container-managed persistence (CMP) 1.1 beans that you assemble into *EJB 2.x modules*. WebSphere Application Server permits the deployment descriptor of a CMP bean to declare the version level of 1.1, regardless of the overall module version.

However, the ability to set isolation level at the method or bean level does **not** apply to other enterprise beans within an EJB 2.x module, including *CMP 2.x beans*. WebSphere Application Server Version 5.0 removed this capability from EJB 2.0 modules to deliver an architecture that ultimately provides more efficient connection use.

Consequently, later versions of the product enforce the following restrictions on declaring isolation level for CMP 2.x beans—as well as session beans, message-driven beans, and bean managed persistence (BMP) beans that you assemble into EJB 2.x modules:

- You cannot specify isolation level on the EJB method level or bean level.
- If you configure a JDBC application, a bean-managed persistence (BMP) bean, or a servlet to participate in global transactions, any connection that is shared cannot accept a user-specified isolation level. WebSphere Application Server can only set a user-specified isolation level on a connection that is not shared within a global transaction. *Generally, you want to refrain from specifying isolation levels on shareable connections.*

The configuration for the isolation level is determined by the type of bean that is used by the component:

**Isolation level on connections used by 2.x CMP beans**
: In a EJB 2.x module, when a CMP 2.x bean uses a new data source to access a backend database, the isolation level is determined by the WebSphere Application Server run time, based on the type of access intent assigned to the bean or the calling method. Other non-CMP connection users can access this same data source and also use the access intent and application profile support to manage their concurrency control.

**Connections used by other 2.x enterprise beans and other non-CMP components**
: For all other JDBC connection instances (connections other than those used by CMP beans), you can specify an isolation level on the data source resource reference. For shareable connections that run in global transactions, this method is the only way to set the *isolationLevel* for

connections. Trying to directly set the isolation level through the *setTransactionIsolation()* method on a shareable connection that runs in a global transaction is not allowed. To use a different isolation level on connections, you must provide a different resource reference. Set these defaults through your assembly tool.

Each resource reference associates with one isolation level. When your application uses this resource reference Java Naming and Directory Interface (JNDI) name to look up a data source, every connection returned from this data source using this resource reference has the same isolation level.

Components needing to use shareable connections with multiple isolation levels can create multiple resource references, giving them different JNDI names, and have their code look up the appropriate data source for the isolation level they need. In this way, you use separate connections with the different isolation levels enabled on them.

It is possible to map these multiple resource references to the same configured data source. The connections still come from the same underlying pool, however; the connection manager does not allow sharing of connections requested by resource references with different isolation levels. Consider the following scenario:

- A data source is bound to two resource references: *jdbc/RRResRef* and *jdbc/RCResRef*.
- RRResRef has the *RepeatableRead* isolation level defined. RCResRef has the *ReadCommitted* isolation level defined.

If your application wants to update the tables or a BMP bean updates some attributes, it can use the *jdbc/RRResRef* JNDI name to look up the data source instance. All connections returned from the data source instance have a RepeatableRead isolation level. If the application wants to perform a query for read only, then it is better to use the *jdbc/RCResRef* JNDI name to look up the data source.

***If you do not specify the isolation level:***

The product does not require you to set the isolation level on a data source resource reference for a non-CMP application module. If you do not specify isolation level on the resource reference, or if you specify TRANSACTION_NONE, the WebSphere Application Server run time uses a default isolation level for the data source. Application Server uses a default setting based on the JDBC driver.

For most drivers, WebSphere Application Server uses an isolation level default of TRANSACTION_REPEATABLE_READ. For Oracle drivers, however, Application Server uses an isolation level of TRANSACTION_READ_COMMITTED. Use the following table for quick reference:

| **Database:** | DB2 | Oracle | Sybase | Informix | Apache Derby | SQL Server |
|---|---|---|---|---|---|---|
| **Default isolation level:**<br><br>*(for connections used by non-CMP entities)* | RR | RC | RR | RR | RR | RR |

- **Note:** These same default isolation levels are used in cases of direct JNDI lookups of a data source.
- RR = JDBC Repeatable read (TRANSACTION_REPEATABLE_READ)
- RC = JDBC Read committed (TRANSACTION_READ_COMMITTED)

To customize the default isolation level, you can use the webSphereDefaultIsolationLevel custom property for the data source. In most cases you should define the isolation level in the deployment

descriptor when you package the EAR file, but in certain situations you might need to customize the default isolation level. This property will have no effect if any of the above options are used, and this custom property is provided for those situations in which there is no other means of setting the isolation level.

Use the following values for webSphereDefaultIsolationLevel custom property:

| Possible values | JDBC isolation level | DB2 isolation level |
|---|---|---|
| 8 | TRANSACTION_SERIALIZABLE | Repeatable Read (RR) |
| 4 (default) | TRANSACTION_REPEATABLE_READ | Read Stability (RS) |
| 2 | TRANSACTION_READ_COMMITTED | Cursor Stability (CS) |
| 1 | TRANSACTION_READ_UNCOMMITTED | Uncommitted Read (UR) |

To define this custom property for a data source:

1. Click **Resources** > **JDBC provider** > ***JDBC_provider***.
2. Click **Data sources** in the Additional Properties section.
3. Click the name of the data source.
4. Click **Custom properties**.
5. Create the webSphereDefaultIsolationLevel custom property.
   a. Click **New**.
   b. Enter webSphereDefaultIsolationLevel for the name field.
   c. Enter one of the possible values in the value field.

Application Server sets the isolation level by prioritizing the available settings. Application Server will set the isolation level based on the values for the following, in this order:

1. Resource reference isolation level
2. Isolation level that is specified by the access intent policy
3. Custom property that configures an isolation level
4. Application Server's default setting.

*Data source lookups for enterprise beans and web modules:*

During either application assembly or deployment, you must bind the resource reference to the Java Naming and Directory Interface (JNDI) name of the actual resource in the runtime environment. You can take this action in the assembly tool or as one of the steps during installation of the application enterprise archive (EAR) file.

*Bean-managed persistence bean:* When developing your bean-managed persistence (BMP) bean you generally lack knowledge about the name of the data source on the target application server. In your code, do not look up the data source directly. Instead, you look up the resource reference from the *java:comp/env namespace* file. Let us assume that you look up the resource reference named *ref/ds* as illustrated in the code below.

```
javax.sql.DataSource dSource = (javax.sql.DataSource)((new InitialContext()).lookup("java:comp/env/ref/ds"));
```

In the assembly tool, you specify the name **ref/ds** in the Resource Reference page on the General Tab. If you know the name of the data source you can specify it in this Resource References page on the Bindings Tab. Note that if you do not specify it here , you must provide this JNDI name when you install the application EAR file.

*Container-managed persistence bean:* The data source binding process for the container-managed persistence (CMP) bean is the same process that you perform for bean-managed persistence (BMP) beans. Use the data source JNDI name as a WebSphere binding property for each bean during application assembly.

*Servlets and JavaServer Pages Files:* In a servlet application, you look up the data source exactly as you look it up in the BMP bean case.

*Direct and indirect JNDI lookup methods for data sources:*

You can use a direct or indirect method for the Java Naming and Directory Interface (JNDI) name (such as jdbc/DataSource) to look up a data source.

**Direct**

When you use a JNDI name such as jdbc/myDatasource, the application server assigns default values to the resource reference data. An informational message resembling the following is logged to document the default values:

```
[10/5/07 11:40:38:468 CDT] 0000002e ConnectionFac W
 J2CA0294W: Direct JNDI lookup of resource jdbc/myDatasource.
   The following default values are used:

[Resource-ref CMConfigData key items]
res-auth:                 1 (APPLICATION)
res-isolation-level:      0 (TRANSACTION_NONE)
res-sharing-scope:        true (SHAREABLE)
loginConfigurationName:   null
loginConfigProperties:    null

[Resource-ref non-key items]
isCMP1_x:                 false (not CMP1.x)
isJMS:                    false (not JMS)
commitPriority            0
Java EE Name:                not set
Resource ref name:        not set
isCMP:                    false (not set)
```

The first of these attributes, *res-auth*, dictates what type of authentication is done. This default setting says that the component-managed authentication alias is used if you do not specify an activation specification or you do not specify the username and password on the getConnection call. It says that the container-managed alias is not used.

The second of these settings, *res-isolation-level*, says that the isolation level is set to the "default" settings. For an enterprise bean, you can set this in the Enterprise JavaBeans (EJB) bean itself. For a servlet getting a connection, this results in the isolation level being Repeatable_Read. This is a fairly restrictive isolation level. This can lead to lowered performance, because application requests will lock more rows than with a less restrictive isolation level.

Finally, the *res-sharing-scope* is set to **Shareable**, meaning a Shareable connection is used. For some applications, a Shareable connection is fine. For others, in particular those servlets that get multiple connections within a single service() method, it is not.

To avoid any surprises that might accompany these settings, you should change your application to use an indirect JNDI name instead of the direct JNDI name, and you should create a resource reference.

**Indirect**

To use values that are different from the defaults, use an assembly tool to define your resource reference. The resource reference can also be created in the EJB Deployment Descriptor (ejb-jar.xml), Web Deployment Descriptor (web.xml), or Application Client Deployment Descriptor (application-client.xml) editors using an assembly tool. After you define the resource reference, you can do an indirect JNDI lookup (using the java:comp/env context). Then the values for the resource reference properties that are defined in the resource reference are used and the J2CA0122I message no longer appears. Read the topic on creating a resource reference for more information.

*Access intent service:*

The access intent service enables developers to precisely tune the management of application persistence.

Access intent enables developers to configure applications so that the Enterprise JavaBeans (EJB) container and its agents can make performance optimizations for entity bean access. Entity beans and entity bean methods are configured with access intent policies. A policy is acted upon by either the combination of the WebSphere EJB container and Persistence Manager (for container-managed persistence (CMP) entities) or by bean-managed persistence (BMP) entities directly. Note that access intent policies apply to entity beans only.

**Predefined access intent policies**

Seven predefined access intent policies are available. The policies are composed of different attributes. The *access type* is of primary interest and controls the isolation level, lock type, and duration of locks obtained when bean data is read from the database.

A pessimistic access type indicates to hold locks for the duration of the transaction under which the data loads. An optimistic type indicates to drop locks immediately after the data is read from the backend. A *read* type indicates that the run time must not allow updates to the data; any attempt to do so on data read under a *read* type results in an exception. *Update* types permit you to change data.

Though a pessimistic update policy is designed to hold update locks on data records, it does not block threads with other policies that try to access the same data records. When two threads that run pessimistic update policies access a given record, they serialize (but not block) other threads that run pessimistic read or optimistic policies and try to access the same record.

The seven access intent policies and their attribute definitions follow:

**wsPessimisticUpdate**
- Access type = Pessimistic update
- Collection scope = Transaction
- Collection increment = 1
- Resource manager prefetch increment = 0
- Read ahead hint = null

**wsOptimisticUpdate**
- Access type = Optimistic update
- Collection scope = Transaction
- Collection increment = 25
- Resource manager prefetch increment = 0
- Read ahead hint = null

**wsOptimisticRead**
- Access type = Optimistic read
- Collection scope = Transaction
- Collection increment = 25
- Resource manager prefetch increment = 0
- Read ahead hint = null

**wsPessimisticRead**
- Access type = Pessimistic read
- Collection scope = Transaction
- Collection increment = 25
- Resource manager prefetch increment = 0
- Read ahead hint = null

**wsPessimisticUpdate-Exclusive**
- Access type = Pessimistic update
- Exclusive = true

- Collection scope = Transaction
- Collection increment = 1
- Resource manager prefetch increment = 0
- Read ahead hint = null

**wsPessimisticUpdate-NoCollision**

- Access type = Pessimistic update
- No collision = true
- Collection scope = Transaction
- Collection increment = 25
- Resource manager prefetch increment = 0
- Read ahead hint = null

**wsPessimisticUpdateWeakestLockAtLoad**

- ***default policy**
- Access type = Pessimistic Update
- Promote = true
- Collection scope = transaction
- Collection increment = 25
- Resource manager prefetch increment = 0
- Read ahead hint = null

To support connection sharing, you must ensure that all data loaded in the same transaction is under the same isolation level. Verify that all participating methods that drive loads are configured with either a pessimistic access type or an optimistic access type.

*Access intent -- isolation levels and update locks:*

WebSphere Application Server access intent policies provide a consistent way of defining the isolation level for CMP bean data across the different relational databases in your environment.

Within a deployed application, the combination of an access intent policy *concurrency definition* and *access type* signifies the isolation level value that Application Server sets on a database connection. See the articles, Concurrency control, and Access intent and isolation, for more information on concurrency and access type. This combination of properties also signifies the update lock flag that Application Server passes to the database through a JDBC prepared statement.

Databases do not provide as many isolation level definitions as WebSphere Application Server. Databases define an isolation level as one of only three types. Furthermore, only one parameter indicates the type of isolation level that the databases set on incoming connections. Each of the three types can be represented by a *different* parameter value, as determined by each database vendor. For example, one database might define an isolation level as RR (JDBC Repeatable read), whereas a different database might define the same isolation level as RC (JDBC Read committed).

Because of this inconsistency, WebSphere Application Server does not map access intent policies to the parameter values. Instead, Application Server maps access intent policies to the types of isolation level that are common across all database vendors.

*Table 45. Access intent policies relationship to database isolation levels and update lock settings. The following matrix shows how access intent policies correspond to different database isolation levels and update lock settings.*

| Access Intent profile | Isolation level | | | | | | Update lock implementation |
|---|---|---|---|---|---|---|---|
| | DB2 | Oracle* | SyBase | Informix | Apache Derby | SQL Server | |
| wsPessimisticUpdate-Weakest LockAtLoad (Default policy) | RR | RC | RR | RR | RR | RR | No (*Oracle, Yes) |
| wsPessimisticUpdate | RR | RC | RR | RR | RR | RR | Yes |
| wsPessimisticRead | RR | RC | RR | RR | RR | RR | No |
| wsOptimisticUpdate | RC | RC | RC | RC | RC | RC | No |

*Table 45. Access intent policies relationship to database isolation levels and update lock settings (continued). The following matrix shows how access intent policies correspond to different database isolation levels and update lock settings.*

| Access Intent profile | Isolation level | | | | | | Update lock implementation |
|---|---|---|---|---|---|---|---|
| | DB2 | Oracle* | SyBase | Informix | Apache Derby | SQL Server | |
| wsOptimisticRead | RC | RC | RC | RC | RC | RC | No |
| wsPessimisticUpdate No-Collisions | RC | RC | RC | RC | RC | RC | No |
| wsPessimisticUpdate-Exclusive | S | S | S | S | S | S | Yes |

- RC = JDBC Read Committed
- RR = JDBC Repeatable Read
- S = JDBC Serializable
- * Oracle does not support JDBC Repeatable Read (RR). Therefore, wsPessimisticUpdate-weakestLockAtLoad and wsPessimisticUpdate behave the same way on Oracle as do wsPessismisticRead and wsOptimisticRead. Because of an Oracle restriction, the OracleXADataSource JDBC class cannot run with an S transaction isolation level. Therefore, you cannot use this class to run an application containing enterprise beans with access intent policies that are configured to cause the bean to load with S isolation.
- Setting access intent policies per EJB method support is deprecated for Version 6.0. It is recommended that you set access intent only for the entire bean.

**New for MS SQL Server 2005:** MS SQL Server 2005 offers a new option for the Read Committed isolation level and a new option for the Serializable isolation level:

- Read Committed with Snapshots
- Transaction Snapshot (for Serializable)

Both options use optimistic locking. To use Read Committed with Snapshots instead of Read Committed, enable the READ_COMMITTED_SNAPSHOT setting for the database according to the MS SQL Server 2005 documentation. To use Transaction Snapshot instead of Serializable, configure the custom data source property, snapshotSerializable, to "true" and enable the ALLOW_SNAPSHOT_ISOLATION setting for the database according to the MS SQL Server 2005 documentation.

### Structured Query Language (SQL) keywords and restrictions

*Table 46. SQL keywords and restrictions. The following table shows which SQL keywords are used during update intent locking, as well as any restrictions imposed on the SQL.*

| Database | SQL syntax used for locking update | join restrictions | order by restrictions | subselect restrictions | aggregation restrictions |
|---|---|---|---|---|---|
| DB2 | FOR UPDATE OF | not allowed | not allowed | not allowed | not allowed |
| DB2 UDB for iSeries® (V5R3 and earlier) | FOR UPDATE OF | not allowed | allowed with limitations* | allowed with limitations* | not allowed |
| DB2 UDB for iSeries (V5R4 and later) | WITH RS/RR USE AND KEEP EXCLUSIVE LOCKS | not allowed | allowed with limitations* | allowed with limitations* | not allowed |
| DB2 on z/OS V8.x | WITH RS/RR USE AND KEEP UPDATE LOCKS | none | none | none | none |
| DB2 UDB workstation V8.2 | WITH RS/RR USE AND KEEP UPDATE LOCKS | none | none | none | none |
| Oracle | FOR UPDATE | none | none | none | none |
| Apache Derby | FOR UPDATE OF | not allowed | not allowed | not allowed | not allowed |
| Informix | FOR UPDATE | not allowed | not allowed | not allowed | not allowed |

*Table 46. SQL keywords and restrictions (continued). The following table shows which SQL keywords are used during update intent locking, as well as any restrictions imposed on the SQL.*

| Database | SQL syntax used for locking update | join restrictions | order by restrictions | subselect restrictions | aggregation restrictions |
|---|---|---|---|---|---|
| Sybase | FOR UPDATE | not allowed | not allowed | not allowed | not allowed |
| Sqlserver | UPDLOCK | not allowed | not allowed | not allowed | not allowed |

* Note: For details on the limitations for these permitted SQL restrictions, refer to the DB2 Universal Database™ for iSeries SQL Reference. You can find this document in the iSeries Information Center, Version 5 Release 4. In the Contents navigation area, click **Database** > **Reference** > **SQL Reference**.

*Custom finder SQL dynamic enhancement:*

To ensure data integrity for applications using custom finders defined on Enterprise JavaBeans (EJB) version 1.1 home interfaces, WebSphere Application Server Version 6.x uses custom finder Structured Query Language (SQL) dynamic enhancement to maintain correct SQL locking semantics.

WebSphere Application Server uses SQL clauses applied to the custom finder SQL statements for those custom finders defined with the *Update* attribute and certain method-level isolation level settings. These dynamic enhancements are applied only if the backend data store supports these clauses.

This support takes affect at run time when the run time attempts to execute container-managed persistence (CMP) persistence operations associated with the custom finders. To ensure that the SQL dynamic enhancements occur correctly for custom finders defined on an EJB version 1.1 home interface accessing a backend data store that requires the special SQL locking clauses, WebSphere Application Server provides new Java Virtual Machine (JVM) and bean (module) properties. These properties enable you to indicate which custom finders should be enhanced, provided the backend store supports the SQL clauses. For more information about these properties, Custom finder SQL dynamic enhancement properties.

There are several important items to consider when using this functionality:

- This support **only** applies to EJB version 1.1 CMP Custom Finder methods
- Option A CMP beans and CMP beans involved in an inheritance relationship are not supported

*Custom finder SQL dynamic enhancement properties:*

Use this page to modify custom finder SQL dynamic enhancement properties settings.

To ensure that the Structured Query Language (SQL) dynamic enhancements occur correctly for custom finders defined on an EJB 1.1 Home interface that uses a backend data store that requires the special SQL locking clauses, the following Java virtual machine (JVM) and bean (module) properties are provided. These properties enable you to indicate which custom finders to enhance, assuming the backend data store supports the SQL clauses.

For IBM i and distributed platforms, to view this administrative console page, click **Servers > Server Types > WebSphere application servers >** *server_name* **> Java and process management > Process definition > Java virtual machine > Custom properties**

*com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent:*

Used to indicate which enterprise beans should have custom finder SQL dynamic enhancement enabled at runtime.

This property takes effect at the server level. Any EJB 1.1 home interface-defined custom finder (prefix named *find*) that has *Update* as an access intent is a candidate for custom finder SQL dynamic

enhancement based on its specified isolation level. If the backend data store requires special SQL semantics, they are applied. The particular SQL used varies according to the isolation level you choose for beans in the application, as well the backend data base being used. If set to **all**, custom finder SQL dynamic enhancement is enabled for all custom finders defined in any beans that are installed into the container. If set to **J2EENAME[:J2EENAME]**, where *J2EENAME* is a fully qualified package or bean name, custom finder SQL dynamic enhancement is enabled for only the custom finders defined in the beans that are installed into the container and represented by the bean names denoted.

| | |
|---|---|
| **Data type** | String |
| **Range** | Valid values are **all** or **J2EENAME[:J2EENAME]** |
| **Default** | Enhancement behavior not active |

**Note:** Some of your applications might use custom finders that have been manually coded and already contain the SQL locking clauses, or keywords *ORDER BY* and *DISTINCT* on the *SELECT* operation. In these instances, if the run time attempts SQL dynamic enhancement, the possibility exists of introducing malformed SQL statements to the underlying backend data store. If an application contains these custom finders, then you must be careful when specifying the value for the JVM property *com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent*. A value of **all** causes custom finder SQL dynamic enhancement to occur for every custom finder method defined with an access intent of *Update* found in all beans that are installed in the application server, thus introducing malformed SQL for that subset of custom finders.

To prevent this from happening, ***do not*** set the server-wide setting to **all**. Instead, use the bean method level property, *com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent.methodLevel* to indicate on a per bean basis only those custom finder methods that should have the custom finder SQL dynamic enhancement executed on them at run time.

*com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent.methodLevel:*

Used to indicate custom finder SQL dynamic enhancement be enabled at the method level on a particular bean.

When a bean is defined with this property set to a list of one or more custom finder methods, any custom finder (prefix named *find*) defined on the home interface that has a matching method name and parameter signature has SQL locking semantics applied at run time. This occurs only if the custom finder method has an access intent of *Update* specified and the backend data store supports the SQL clauses. The particular SQL used varies according to the isolation level chosen for the application as well as the backend data store being used.

| | |
|---|---|
| **Data type** | String |
| **Range** | Valid value is a string of this form: **method1(parm1,parm2,..parmn):method2(parm1,parm2,..parmn):methodn(...)** |

## Accessing data using Java EE Connector Architecture connectors

To access data from a Java EE Connector Architecture (JCA) compliant application in WebSphere Application Server, you configure and use resource adapters and connection factories.

### About this task

An application component uses a connection factory to access a connection instance, which the component then uses to connect to the underlying enterprise information system (EIS). Examples of connections include database connections, Java Message Service connections, and SAP R/3 connections.

As indicated in the Java EE Connector Architecture (JCA) Specification, each enterprise information system (EIS) needs a resource adapter and a connection factory. This connection factory is then accessed through the following programming model. If you use Rational Application Development tools, most of the following deployment descriptors and code are generated for you. This example shows the manual method of accessing an EIS resource.

## Procedure

1. Declare a connection factory resource reference in your application component deployment descriptors, as described in this example:

```
<resource-ref>
   <description>description</description>
   <res-ref-name>eis/myConnection</res-ref-name>
   <res-type>javax.resource.cci.ConnectionFactory</res-type>
   <res-auth>Application</res-auth>
</resource-ref>
```

2. During the deployment process, configure each resource adapter and associated connection factory through the console. See the topics on installing a resource adapter and configuring a connection factory for more information.
3. Locate the corresponding connection factory for the EIS resource adapter using Java Naming and Directory Interface (JNDI) lookup in your application component, during run time.
4. Get the connection to the EIS from the connection factory.
5. Create an interaction from the connection object.
6. Create an *InteractionSpec* object. Set the function to execute in the InteractionSpec object.
7. Create a record instance for the input and output data used by function.
8. Execute the function through the Interaction object.
9. Process the record data from the function.
10. Close the connection.

## Example

The following code segment shows how an application component might create an interaction and implement it on the EIS:

```
javax.resource.cci.ConnectionFactory connectionFactory = null;
javax.resource.cci.Connection connection = null;
javax.resource.cci.Interaction interaction = null;
javax.resource.cci.InteractionSpec interactionSpec = null;
javax.resource.cci.Record inRec = null;
javax.resource.cci.Record outRec = null;

try {
// Locate the application component and perform a JNDI lookup
   javax.naming.InitialContext ctx = new javax.naming.InitialContext();
   connectionFactory = (javax.resource.cci.ConnectionFactory)
ctx.lookup("java:comp/env/eis/myConnection");

// create a connection
   connection = connectionFactory.getConnection();

// Create Interaction and an InteractionSpec
   interaction = connection.createInteraction();
   interactionSpec = new InteractionSpec();
   interactionSpec.setFunctionName("GET");

// Create input record
   inRec = new javax.resource.cci.Record();

// Execute an interaction
   interaction.execute(interactionSpec, inRec, outRec);
```

```
// Process the output...

} catch (Exception e) {
   // Exception Handling
}
finally {
    if (interaction != null) {
         try {
              interaction.close();
         }
         catch (Exception e) {/* ignore the exception*/}
   }
   if (connection != null) {
        try {
             connection.close();
        }
        catch (Exception e) {/* ignore the exception */}
   }
}
```

## JDBC application cursor holdability support

The cursor holdability feature can reduce the overhead of JDBC interaction with your relational database, thereby helping to increase application performance.

By activating cursor holdability, you keep a result set available across transaction boundaries for use by multiple JDBC calls. The holdability setting triggers a database cursor to keep newly updated rows active beyond the commit of the transaction that generated the new values, or result set. Hence the cursor makes the result set available for use by statements in a subsequent transaction.

### Setting cursor holdability

Use one of the following techniques to set cursor holdability. For more details, see the JDBC 3.0 specification, available at the Sun Microsystems, Inc., website at http://java.sun.com.

- Specify the ResultSet.HOLD_CURSORS_OVER_COMMIT parameter when creating or preparing a statement using the createStatement, prepareStatement, or prepareCall methods.
- Invoke the setHoldability method on the Connection object. The cursor holdability value that you set with this method becomes the default. If you specify cursor holdability on the Statement object, that value overrides the value that you specified on the connection.

  You cannot specify cursor holdability on a shareable connection after that connection is referenced by a second handle. Invoking the holdability method at this point generates an exception. If you want to set cursor holdability on a shareable connection, invoke the method before the connection is enlisted. Otherwise a shareable connection retains the same holdability value that applied in the previous enlistment.
- Check your database documentation to see if the product supports cursor holdability as a data source property. DB2, for example, responds to the holdability trigger if you set it as a data source custom property. See the topic, Custom property settings, for more information.

### The impact of connection and transaction behaviors on cursor holdability

Setting cursor holdability in WebSphere Application Server results in the following behavior for different transaction events:

- When a connection is closed, all statements and result sets are closed even if you have set cursor holdability.
- When a transaction is rolled back, all result sets are closed even if you have set cursor holdability.
- When a local transaction is committed, both shareable and unshareable connections can have an open result set across a transaction boundary.

- When a global transaction is committed, unshareable connections can have an open result set across a transaction boundary. For shareable connections, the statements and result sets are closed even if you have set cursor holdability; the holdability value does not impact shareable connections participating in global transactions.
- When a local transaction scope ends, either at the method level or the activity session level, all statements and result sets for shareable connections are closed. Statements and result sets for unshareable connections remain open until the close method is called on the connection.

**Note:** For a global transaction with an unshareable connection, the backend database has responsibility for supporting cursor holdability.

## Data access bean types

For easy data access programming, WebSphere Application Server provides a special class library that implements many methods of the Java Database Connectivity (JDBC) API for you. The library is essentially a set of Service Data Objects (SDO).

To make things clearer, you can refer to the classes by the name of the Java archive (JAR) file that contains them:

*databeans.jar* - This JAR file ships with WebSphere Application Server. This file contains classes that enable you to access the database using the JDBC API.

*ivjdab.jar* - This JAR file ships with Visual Age for Java. This file contains all of the classes in the databeans.jar file and classes that support easy use of the data access beans from the Visual Age for Java Visual Composition Editor.

*dbbeans.jar* - This JAR file ships with Rational Application Developer. This file contains a set of data access beans to more closely conform to the JDBC 2.0 *RowSet* standard.

The *com.ibm.db* package is provided to support existing applications that use data access beans.

IBM strongly suggests that any new applications using data access beans be developed using the *com.ibm.db.beans* package that is provided with Rational Application Developer.

**Example: Using data access beans.** Data access beans are essentially a class library that makes it easier to access a database. The library contains a set of beans with methods that access the database through the Java Database Connectivity (JDBC) API. This example shows using data access beans in WebSphere Application Server Version 5 and later to create new applications that use the com.ibm.db.beans package.

```
package example;
import com.ibm.db.beans.*;
import java.sql.SQLException;

public class DBSelectExample {

 public static void main(String[] args) {

  DBSelect select = null;

  select = new DBSelect();
  try {

   // Set database connection information
   select.setDriverName("COM.ibm.db2.jdbc.app.DB2Driver");
   select.setUrl("jdbc:db2:SAMPLE");
   select.setUsername("userid");
   select.setPassword("password");

   // Specify the SQL statement to be executed
```

```
   select.setCommand("SELECT * FROM DEPARTMENT");

   // Execute the statement and retrieve the result set into the cache
   select.execute();

   // If result set is not empty
   if (select.onRow()) {
    do {
     // display first column of result set
     System.out.println(select.getColumnAsString(1));
     System.out.println(select.getColumnAsString(2));
    } while (select.next());
   }

   // Release the JDBC resources and close the connection
   select.close();

  } catch (SQLException ex) {
   ex.printStackTrace();
  }
 }
}
```

## Accessing data from application clients

To access a database directly from a Java Platform, Enterprise Edition (Java EE) application client, you retrieve a *javax.sql.DataSource* object from a resource reference configured in the client deployment descriptor. This resource reference is configured as part of the deployment descriptor for the client application, and provides a reference to a pre-configured data source object.

### About this task

Note that data access from an application client uses the JDBC driver connection functionality directly from the client side. It does not take advantage of the additional pooling support available in the application server run time. For this reason, your client application should utilize an enterprise bean running on the server side to perform data access. This enterprise bean can then take advantage of the connection reuse and additional added functionality provided by the product run time.

### Procedure

1. Import the appropriate JDBC API and naming packages:
   ```
   import java.sql.*;
   import javax.sql.*;
   import javax.naming.*;
   ```
2. Create the initial naming context:
   ```
   InitialContext ctx = new InitialContext();
   ```
3. Use the *InitialContext* object to look up a data source object from a resource reference.
   ```
   javax.sql.DataSource ds = (DataSource)ctx.lookup("java:comp/env/jdbc/myDS");
   //where jdbc/myDS is the name of the resource reference
   ```
4. Get a *java.sql.Connection* from the data source.
   - If no user ID and password are required for the connection, or if you are going to use the *defaultUser* and *defaultPassword* that are specified when the data source is created in the Application Client Resource Configuration tool (ACRCT) in a future step, use this approach:
     ```
     java.sql.Connection conn = ds.getConnection();
     ```
   - Otherwise, you should make the connection with a specific user ID and password:
     ```
     java.sql.Connection conn = ds.getConnection("user", "password");
     //where user and password are the user id and password for the connection
     ```
5. Run a database query using the *java.sql.Statement*, *java.sql.PreparedStatement*, or *java.sql.CallableStatement* interfaces as appropriate.

```
Statement stmt = conn.createStatement();
String query = "Select FirstNme from " + owner.toUpperCase() + ".Employee where LASTNAME = '" + searchName + "'";
ResultSet rs = stmt.executeQuery(query);
while (rs.next()) { firstNameList.addElement(rs.getString(1));
}
```

6. Close the database objects used in the previous step, including any *ResultSet*, *Statement*, *PreparedStatement*, or *CallableStatement* objects.
7. Close the connection. Ideally, you should close the connection in a *finally* block of the *try...catch* statement wrapped around the database operation. This action ensures that the connection gets closed, even in the case of an exception.

```
conn.close();
```

## Service Data Objects version 2.1.1

Service Data Objects (SDO) is a framework for data application development that provides an architecture and application programming interfaces (API). The product includes an implementation of SDO 2.1.1 interfaces. After the product is installed and SDO is enabled, SDO 2.1.1 becomes the default SDO implementation when programming with SCA or SDO interfaces.

**transition:** For backwards compatibility, deprecated functions like JDBMediator continue to use previous SDO implementations described in "Data access with Service DataObjects, API versions 1.0 and 2.01." Otherwise, SDO clients are bound to the SDO 2.1.1 implementation.

SDO 2.1.1 is a Java standard approved by the Java Community Process (JSR 235). For details on SDO 2.1.1, refer to the JSR 235 specification.

The product implementation complies with JSR 235, and provides some implementation-specific extensions. These extensions align with the latest direction of the SDO 3.0 specification under development at OASIS. Although there is no guarantee, these 3.0 API extensions will likely be officially standardized in future versions of SDO. Table 1 lists the 3.0 API extensions included in the product.

*Table 47. SDO 3.0 API extensions included in the product. The SDO 3.0 API extensions might be standardized in future specifications.*

| SDO interface or class name | Method or constant | SDO 3.0 extension change |
|---|---|---|
| interface commonj.sdo.Type; | getHelperContext() | New SDO 3.0 method |
| interface commonj.sdo.helper.TypeHelper: | SDO_URI | New SDO 3.0 constant |
| | SDO_JAVA_URI | New SDO 3.0 constant |
| | SDO_XML_URI | New SDO 3.0 constant |
| interface commonj.sdo.Sequence: | add(String) | Removed deprecated method |
| | add(int, String) | Removed deprecated method |
| interface commonj.sdo.helper.HelperContext: | getIdentifier() | New SDO 3.0 method |
| class commonj.sdo.helper.HelperProvider: | | Replaced SPI with SDO 3.0 version |
| class commonj.sdo.helper.SDO | | New API in SDO 3.0 |
| interface commonj.sdo.helper.HelperContextFactory | | New API in SDO 3.0 |
| class commonj.sdo.impl.Environment | | New SPI in SDO 3.0 |
| class commonj.sdo.impl.Resolvable | | New SPI in SDO 3.0 |

For information on SDO HelperContext, see "Creating and accessing SDO HelperContext."

### *Creating and accessing SDO HelperContext objects:*

The Service Component Architecture (SCA) implementation complies with Service Data Objects (SDO) 2.1.1 (JSR 235), and provides some implementation-specific extensions. These extensions align with the

latest direction of the OASIS SDO 3.0 specification under development. One of the extensions introduces an API for creating and managing HelperContext objects, which are in the SDO class and HelperContextFactory interface.

**Before you begin**

Install the product and enable the SDO feature. See topics on enabling the SDO feature in the installation topics for your operating system.

**About this task**

This topic describes how to create and access SDO HelperContext in non-SCA applications.

In versions of SDO previous to 3.0, including SDO 2.1.1, there is no standard way to create HelperContext objects. SDO helper classes are accessible from the default HelperContext and are typically accessed using their corresponding INSTANCE fields, for example, TypeHelper.INSTANCE. The use of INSTANCE fields is discouraged in SDO 2.1.1, and will likely be deprecated in SDO 3.0. Instead of using INSTANCE fields, code your applications to access helpers using their corresponding accessor method on the HelperContext interface, for example, helperContext.getTypeHelper(). In SDO 2.1.1, the only HelperContext available through standard APIs is the default helper context: HelperProvider.getDefaultContext().

The proposed SDO 3.0 scoping solution, which is available in the product, is more flexible and is described in this topic.

A HelperContext represents a metadata scope in SDO. In SDO 3.0 available in the product, a HelperContext is created using a HelperContextFactory. The HelperContextFactory interface is as follows:

```
public interface HelperContextFactory {

  /**
  * Create a new HelperContext in this implementation.  Once created the HelperContext
  * can be looked up as follows (Note if the identifier is null or "" it is not registered):
  * SDO.getHelperContext(identifier);
  * @param identifier - A unique identifier that can be used to access the HelperContext.
  * @param properties - Properties required to initialize the HelperContext.
  * @return a HelperContext object
  * @throws IllegalArgumentException If a different HelperContext is already
  * registered with the specified identifier.
  */
  public HelperContext createHelperContext(String identifier, Map<String, Object> properties)
       throws IllegalArgumentException;
    /**
    * Create a new HelperContext in this implementation.  Once created the HelperContext
    * can be looked up as follows (Note if the identifier is null or "" it is not registered):
    * SDO.getHelperContext(identifier);
    * @param identifier - A unique identifier that can be used to access the HelperContext.
    * @param classLoader - The class loader for the generated static classes (if any).
    * @param properties - Properties required to initialize the HelperContext.
    * @return a HelperContext object
    * @throws IllegalArgumentException If a different HelperContext is already
    * registered with the specified identifier.
    */
  public HelperContext createHelperContext(String identifier, ClassLoader classLoader,
       Map<String, Object> properties) throws IllegalArgumentException;
}
```

There can be more than one HelperContextFactory available in an SDO environment, but one is the default. The default HelperContextFactory is accessible through the interface commonj.sdo.helper.SDO.

### Procedure

1. Using the default factory, create a HelperContext object in your code.

   The following example uses the default factory to create the HelperContext `hc`:

```
HelperContext hc =
SDO.getHelperContextFactory().createHelperContext("ScopeManagerTestID", options);
```

   The identifier string, `"ScopeManagerTestID"`, must be unique within a Java virtual machine (JVM). If you are not concerned with the actual value, generate a guaranteed unique one using the Java UUID class, for example:

```
hc = SDO.getHelperContextFactory().createHelperContext(
    UUID.randomUUID().toString(), options);
```

2. Access the HelperContext object in your code.

   The SDO run time manages HelperContext objects. Access an existing HelperContext object using the SDO.getHelperContext(identifier) method:

```
hc = SDO.getHelperContext("ScopeManagerTestID");
```

   The identifier of a HelperContext can be accessed using the getIdentifier() method:

```
String id = hc.getIdentifier();
```

### Results

A HelperContext object is defined and accessible.

### What to do next

Use SDO in an SCA application. When SDO is used in an SCA application, the SCA run time typically creates the HelperContext objects and identifiers. Refer to topics on using SDO 2.1.1 in SCA applications.

Because the SCA run time manages the HelperContext objects and identifiers when using SDO in SCA applications, the method used to create and access SDO HelperContext in SCA applications is different than that used in non-SCA applications. An SCA application can access SDO HelperContext using a DefaultHelperContext annotation; for example:

```
import com.ibm.websphere.soa.sca.sdo.DefaultHelperContext;

@DefaultHelperContext
public HelperContext defaultHelperContext;
```

### *Using SDO 2.1.1 in SCA applications:*

The Service Component Architecture (SCA) implementation complies with Service Data Objects (SDO) 2.1.1 (JSR 235). You can use SDO 2.1.1 in your SCA applications.

### Before you begin

Install the product and enable SDO. Instructions on enabling the SDO feature are in the installation topics for your operating system.

Read SDO data binding for SCA applications to better understand how to work with SDO in SCA Java clients and implementations. For more information, read about using business exceptions with SCA interfaces.

Consider installing a Rational Application Developer product with SCA Development Tools that you can use to assemble service-oriented application components based on open SCA specifications. See the Rational Application Developer documentation.

### About this task

To use SDO 2.1.1 in an SCA application, access the default HelperContext programmatically in a Java or Java Platform, Enterprise Edition (Java EE) component implementation type and then develop one or

more SCA composites that use SDO following a bottom-up or top-down approach.

**Procedure**

1. Develop one or more SCA components that use SDO.
   a. Decide whether you are going to use a top-down or bottom-up approach to developing your SCA component implementations.

      The section on top-down and bottom-up development in SDO data binding for SCA applications describes the approaches. The top-down approach is typically preferred in SCA service architecture and development. When you start with a composite definition file that uses `<interface.wsdl>`:

      - The top-down approach is strongly typed.
      - The top-down approach has an implied schema, `anyType`, that does not need to be generated.
      - The bottom-up approach has more flexibility than the top-down approach.

      `Java.lang.object` is a restriction.
   b. Use a top-down approach (starting from WSDL and XSD files) or a bottom-up approach (starting from Java files) to develop SCA composites that use SDO.
      - Use a top-down approach to develop SCA composites.
      - Use a bottom-up approach to develop SCA composites.
   c. Access the default HelperContext programmatically.

      You can access the default HelperContext programmatically in a Java or Java EE component implementation type. You cannot access the default HelperContext programmatically in a Spring component implementation type.

   **Restriction:** You cannot use array types for Java parameters. You cannot map from schema elements declared with the attribute, `maxOccurs="unbounded"` to array types. Instead, map the element to a List, such as a `List<DataObject>` or `List<String>`.
2. If you are using a top-down development approach, package your WSDL and XSD files in an SCA contribution.

   Packaging WSDL and XSD files in an appropriate contribution enables your component to access the schema definitions. The section on schema registration in SDO data binding for SCA applications describes the registration.

   Consider packaging your WSDL and XSD files so that they can be accessed across various parts of your application from a shared in-memory instance. For details, see Implementing shared scopes in SCA applications that use SDO.
3. Deploy your SCA composites that use SDO in an SCA business-level application.

   See topics on SCA contributions and shared scopes for information on how to establish a shared SDO scope. Otherwise, there are no special deployment considerations for applications using the SDO data binding.

**Results**

You have developed and deployed an SCA composite that uses SDO in a business-level application.

**What to do next**

Test the deployed SCA composites.

*SDO data binding for SCA applications:*

Service Data Objects (SDO) is a framework for data application development that provides an architecture and application programming interfaces (API). Product support for Service Component Architecture (SCA) includes an implementation of SDO 2.1.1 interfaces. To work with SDO in SCA Java clients and implementations, it is helpful to understand SDO data binding concepts.

The SDO data binding support consists of the following concepts:
- Scope management
- Wire format serialization or deserialization
- Top-down and bottom-up development
- Schema registration
- Shared scopes
- JAX-WS based programming model

**Scope management**

In SDO, a scope typically corresponds to a commonj.sdo.helper.HelperContext instance. This scope sets visibility boundaries for SDO types. In the product runtime environment, the SCA layer defines HelperContext objects on SCA application boundaries, which are meaningful boundaries from an SCA perspective. Together, SCA and SDO define a default HelperContext for a given application and enable the SCA application to access the HelperContext programmatically.

In the product runtime environment, the primary SCA application scope is tied to the deployable composite. There is a 1-1 relationship between a deployable composite and an SCA default HelperContext that is managed in the runtime environment. To determine the default HelperContext of an SCA component, you must identify the deployable composite which defines this component to the SCA domain.

**Wire format serialization or deserialization**

An important use of SDO is to serialize or deserialize application data to and from the data format "on the wire" (the "wire format") for the various binding configurations. The SCA runtime environment uses the default HelperContext with its registered schema definitions to perform this serialization or deserialization. This process is relevant for serializing or deserializing input argument values and return values of SCA service interfaces when the client or implementation uses the SDO data binding.

**Top-down and bottom-up development**

Both top-down (starting from WSDL and XSD files) and bottom-up (starting from Java files) approaches can be used with SDO in SCA applications. This section briefly explains three different usage patterns. You can combine aspects of all three patterns in a single application.

- Top-down, strongly typed

  In this usage pattern, start with a composite definition file that uses the `<interface.wsdl>` element in describing a component service interface; for example:

```
<service ...>
  <interface.wsdl ...> Refers to WSDL with updateAccount
```

  The doc-lit-wrapped WSDL and XSD definition uses a specific type, and not `xsd:anyType`:

```
<element name="updateAccount">
  <complexType>
    <sequence>
      <element name="person" type="p:Person"/>
```

  This definition maps to a Java method; for example:

```
void updateAccount(DataObject person)
```

  With this usage pattern, you can write your Java code so that is reusable, even later with types other than `p:Person`. You can potentially reuse the same dynamically typed Java code with multiple strongly typed interfaces, without having to regenerate any Java code.

  You can also write your Java code so that the SDO usage is tightly coupled with a specific XSD type. Further, you can mix the tightly coupled and dynamically typed programming styles in the same SCA Java application.

- Top-down, weakly typed

  In this usage pattern, start with a composite definition file that uses the `<interface.wsdl>` element; for example:

```
<service ...>
  <interface.wsdl ...> Refers to WSDL with updateAccount
```

The doc-lit-wrapped WSDL and XSD definition uses `xsd:anyType`:

```
<element name="updateAccount">
  <complexType>
    <sequence>
      <element name="arg0" type="xsd:anyType"/>
```

This definition maps to a Java method; for example:

```
void updateAccount(DataObject arg0)
```

This usage pattern is like top-down, strongly-typed. With the top-down, weakly typed usage pattern both WSDL and XSD files map to equivalent Java code. However, you might write your Java code to enable it to handle any type of data, as opposed to the top-down, strongly-typed usage pattern where you expect a specific type, even though you work with it through the dynamic SDO APIs.

- Bottom-up

  In this usage pattern, you start with a Java interface method such as:

```
void updateAccount(DataObject arg0)
```

  The method maps to a WSDL or XSD definition such as:

```
<element name="updateAccount">
  <complexType>
    <sequence>
      <element name="arg0" type="xsd:anyType"/>
```

  Depending on the bindings, you might view or work directly with the WSDL and XSD files to which the Java object maps. When mapping from Java to XSD, the SCA runtime environment maps `commonj.sdo.DataObject` to `xsd:anyType`.

  You cannot use `java.lang.Object` as a dynamic, generic interface method parameter or return type, instead of `commonj.sdo.DataObject`. The SCA runtime environment relies on introspection of the method type to signal that it uses SDO, and not JAXB, to work with this type; for example, to construct the argument values upon deserializing data on the wire.

In each of the usage patterns, you can mix styles within a single operation. For example, suppose you have the following doc-lit-wrapped WSDL definition:

```
<element name="updateAccount">
  <complexType>
    <sequence>
      <element name="arg0" type="xsd:anyType"/>
      <element name="id" type="xsd:string"/>
```

The WSDL definition maps to the following Java method:

```
void updateAccount(DataObject arg0, String id)
```

The `arg0` field is dynamically typed by DataObject, while the `id` field is statically typed by String.

### Schema registration

The SCA runtime environment provides mechanisms to register schema definitions from your SCA application (for example, in WSDL and XSD files packaged with your application) to the default HelperContext of your SCA application. All schema definitions packaged within the same contribution Java archive (JAR) file as the one your deployable composite is contributed within are registered with the default HelperContext of that deployable composite.

Schema registration is important because it affects the exact details of your application SDO programming model. For example, the `DataFactory.create()` methods can be used to create DataObject instances of the corresponding schema definitions that are registered in the runtime environment, without having to reference or load the XSD files containing these schema definitions in application code.

Some styles of interface definition and programming result in DataObject instances of unknown type. Within the SDO type system, the XSD type of such an object is the SDO-equivalent of `xsd:anyType`. Methods might return different values depending on whether the instance is of a known, specific type or the `anyType-equivalent`.

For example, SDO API calls such as the following might return different results depending on whether the object instances are recognized in the SDO type system as instances of a registered XSD type. For the following call, `get(int propertyIndex)` returns a List for `xsd:anyType`:

```
dataObjectInstance.get(1);
```

The following call returns an empty List for `xsd:anyType`:

```
dataObjectInstance.getType().getDeclaredProperties();
```

**Shared scopes**

SCA contribution support enables convenient packaging of WSDL and XSD definition files used by multiple SCA application composites using the contribution import and export mechanism. The common WSDL and XSD files can be packaged into a single contribution JAR file, which is like a shared library.

The SDO data binding function further uses the SCA contribution support by enabling you to establish a shared scope (HelperContext) for your SDO types. This reduces the memory footprint involved in loading schema definitions from large WSDL and XSD files used across your application and in constructing the corresponding SDO Type definitions from them.

The shared scope is maintained at the level of a business-level application. For any business-level application, all references to an SDO Type that correspond to a schema definition from an XSD or WSDL file imported from a shared contribution resolve to a single SDO Type instance in a single scope (HelperContext).

For shared scopes, there are two restrictions:

- A contribution that exports schema definitions cannot, in turn, import other schema definitions from another contribution.
- You cannot divide namespaces across more than one contribution. That is, you cannot package schema definitions in a given target namespace in one contribution and then import others in that same target namespace from a second contribution.

**JAX-WS based programming model**

In the product, the mapping between a WSDL operation and Java method is defined by JAX-WS. Within that operation-level mapping, it is the mapping between specific XSD types and the corresponding Java parameter types that is defined by the particular data binding (SDO in this case, rather than JAXB). Other than the type mapping, the programming model is independent of the choice of data binding.

One consequence of this capability is that the JAX-WS annotations such as @RequestWrapper, @ResponseWrapper, @WebParam, @WebResult are significant in SCA applications using SDO.

Another important consequence is that the product uses JAX-WS to define the mapping between a Java exception that occurs in Java clients and implementations, and the fault bean that is serialized on the wire. Thus, the fault bean can be an SDO (of type commonj.sdo.DataObject). In which case, SDO is used to serialize or deserialize the fault bean to or from the wire format.

*Using a top-down approach to develop SCA components that use SDO:*

You can use a top-down approach that starts from Web Services Description Language (WSDL) or XML definition files to develop Service Component Architecture (SCA) component implementations that use Service Data Objects (SDO) 2.1.1 (JSR 235).

**Before you begin**

Install the product and enable SDO. Instructions on enabling the SDO feature are in the installation topics for your operating system.

Consider installing a Rational Application Developer product with SCA Development Tools that you can use to assemble service-oriented application components based on open SCA specifications. See the Rational Application Developer documentation.

Access the default HelperContext programmatically in a Java or Java Platform, Enterprise Edition (Java EE) component implementation type. Complete step 1 of Using SDO 2.1.1 in SCA applications.

### About this task

This topic describes how to develop SCA composites that use SDO following a top-down approach.

### Procedure

1. Describe the service interface in your WSDL and XSD definition files.

   The following example WSDL and XSD files describe a service interface.

   **Example WSDL file, test.wsdl:**

```
<?xml version="1.0" encoding="UTF-8"?>

<wsdl:definitions targetNamespace="http://test" xmlns:tns="http://test"
        xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
        xmlns:wsdlsoap="http://schemas.xmlsoap.org/wsdl/soap/"
        xmlns:xsd="http://www.w3.org/2001/XMLSchema" name="Test">

  <wsdl:types>
    <schema targetNamespace="http://test" xmlns="http://www.w3.org/2001/XMLSchema" xmlns:p="http://person">
      <import namespace="http://person" schemaLocation="person.xsd"/>

      <element name="updateAccount">
        <complexType>
          <sequence>
            <element name="person" type="p:Person"/>
            <element name="code" type="xsd:string"/>
          </sequence>
        </complexType>
      </element>

      <element name="updateAccountResponse">
        <complexType>
          <sequence>
            <element name="response" type="p:Status"/>
          </sequence>
        </complexType>
      </element>
    </schema>
  </wsdl:types>

  <wsdl:message name="PersonRequestMessage">
    <wsdl:part element="tns:updateAccount" name="parameters"/>
  </wsdl:message>

  <wsdl:message name="PersonResponseMessage">
    <wsdl:part element="tns:updateAccountResponse" name="parameters"/>
  </wsdl:message>

  <wsdl:portType name="Test">
    <wsdl:operation name="updateAccount">
      <wsdl:input message="tns:PersonRequestMessage" name="ReqMsgName"/>
      <wsdl:output message="tns:PersonResponseMessage" name="RespMsgName"/>
    </wsdl:operation>
  </wsdl:portType>

  <wsdl:binding name="TestSoapBinding" type="tns:Test">
    <wsdlsoap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>
    <wsdl:operation name="updateAccount">
      <wsdlsoap:operation soapAction="urn:updateAccount"/>
      <wsdl:input name="ReqMsgName">
        <wsdlsoap:body use="literal"/>
      </wsdl:input>
      <wsdl:output name="RespMsgName">
        <wsdlsoap:body use="literal"/>
      </wsdl:output>
    </wsdl:operation>
  </wsdl:binding>

  <wsdl:service name="TestService">
    <wsdl:port binding="tns:TestSoapBinding" name="TestSoapPort">
      <wsdlsoap:address location=""/>
```

```
    </wsdl:port>
  </wsdl:service>

</wsdl:definitions>
```

**Example XSD file, person.xsd, that test.wsdl imports:**

```
<?xml version="1.0" encoding="UTF-8"?>

  <schema targetNamespace="http://person"  xmlns="http://www.w3.org/2001/XMLSchema">
    <complexType name="Person">
      <sequence>
        <element name="firstName" type="string"/>
        <element name="lastName" type="string"/>
      </sequence>
    </complexType>

    <complexType name="Status">
      <sequence>
        <element name="statusCode" type="int"/>
        <element name="message" type="string"/>
      </sequence>
    </complexType>
  </schema>
```

2. Produce a corresponding Java interface.

   If you are using an IBM Rational tool that supports SCA, you do not need to complete this step. The tool generates the code for you. Proceed to step 3.

   If you are not using a Rational tool that supports SCA, you can manually produce a Java interface from a WSDL file by completing this step 2, which provides an example that modifies generated code. There is not an automated tool to produce a Java interface from a command-line interface.

   a. Identify the WSDL and XSD files from which you want to produce Java interfaces.

      This example uses the `test.wsdl` and `person.xsd` files in step 1.

   b. Run the wsimport command with the `-s` option to save source files.

```
wsimport.bat -s . test.wsdl
```

   c. Among the generated Java files, identify the SEI.

      The SEI is a Java interface, and not a class file, with a class-level @WebService annotation, javax.jws.WebService.

      In this example, the Java interface is the `test/Test.java` file. Running the wsimport command produces the following output:

```
//
// Generated By:JAX-WS RI, IBM 2.1.1 in JDK 6 (JAXB RI, IBM JAXB 2.1.3 in JDK 1.6)
//

package test;

import javax.jws.WebMethod;
import javax.jws.WebParam;
import javax.jws.WebResult;
import javax.jws.WebService;
import javax.xml.bind.annotation.XmlSeeAlso;
import javax.xml.ws.RequestWrapper;
import javax.xml.ws.ResponseWrapper;
import person.Person;
import person.Status;

@WebService(name = "Test", targetNamespace = "http://test")
@XmlSeeAlso({
    person.ObjectFactory.class,
    test.ObjectFactory.class
})
public interface Test {

    /**
     *
     * @param person
     * @param code
     * @return
     *     returns person.Status
     */
    @WebMethod(action = "urn:updateAccount")
    @WebResult(name = "response", targetNamespace = "")
    @RequestWrapper(localName = "updateAccount", targetNamespace =
            "http://test", className = "test.UpdateAccount")
    @ResponseWrapper(localName = "updateAccountResponse", targetNamespace =
            "http://test", className = "test.UpdateAccountResponse")
    public Status updateAccount(
        @WebParam(name = "person", targetNamespace = "")
```

```
        Person person,
        @WebParam(name = "code", targetNamespace = "")
        String code);
}
```

d. Modify the SEI.

1) For all parameter and return values of generated (JAXB) types, change the Java type to `commonj.sdo.DataObject`. All complex schema types must map to `commonj.sdo.DataObject` Java types. Also, remove all imports of these generated JAXB types.

2) For each @RequestWrapper and @ResponseWrapper annotation, change the value of the `className` element to `commonj.sdo.DataObject`. Otherwise, leave the JAX-WS annotations because they are significant.

3) Remove or comment out the @XmlSeeAlso block.

Completing these steps results in the following Java interface:

```
//
// Generated By:JAX-WS RI, IBM 2.1.1 in JDK 6 (JAXB RI, IBM JAXB 2.1.3 in JDK 1.6)
//

package test;

import javax.jws.WebMethod;
import javax.jws.WebParam;
import javax.jws.WebResult;
import javax.jws.WebService;
import javax.xml.bind.annotation.XmlSeeAlso;
import javax.xml.ws.RequestWrapper;
import javax.xml.ws.ResponseWrapper;
import commonj.sdo.DataObject;

@WebService(name = "Test", targetNamespace = "http://test")

public interface Test {

    /**
     *
     * @param person
     * @param code
     * @return
     *     returns person.Status
     */
    @WebMethod(action = "urn:updateAccount")
    @WebResult(name = "response", targetNamespace = "")
    @RequestWrapper(localName = "updateAccount", targetNamespace =
            "http://test", className = "commonj.sdo.DataObject")
    @ResponseWrapper(localName = "updateAccountResponse", targetNamespace =
            "http://test", className = "commonj.sdo.DataObject")
    public DataObject updateAccount(
        @WebParam(name = "person", targetNamespace = "")
        DataObject person,
        @WebParam(name = "code", targetNamespace = "")
        String code);
}
```

The following example shows the resulting code with JAX-WS annotations removed for readability only. Do not remove the annotations before compiling to use the example code.

```
package test;
import commonj.sdo.DataObject;
public interface Test {
    public DataObject updateAccount(DataObject person, String code);
}
```

3. Write your SCA Java client or component implementation using the dynamic SDO programming model.

The following example code shows a service implementation in Java:

```
package test.impl;

import test.Test;
import org.osoa.sca.annotations.Service;

import commonj.sdo.DataObject;
import commonj.sdo.helper.DataFactory;
import commonj.sdo.helper.HelperContext;

import com.ibm.websphere.soa.sca.sdo.DefaultHelperContext;

@Service(Test.class)
public class TestImpl implements Test {

    @DefaultHelperContext
    protected HelperContext myDefaultHC;
```

```
    public DataObject updateAccount(DataObject person, String code) {
        String error_msg = null;
        if (code.equals("ERROR_STRING_IN_FIELD1")) {
            error_msg = "ERROR firstName: " +  person.getString("firstName"0);
            HelperContext defaultHC = ContextHelper.getCurrentHelperContext();
            DataFactory dataFactory = myDefaultHCdefaultHC.getDataFactory();
            DataObject returnDO = dataFactory.create("http://person","Status");
            returnDO.setInt("statusCode", -1);
            returnDO.setString("message", error_msg);
            return returnDO;
        } else {
            // process(person);
            ...
        }
     }
}
```

The input `person` DataObject is of type `{http://person}Person`. The returned output DataObject is of type `{http://person}Status`. Both the input and output are registered in the SCA application default HelperContext that is accessed using the `myDefaultHC` object.

4. In a composite definition, declare your component reference or component service interface with an `<interface.wsdl>` element that refers to the original `portType` value.

   **Example accountTest.composite file:**

```
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
    targetNamespace="http://www.ibm.com/test/soa/sca/sdo/"
    name="AccountTestComposite">
  <component name="AccountTestComponent">
    <implementation.java class="test.impl.TestImpl"/>
    <service name="Test">
      <interface.wsdl interface="http://test#wsdl.interface(Test)"/>
    </service>
  ...
  </component>
</composite>
```

5. Package the composite and deploy the component with the authored implementation along with the WSDL or XSD files into a single contribution JAR file.

   Suppose the example files are packaged into a single file, `MyAccountTestContribution.jar`. A listing of the JAR file contents from the command line is as follows:

```
$ jar tf MyAccountTestContribution.jar

wsdl/test.wsdl
wsdl/person.xsd
test/Test.class
test/impl/TestImpl.class
META-INF/accountTest.composite
META-INF/sca-contribution.xml
```

### Results

You have developed an SCA composite that uses SDO following a top-down approach.

### What to do next

Optionally, implement shared scopes. See the topic on using SDO 2.1.1 in SCA applications.

Deploy your files that use SDO in an SCA business-level application.

*Using a bottom-up approach to develop SCA components that use SDO:*

You can use a bottom-up approach that starts from Java files to develop Service Component Architecture (SCA) component implementations that use Service Data Objects (SDO) 2.1.1 (JSR 235).

### Before you begin

Install the product and enable SDO. Instructions on enabling the SDO feature are in the installation topics for your operating system.

Consider installing a Rational Application Developer product with SCA Development Tools that you can use to assemble service-oriented application components based on open SCA specifications. See the Rational Application Developer documentation.

Access the default HelperContext programmatically in a Java or Java Platform, Enterprise Edition (Java EE) component implementation type. Complete step 1 of Using SDO 2.1.1 in SCA applications.

### About this task

This topic describes how to develop SCA composites that use SDO following a bottom-up approach.

### Procedure

1. Start from a Java interface or implementation using type commonj.sdo.DataObject for one or more parameters or return types.

   The following example Java file provides an interface.

   **Logger.java (interface):**

```
package logger;
import commonj.sdo.DataObject;
public interface Logger {
    public String logDataObjectProperties (DataObject input);
}
```

2. Write your SCA Java client or component implementation using the dynamic SDO programming model.

   The following example Java file provides a component implementation.

   **LoggerImpl.java (component implementation):**

```
package logger.impl;

import logger.Logger;
import org.osoa.sca.annotations.Service;

import commonj.sdo.DataObject;
import commonj.sdo.helper.DataFactory;
import commonj.sdo.helper.HelperContext;

@Service(Logger.class)
public class LoggerImpl implements Logger {

    public String logDataObjectProperties (DataObject input) {
        String logMsg =  "==========\n";
        List props = input.getInstanceProperties();
        for (int i=0; i < props.size(); i++){
            Property prop = (Property)props.get(i);
            logMsg += "  prop[" + i + "], name = " + prop.getName() + ", val = " +
                input.get(prop).toString() + "\n";
        }
        logMsg += "==========\n";
        return logMsg;
    }
}
```

   The SDO application programming interfaces used are generic in that they do not depend on any particular schema definitions. This behavior fits the bottom-up approach because, without a WSDL interface describing this service, the runtime environment cannot associate the input object that is built during deserialization with a specific XSD or SDO type.

### Results

You have developed an SCA composite that uses SDO following a bottom-up approach.

### What to do next

Optionally, implement shared scopes. See the topic on using SDO 2.1.1 in SCA applications.

Deploy your files that use SDO in an SCA business-level application.

*Accessing default HelperContext objects in SCA applications:*

A Service Component Architecture (SCA) application can access a Service Data Objects (SDO) 2.1.1 HelperContext object. This object either uses DefaultHelperContext annotation or implements a application programming interface (API) that uses the commonj.sdo.helper.SDO class.

**Before you begin**

Install the product and enable SDO. Instructions on enabling the SDO feature are in the installation topics for your operating system.

Read SDO data binding for SCA applications to better understand how to work with SDO in SCA Java clients and implementations.

Develop one or more SCA composites that use SDO following a top-down or bottom-up approach.

**About this task**

This topic describes how to create and access SDO HelperContext in SCA applications. For information about accessing SDO HelperContext in non-SCA applications, see Creating and accessing SDO HelperContext objects.

Because the SCA run time manages the HelperContext objects and identifiers when using SDO in SCA applications, the method used to create and access SDO HelperContext in SCA applications is different from that used in non-SCA applications. An SCA application can access SDO HelperContext using a DefaultHelperContext annotation, `@DefaultHelperContext`.

Alternatively, an SCA application can implement an API that uses the commonj.sdo.helper.SDO class, to obtain the same SCA-managed HelperContext instance. This approach is an alterative to the annotation. To use this approach, pass the String ID of the SCA-managed HelperContext, which is sca-default, into the SDO.getHelperContext method.

You can access the default HelperContext programmatically in a Java or Java Platform, Enterprise Edition (Java EE) component implementation type using either annotation injection or an API. You cannot access the default HelperContext programmatically in a Spring component implementation type. When you use an OSGI application as an implementation of an SCA component, you can access the default HelpContext instance using the API mechanism. However, you *cannot* access the instance using the annotation injection mechanism.

**Procedure**

1. Add a public or protected field or setter method of the `commonj.sdo.helper.HelperContext` type to your Java implementation class.

   The method can either be a Java component implementation, such as `<implementation.java>`, or a Java EE implementation class, such as an EJB implementation class.
2. Annotate the field or setter method with `@com.ibm.websphere.soa.sca.sdo.DefaultHelperContext`.

   The following example shows a field annotation:

```
@DefaultHelperContext
protected HelperContext myDefaultHC;
```

   The following example shows an annotation of a setter method:

```
private HelperContext helperContext;

@DefaultHelperContext
public void setHelperContext(HelperContext hc) {
   this.helperContext = hc;
}
```

   Alternative step: The following example uses the API rather than annotation:

```
import commonj.sdo.helper.SDO;
import com.ibm.websphere.sdox.SDOUtil;
```

```
HelperContext helperContext = SDO.hetHelperContext("sca-default")
// Or the following line is equivalent to using the string value directly
HelperContext helperContext = SDO.getHelperContext(SDOUtil.SCA_DEFAULT_SCOPE);
```

3. Use the injected HelperContext in your implementation logic.

   When your component starts, the container will inject this field, or call this setter, with the default HelperContext instance for this component so you can use it in your implementation.

```
import com.ibm.websphere.soa.sca.sdo.DefaultHelperContext;
import commonj.sdo.helper.HelperContext;
import org.osoa.sca.annotations.Service;
...

// This is a Java implementation of an SCA component
@Service(AccountService.class)
public class AccountServiceImpl implements AccountService {

    private HelperContext helperContext;

    @DefaultHelperContext
    public void setHelperContext(HelperContext hc) {
        this.helperContext = hc;
    }

    @Override
    public DataObject accountMethod(DataObject account, String name) {
        // ....

        // Get dataFactory to create return object
        DataFactory dataFactory = this.helperContext.getDataFactory();
        DataObject retVal = dataFactory.create("http://myns", "Response");

        retVal.set(..)    // ... Set properties on return object

        return retVal;
    }
```

### Results

You have written code that accesses the default HelperContext.

### What to do next

Develop one or more SCA composites that use SDO following a bottom-up or top-down approach.

*Implementing shared scopes in SCA applications that use SDO:*

You can package your WSDL and XSD files so they can be accessed across various parts of a Service Component Architecture (SCA) application that uses Service Data Objects (SDO) 2.1.1.

### Before you begin

Develop one or more SCA composites that use SDO following a top-down approach.

If you are using a top-down development approach, you must package WSDL and XSD files in an appropriate SCA contribution so the component can access the schema definitions. Read the section on schema registration in SDO data binding for SCA applications for details.

### About this task

This topic discusses how to package WSDL and XSD files so that they can be accessed across various parts of your application from a shared in-memory instance. The packaging establishes a shared SDO scope.

### Procedure

1. Package the WSDL and XSD files that have schema definitions which you want to share into a shared contribution JAR file.

2. In the `META-INF/sca-contribution.xml` file within the shared contribution JAR file, export the namespaces for which you want to share schema definitions within SDO scopes.

   To export the namespaces, use the `<export namespace="...">` statement.

   The examples in this topic continue the example scenario described in the topic on using SDO 2.1.1 in SCA applications.

   **Example META-INF/sca-contribution.xml for mySharedDefs.jar:**

```
<?xml version="1.0" encoding="UTF-8"?>
<contribution xmlns="http://www.osoa.org/xmlns/sca/1.0"
    targetNamespace="http://www.ibm.com/test/soa/sca/sdo/scope/">
  <export namespace="http://www.ibm.com/test/soa/sca"/>
  <export namespace="http://www.ibm.com/test/soa/sca/person"/>
  <export namespace="http://www.ibm.com/test/soa/sca/address"/>
  ...
</contribution>
```

3. For composite applications that reference the shared WSDL and XSD schema definitions, import the desired namespaces from the appropriate `META-INF/sca-contribution.xml` file.

   Import namespaces from the `sca-contribution.xml` file of the contribution JAR that contributes the deployable composite which deploys the application components that reference the shared schema definitions as SDO definitions. To import the namespaces, use the `<import namespace="...">` statement.

   **Example META-INF/sca-contribution.xml for myImportingComposite1.jar:**

```
<?xml version="1.0" encoding="UTF-8"?>
<contribution xmlns="http://www.osoa.org/xmlns/sca/1.0"
    targetNamespace="http://www.ibm.com/test/soa/sca/sdo/scope/"
    xmlns:sdoscope="http://www.ibm.com/test/soa/sca/sdo/scope/">

  <deployable composite="sdoscope:MyShippingComposite"/>

  <import namespace="http://www.ibm.com/test/soa/sca"/>
  <import namespace="http://www.ibm.com/test/soa/sca/person"/>
  <import namespace="http://www.ibm.com/test/soa/sca/address"/>
  ...
</contribution>
```

   **Example META-INF/sca-contribution.xml for myImportingComposite2.jar:**

```
<?xml version="1.0" encoding="UTF-8"?>
<contribution xmlns="http://www.osoa.org/xmlns/sca/1.0"
    targetNamespace="http://www.ibm.com/test/soa/sca/sdo/scope/"
    xmlns:sdoscope="http://www.ibm.com/test/soa/sca/sdo/scope/">

  <deployable composite="sdoscope:MyLoggingComposite"/>

  <import namespace="http://www.ibm.com/test/soa/sca"/>
  <import namespace="http://www.ibm.com/test/soa/sca/person"/>
  <import namespace="http://www.ibm.com/test/soa/sca/address"/>
  ...
</contribution>
```

### Results

The packaging establishes a shared SDO scope.

Assuming the composites `MyShippingComposite` and `MyLoggingComposite` are deployed using the same business-level application, then all SDO references to schema definitions in the namespaces exported from the `mySharedDefs.jar` file (and imported from the respective JAR files contributing these two composites) are scoped to a common, shared scope associated with the `mySharedDefs.jar` file. If sharing has not been established through this mechanism, the schema definitions are created separately in each of the two separate scopes associated with the each of the deployable composites.

### What to do next

Deploy your files that use SDO in an SCA business-level application.

## Data access with Service DataObjects, API versions 1.0 and 2.01

The Service Data Objects (SDO) framework is a data-centric, disconnected, XML-integrated, data access mechanism that provides a source-independent result set.

- SDO is data-centric because it eliminates the need for client applications to work with special formats of data, such as the object representations of the Enterprise JavaBeans (EJB) API. Instead, clients work with easily traversable graphs of DataObjects.
- SDO is disconnected because the retrieved result is independent of any back-end data store connections or transactions.
- SDO is XML-integrated in that it provides services to easily convert retrieved data to and from XML format.

Put simply, SDO is a framework for data application development, which includes an architecture and API. SDO does the following:
- Simplifies the Java Platform, Enterprise Edition (Java EE) data programming model.
- Abstracts data in a service-oriented architecture (SOA).
- Unifies data application development.
- Supports and integrates XML.
- Incorporates Java EE patterns and best practices.

The Service Data Objects framework provides a unified framework for data application development. With SDO, you do not need to be familiar with a technology-specific API in order to access and use data. You need to know only one API, the SDO API, which lets you work with data from multiple data sources, including relational databases, entity EJB components, XML pages, web services, the Java Connector Architecture, JavaServer Pages, and more.

Unlike some of the other data integration models, SDO does not stop at data abstraction. The SDO framework also incorporates a good number of Java EE patterns and best practices, making it easy to incorporate proven architecture and designs into your applications. For example, most web applications today are not (and cannot) be connected to backend systems 100 percent of the time; so SDO supports a disconnected programming model. Likewise, many applications tend to be remarkably complex, comprising many layers of concern. How will data be stored? Sent? Presented to users in a GUI framework? The SDO programming model prescribes patterns of usage that allow clean separation of each of these concerns.

## SDO components

An architectural overview of SDO describes each of the components that make up the framework and explains how they work together. The first three components listed are "conceptual" features of SDO: They do not have a corresponding interface in the API.

**SDO clients**

SDO clients use the SDO framework to work with data. Instead of using technology-specific APIs and frameworks, they use the SDO programming model and API. SDO clients work on SDO DataObjects and do not need to know how the data they are working with is persisted or serialized.

**Data mediator services**

Data mediators services (DMS) are responsible for creating a DataGraph from data sources, and updating data sources based on changes made to a DataGraph. (A DataGraph is an envelope object that contains service data objects.)

The DMS provides the mechanism to move data between a client and a data source. It is created with back end specific metadata. The metadata defines the structure of the DataGraph that is produced by the DMS as well as the query to be used against the back end. When the DMS is requested to produce a DataGraph, it queries its targeted back end and transforms the native result set into the DataGraph format. Once the DataGraph is returned, the DMS no longer has any reference to it, making it stateless with respect to the DataGraph. When the DMS is requested to flush modifications of an existing DataGraph to the back end, it extracts the changes made from

the original state of the DataGraph and flushes those changes to the back end. A DMS typically employs some form of optimistic concurrency control strategy to detect update collisions.

WebSphere Application Server provides functionality for two separate Data Mediator Services. If you simply need to retrieve data from a relational data source and return a DataGraph, using the Java Database Data Mediator Service is a good choice. However, if you have business logic, then you probably want an object-oriented (OO) rendering of the data into entity beans. One could consider SDO as an object rendering of data like entity beans. But entity beans have better Object-Relational (OR) mapping tools, and the EJB container and persistence manager for entity beans offer more sophisticated caching policies. Your best choice then is the EJB Data Mediator Service. The EJB mediator can work with these caches. Also, the entity bean programming model is a single level store model. You can navigate from entity to entity and the container and persistence manager either prefetches or lazily fetches in data as needed. On update, the programmer commits the transaction and the container and persistence manager do the work of tracking updated beans and writing them back to the data store and in memory cache.

**Data sources**

Data sources are not restricted to backend data sources (for example, persistence databases). A data source contains data in its own format. As to the SDO 1.0 API, only the DMS accesses data sources; SDO applications do not. The applications only work with SDO 1.0 DataGraphs.

Each of the following components corresponds to a Java interface in the SDO programming model.

**DataObjects**

As the fundamental components of SDO, DataObjects provide a common view of structured data for SDO clients. DataObjects can hold multiple different attributes of any serializable type (such as string or integer); more complex DataObjects can also contain simpler DataObjects. DataObjects hold all of their data in *properties*.

SDO version 1.0 DataObjects are always linked together and contained in DataGraphs. The version 1.0 DataObject interface provides simple creation and deletion methods (createDataObject() with various signatures and delete()), and reflective methods to get their types (instance class, name, properties, and namespaces). The interface also supports static object types that you create from external code generators. See the article "Dynamic and static object types for the JDBC DMS" for more information.

**DataGraphs**

A DataGraph is a structured result returned in response to a service request. The DMS transforms the native backend query results into the DataGraph, which is independent of the originating backend data store. This makes the DataGraph easily transferable between different data sources. The DataGraph is composed of interconnected nodes, each of which is an SDO DataObject. It is independent of connections and transactions of the originating data source. The DataGraph tracks changes made to it from its original source. This change history can be used by the DMS to reflect changes back to the original data source. DataGraphs can easily be converted to and from XML documents enabling them to be transferred between layers within a multi-tiered system architecture. A DataGraph can be accessed in either breadth-first or depth-first manner, and it provides a disconnected data cache that can be serialized for web services

The DataGraph returned by the mediator can contain either dynamic or generated static DataObjects. Use of generated classes gives type safe interfaces for easier programming and better runtime performance. The EMF generated classes must be consistent in name and type with the schema that would be created for dynamic DataObjects except that additional attributes and references can be defined. Only those attributes and references specified in the query are filled in with data. Remaining attributes and references are not set.

**Change summary**

SDO 1.0 change summaries are contained by DataGraphs and are used to represent the changes that have been made to a DataGraph returned by the DMS. They are initially empty (when the

DataGraph is returned to a client) and populated as the DataGraph is modified. Change summaries are used by the DMS at backend update time to apply the changes back to the data source. They enable the DMS to efficiently and incrementally update data sources by providing lists of the changed properties (along with their old values) and the created and deleted DataObjects in the DataGraph. Information is added to the change summary of a DataGraph only when the change summary's logging is activated. Change summaries provide methods for DMS to turn logging on and off.

**Note:** The SDO 1.0 change summary is not a client API; it is used only by the DMS.

**Properties, types, and sequences**

DataObjects hold their contents in a series of properties. Each property has a type, which is either an attribute type such as a primitive (for example, int) or a commonly used data type (for example, Date) or, if a reference, the type of another DataObject. Each DataObject provides read and write access methods (getters and setters) for its properties. Several overloaded versions of these accessors are provided, allowing the properties to be accessed by passing the property name (String), number (int), or property metaobject itself. The String accessor also supports an XPath-like syntax for accessing properties. For example, you can call get("department[number=123]") on a company DataObject to get its first department whose number is 123. Sequences are more advanced. They allow order to be preserved across heterogeneous lists of property-value pairs.

## For more introductory information

For a good introduction to SDO 1.0 that also includes a small sample application, refer to the IBM developerWorks® paper "Introduction to Service DataObjects."

**Note:** To fully understand the EJB data mediator service you need a good understanding of the EJB programming model. For more information refer to the articles "Task overview: Using enterprise beans in applications" and "Service Data Objects: Resources for learning."

***Java DataBase Connectivity Mediator Service:***

The Java Database Connectivity (JDBC) Data Mediator Service (DMS) is the Service Data Objects (SDO) component that connects to any database that supports JDBC connectivity. It provides the mechanism to move data between a DataGraph and a database.

A regular JDBC call returns a result set in a tabular format. This format does not directly correspond to the object-oriented data model of Java, and can complicate navigation and update operations. When a client sends a query for data through the JDBC DMS, the JDBC result set of tabular data is transformed into a DataGraph composed of related DataObjects. This enables clients to navigate through a graph to locate relevant data rather than iterating through rows of a JDBC result set. After altering the DataGraph, all of the changes can be committed together and propagated back to the database by the JDBC DMS. Between the processes of being populated and being committed, the DataGraph is disconnected from the database, and there are no locks held on the data accessed. Being disconnected allows multiple changes to be made to the graph without making additional round trips to the database, improving performance.

The JDBC DMS is created with backend-specific metadata. The metadata defines the structure of the DataGraph that is produced by the DMS, as well as the query to be used against the back end.

*Metadata for Data Mediator Service:*

A Data Mediator Service (DMS) is the Service Data Object (SDO) component that connects to the back end database. It is created with back end specific metadata. The metadata defines the structure of the DataGraph that is produced by the DMS as well as the query to be used against the back end.

Metadata is composed of the following components:

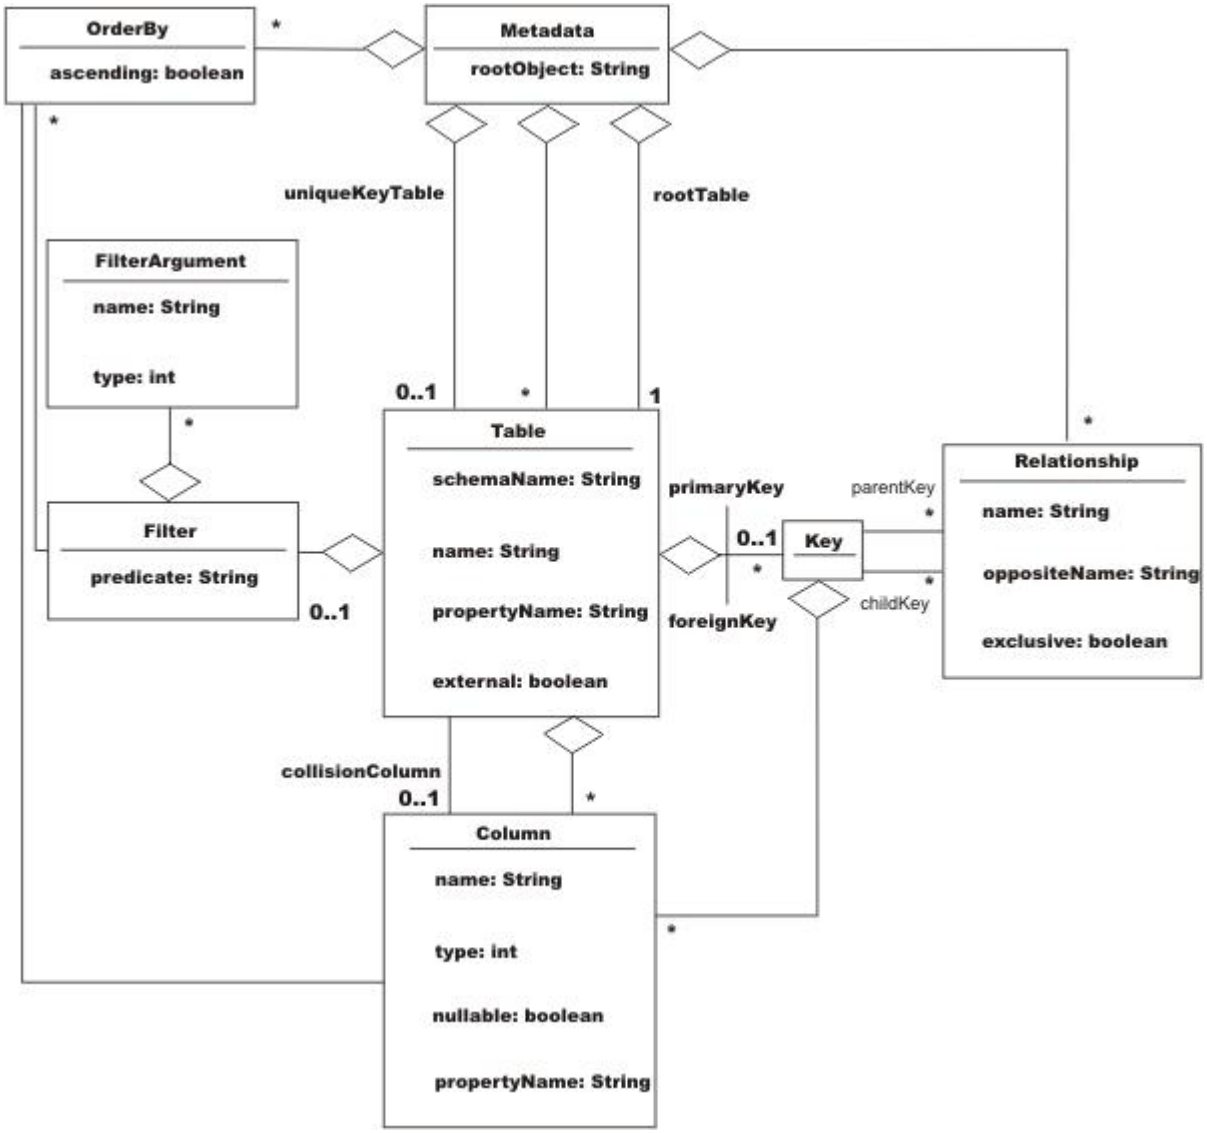

**Table** This represents a table within the target database and is composed of the following items:

**Name** This is the database table name. A table might also have a property name that can be used to specify the name of the DataObject that corresponds to this table. By default, the property name is the same as the table name.

**Columns**
The subset of database table columns to return from the database. A column has a type that corresponds to a JDBC type and it can prohibit null entries. A column has a name that corresponds to the name in the database and an optional property name that identifies the column name in the DataObject. By default, the property name is the same as the column name in the database.

**Primary Key**
The column (or columns) used to uniquely identify a row within the table.

**Note:** Keys may be composed of multiple columns. The following example illustrates creation of a compound primary key :

```
Key pk = MetadataFactory.eINSTANCE.createKey();
pk.getColumns().add(xColumn);
pk.getColumns().add(yColumn);
coordinateTable.setPrimaryKey(pk);
```

If a table is related to this one and is the child table, it uses the same method to create the foreign key to point to this coordinate table.

**Foreign Key**

The column (or columns) used to relate the table to another table in the metadata. There is an assumed positional mapping between compound primary keys and foreign keys. For example, if a parent table has a primary key such as (x,y) with respective types (integer, string), then it is expected that any pointing foreign key is also (x', y') with respective types (integer, string).

**Note:** Keys may be composed of multiple columns. The following example illustrates the creation of a compound foreign key :

```
Key fk = MetadataFactory.eINSTANCE.createKey();
fk.getColumns().add(xColumn);
fk.getColumns().add(yColumn);
coordinateTable.getForeignKeys().add(fk);
```

If a table is related to this one and is the child table, it uses the same method to create the foreign key to point to this coordinate table.

**Filter** A structured query language (SQL) WHERE clause predicate that can be given with or without parameters to fill in later. This is added to the DataGraph SELECT statement WHERE clause. It is not parsed or interpreted in any way; it is used as is. If given with parameters to fill in later, these parameters become arguments passed into the JDBC DMS when getting the DataGraph. Filters are used with generated queries only. If a supplied query is given, the metadata filters are ignored.

**Relationship**

Relates two tables through the primary key of the parent table and the foreign key of the child table. Relationships are composed of the following items:

**Name** This is the name given to the relationship, usually associated with how the two tables are related. If *Customers* is the parent table and *Orders* is the child table, then the default name of the relationship is Customers_Orders.

**Opposite Name**

This is the name used to navigate from the child DataObject to the parent DataObject.

**Parent Key**

The primary key of the parent table.

**Child Key**

The foreign key of the child table that points to the parent key.

**Exclusive**

By default, a Relationship causes the generated query to use an inner join operation on the two tables involved in the relationship. This means that it only returns the parent entries that have children, that is, child entries pointing to them. If the value of the Exclusive attribute is set to false, the query uses a left outer join operation instead and returns all parent entries, even those without children.

**Ordering**

Columns used for ordering the tables. Can be either ascending or descending. When specified, this causes generated queries to contain an ORDER BY clause.

*Dynamic and static object types for the JDBC DMS:*

DataObjects of the Service Data Object (SDO) 1.0 Specification can use static types as well as dynamic types. If you know that a particular dataGraph schema meets all of your application query requirements, you can generate static SDO code for potential runtime benefits.

With dynamic types, the information that defines the shape of a DataGraph is constructed at runtime. The DataGraph schema is created by the JDBC data mediator service (DMS) from the metadata provided upon creation. The JDBC DMS only requires the metadata and a connection to a data source to produce the DataGraph with dynamic typing. This is the default method for creating the JDBC DMS.

If you know the shape of the DataGraph at development time, you can use a code generator to create strongly typed interfaces (static data API code) that simplify DataGraph navigation, provide better compile-time checking for errors, and improve performance. For more information about the metamodels from which you can generate static SDO code, consult the introduction of the SDO 1.0 Specification. The introduction contains a list of the specification scope requirements, where you can find a brief discussion on support for static data API. Note that the dynamic API is still available when you use strongly typed DataObjects.

With the code generator you create classes for each DataObject type in the DataGraph. Each class contains *getter()* and *setter()* methods for each property in the DataObject. This enables a client to call type-safe methods rather than passing in the name of a property. For example, instead of calling the property *DataObject.get("CUSTFIRSTNAME")*, the generated types can contain a DataObject.getCustFirstName() method. If you are accessing a related DataObject, an accessor returns a strongly-typed DataObject rather than a regular DataObject. For example, *DataObject.get("Customers_Orders")* returns a DataObject, but *DataObject.getOrders()* returns an object of type Order.

To use static typing with the JDBC DMS, the metadata, a connection to the data source, and the DataGraph schema need to be provided to the JDBCMediatorFactory class *create* methods. In this case, the JDBC DMS metadata does not determine the shape of the DataGraph, but does give the DMS information about the backend data source and the way it maps to a DataGraph.

When using strongly typed DataObjects, it is important to make sure that the query matches the DataGraph schema. The query is not required to fill all of the data objects and properties in the schema, but a query cannot return data objects or properties that are not defined in the DataGraph schema. For example, a DataGraph schema might define *Customer* and *Order* DataObjects, but a query might only return Customer objects. Also, the Customer object might define properties for *ID*, *Name*, and *Address*, but the query might not return an address. In this case, the value of the address property is null, and the value is not updated in the database when the *applyChanges()* method is called. In this example, the query could not return a *Phone* property because it has not been defined as a property on the Customer object. When a query attempts this, the DMS returns an invalid metadata exception.

*JDBC mediator supplied query:*

An SDO client can supply the JDBC Data Mediator Service (DMS) with a SELECT statement to replace the statement that is generated from the DMS metadata.

When the SDO client instantiates a DMS, the DMS uses the defining metadata to generate a basic SELECT statement. Substituting that query gives you the ability to specify parameter markers; therefore you have more control over the client data that populates a dataGraph. Use a standard SQL SELECT string for a client-supplied query.

With both supplied queries and generated queries, UPDATE, INSERT, and DELETE statements are automatically generated for each DataObject. They are applied when the mediator commits the changes made to the DataGraph back to the database.

### Parameter DataObjects for supplied queries

Clients can use a parameter DataObject to supply arguments to an SQL SELECT query. A parameter DataObject is a DataObject, but is not part of any DataGraph. It is constructed by the JDBC DMS when requested by the client. The ParameterDataObject for supplied queries is created based on the query given to the mediator. Every parameter in the query is given a name like *arg0, arg1, ..., argX*.

Because a parameter DataObject is a DataObject, you can set its properties using either the property name or an index value. The properties can be referenced by their argX name, or by the number associated with that parameter, 0, 1, ... , X. For example, your query is “SELECT CUSTFIRSTNAME WHERE CUSTSTATE = ? AND CUSTZIP = ?”. This supplied query contains two parameters. The first parameter corresponds with CUSTSTATE and can be set using the string “arg0” or the index 0. The second parameter corresponds with CUSTZIP and can be set using the string “arg1” or the index 1. Here is sample code of how they are set. This code assumes that you have already set up the metadata and mediator with the metadata and the aforementioned supplied query. Using the index value method, you code:

```
DataObject parameters = mediator.getParameterDataObject();
parameter.setString(0, "NY");
parameter.setInt(1, 12345);
DataObject graph = mediator.getGraph(parameters);
```

Using the property name method, you code:

```
DataObject parameters = mediator.getParameterDataObject();
parameters.setString("arg0", "NY");
parameters.setInt("arg1", 12345);
DataObject graph = mediator.getGraph(parameters);
```

The results are the same for both cases.

### Limitations

The JDBC DMS generated SQL SELECT query is not fully supported on Oracle or Informix. This is because the mediator takes advantage of the ResultSetMetaData interface in JDBC 2.0 and requires it to be fully implemented. Oracle, Informix, DB2/390, and older supported versions of Sybase do not implement the ResultSetMetaData interface completely. The supplied select approach can still be used with these databases with one limitation: **column names in the Metadata must be unique across all tables.** An InvalidMetadataException occurs if the select statement returns a column with a name that appears multiple times in the metadata. For instance, if the Customer and the Order tables both contain a column named “ID”, this would be invalid and cause problems. The way to fix this is to change the name of at least one of the matching columns in the database to better distinguish the two columns from each other. For the Customer table, the column name could be changed to “CUSTID,” as it is in the examples. The Order column name could be changed to “ORDERID”. If you change the Customer column name, you do not have to change the Order column name, but for consistency it may be a good idea.

*JDBC mediator generated query:*

If you do not provide a structured query language (SQL) SELECT statement, then the data mediator service (DMS) generates one using the metadata provided at instance creation.

The internal query engine uses information in the metadata about tables, columns, relationships, filters, and order bys to construct a query. As with the supplied queries, UPDATE, DELETE, and INSERT statements are automatically generated for each DataObject to be applied when the mediator commits the changes made to the DataGraph back to the database.

### Filters

Filters define an SQL WHERE clause that might contain parameter markers. These are added to the DataGraph SELECT statement WHERE clause. Filters are used as is; they are not parsed or interpreted in any way so there is no error checking. If you use the wrong name, predicate, or function, it is not detected and the generated query is not valid. If a Filter WHERE clause contains parameter markers, then the corresponding parameter name and type are defined using Filter arguments. Parameter DataObjects fill in these parameters before the graph is retrieved. An example of the Filters and Parameter DataObjects for generated queries follows.

**Limitation:** Because of the tree-like nature of the DataGraph, any table at a branch appears in more than one subquery in the final union with the root table appearing in all paths. This means that it is not possible to filter on a table that appears in more than one path independent of all other paths. All filters defined on a particular table are joined by a boolean AND, and used everywhere that table appears.

### Parameter DataObjects for generated queries

Clients use a Parameter DataObject to supply arguments that are applied to the filters provided in the DMS metadata. A Parameter DataObject is a DataObject, but is not part of any DataGraph. It is constructed by the JDBC DMS when requested by the client. The Parameter DataObject for generated queries is created based on the mediator's metadata. Every argument of every filter of every table is put into the Parameter DataObject. Unlike the supplied query Parameter DataObject, the parameters have the name assigned to them by the Filter arguments. The Parameter DataObject uses this name to map to the parameter to be filled in. The following sample code illustrates how a filter is created for a table in the mediator metadata. It also demonstrates the use of a Parameter DataObject to pass filter parameter values to a mediator instance. The sample assumes that the Customer table has already been defined:

```
// The factory is a MetadataFactory object
Filter filter = factory.createFilter();
filter.setPredicate("CUSTSTATE = ? AND CUSTZIP = ?");

FilterArgument arg0 = factory.createFilterArgument();
arg0.setName("customerState");
arg0.setType(Column.String);
queryInfo.getFilterArguments().add(arg0);

FilterArgument arg1 = factory.createFilterArgument();
arg1.setName("customerZipCode");
arg1.setType(Column.Integer);
queryInfo.getFilterArguments().add(arg1);

// custTable is the Customer Table object
custTable.setFilter(filter);

..... // setting up mediator

DataObject parameters = mediator.getParameterDataObject();

// Notice the first parameter is the name given to the
// argument by the FilterArgument.
parameter.setString("customerState", "NY");
parameter.setInt("customerZipCode", 12345);
DataObject graph = mediator.getGraph(parameters);
```

### Order-by

Ordering of query results is specified using OrderBy objects that identify a column from a table to sort the results. This ordering can be either ascending or descending. The OrderBy objects are part of the metadata and are automatically applied to generated queries. An example of this for a customer table results to be sorted by first names is as follows:

```
// This example assumes that the custTable, a table in
// the metadata, and factory, the MetaDataFactory
// object, have already been created.
Column firstName = ((TableImpl)custTable).getColumn("CUSTFIRSTNAME");
OrderBy orderBy = factory.createOrderBy();
orderBy.setColumn(firstName);
orderBy.setAscending(true);
metadata.getOrderBys().add(orderBy);
```

**Limitation:** Even though Order-bys are defined on each table in the metadata, the RDBMS model requires them to be applied to the final query. This has many implications. For example, you cannot order a table and then use that in a join to another table and propagate the ordering in the first table. Because a result set is a union of all the tables in the DataGraph, the nature of the single result set requires that it be padded with nulls, which can affect the order-bys, particularly in the non-root tables. This can give unexpected results.

### External Tables

An external table is a table defined in the metadata that is not needed in the DataGraph returned by the JDBC DMS. This might be appropriate when you want to filter the result set based on data from a table but that table's data is not needed in the result set. An example of this with the Customers and Orders relationship would be to filter the results to return all customers who ordered items with an order date of the first of the year. In this case, you do not want any order information returned, but you do need to filter on the order information. Making the Orders table external excludes the orders information from the DataGraph and therefore reduces the DataGraph's size, improving efficiency. To designate a table as external, you call the *setExternal(true)* method from a table object in the JDBC DMS metadata. If the client tries to access an external table from the DataGraph, an illegal argument exception occurs.

**Limitation:** Many RDBMSs require that an orderby column appear in the final result set; the columns from an external table cannot in general be used to order a result set. Order-bys are actually applied to the result set (the word "set" is key here), and not to intermediate query results.

### General limitations of generated queries

In understanding the limitations of the query generation feature in the JDBC DMS, there are two things to keep in mind. The first is that the DataGraph imposes a model that is a directed, connected graph with no cycles (that is, a model that is a tree) on a relational model that is a non-directed, potentially disconnected graph with cycles. *Directed* means that the developer chooses the orientation of the graph by picking a root table. *Connected* means that all tables that are a member of the DataGraph are reachable from the root. Any tables that are not reachable from the root cannot be included in the DataGraph. In order for a table to be reachable from the root, there must be at least one foreign key relationship defined between each pair of tables in the DataGraph. *No cycles* means that there is only one foreign key relationship between a pair of tables in the DataGraph. The tree nature of the DataGraph determines how the queries are built, and what data is returned from a query.

The second item to keep in mind is the following high level description of how query generation produces read queries for a DataGraph:

1. The JDBC DMS creates a single result set (that is, a DataGraph) whether the DataGraph is composed from a single table or from multiple tables.

2. Each path through the foreign key relationships in DMS Metadata from root to leaves represents a separate path. The data for that path is retrieved by using joins across the foreign keys defined between the tables in the path. The joins are by default inner joins.
3. All the paths in a DataGraph are unioned together in order to create a single result set by the query that is generated by the mediator, and are thus treated independently of one another.
4. Any user-defined filtering is done first on the tables. Then the result is joined to the rest of the path.
5. Relational databases generally require order-bys to be applied to the entire final result set and not on intermediate results.

*JDBC mediator performance considerations and limitations:*

Use these tips to help you determine if a JDBC Data Mediator Service suits the requirements of your application serving environment.

**Miscellaneous database limitations**
- Sybase before Version 12.5.1 does not support in-line queries in the “from” clause, and therefore does not support multiple table DataGraphs with filters. To use the Service Data Object in WebSphere Application Server use Sybase Version 12.5.1.
- The Informix Dynamic Server does not support sub-selects, which are needed for multiple table graphs. Use Informix Extended Parallel Server.
- Oracle 8i does not support the ANSI join syntax. The mediator in multiple table cases requires Oracle 9i or 10g.

**General performance recommendations**
- Evaluate if your target projects are well suited to these technologies. In general, projects that are read-intensive and require disconnected data are good candidates.
- Limit the number of tables in the metadata. One or two is best because relationships, with respect to filters, become ambiguous when graphs have many branches.
- Work with small data sets as often as possible to avoid consuming excessive amounts of memory within your applications. You can limit the amount of data returned to the SDO by specifying filters in the metadata objects or by using paging.
- For web applications, if the DataGraph is not too large and is to be reused later, store it in the user session.

*JDBC mediator transactions:*

You can specify that the JDBC mediator either act as transaction manager, or refrain from such activities in the case of external transaction management (performed by the SDO client).

**Mediator managed transactions**

A JDBC connection is wrapped in a connection wrapper and passed to the Data Mediator Service (DMS) during the instance creation. The ConnectionWrapper object contains the connection that is used by the JDBC DMS and indicates whether the mediator manages the current transaction. When the JDBC DMS manages the transaction, it performs commit and rollback operations as required. However, the DMS does not perform any transaction management activities if the wrapped connection is currently engaged in another transaction.

Using the createConnectionWrapper method for active transaction management is the general practice.

**Non-mediator managed transactions**

When a *passive* connection wrapper is passed to the DMS, the DMS takes no managerial action; a passive wrapper is generally intended for an existing transaction that is under external management. Commit or rollback operations are not performed by the connection wrapper in this case.

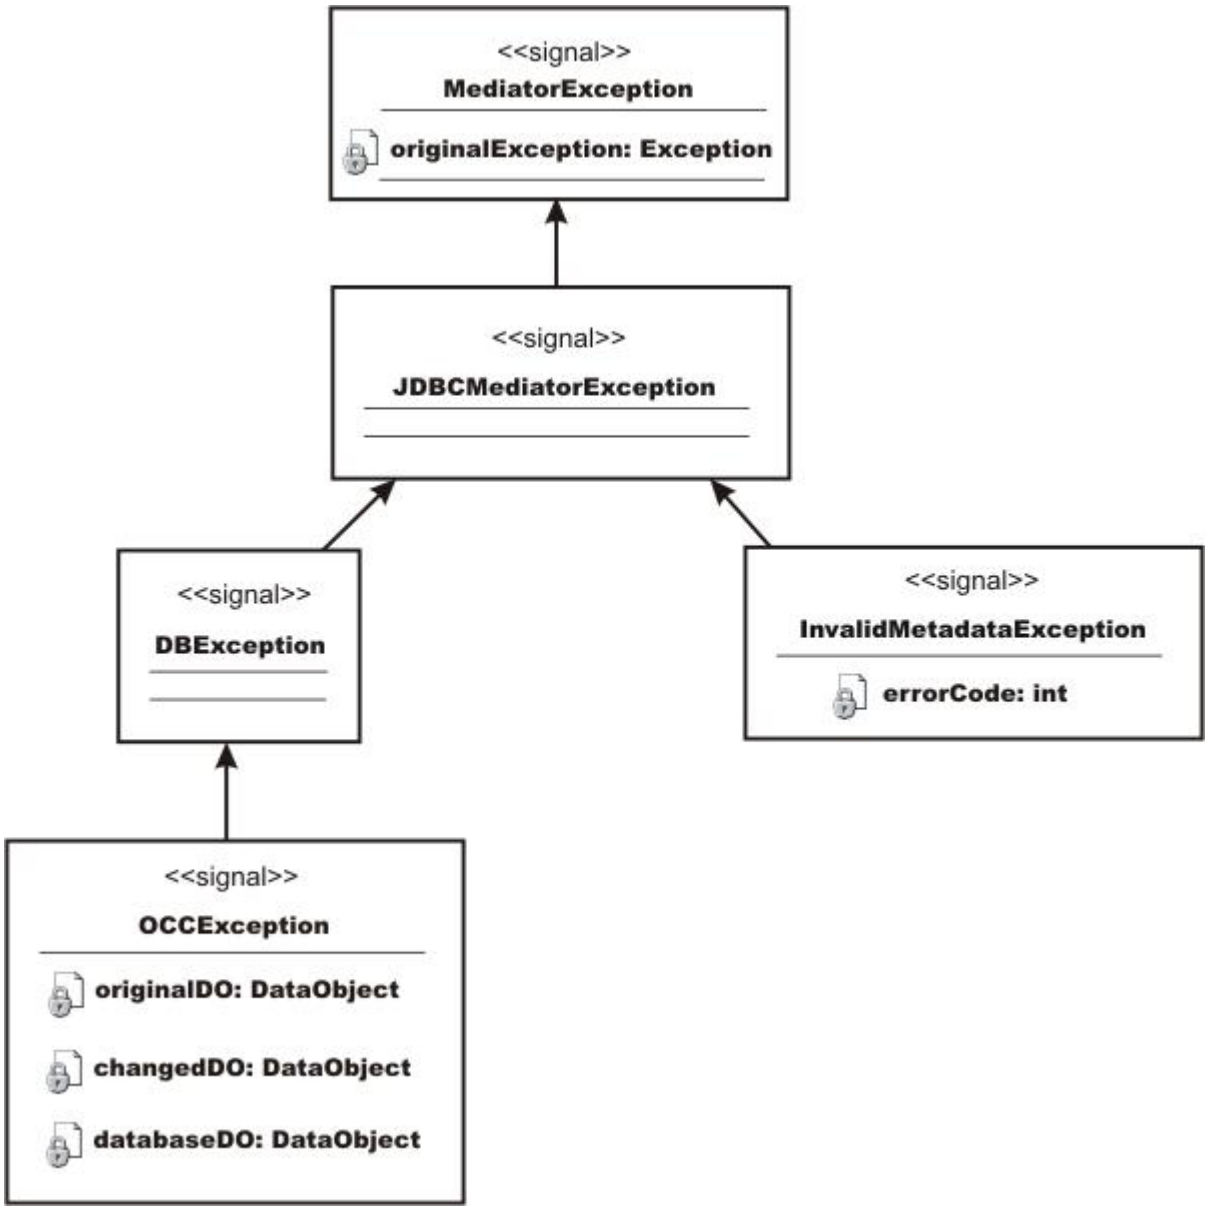
Use the createPassiveConnectionWrapper method.

**Protection against referential integrity (RI) violations**

The JDBC Data Mediator Service safeguards data transactions from incurring RI violations and other database logic violations. When the JDBC DMS applies the updates of a data graph to a back end, it automatically orders the change operations so that they do not violate database RI policy. Similarly, the DMS filters counter operations (such as INSERT and DELETE) so that opposing client requests can perform updates in a logical order. The client deletes one object, and then creates an entirely separate object with the same primary key. The DMS transforms these two operations into an update operation that modifies the existing database object.

*JDBC mediator exceptions:*

JDBC mediator exceptions either surface errors reported by the database, or indicate use of non-valid metadata in the attempt to instantiate the DMS.



The `Mediator` exception is the root exception of all the data mediator services, and the `JDBCMediator` exception is the root exception for the JDBC DMS in particular.

The `DB` exception occurs when an error is reported by the database. This can occur several ways:
- when the connection being used has the AutoCommit property set to *true*, but the JDBC DMS is controlling the transaction and needs it to be set to false
- when an unsupported database is trying to be used
- when other backend database errors occur during commit or rollback.

An optimistic concurrency control (OCC) exception occurs when the applyChanges() operation results in an data collision. When this occurs, the exception contains the original row values, current row values, and the attempted row values. These values are used to help recover from the error.

An `InvalidMetadata` exception occurs for invalid metadata supplied to the JDBC DMS upon creation. This can happen when a query requires tables or columns that are not defined in the metadata, or when there are identical column names for different tables for the Oracle, Informix, and older supported versions of Sybase databases.

**Example: Forcing OCC data collisions and JDBC mediator exceptions,** The following example forces a collision to demonstrate detection and shows the exception that occurs as a result.

```
// This example assumes that a mediator has already
// been created and the first name in the list is Sam.
// It also assumes that the Customer table has an OCC
// column and the metadata has set this column to be
// the collision column.

DataObject graph1 = mediator.getGraph();
DataObject graph2 = mediator.getGraph();

DataObject customer1 = (DataObject)graph1.getList("CUSTOMER").get(0);
customer1.set("CUSTFIRSTNAME", "Bubba");

DataObject customer2 = (DataObject)graph2.getList("CUSTOMER").get(0);
customer2.set("BOWLERFIRSTNAME", "Slim");

mediator.applyChanges(graph2);

try
{
 mediator.applyChanges(graph1);
}
catch (OCCException e)
{
// Since graph1 was obtained before graph2 and
// graph2 has already been submitted, trying to
// apply the same changes to graph1 causes
// this OCC Exception.

assertEquals("Sam", e.getOriginalDO(). getString("CUSTFIRSTNAME"));
assertEquals("Bubba", e.getChangedDO(). getString("CUSTFIRSTNAME"));
assertEquals("Slim", e.getDatabaseDO(). getString("CUSTFIRSTNAME"));
}
```

*Defining optimistic concurrency control for JDBC Mediator:*

Implement an optimistic concurrency control (OCC) strategy for the JDBC DMS to diagnose transaction problems that are caused by update collisions.

### About this task

An *update collision* occurs when client data that populates a data graph is changed in the database before the data graph can submit the modifications of the client. If you configure the JDBC DMS for OCC, the DMS issues an OCC-specific exception when such a data collision happens. The OCC exception contains collision details such as the original row values, current row values, and the attempted row values. The client application uses these values to determine how to recover from the collision. For example, the application can reread the data and restart the transaction.

Be aware, however, that when one exception occurs, there is no way of knowing whether more exceptions exist deeper in the data graph schema and therefore are not displayed.

To activate OCC for the data mediator service, you must incorporate OCC columns into your database tables.

Add an *OCC Integer* column to a given table, and specify that this column is to be used for OCC in the metadata. The defined OCC collision column is reserved for the exclusive use of the mediator. If there is no OCC column defined for a table, the DMS does not monitor and notify you of update collisions. The following generic code segments create this setup.

### Procedure

1. Create the OCC column
   ```
   Column collisionColumn = table.addIntegerColumn("OCC_COUNT");
   ```
2. Ensure that it does not allow null values
   ```
   collisionColumn.setNullable(false);
   ```
3. Designate the column as the table collision column
   ```
   table.setCollisionColumn(collisionColumn);
   ```
   For a fully-fledged code example that forces a collision to demonstrate the OCC exception, see the topic Example: Forcing OCC data collisions and JDBC mediator exceptions.

*JDBC mediator integration with presentation layer:*

The JDBC Data Mediator Service (DMS) can be used in conjunction with web application presentation layer technologies such as JavaServer Pages Standard Tag Library (JSTL) and JavaServer Faces (JSF).

This discussion assumes a general understanding of both of the JavaServer Pages Standard Tag Library (JSTL) and JavaServer Faces (JSF) technologies. In particular for JSF, the UIData component and the general file structure of a JSF dynamic web application should be known. For a brief overview of both JSF and JSTL refer to the topics under Service Data Objects.

The JDBC DMS and JSTL work well together because the JSTL access code is equivalent to the code necessary to access attributes and lists inside of a DataObject. For example, in relation to a root Customer DataObject, the JSTL expression:

```
${rootDO.CUSTOMER[index].CUSTNAME}
```

is equivalent to the Java code for a DataObject of:

```
rootDO.getList("CUSTOMER").get(index).get("CUSTNAME")
```

The reason for this is the dot notation in the JSTL expression language correlates to a *getter()* method in Java code, and the bracket notation allows you to access elements inside a list.

The JDBC DMS and JSF fit well together because the DataGraph produced by the JDBC DMS is able to populate a JSF UIData component without having to be transformed. The UIData component uses a *dataTable* tag that takes a list as its input to populate the table. This works out well with the DataGraph

because all you need to pass into the dataTable is the root list of the DataGraph. The most common way to lay out the DataGraph in the dataTable is to display each attribute of the DataObject from the list retrieved from the root in its own column, and to embed each additional relationship to the DataObject in a new dataTable contained within the parent DataObject's row. Using this method instead of a traditional ResultSet table eliminates duplicate information and makes it easier to see the separation of the parent object's children. An example of how the Customer and Order scenario is laid out in a dataTable is shown in the topic Example: Using JavaServer Faces and JDBC Mediator dataTables.

**Example: Using JavaServer Faces and JDBC Mediator dataTables.**

This example shows code that would be located inside of a Faces JSP page. It demonstrates how to use JavaServer Faces and JDBC Mediator dataTables in an application.

It contains the UIData component dataTable tag with all of the customer's information, along with their orders. Each Customer attribute has its own column. The Customer Orders are embedded in another dataTable containing each of the Order attributes in separate columns. This embedded dataTable of Orders is like any other Customer attribute, having its own column inside each Customer row.

```
<h:dataTable id="table1" value=">{pc_Customers.customer}" var=
"varcustomer" styleClass="dataTable">

  <h:column id="column1">
    <f:facet name="header">
      <h:outputText styleClass="outputText" value="Customerid" id=
        "text1"></h:outputText>
    </f:facet>
    <h:outputText id="text2" value=">{varcustomer.CUSTOMERID}"
    styleClass="outputText">
     <f:convertNumber />
    </h:outputText>
    </h:column>

  <h:column id="column2">

    <f:convertNumber />
  </h:outputText>
</h:column>

   </h:dataTable>
 </h:column>
</h:dataTable>
```

*JDBC mediator paging:*

Paging can be useful for moving through large data sets because it can limit the amount of data pulled into memory at any given time. The JDBC DMS API provides two interfaces that implement paging.

If the metadata provided to the data mediator service (DMS) defines customers and the page size is set to ten, then the first page is a DataGraph containing the first ten customer DataObjects. The next page is another DataGraph with the next ten Customers, and so forth.

One thing to note is that the JDBC DMS provides paging at the root of the graph. That is, there is no restriction on the number of related DataObjects returned. For example, if the metadata provided to the DMS defines customers and related orders, it is the customers that are paged. If the page size is set to ten, then the first page is a graph with the first 10 customers and all related orders for each customer.

There are two interfaces provided by the DMS that you can take advantage of, the **Pager** and the **CountingPager**. The Pager interface provides a cursor-like *next()* method capability. The next() function returns a graph representing the next page of data from the entire data set specified by the mediator metadata. There is also a *previous()* function available with the same capabilities, only going backward. The CountingPager interface enables you to retrieve a specific page number. The following example illustrates paging through a large set of customer instances using a CountingPager interface with a maximum of 5 DataObjects from the root table per page.

```
CountingPager pager = PagerFactory.soleInstance.createCountingPager(5);
int count = pager.pageCount(mediator);
for (int i = 1, i <= count, i++) {
DataObject graph = pager.page(i, mediator);
// Iterate through all returned customers in the
// current page.
Iterator iter = graph.getList("CUSTOMER").iterator();
 while (iter.hasNext()) {
  DataObject cust = (DataObject) iter.next();
System.out.println(cust.getString("CUSTFIRS NAME"));
 }
}
```

If you try to move before the first page or after the last available page, a JDBC mediator exception occurs.

*JDBC mediator serialization:*

The DataGraph produced by the JDBC DMS can be serialized and written out to a file, or sent across a network.

The following example illustrates serialization and de-serialization of a graph:

```
// This example assumes the creation of the Customer
// metadata and the JDBC DMS.

DataObject object = mediator.getGraph();
DataGraph origGraph = object.getDataGraph();

FileOutputStream out = new FileOutputStream("test.datagraph");
ObjectOutputStream oos = new ObjectOutputStream(out);
oos.writeObject(origGraph);
out.close();

FileInputStream in = new FileInputStream("test.datagraph");
ObjectInputStream oin = new ObjectInputStream(in);
DataGraph graph = (DataGraph) oin.readObject();
DataObject obj = (DataObject) graph.getRootObject();

// Now, the DataObject retrieved from the input stream
// obj is equal to the original variable object put
// through the output stream.
```

***Enterprise JavaBeans Data Mediator Service:***

The Enterprise JavaBeans (EJB) Data Mediator Service (DMS) is the Service Data Objects (SDO) Java interface that, given a request in the form of EJB queries, returns data as a DataGraph containing DataObjects of various types.

This is different from a typical EJB finder or ejbSelect method, which also takes an EJB query but returns a collection of EJB objects that are all of the same type or a collection of container managed persistence (CMP) values.

The EJB DMS enables you to specify an EJB query that returns a data graph (the DataGraph) of data objects (DataObjects). The query can be expressed as a compound EJB query that is contained in a string array of EJB query statements. One advantage of using a DataGraph is that much of the code written in an EJB facade session bean that creates, populates, and updates copy helper objects can be replaced with a DataGraph and a DMS.

**Important:** The EJB DMS has support for EJB2.x container managed persistence (CMP) entity beans only. It does not support EJB 3.x modules.

You can obtain a DataGraph using the getGraph call, either from EJB instances cached in the container, or the query request can be compiled into SQL and executed directly against the data source.

Updated DataObjects can be written back to the data store by using the applyChanges method in one of two ways. The updates can be translated into SQL and applied directly to the data store or can be written back through EJB accessor methods. Writing back directly to the data store can improve performance because it avoids EJB activation. However, if business logic or EJB container function is required by the application, writing back through EJB is the preferred approach. When writing back through EJB, you can specify a user-defined MediatorAdapter method to ensure customized handling of changed DataObjects. This customization can include application-specific optimistic concurrency control, invoking business methods on the EJB to perform updates, update of computed values in the DataObject, and calling application-specific create methods on EJBHome.

Update processing is not dependent on how the DataGraph was originally retrieved. In other words, it is possible to retrieve a DataGraph directly from the data source, but have the deferred updates applied through the enterprise bean or the other way around.

Regardless of which update approach you use, an optimistic concurrency control algorithm is used. Fields designated as consistency fields are read during the update to ensure that the current value is equal to the old value DataObject field.

**Runtime processing**

An EJB mediator request is a compound EJB query, which consists of an ordered list of regular EJB queries. Each query in the compound query defines an SDO. The SELECT clause of the query specifies the CMP fields or expressions to return in the DataObject. The WHERE clause specifies the filtering conditions. The first query in the list is considered to be the ROOT node in the DataGraph. The FROM clause of a query, other than the first, specifies an EJB relationship that is used to create references between DataObjects. More details about how the DataGraph schema is derived from the query can be found in the topic DataGraph schema.

*EJB data mediator service programming considerations:*

When you begin writing your applications to take advantage of the Enterprise JavaBeans (EJB) data mediator service (DMS) provided in the product, consider the following items.

**EJB programming model**

Only a subset of the EJB programming model is supported by the EJB data mediator service.

- When using EJB collection parameters to retrieve data from EJB instances, or when using applyChanges to update EJB instances:
  - The EJB DMS uses local interfaces for enterprise beans. *Getter* and *setter* calls for container-managed persistence (CMP) fields must be promoted to the local interface, as well as any EJB methods used in query expressions.
  - For the mediator to create an EJB, there must be a create method using the primary key class as the only argument method defined on the EJB home. If no such method exists, you must supply an adapter that handles the create operation. Also, the EJBLocalHome interface defined for the EJB must include (in addition to the create method) the following method:

    ```
    findByPrimaryKey(<key class>)
    remove (java.lang.Object)
    create (<key class>)
    ```
- When invoking the applyChanges method directly to the database, the following occur:
  - you bypass container update. You should force a refresh as soon as possible by transaction termination and using appropriate container cache options.

  - you bypass EJB container-managed relationship (CMR) maintenance. You must rely on database RI to maintain those relationships not retrieved into the DataGraph.
- CMP fields must be the allowed types. See “EJB mediator query syntax” on page 441 for a list of those types.
- CMP fields of user-defined types that use EJB converters/composer are not supported.

The following table shows limitations in the EJB programming model that are **not** supported by the EJB DMS.

*Table 48. EJB programming model limitations with EJB DMS. The following table shows limitations in the EJB programming model that are* **not** *supported by the EJB DMS.*

| | retrieve direct from db | retrieve from EJB Container | update direct to db | update through EJB |
|---|---|---|---|---|
| EJB persistence inheritance | No | No | No | No |
| EJB cmp field with converter | No | Yes | No | Yes |

### Transactional

- All mediator calls, including create, must be done within a transaction scope – either a user transaction or a container transaction. The various mediator calls including, create, getGraph, and applyChanges, do not have to be called within the same transaction. In fact, most often the calls are done in separate transactions.

### Access intent

- When the mediator query references an EJB using its abstract schema name (ASN), data is retrieved directly from the database. The access intent and isolation level used on the data source connection is the access intent specified in the application profile for EJB dynamic query access intent. It is recommended that you define an optimistic access intent for your application because a DataGraph is intended to be used in a disconnected programming model.
- When the mediator is retrieving data using an EJB collection, the access intent specified in the application profile is used if the EJB requires activation.
- During applyChanges, optimistic concurrency control is used to verify certain fields in the DataObject before applying changes to the database. Updates are typically processed under a different transaction from the retrieval. Therefore, to avoid lost updates it is necessary to verify that another transaction has not updated the data. When defining the EJB to RDB mapping you can specify one or more EJB fields as optimistic Predicates. The fields are used for verification by comparing the current database value to the old value from the DataGraph change log. If the verification succeeds, then the current value of the fields is written to the database. If the comparison returns false and the update fails, an exception occurs. All of this is accomplished in a single update statement with extra predicates added, such as in the following example. The optimisticPredicate field is *myColumn1*.

```
update  myTable set  myColumn1 = 'new value1', myColumn2='new value2'
where myKey= 'key value' and myColumn1 ='old value1'
```

- When applyChanges is done through the EJB container, the current values of the enterprise beans are compared with the old values of the optimistic predicates fields. If the values are unequal an exception occurs.
- Provided that you have defined one or more EJB fields as optimisticPredicates, then for the SDO to be updateable, at least one of the optmisticPredicate fields must be retrieved into the data object. Otherwise, applyChanges returns an exception. The field should be updated either by the caller or a database trigger – the mediator does not automatically increment or set the field.
- Not all fields are verified, only those fields marked as optimisticPredicate in the EJB-RDB mapping.

- Note that the EJB mapping tool allows for the possibility of no optimisticPredicate fields. In this case the mediator will perform updates without any verification.
- Creation and deletion operations do not make use of the optimistic predicate fields.
- When applying changes through EJB instances, the EJB might have to be activated first. In this case, the appropriate access intent associated with the EJB methods apply. It is recommended that you run applyChanges in a profile that has pessimistic access intent, otherwise the optimistic concurrency logic is invoked twice – once when copying data object values to the EJB, and a second time when the persistence manager compares the old values of the EJB field values against the database record.
- The access intent used by the mediator when retrieving directly from the database is the default access intent defined for the EJB named in the first query statement.

**Best practices**

- You can call getGraph on one mediator instance, update the returned DataGraph, and then call applyChanges on a different mediator instance. However, while they do not need the same mediator instance, they do need the same *query shape*. The query shape is the number and order of query statements, the fields and relationships specified in the SELECT and FROM clauses, and so on.
- Avoid repeated calls to createMediator if possible. Use parameterized queries and use getGraph to pass in different parameter values.

*EJB data mediator service data retrieval:*

An Enterprise JavaBeans (EJB) mediator request is a compound EJB query. You can obtain a DataGraph using the *getGraph* call.

**Directly from the data source**

To retrieve data directly from the data source, specify your first EJB query to reference the Abstract Schema Name (ASN) of the enterprise bean.

**From the EJB container**

To retrieve data through the EJB container, specify your first query to use an input parameter in the FROM clause referring to the EJB collection desired.

You should use this method when there is high likelihood that your EJB instances will be cached in the container. This way you avoid container flush and then read from the database to retrieve data.

For an example, see the topic Using the EJB data mediator service for data access.

*EJB data mediator service data update:*

An Enterprise JavaBeans (EJB) mediator request is a compound EJB query. You can write an updated DataGraph back to the data source by using the applyChanges method.

The update can be applied directly to the data source or through EJB instances.

When applying changes through EJB instances an optional adapter class can be specified on the applyChanges method. Each changed data object is first passed to the adapter applyChange method. The adapter can process the change itself and return **true**, or have the EJB Mediator process the change by returning **false**.

The adapter can be used to customize the optimistic concurrency (OCC) logic, or process changes to read only DataGraph attributes, or process changes that require business logic.

There are two forms of the applyChanges method. The first, *applyChanges( DataObject)* takes the updated DataGraph and runs structured query language (SQL) insert, update, and delete statements directly against the database, bypassing the EJB container. The second form, *applyChanges( DataObject, MediatorAdapter )* processes updates using EJB instances and accessors. A null value for the MediatorAdapter is supported.

**When to use an adapter with applyChanges**

- Use when there are create methods other than create(PrimaryKey)
- Use when business methods must be called instead of container-managed persistence (CMP) *setter* methods
- Use when special optimistic caching logic is needed

**How the adapter works**

Three passes are made over the DataGraph log, passing changed DataObject to the adapter:

1. New DataObjects are passed. The adapter can create the object and set the CMP fields. Container-managed relationships (CMR) that reference enterprise beans not yet created are deferred until pass 2.
2. New and updated DataObjects are passed. CMRs deferred from pass 1 can be set at this time.
3. Deleted DataObjects are passed.

*EJB mediator query syntax:*

When you begin writing your applications to take advantage of the Enterprise JavaBeans (EJB) data mediator service (DMS) provided in the product, consider the following items.

- The EJB DMS takes as an input argument a compound EJB query which consists of an array containing EJB query language (QL) statements and an optional XREL command. The XREL command is a list of EJB relationships and must appear last in the array.
- Each EJB QL query returns data in the form of a Service DataObjects (SDO) instance. All of the SDO instances are merged into a DataGraph. The SELECT clause of each query specifies the container-managed persistence (CMP) fields or expressions to return in the SDO. The WHERE clause specifies the filtering conditions and you can define an ORDER BY clause. If two or more SELECTs return the same SDO type, each SELECT must project the same CMP fields and expressions. For updatability, the primary key fields of the EJB must be projected. JOINs, UNIONs, and aggregation are not supported except in subqueries.
- A query in the array can refer to a prior query in the FROM clause by using the identification variable defined in the prior query and a relationship name. This relationship can be single or collection valued.
- Relationships are constructed between data object instances in the graph when a relationship is used in either the FROM clause or in the XREL command.
- Collection valued input arguments are supported in FROM clause If ?1 refers to a collection of Dept EJBs then the following query is valid for the mediator. The cast syntax is required to tell the query compiler the collection element type.

  ```
  select d.deptno from (Dept) ?1 as d
  ```

- The collection input argument is useful when it is desired to build a DataGraph from EJB instances that are cached in the EJB Container or persistence manager data cache.
- The SELECT clause can specify a list of CMP fields to retrieve (the wildcard * notation can be used to retrieve all CMP fields) or valid EJB query language expressions. CMP fields and expressions must be one of the following types:
  - Primitive types: boolean, byte, short, integer, long, float, double, char
  - Object wrapper types for the primitive types
  - Java.lang.String
  - Java.math.BigDecimal
  - java.math.BigInteger

  - byte [ ]
  - Java.sql.Date
  - java.sql.Time
  - java.sql.Timestamp
  - java.util.Date
  - java.util.Calendar
- All primary key CMP fields must be retrieved in order for the Service Data Objects (SDO) to be updateable; otherwise, applyChanges returns an exception.
- SDO attributes that come from EJB query language expressions such as *e.salary + e.bonus AS TOTAL_PAY* cannot be updated. If you try to make an update, applyChanges returns a QueryException.
- Aggregate expressions such as *SUM(e.salary)* are not allowed even though they are part of the EJB query language. Aggregate expressions can be used in subselects in the WHERE clause.

*XREL keyword:*

The XREL keyword is used to build relationships independent of how the data was retrieved. XREL is valid only in Enterprise JavaBeans (EJB) Mediator queries.

XREL does not retrieve additional data, it only builds relationships from data already retrieved by the select statements. The relationships can be one-to-one, one-to-many, many-to-one, or many-to-many. The relationships can be unidirectional or bidirectional. If you specify a bidirectional relationship in an XREL, the inverse relationship is also established in addition to the specified relationship.

```
xrel := XREL identification_variable . { single_valued_cmr_field | collection_valued_cmr_field }
            [ , identification_variable . { single_valued_cmr_field | collection_valued_cmr_field } ]*
```

**Examples: XREL keyword**

This example retrieves all employees and all departments, and establishes the *emps* and *mgr* relationships.

```
select e.name from EmpBean e
  select  d.name from DeptBean d
  xrel  d.emps, d.mgr
```

Notice that the employees are retrieved through d.emps relationship, xrel d.mgr is to establish the *mgr* relationship for those employees who are also a manager.

```
 select  d.name from DeptBean d
   select e.name from in(d.emps) e
   xrel  d.mgr
```

*DataGraph schema:*

**DataGraph schema created by the EJB mediator**

The schema created by the mediator for a query consists of an Eclass for each query statement. The name of the Eclass is the Abstract Schema Name (ASN) of the Enterprise JavaBeans (EJB). The Eattributes of the Eclass correspond to the container-managed persistence (CMP) fields or expressions returned by the query statement.

For static DataObjects, the Eclass name can be different provided that the Map argument is used on the createMediator call.

Each EJB relationship specified in the FROM or XREL clause adds an Ereference into the schema. EJB relationships can be unidirectional or bidirectional. However, all Ereferences are defined as bidirectional as this is needed to efficiently navigate the DataGraph on update. An inverse relationship name is generated in the case of a unidirectional EJB relationship. A generated name is of the format

<ASName_source><ASName_target>. For example, if the ASNames are EmpBean and DeptBean, and the unidirectional relationship is *dept* going from EmpBean to DeptBean, the generated inverse name is **DeptBeanEmpBean**.

If no ECLass argument is used on createMediator, then the mediator creates a DataGraph schema with the following characteristics:
- the DataObject Eclass names are the corresponding EJB Abstract Schema Names (ASN)
- the DataObject attributes names and types are the expression names and types in the query SELECT clauses
- the DataObject reference names and types come from the EJB relationships referenced in the FROM clauses.

A *dummy* DataObject with the Eclass name of *DataGraphRoot* is also created and has containment reference to all the DataObjects. The reference is multivalued, using the EJB ASN name.

```
DataObject root =  m.getGraph( parms );
root.getType().getName();   // this would return the string "DataGraphRoot"

List depts = (List) root.get("DeptBean");
// the list of all DeptBean SDOs in the DataGraph

List emps = (List) root.get("EmpBean");
// the list of all EmpBean SDOs in the DataGraph
```

**DataGraph containment patterns**

References between Service Data Objects (SDO) can be defined as containment references, in which case when an SDO is deleted the delete is cascaded to all of the contained SDO. Also, when the DataGraph is serialized as an XML document, the contained SDO are nested within the parent SDO. Noncontained references are expressed as path expressions in the XML document.

Containment must be defined in the DataGraph schema. When the mediator defines the schema, the root SDO (named *DataGraphRoot*) contains all other SDO. EJB relationships are defined as noncontained SDO references.

When the caller defines the DataGraph schema, there are three patterns.

**ROOT_CONTAINS_ALL**
: In this pattern there is a dummy SDO that is the root. It is a dummy in the sense that it does not correspond to any EJB. Its purpose is to contain all other SDOs. If the mediator generates the graph schema, the dummy root has a class name of DataGraphRoot and it will have containing references whose names are the EJB ASN names. If the caller uses static schema, the root can have any name. The Eclass of the root is passed on the createMediator call.

**ROOT_CONTAINS_SOME**
: This pattern is applicable only for static schema. There is still a dummy SDO that is the graph root. Other SDO must either be contained by the Ereference that corresponds to the EJB relationship used in the query statement or the SDO must be contained by the dummy root.

**NO_DUMMY ROOT**
: This pattern is applicable only for static schema. There is no dummy root. The root SDO corresponds to the first query statement which must return only a single instance. Non-root SDOs must be contained by the Ereference corresponding to the EJB relationship used in the query statement.

## Using the Java Database Connectivity data mediator service for data access

The following steps demonstrate how to create the metadata for a Java Database Connectivity (JDBC) data mediator service (DMS), as well as how to instantiate the DMS dataGraph.

## Procedure

1. Create the metadata factory. This can be used for creating metadata, tables, columns, filters, filter arguments, database constraints, keys, order-by objects, and relationships.

   ```
   MetadataFactory factory = MetadataFactory.eINSTANCE;
   Metadata metadata = factory.createMetadata();
   ```

2. Create the table for the metadata. You can do this two ways. Either the metadata factory can create the table and then the table can add itself to the already created metadata, or the metadata can add a new table in which case a new table is created. Because it involves fewer steps, this example uses the second option to create a table called CUSTOMER.

   ```
   Table custTable = metadata.addTable("CUSTOMER");
   ```

3. Set the root table for the metadata. Again, you can do this in two ways. Either the table can declare itself to be the root or the metadata can set its own root table. For the first option, code:

   ```
   custTable.beRoot();
   ```

   If you want to use the second option, you code:

   ```
   metadata.setRootTable(custTable)
   ```

4. Set up the columns in the table. The example table is called CUSTOMER. Each column is created using its type. The column types in the metadata can only be the types supported by the JDBC driver being used. If you have questions on which types the JDBC driver being used supports, consult the JDBC driver documentation.

   ```
   Column custID = custTable.addIntegerColumn("CUSTID");
   custID.setNullable(false);
   ```

   This example creates a column object for this column, but does not for the remainder. The reason is because this column is the primary key, and is used to set the table's primary key after the rest of the columns are added. A primary key cannot be null; therefore custID.setNullable(false) prohibits this from happening. Adding the rest of the columns:

   ```
   custTable.addStringColumn("CUSTFIRSTNAME");
   custTable.addStringColumn("CUSTLASTNAME");
   custTable.addStringColumn("CUSTSTREETADDRESS");
   custTable.addStringColumn("CUSTCITY");
   custTable.addStringColumn("CUSTSTATE");
   custTable.addStringColumn("CUSTZIPCODE");
   custTable.addIntegerColumn("CUSTAREACODE");
   custTable.addStringColumn("CUSTPHONENUMBER");

   custTable.setPrimaryKey(custID);
   ```

5. Create other tables as needed. For this example, create the Orders table. Each order is made by one Customer.

   ```
   Table orderTable = metadata.addTable("ORDER");

   Column orderNumber = orderTable.addIntegerColumn("ORDERNUMBER");
   orderNumber.setNullable(false);

   orderTable.addDateColumn("ORDERDATE");
   orderTable.addDateColumn("SHIPDATE");
   Column custFKColumn = orderTable.addIntegerColumn("CUSTOMERID");

   orderTable.setPrimaryKey(orderNumber);
   ```

6. Create foreign keys for the tables that need relationships. In this example, orders have a foreign key that points to the customer who made the order. In order to create a relationship between the two tables, you must first make a foreign key for the Orders table.

   ```
   Key custFK = factory.createKey();
   custFK.getColumns().add(custFKColumn);

   orderTable.getForeignKeys().add(custFK);
   ```

The relationship takes two keys, the parent key and the child key. Because no specific name is given, the default concatenation of CUSTOMER_ORDER is the name used for this relationship.

```
metadata.addRelationship(custTable.getPrimaryKey(), custFK);
```

The default relationship includes all customers who have orders. To get all customers, even if they do not have orders, you need this line as well:

```
metadata.getRelationship("CUSTOMER_ORDER")
                            .setExclusive(false);
```

Now that the two tables are related to one another you can add a filter to the Customer table to find customers with specific characteristics.

7. Specify any filters needed. In this example, set filters to the Customer table to find all the customers in a particular state, with a certain last name, who have made orders.

```
Filter filter = factory.createFilter();
filter.setPredicate("CUSTOMER.CUSTSTATE = ? AND CUSTOMER.CUSTLASTNAME = ?");

FilterArgument arg1 = factory.createFilterArgument();
arg1.setName("CUSTSTATE");
arg1.setType(Column.STRING);
filter.getFilterArguments().add(arg1);

FilterArgument arg2 = factory.createFilterArgument();
arg2.setName("CUSTLASTNAME");
arg2.setType(Column.STRING);
filter.getFilterArguments().add(arg2);

custTable.setFilter(filter);
```

8. Add any order by objects needed. In this example, set the order by object to sort by the customer's first name.

```
Column firstName = ((TableImpl)custTable).getColumn("CUSTFIRSTNAME");
OrderBy orderBy = factory.createOrderBy();
orderBy.setColumn(firstName);
orderBy.setAscending(true);
metadata.getOrderBys().add(orderBy);
```

This completes the creation of the metadata for this JDBC DMS.

9. Create a connection to the database. This example does not show the creation of the connection to the database; it assumes that the SDO client calls the method *connect()* that does that. See the topic,
10. Instantiate and initialize the JDBC DMS object (dataGraph). The SDO client performs these actions. For this example:

```
ConnectionWrapperFactory factory = ConnectionWrapperFactory.soleInstance;
connectionWrapper = factory.createConnectionWrapper(connect());
JDBCMediatorFactory mFactory = JDBCMediatorFactory.soleInstance;
JDBCMediator mediator = mFactory.createMediator(metadata, connectionWrapper);
DataObject parameters = mediator.getParameterDataObject();
parameters.setString("CUSTSTATE", "NY");
parameters.setString('CUSTLASTNAME', 'Smith');
DataObject graph = mediator.getGraph(parameters);
```

Now that you have the dataGraph, you can manipulate the information. The example below contains basic manipulation of data in a DataGraph object.

**Example: Manipulating data in a DataGraph object**

Using the simple DataGraph that was created during the task Using the Java Database Connectivity data meditaor service for data access, some typical data manipulation follows.

First **get the list of customers**, then for each customer **get every order**, then **print out** the customer's first name and order date. (For this example, assume that you already know the last name is Smith).

```
List customersList = graph.getList("CUSTOMER");
Iterator i = customersList.iterator();
while (i.hasNext())
{
 DataObject customer = (DataObject)i.next();
List ordersList = customer.getList("CUSTOMER_ORDER");
Iterator j = ordersList.iterator();
while (j.hasNext())
{
DataObject order = (DataObject)j.next();
System.out.print( customer.get("CUSTFIRSTNAME") + " ");
System.out.println( order.get("ORDERDATE"));
 }
}
```

Now **change** every customer with the name Will to be Matt.

```
i = customersList.iterator();
while (i.hasNext())
{
 DataObject customer = (DataObject)i.next();
 if (customer.get("CUSTFIRSTNAME").equals("Will"))
 {
  customer.set("CUSTFIRSTNAME", "Matt");
 }
}
```

**Delete** the first Customer entry.

```
((DataObject) customersList.get(0)).delete();
```

**Add** a new DataObject to the graph

```
DataObject newCust = graph.createDataObject("CUSTOMER");
newCust.setInt("CUSTID", 12345);
newCust.set("CUSTFIRSTNAME", "Will");
newCust.set("CUSTLASTNAME", "Smith");
newCust.set("CUSTSTREETADDRESS", "123 Main St.");
newCust.set("CUSTCITY", "New York");
newCust.set("CUSTSTATE", "NY");
newCust.set("CUSTZIPCODE", "12345");
newCust.setInt("CUSTAREACODE", 555);
newCust.set("CUSTPHONENUMBER", "555-5555");

graph.getList("CUSTOMER").add(newCust);
```

**Submit** the changes.

```
mediator.applyChanges(graph);
```

11. Submit the changed information to the DMS for updating the database.

## Using the EJB data mediator service for data access

The following steps use code samples to describe a simple instance of how to create the Enterprise JavaBeans (EJB) data mediator service (DMS) metadata.

### Procedure

1. A mediator instance is created using one of the create methods on the mediator factory (com.ibm.websphere.sdo.mediator.ejb.MediatorFactory) as in the following example

```
import com.ibm.websphere.sdo.mediator.ejb.Mediator;
import com.ibm.websphere.sdo.mediator.ejb.MediatorFactory;
import com.ibm.webpshere.ejbquery.QueryException;
import commonj.sdo.DataObject;

try{
 String[] query =  { "select d.deptno,d.name from DeptBean as d" };
 Mediator m = MediatorFactory.getInstance().createMediator( query, null);
 DataObject root = m.getGraph();
} catch (QueryException e) { ... }
```

2. There are 3 different forms of the createMediator method. The arguments are explained as follows:

```
createMediator( query, parms)
createMediator( query, parms, schema )
createMediator( query, parms, schema,  typeMap,  pattern)
```

*Table 49. createMediator method arguments. The arguments are explained in the following table:*

| | | |
|---|---|---|
| String | query | array of EJB query statements |
| Object | parms | values for input parameters of the query statements |
| Eclass* | schema | the EClass of the root DataObject |
| Map* | typeMap | a java.util.Map that maps EJB Abstract Schema Names from the query statement into Eclass names |
| int* | pattern | the pattern used for containment |
| | | |
| * used only when using caller provided schema | | |

## Example

### Using query arguments with EJB mediator.

The following examples show how you can fine-tune your Enterprise JavaBeans (EJB) mediator query arguments.

#### A simple example

This query returns a DataGraph containing multiple instances of DataObjects of type (Eclass name) *Emp*. The data object attributes are *empid* and *name* and their data types correspond to the container-managed persistence (CMP) field types.

```
select  e.empid, e.name
from Emp as e
where e.salary > 100
```

The returned DataGraph serialized in its XML format looks like this:

```
  <?xml version="1.0" encoding="ASCII"?>
<datagraph:DataGraphSchema xmlns:datagraph="datagraph.ecore">
<root>
<Emp empid="1003" name="Eric" />
<Emp empid="1004" name="Dave" />
</root>
</datagraph:DataGraphSchema>
```

#### Query parameters

This example shows how parameter markers can be used. Recall that the syntax for parameter markers in an EJB query is a question mark followed by a number (?n). When calling the getGraph ( ) method on the EJBMediator, you can optionally pass an array of values. ?n refers to the value of parm[n-1]. The array of values can also be passed on the factory call to create the EJBMediator. Parameters passed on the getGraph( ) override any parameters passed on the create call.

```
select  e.empid, e.name
from Emp as e
where e.salary > ?1
```

#### Returning expressions and methods

This example illustrates that the data object attributes can be the return values of query expressions. EJB query expressions include arithmetic, date-time, path expressions, and methods. Input arguments and return values from methods are restricted to the list of supported data types see the topic EJB mediator query syntax. A data object containing an

updated attribute derived from an expression causes an exception to occur during the applyChanges process unless the user has provided a MediatorAdapter to handle the change.

```
select  e.empid as employeeId,
  e.bonus+e.salary as totalPay,
  e.dept.mgr.name as managerNam,
  e.computePension( ) as pension
from Emp as e
where e.salary > 100
```

Data object attribute names are derived from the CMP field names but can be overridden by using the *AS* keyword in the query. When specifying an expression, the *AS* keyword should always be used to give a name to the expression.

**The * syntax**

The notation *e.** is a short cut for specifying all the CMP fields (but not container-managed relationships) for an EJB. The following query means the same thing as *e.empid, e.name e.salary, e.bonus*.

```
select e.* from Emp as e
```

**No primary key in select clause**

This example shows a query that does not return the primary key field. However, unless the data object contains all the primary key fields for an EJB, updates to the DataGraph cannot be processed by the mediator. This is because the primary key is required to translate the changes into structured query language (SQL), or to convert DataObject references to EJB references. An exception when applyChanges tries to run.

```
select e.name, e.salary from Emp as e
```

**Order by**

DataObjects can be ordered.

```
select d.* from Dept d  order by d.name
 select e.* from in(d.emps) e order by e.empid desc
```

This results in the *Dept* objects being ordered by name and the *Emp* objects within each *Dept* being order by *empid* in descending order.

**Navigating a multi-valued relationship**

This compound query returns a DataGraph with DataObject classes *Dept* and *Emp*. The shape of the DataGraph reflects the path expressions used in the FROM clauses.

```
select d.deptno, d.name, d.budget from Dept d
   where d.deptno < 10
select e.empid, e.name, e.salary  from in(d.emps) e
   where e.salary > 10
```

In this case *Dept* is the root node in the DataGraph and there is a multivalued reference from *Dept* to *Emp* as shown:

```
<?xml version="1.0" encoding="ASCII" ?>
<datagraph:DataGraphSchema xmlns:datagraph="datagraph.ecore">
<root>
<Dept deptno="1" name="WAS_Sales" budget="500.0"
   emps="//@root/@Emp.1 //@root/@Emp.0" />
<Dept deptno="2" name="WBI_Sales" budget="450.0"
   emps="//@root/@Emp.3 //@root/@Emp.2" />
<Emp empid="1001" name="Rob" salary="100.0" EmpDept="//@root/@Dept.0" />
<Emp empid="1002" name="Jason" salary="100.0" EmpDept="//@root/@Dept.0" />
```

```
<Emp empid="1003" name="Eric" salary="200.0" EmpDept="//@root/@Dept.1" />
<Emp empid="1004" name="Dave" salary="500.0" EmpDept="//@root/@Dept.1" />
</root>
</datagraph:DataGraphSchema>
```

### More on query parameters

Search conditions can be specified on any query. Input arguments are global to the query and can be referenced by number anywhere in the compound query. In the example above, the query arguments passed on the create or getGraph call should be in order { deptno value, salary value, deptno value }.

```
select d.* from Dept as d
   where d.deptno between ?1 and ?3
select e.* from in(d.emps) e
   where e.salary < ?2
```

### Navigating a path with multiple relationships

The following query navigates the path composed of EJB relationships Dept.projs and Project.tasks and returns DataObjects for Dept, Emp and Project containing selected CMP fields.

```
select d.deptno, d.name from Dept as d
select p.projid  from in(d.projects) p
select t.taskid, t.cost from  in (p.tasks) t
```

The resulting data graph in XML format is shown here.

```
<?xml version="1.0" encoding="ASCII" ?>
<datagraph:DataGraphSchema xmlns:datagraph="datagraph.ecore">
<root>
<Dept deptno="1" name="WAS_Sales" projects="//@root/@Project.0" />
<Dept deptno="2" name="WBI_Sales" projects="//@root/@Project.1" />
<Project projid="1" ProjectDept="//@root/@Dept.0"
      tasks="//@root/@Task.0   //@root/@Task.2 //@root/@Task.1" />
<Project projid="2" ProjectDept="//@root/@Dept.1"
      tasks="//@root/@Task.3" />
<Task taskid="1" cost="50.0" TaskProject="//@root/@Project.0" />
<Task taskid="2" cost="60.0" TaskProject="//@root/@Project.0" />
<Task taskid="3" cost="900.0" TaskProject="//@root/@Project.0" />
<Task taskid="7" cost="20.0" TaskProject="//@root/@Project.1" />
</root>
</datagraph:DataGraphSchema>
```

### Navigating multiple paths

Here is a mediator query returning a DataGraph with DataObjects for Dept with related employees and a second path that retrieves related projects and tasks.

```
select d.deptno, d.name from Dept d
select e.empid, e.name  from in(d.emps) e
select p.projid from in(d.projects) p
select t.taskid, t.cost from in(p.tasks) where t.cost > 10
```

The returned DataGraph looks like this:

```
<?xml version="1.0" encoding="ASCII" ?>
    <datagraph:DataGraphSchema xmlns:datagraph="datagraph.ecore">
    <root>
        <Dept deptno="1" name="WAS_Sales" projects="//@root/@Project.0"
 emps="//@root/@Emp.1 //@root/@Emp.0" />
        <Dept deptno="2" name="WBI_Sales" projects="//@root/@Project.1"
     emps="//@root/@Emp.3 //@root/@Emp.2" />
        <Project projid="1" ProjectDept = "//@root/@Dept.0"
     tasks="//@root/@Task.0 //@root/@Task.2 //@root/@Task.1" />
        <Project projid="2" ProjectDept="//@root/@Dept.1" tasks="//@root/@Task.3" />
      <Task taskid="1" cost="50.0" TaskProject="//@root/@Project.0" />
        <Task taskid="2" cost="60.0" TaskProject="//@root/@Project.0" />
```

```
        <Task taskid="3" cost="900.0" TaskProject="//@root/@Project.0" />
        <Task taskid="7" cost="20.0" TaskProject="//@root/@Project.1" />
        <Emp empid="1001" name="Rob" EmpDept="//@root/@Dept.0" />
        <Emp empid="1002" name="Jason" EmpDept="//@root/@Dept.0" />
         <Emp empid="1003" name="Eric" EmpDept="//@root/@Dept.1" />
         <Emp empid="1004" name="Dave" EmpDept="//@root/@Dept.1" />
  </root>
  </datagraph:DataGraphSchema>
```

### Navigating a single valued relationship

The important thing to point out here is that even though Emp is the root data object in the graph, multiple Emp data objects will be related to the same Dept data object. So unlike the previous examples, the data graph does not have a tree shape when you look at the data object instances – there are multiple root Emp objects related to the same Dept object. But then after all it is a data graph, not a data tree. Note that mediator queries allow single valued path expressions in the FROM clause. This is a change from the standard EJB query syntax.

```
select e.empid, e.name  from Emp e
select d.deptno, d.name  from in(e.dept) d
```

And the DataGraph in XML format looks like:

```
<?xml version="1.0" encoding="ASCII" ?>
   <datagraph:DataGraphSchema xmlns:datagraph="datagraph.ecore">
   <root>
   <Emp empid="1001" name="Rob" dept="//@root/@Dept.0" />
   <Emp empid="1002" name="Jason" dept="//@root/@Dept.0" />
   <Emp empid="1003" name="Eric" dept="//@root/@Dept.1" />
   <Emp empid="1004" name="Dave" dept="//@root/@Dept.1" />
   <Dept deptno="1" name="WAS_Sales"
DeptEmp="//@root/@Emp.1 //@root/@Emp.0" />
   <Dept deptno="2" name="WBI_Sales"
 DeptEmp="//@root/@Emp.3 //@root/@Emp.2" />
 </root>
 </datagraph:DataGraphSchema>
```

### Path expressions in the SELECT clause

This query is similar to the preceding one (both queries return employee data along with department number and name) but note the data graph contains only one data object type in this query (vs. two in the previous query). The fields deptno and name field are read only because they are result of a path expression in the SELECT clause and are not CMP fields of the Emp EJB.

```
select  e.empid as EmplId , e.name as EmpName ,
   e.dept.deptno as DeptNo , e.dept.name as DeptName
from Emp as e
```

### Navigating a many: many relationship

The Emp to Task relationship is deemed a *many:many* relationship. The following query retrieves employees, tasks, and projects. There is only a single occurrence of any particular task DataObject in the DataGraph, even though it can be related to many employees.

```
select e.empid, e.name from Emp as e
select t.taskid, t.description from in(e.tasks) as t
select p.projid, p.cost from in(t.proj) as p
```

### Multiple links between data objects

The EJB mediator enables you to retrieve data based on relationships and use the XREL command to construct one or more additional relationships based on data already retrieved. The mediator also enables retrieval of data based on ASNname and then construction of one or more relationships based on the data retrieved using the XREL

command. The following query retrieves departments, employees that work in the departments, and the employees that manage the departments.

```
select d.deptno, d.name from Dept d where d.name like '%Dev%'
select e.empid, e.name from in (d.emps) as e
select m.empid, m.name from in(d.manager) as m
```

The second and third *select* clauses both return instances of Emp DataObject. It is possible that the same Emp instance is retrieved through the d.emps relationship and the d.manager relationship. The EJB mediator creates one Emp instance, but creates both relationships.

The following query is processed as follows. Dept DataObjects are created from the data in the first query. Emp DataObjects are created from the data in the second query. Relationships in the graph are then constructed for any relationship used in either the FROM clause or an XREL keyword. During relationship construction, no additional data is retrieved. In this example, an employee who works in a department named *Dev* appears in the DataGraph. If this employee manages a department called *Sales*, the *manages* reference is empty. The Dev department was retrieved in the first query, not the Sales department.

```
select d.deptno, d.name from Dept d where d.name like '%Dev%'
select e.empid, e.name from in (d.emps) as e
xrel d.manager
```

The emps and manager relationship are constructed based on the DataObject instances created from the queries. An employee whose name is ‘Dev' but works in department ‘Sales' will have a null dept relationship in the graph.

```
select d.deptno, d.name from Dept d where d.name like '%Dev%'
select e.empid, e.name from Emp e where e.name like 'Dev%'
xrel d.emps, d.manager
```

The next example shows the retrieval of data objects for all the employees, projects, and tasks for a given department, and the linkage of employees with tasks.

```
select d.deptno from Dept d where d.deptno = 42
select e.empid from in(d.emps) e
select p.projid from in(d.projs) p
select t.* from in(p.tasks) t
  xrel e.tasks
```

If a task is assigned to an employee in department 42 then that link appears in the data graph. If the task is assigned to an employee not in department 42, then that link does not appear in the data graph because the data object was filtered out by the query. An XREL keyword can be followed by one or more EJB relationships. Bidirectional relationships can refer to either role name. Both source and target of the relationship must be retrieved by one or more queries.

**Retrieving unrelated objects**

The following query retrieves Dept and Task.

```
select d.deptno, d.name from Dept d where d.name like '%Dev%'
select t.taskid, t.startDate from Task t where t.startDate > '2005'
```

The following query retrieves Dept and Emps. Even though there are relationships between Dept and Emp (namely mgr and emps), neither relationship is used in FROM or XREL and so the resulting graph does not contain the relationship values.

```
select d.deptno, d.name from Dept d where d.name like '%Dev%'
select e.empid, e.name from Emp e where e.dept.name like '%Dev%'
```

**Retrieving null or empty relationships**

This query returns departments that have no employees and employees with no department. Presumably the application wants to assign the employees to one of the departments. The purpose of xrel is to define the e.dept relationship (and the inverse role d.emps) into the graph schema.

```
select d.deptno, d.name from Dept d where d.emps is empty
select e.empid, e.name from Emp e where e.dept is null
xrel e.dept
```

### Collection Input parameter

A collection of enterprise beans can be passed as an input argument to the ejb mediator and referenced in the FROM clause. Using a collection parameter satisfies the requirement to construct a data graph from a user collection of already activated enterprise beans.

```
select d.deptno, d.name from ((Dept) ?1) as d
select e.empid, e.name from in(d.emps) as e where e.salary > 10
```

The above query iterates through the collection of Dept beans and related Emp beans applying the query predicates and constructing the data graph. Values will be obtained from current values of the beans. An example of a program using an ejb collection parameter.

```
// this method runs in an EJB context and within a transaction scope
public DataGraph myServiceMethod() {
      InitialContext ic = new InitialContext();
      DeptLocalHome deptHome = ic.lookup("java:comp/env/ejb/Dept");
      Integer deptKey = new Integer(10);
      DeptEJB dept = deptHome.findByPrimaryKey( deptKey));
      Iterator i = dept.getEmps().iterator();
      while (i.hasNext()) {
       EmpEJB e = (EmpEJB)i.next();
       e.setSalary( e.getSalary() * 1.10); // give everyone a 10% raise
      }

      // create the query collection parameter
      Collection c = new LinkedList();
      c.add(dept);
      Object[] parms = new Object[] { c};  // put ejb collection in parm array.

      // collection containing the dept EJB is passed to EJB Mediator

      String[] query = new String[]
          { "select d.deptno, d.name from ((Dept)?1 ) as d",
             "select e.empid, e.name, e.salary " +
                 " from in (d.employees) as e",
            "select p.projno, p.name from in (d.projects) as p" };

      Mediator m = EJBMediatorFactory.getInstance().createMediator(
 query, parms);
      DataGraph dg = m.getGraph();
      return dg;
      // the DataGraph contains the updated and as yet uncommitted
//  salary information.  Dept and Emp data
      // is fetched through EJB instances active in the EJBContainer.
      //  Project data is retrieved from database using
      //   container managed relationships.
   }
```

### Using MediatorAdapter

In this example, the adapter processes CREATE events for an EMP data object. The name and salary attributes are extracted from the data object and passed to the create method on the EmpLocalHome.

The create method returns an instance of Emp EJB and the primary key value is copied back to the DataObject. The caller can then obtain the generated key value. After processing, the adapter returns a value of **true**. All other changes are ignored by the adapter and processed by the EJB Mediator.

```
package com.example;
import com.ibm.websphere.sdo.mediator.ejb.*;
import javax.naming.InitialContext;
import commonj.sdo.ChangeSummary;
import commonj.sdo.DataObject;
import commonj.sdo.DataGraph;
import commonj.sdo.ChangeSummary;

// example of Adapter class calling a EJB create method.

public class SalaryAdapter implements MediatorAdapter{

 ChangeSummary log = null;
      EmpLocalHome empHome = null;

 public boolean applyChange(DataObject object,  int phase){

  if (object.getType().getName().equals("Emp")
       && phase == MediatorAdapter.CREATE){
   try{
    String name = object.getString("name");
    double salary = object.getDouble("salary");
    EmpLocal emp = empHome.create(name, salary);
    object.set("empid", emp.getPrimaryKey() ); // set primary key in SDO
    return true;
   } catch(Exception e){ // error handling code goes here
                  }
  }
  return true;
 }

 public void init (ChangeSummary log){
         try {
  this.log = log;
  InitialContext ic = new InitialContext();
  empHome = (EmpLocalHome)ic.lookup( "java:comp/env/ejb/Emp");
         } catch (Exception e) { // error handling code goes here
         }
 }

 public void end(){}
}
```

## Developing a custom DataStoreHelper class

Apply the WebSphere extension, GenericDataStoreHelper class, to create your own data store helper for data sources that the application server does not support. With this helper class, your JDBC configuration can use database-specific functions during transactions.

### Before you begin

If you are using a configuration with a data source that is not supported by the application server, you might want to create a custom data store helper. This helper will allow you to leverage the database to perform functions during a transaction that would not otherwise be available. You will need to create a user-defined DataStoreHelper class, and there is information for creating a new exception handler to catch any exceptions that might be created with the use of your custom data handler.

## About this task

**Note:** The CUSTOM_HELPER constant field in the com.ibm.websphere.rsadapter.DataStoreHelper class API is deprecated. If you create your own DataStoreHelper implementation class, do not invoke setHelperType(DataStoreHelper.CUSTOM_HELPER). Instead, let the HelperType value be set by the implementation class from which it inherits.

## Procedure

1. Create a class that extends the existing data store helpers. Use the following code as an example; this type of data source is based on a user-defined JDBC provider:

```
package com.ibm.websphere.examples.adapter;

import java.sql.SQLException;
import javax.resource.ResourceException;

import com.ibm.websphere.appprofile.accessintent.AccessIntent;
import com.ibm.websphere.ce.cm.*;
import com.ibm.websphere.rsadapter.WSInteractionSpec;

/**
* Example DataStoreHelper class, demonstrating how to create a user-defined DataStoreHelper.
* The implementation for each method is provided only as an example.  More detail is probably
* required for any custom DataStoreHelper that is created for use by a real application.
* In this example, we will override the doStatementCleanup(),getIsolationLevel(), and set userDefined
* exception map.
*/
public class ExampleDataStoreHelper extends com.ibm.websphere.rsadapter.GenericDataStoreHelper
{

    public ExampleDataStoreHelper(java.util.Properties props)
    {
        super(props);

        // Update the DataStoreHelperMetaData values for this helper.
        getMetaData().setGetTypeMapSupport(false);

        // Update the exception mappings for this helper.
        java.util.Map xMap = new java.util.HashMap();

        // Add an Error Code mapping to StaleConnectionException.
        xMap.put(new Integer(2310),  StaleConnectionException.class);
        // Add an Error Code mapping to DuplicateKeyException.
        xMap.put(new Integer(1062),  DuplicateKeyException.class);
        // Add a SQL State mapping to the user-defined ColumnNotFoundException
        xMap.put("S0022",            ColumnNotFoundException.class);
        // Undo an inherited StaleConnection SQL State mapping.
        xMap.put("S1000",            Void.class);

        setUserDefinedMap(xMap);

        // If you are extending a helper class, it is
        // normally not necessary to issue 'getMetaData().setHelperType(...)'
        // because your custom helper will inherit the helper type from its
        //  parent class.

         }

    public void doStatementCleanup(java.sql.PreparedStatement stmt) throws SQLException
    {
        // Clean up the statement so it may be cached and reused.

        stmt.setCursorName("");
        stmt.setEscapeProcessing(true);
        stmt.setFetchDirection(java.sql.ResultSet.FETCH_FORWARD);
        stmt.setMaxFieldSize(0);
        stmt.setMaxRows(0);
        stmt.setQueryTimeout(0);
    }

    public int getIsolationLevel(AccessIntent intent) throws ResourceException
    {
        // Determine an isolation level based on the AccessIntent.

        // set WebSphere default isolation level to TRANSACTION_SERIALIZABLE.
        if (intent == null) return java.sql.Connection.TRANSACTION_SERIALIZABLE;

        return intent.getConcurrencyControl() == AccessIntent.CONCURRENCY_CONTROL_OPTIMISTIC ?
               java.sql.Connection.TRANSACTION_READ_COMMITTED :
               java.sql.Connection.TRANSACTION_REPEATABLE_READ;
    }
```

```
        public int getLockType(AccessIntent intent) {
           if ( intent.getConcurrencyControl() == AccessIntent.CONCURRENCY_CONTROL_PESSIMISTIC) {
              if ( intent.getAccessType() == AccessIntent.ACCESS_TYPE_READ ) {
                  return WSInteractionSpec.LOCKTYPE_SELECT;
              }
              else {
                  return WSInteractionSpec.LOCKTYPE_SELECT_FOR_UPDATE;
               }
           }
           return WSInteractionSpec.LOCKTYPE_SELECT;
        }
}
```

2. Optional: Create your own exception handler class. Use the following code as a guide:

```
package com.ibm.websphere.examples.adapter;

import java.sql.SQLException;
import com.ibm.websphere.ce.cm.PortableSQLException;

/**
* Example PortableSQLException subclass, which demonstrates how to create a user-defined
* exception for exception mapping.
*/
public class ColumnNotFoundException extends PortableSQLException
{
    public ColumnNotFoundException(SQLException sqlX)
    {
        super(sqlX);
    }
}
```

3. Compile the newly created DataStoreHelper class or classes. You will need the following JAR files in your classpath to compile them:
   - *app_server_root*/dev/JavaEE/j2ee.jar
   - *app_server_root*/dev/was_public.jar

     **Note:** was_public.jar contains classes from *app_server_root*/lib/rsahelpers.jar that are needed to compile a custom DataStoreHelper class.
   - *app_server_root*/plugins/com.ibm.ws.runtime.jar
   - If you are using a development environment, such as Eclipse, you need to set the above JAR files in your classpath to be able to compile. Then, create a JAR file of the project after you have finished editing your files (see the help documentation for your development environment for specific instructions).
   - If you do not have development environment, and you are using the javac compiler:
     a. Create your .java file that extends the GenericDataStoreHelper or any other data store helper, as shown in Step 1.
     b. Change to your home directory after you are done editing your file or files in the command line utility.
     c. Set the classpath using this command:

        Windows

```
set CLASSPATH=%CLASSPATH%;app_server_root\dev\JavaEE\j2ee.jar;app_server_root\dev\was_public.jar;app_server_root\plugins\com.ibm.ws.runtime.jar
```

        AIX HP-UX Linux Solaris

```
set CLASSPATH=$CLASSPATH:app_server_root/dev/JavaEE/j2ee.jar:app_server_root/dev/was_public.jar:app_server_root/plugins/com.ibm.ws.runtime.jar
```

     d. Compile your class or classes. For example, on Windows operating systems enter the following command (this will compile all the .java files in the directory that you specify):

        ```
        C:\javac your_directory\*.java
        ```

     e. From the Java directory, create a JAR file of all the compiled class files in your directory. For example, enter the following command on Windows operating systems (change *myFile* to the name you want for your JAR file):

        ```
        C:\Java> jar cf myFile.jar *.class
        ```

        For more information on using the javac compiler go to the website for the Java compiler at Sun Microsystems.

4. Place your compiled JAR files in a directory, and update the class path for the JDBC provider to include that location. For example, if your JAR file is `c:\myFile.jar`, then make sure to modify the JDBC class path to include c:\myFile.jar.
   a. Click **Resources** > **JDBC** > **JDBC Providers** > ***JDBC_provider***.
   b. In the **Class path** field, add the location of the JAR files that you compiled. For example, press ENTER in the field and add a new line:
      ```
      c:\myFile.jar
      ```
5. Configure the application server to use your new custom DataStoreHelper class.
   a. From the administrative console select **Resources** > **JDBC** > **Data Sources**.
   b. Select the data source that you want to configure with your custom DataStoreHelper class.
   c. In the section labeled **Data store helper class name**, select **Specify a user-defined data store helper**.
   d. Enter the class name for the data store helper that you created.
   e. Apply your changes and select **OK**.

## Example: Setting client information with the setClientInformation(Properties) API

You can set WebSphere Application Server client information on connections to pass that information to your database with this API.

The following example code calls setClientInformation(Properties) on the com.ibm.websphere.rsadapter.WSConnection object.

```
import com.ibm.websphere.rsadapter.WSConnection;
.....
try {
   InitialContext ctx = new InitialContext();
   //Perform a naming service lookup to get the DataSource object.
   DataSource ds = (javax.sql.DataSource)ctx.lookup("java:comp/jdbc/myDS");
  }catch (Exception e) {System.out.println("got an exception during lookup: " + e);}

  WSConnection conn = (WSConnection) ds.getConnection();
  Properties props = new properties();
  props.setProperty(WSConnection.CLIENT_ID, "user123");
  props.setProperty(WSConnection.CLIENT_LOCATION, "127.0.0.1");
  props.setProperty(WSConnection.CLIENT_ACCOUNTING_INFO, "accounting");
  props.setProperty(WSConnection.CLIENT_APPLICATION_NAME, "appname");
  props.setProperty(WSConnection.CLIENT_OTHER_INFO, "cool stuff");
  conn.setClientInformation(props);
  conn.close()
```

### Parameters

**props** contains the client information to be passed. Possible values are:

- WSConnection.CLIENT_ACCOUNTING_INFO
- WSConnection.CLIENT_LOCATION
- WSConnection.CLIENT_ID
- WSConnection.CLIENT_APPLICATION_NAME
- WSConnection.CLIENT_OTHER_INFO
- WSConnection.OTHER_CLIENT_TYPE

Refer to the WSConnection documentation for more details on which client information is passed to the backend database. To reset the client information, call the method with a null parameter.

### Exceptions

This API creates an SQL exception if the database issues an exception when setting the data.

Passing client info to a db cdat_clientinfo

## Changing the error detection model to use the Exception Checking Model

The error detection model has been expanded and the data source has a configuration option that you can use to select the exception mapping model or the exception checking model for error detection. This configuration option allows the Error Detection Model to comply with Java Database Connectivity (JDBC) 4.0.

### About this task

By default, the exception mapping Error Detection Model configuration is selected. The exception mapping Error Detection Model replaces some exceptions raised by the JDBC driver. Exception checking does not do this. If you want to use this configuration, no changes are needed. If you want to use the exception checking model, you need to configure the error detection model in the application server. If you previously changed the **Error Detection Model**, you can also use these steps to change the configuration back to using to the exception mapping model.

### Procedure

1. Open the administrative console.
2. Go to the **WebSphere Application Server Data Source properties** panel for the data source.
   a. Select **Resources** > **JDBC** > **Data Sources** > ***data_source***
   b. Select **WebSphere Application Server Data Source properties**.
3. In the **Error Detection Model** section, click **Use the WebSphere Application Server Exception Checking Model**.

## Exceptions pertaining to data access

All enterprise bean container-managed persistence (CMP) beans under the Enterprise JavaBeans (EJB) 2.x specification receive a standard EJB exception when an operation fails. Java Database Connectivity (JDBC) applications receive a standard SQL exception if any JDBC operation fails. The product provides special exceptions for its relational resource adapter (RRA), to indicate that the connection currently held is no longer valid.

- The connection wait timeout exception indicates that the application has waited for the number of seconds specified by the connection timeout setting and has not received a connection. This situation can occur when the pool is at maximum size and all of the connections are in use by other applications for the duration of the wait. In addition, there are no connections currently in use that the application can share because either the connection properties do not match, or the connection is in a different transaction.

  For a Version 4.0 data source, the ConnectionWaitTimeout object creates an exception that is instantiated from the com.ibm.ejs.cm.pool.ConnectionWaitTimeoutException class.

  For Java 2 Connector (J2C) connection factories, the ConnectionWaitTimeout object generates a resource exception of the com.ibm.websphere.ce.j2c.ConnectionWaitTimeoutException class.

  When the error detection model is configured to exception mapping, later versions of data sources issue an SQL exception of the com.ibm.websphere.ce.cm.ConnectionWaitTimeoutException subclass. When the error detection model is configured to exception checking, later versions of data sources issue an SQL exception of the java.sql.SQLTransientConnectionException class with a chained exception of the com.ibm.websphere.ce.cm.ConnectionWaitTimeoutException class.

- When the error detection model is configured to exception mapping, the stale connection exception indicates that the connection is no longer valid. When the error detection model is configured to exception checking, the JDBC driver raises a JDBC 4.0 exception, such as java.sql.SQLRecoverableException or java.sql.SQLNonTransientConnectionException, or the JDBC driver specifies an appropriate SQLState to indicate that the connection is no longer valid. Read the topic Stale connections for more information about this type of exception.

**Note:** The userDefinedErrorMap custom property overlays existing entries in the error map by starting the DataStoreHelper.setUserDefinedMap method. You can use the custom property to add, change, or remove entries from the error map.

- Entries are delimited by a ; (semicolon).
- Each entry consists of a key and value, where the key is an error code (numeric value) or SQLState, which is text enclosed in quotation marks.
- Keys and values are separated by the = (equals sign).

For example, to remove the mapping of SQLState S1000, add a mapping of error code 1062 to duplicate key, and add a mapping of SQLState 08004 to stale connection, you can specify the following value for userDefinedErrorMap:

```
"S1000"=;1062=com.ibm.websphere.ce.cm.DuplicateKeyException;"08004"=
com.ibm.websphere.ce.cm.StaleConnectionException
```

userDefinedErrorMap can be located in the administrative console by selecting the data source and configuring the custom properties.

## Stale Connections

The product provides a special subclass of the java.sql.SQLException class for using connection pooling to access a relational database. This com.ibm.websphere.ce.cm.StaleConnectionException subclass exists in both a WebSphere 4.0 data source and in the most recent version data source that use the relational resource adapter. This class serves to indicate that the connection currently held is no longer valid.

This situation can occur for many reasons, including the following:

- The application tries to get a connection and fails, as when the database is not started.
- A connection is no longer usable because of a database failure. When an application tries to use a previously obtained connection, the connection is no longer valid. In this case, all connections currently in use by the application can get this error when they try to use the connection.

- The connection is orphaned (because the application had not used it in at most two times the value of the unused timeout setting) and the application tries to use the orphaned connection. This case applies only to Version 4.0 data sources.
- The application tries to use a JDBC resource, such as a statement, obtained on a stale connection.
- A connection is closed by the Version 4.0 data source auto connection cleanup feature and is no longer usable. Auto connection cleanup is the standard mode in which connection management operates. This mode indicates that at the end of a transaction, the transaction manager closes all connections enlisted in that transaction. This enables the transaction manager to ensure that connections are not held for excessive periods of time and that the pool does not reach its maximum number of connections prematurely.

  A negative ramification does ensue, however, when the transaction manager closes the connections and returns the connection to the free pool after a transaction ends. An application cannot obtain a connection in one transaction and try to use it in another transaction. If the application tries this connection, a stale connection exception occurs because the connection is already closed.

If you are trying to use an orphaned connection or a connection that is made unavailable by auto connection cleanup, a stale connection exception indicates that the application has attempted to use a connection that is already returned to the connection pool. It does not indicate an actual problem with the connection. However, other cases of a stale connection exception indicate that the connection to the database has gone bad, or stale. Once a connection has gone stale, you cannot recover it, and you must completely close the connection rather than returning it to the pool.

**Detecting stale connections**

When a connection to the database becomes stale, operations on that connection result in an SQL exception from the JDBC driver. Because an SQL exception is a rather generic exception, it contains state and error code values that you can use to determine the meaning of the exception. However, the meanings of these states and error codes vary depending on the database vendor. The connection pooling run time maintains a mapping of which SQL state and error codes indicate a stale connection exception for each database vendor supported. When the connection pooling run time catches an SQL exception, it checks to see if this SQL exception is considered a stale connection exception for the database server in use.

**Recovering from stale connections**

An application can catch a stale connection exception, depending on the type of error detection model that is configured on the data source:

- When the error detection model is configured to exception mapping, the application server replaces the exception that is raised by the JDBC driver with StaleConnectionException. In this case, the application might trap for a stale connection exception.
- When the error detection model is configured to exception checking, the application server still consults the error map in order to manage the connection pool, but it does not replace the exception. In this case, the application should not trap for a stale connection exception.

Because of the differences between error detection models, the application server provides an API that applications can use with either case to identify stale connections. The API is com.ibm.websphere.rsadapter.WSCallHelper.getDataStoreHelper(datasource).isConnectionError(sqlexception).

Applications are not required to explicitly identify a stale connection exception. Applications are already required to catch the java.sql.SQLException, and the stale connection exception or the exception that is raised by the JDBC driver, always inherits data from the java.sql.SQLException. The stale connection exception, which can result from any method that is declared to raise SQLException, is caught automatically in the general catch-block. However, explicitly identifying a stale connection exception makes it possible for an application to recover from bad connections. When application code identifies a stale

connection exception, it should take explicit steps to recover, such as retrying the operation under a new transaction and new connection.

## Example: Handling data access exception - stale connection

These code samples demonstrate how to programmatically address stale connection exceptions for different types of data access clients in different transaction scenarios.

When an application receives a stale connection exception on a database operation, it indicates that the connection currently held is no longer valid. Although it is possible to get an exception for a stale connection on any database operation, the most common time to see a stale connection exception issued is after the first time the connection is retrieved. Because connections are pooled, a database failure is not detected until the operation immediately following its retrieval from the pool, which is the first time communication to the database is attempted. It is only when a failure is detected that the connection is marked stale. The stale connection exception occurs less often if each method that accesses the database gets a new connection from the pool.

Many stale connection exceptions are caused by intermittent problems with the network of the database server. Obtaining a new connection and retrying the operation can result in successful completion without exceptions. In some cases it is advantageous to add a small wait time between the retries to give the database server more time to recover. However, applications should not retry operations indefinitely, in case the database is down for an extended time.

**Note:** If you are developing applications for the Application Server with an integrated development environment (IDE) like Eclipse, you might must import the *app_server_root*/plugins/com.ibm.ws.runtime.jar file into the development environment to take advantage of code that is provided.

Before the application can obtain a new connection for a retry of the operation, roll back the transaction in which the original connection was involved and begin a new transaction. You can break down details on this action into the following two categories:

**Objects operating in a bean-managed global transaction context begun in the same method as the database access**

A servlet or session bean with bean-managed transactions (BMT) can start a global transaction explicitly by calling *begin()* on a *javax.transaction.UserTransaction* object, which you can retrieve from naming or from the bean *EJBContext* object. To commit a bean-managed transaction, the application calls *commit()* on the *UserTransaction* object. To roll back the transaction, the application calls *rollback()*. Entity beans and non-BMT session beans cannot explicitly begin global transactions.

If an object that explicitly started a bean-managed transaction receives a stale connection exception on a database operation, close the connection and roll back the transaction. At this point, the application developer can decide to begin a new transaction, get a new connection, and retry the operation.

The following code fragment shows an example of handling stale connection exceptions in this scenario:

```
//get a userTransaction
javax.transaction.UserTransaction tran = getSessionContext().getUserTransaction();
//retry indicates whether to retry or not
//numOfRetries states how many retries have
// been attempted
boolean retry = false;
int numOfRetries = 0;
java.sql.Connection conn = null;
java.sql.Statement stmt = null;
do {
  try {
    //begin a transaction
    tran.begin();
```

```
    //Assumes that a datasource has already been obtained
    //from JNDI
    conn = ds.getConnection();
    conn.setAutoCommit(false);
    stmt = conn.createStatement();
    stmt.execute("INSERT INTO EMPLOYEES VALUES
              (0101, 'Bill', 'R', 'Smith')");
    tran.commit();
    retry = false;
  } catch(java.sql.SQLException sqlX)
  {
    // If the error indicates the connection is stale, then
    // rollback and retry the action
    if (com.ibm.websphere.rsadapter.WSCallHelper
        .getDataStoreHelper(ds)
        .isConnectionError(sqlX))
    {
      try {
        tran.rollback();
      } catch (java.lang.Exception e) {
        //deal with exception
        //in most cases, this can be ignored
      }
      if (numOfRetries < 2) {
        retry = true;
        numOfRetries++;
      } else {
        retry = false;
      }
    }
    else
    {
      //deal with other database exception
      retry = false
    }
  } finally {
    //always cleanup JDBC resources
    try {
      if(stmt != null) stmt.close();
    } catch (java.sql.SQLException sqle) {
      //usually can ignore
    }
    try {
      if(conn != null) conn.close();
    } catch (java.sql.SQLException sqle) {
      //usually can ignore
    }
  }
} while (retry) ;
```

**Objects operating in a global transaction context and transaction not begun in the same method as the database access.**

When the object which receives the stale connection exception does not have direct control over the transaction, such as in a container-managed transaction case, the object must mark the transaction for rollback, and then indicate to its caller to retry the transaction. In most cases, you can do this by creating an application exception that indicates to retry that operation. However this action is not always allowed, and often a method is defined only to create a particular exception. This is the case with the ejbLoad() and ejbStore() methods on an enterprise bean. The next two examples explain each of these scenarios.

**Example 1: Database access method creates an application exception**

When the method that accesses the database is free to create whatever exception is required, the best practice is to catch the stale connection exception and create some application exception that you can interpret to retry the method. The following example shows an EJB client calling a method on an entity bean with transaction demarcation *TX_REQUIRED*, which means that the container begins a global transaction when *insertValue()* is called:

```
public class MyEJBClient
{
  //... other methods here ...

  public void myEJBClientMethod()
  {
```

```
    MyEJB myEJB = myEJBHome.findByPrimaryKey("myEJB");
    boolean retry = false;
    do
    {
      try
      {
        retry = false;
        myEJB.insertValue();
      }
      catch(RetryableConnectionException retryable)
      {
        retry = true;
      }
      catch(Exception e) { /* handle some other problem */ }
    }
    while (retry);
  }
}  //end MyEJBClient

public class MyEJB implements javax.ejb.EntityBean
{
  //... other methods here ...
  public void insertValue() throws RetryableConnectionException,
         java.rmi.EJBException
  {
    try
    {
      conn = ds.getConnection();
      stmt = conn.createStatement();
      stmt.execute("INSERT INTO my_table VALUES (1)");
    }
    catch(java.sql.SQLException sqlX)
    {
      // Find out if the error indicates the connection is stale
      if (com.ibm.websphere.rsadapter.WSCallHelper
          .getDataStoreHelper(ds)
          .isConnectionError(sqlX))
      {
        getSessionContext().setRollbackOnly();
        throw new RetryableConnectionException();
      }
      else
      {
        //handle other database problem
      }
    }
    finally
    {
      //always cleanup JDBC resources
      try
      {
        if(stmt != null) stmt.close();
      }
      catch (java.sql.SQLException sqle)
      {
        //usually can ignore
      }
      try
      {
        if(conn != null) conn.close();
      }
      catch (java.sql.SQLException sqle)
      {
        //usually can ignore
      }
    }
  }
}  //end MyEJB
```

*MyEJBClient* first gets a *MyEJB* bean from the home interface, assumed to have been previously retrieved from the Java Naming and Directory Interface (JNDI). It then calls *insertValue()* on the bean. The method on the bean gets a connection and tries to insert a value into a table. If one of the methods fails with a stale connection exception, it marks the transaction for *rollbackOnly* (which forces the caller to roll back this transaction) and creates a new *retryable connection* exception, cleaning up the resources before the exception is thrown. The retryable connection exception is simply an application-defined exception that tells the caller to retry the method. The caller monitors the retryable connection exception and, if it is caught, retries the method. In this example, because the container is beginning and ending the transaction; no transaction management is needed

in the client or the server. Of course, the client could start a bean-managed transaction and the behavior would still be the same, provided that the client also committed or rolled back the transaction.

**Example 2: Database access method creates an onlyRemote exception or an EJB exception**

Not all methods are allowed to throw exceptions defined by the application. If you use bean-managed persistence (BMP), use the *ejbLoad()* and *ejbStore()* methods to store the bean state. The only exceptions issued from these methods are the java.rmi.Remote exception or the javax.ejb.EJB exception, so you cannot use something similar to the previous example.

If you use container-managed persistence (CMP), the container manages the bean persistence, and it is the container that sees the stale connection exception. If a stale connection is detected, by the time the exception is returned to the client it is simply a remote exception, and so a simple catch-block does not suffice. There is a way to determine if the root cause of a remote exception is a stale connection exception. When a remote exception is created to wrap another exception, the original exception is usually retained. All remote exception instances have a detail property, which is of type *java.lang.Throwable*. With this detail, you can trace back to the original exception and, if it is a stale connection exception, retry the transaction. In reality, when one of these remote exceptions flows from one Java Virtual Machine API to the next, the detail is lost, so it is better to start a transaction in the same server as the database access occurs. For this reason, the following example shows an entity bean accessed by a session bean with bean-managed transaction demarcation.

```
public class MySessionBean extends javax.ejb.SessionBean
{
  ... other methods here ...
  public void mySessionBMTMethod() throws
    java.rmi.EJBException
  {
    javax.transaction.UserTransaction tran =
    getSessionContext().getUserTransaction();
    boolean retry = false;
    do
    {
      try
      {
        retry = false;
        tran.begin();
        // causes ejbLoad() to be invoked
        myBMPBean.myMethod();
        // causes ejbStore() to be invoked
        tran.commit();
      }
      catch(java.rmi.EJBException re)
      {
        try
        {
          tran.rollback();
        }
        catch(Exception e)
        {
          //can ignore
        }
        if (causedByStaleConnection(re))
          retry = true;
        else
          throw re;
      }
      catch(Exception e)
      {
        // handle some other problem
      }
      finally
      {
        //always cleanup JDBC resources
        try
        {
          if(stmt != null) stmt.close();
        }
        catch (java.sql.SQLException sqle)
        {
          //usually can ignore
```

```
        }
        try
        {
          if(conn != null) conn.close();
        }
        catch (java.sql.SQLException sqle)
        {
          //usually can ignore
        }
      }
    }
    while (retry);
  }

  public boolean causedByStaleConnection(java.rmi.EJBException re)
  {
    // Search the exception chain for errors
    // indicating a stale connection
    for (Throwable t = re; t != null; t = t.getCause())
      if (t instanceof RetryableConnectionException)
        return true;

    // Not found to be stale
    return false;
  }
}

public class MyEntityBean extends javax.ejb.EntityBean
{
  ... other methods here ...
  public void ejbStore() throws java.rmi.EJBException
  {
    try
    {
      conn = ds.getConnection();
      stmt = conn.createStatement();
      stmt.execute("UPDATE my_table SET value=1 WHERE
      primaryKey=" + myPrimaryKey);
    }
    catch(java.sql.SQLException sqlX)
    {
      // Find out if the error indicates the connection is stale
      if (com.ibm.websphere.rsadapter.WSCallHelper
          .getDataStoreHelper(ds)
          .isConnectionError(sqlX))
      {
        // rollback the tran when method returns
        getEntityContext().setRollbackOnly();
        throw new java.rmi.EJBException(
          "Exception occurred in ejbStore",
          new RetryableConnectionException(sqlX));
      }
      else
      {
        // handle some other problem
      }
    }
    finally
    {
      //always cleanup JDBC resources
      try
      {
        if(stmt != null) stmt.close();
      }
      catch (java.sql.SQLException sqle)
      {
        //usually can ignore
      }
      try
      {
        if(conn != null) conn.close();
      }
      catch (java.sql.SQLException sqle)
      {
        //usually can ignore
      }
    }
  }
}
```

In *mySessionBMTMethod()* of the previous example:

- The session bean first retrieves a *UserTransaction* object from the session context and then begins a global transaction.

- Next, it calls a method on the entity bean, which calls the *ejbLoad()* method. If *ejbLoad()* runs successfully, the client then commits the transaction, causing the *ejbStore()* method to be called.
- In *ejbStore()*, the entity bean gets a connection and writes its state to the database; if the connection retrieved is stale, the transaction is marked *rollbackOnly* and a new *EJBException* that wraps the *RetryableConnectionException* is thrown. That exception is then caught by the client, which cleans up the JDBC resources, rolls back the transaction, and calls *causedByStaleConnection()*, which determines if a stale connection exception is buried somewhere in the exception.
- If the method returns true, the retry flag is set and the transaction is retried; otherwise, the exception is re-issued to the caller.
- The *causedByStaleConnection()* method looks through the chain of detail attributes to find the original exception. Multiple wrapping of exceptions can occur by the time the exception finally gets back to the client, so the method keeps searching until it encounters stale connection exception and *true* is returned; otherwise, there is no stale connection exception in the list and *false* is returned.
- If you are talking to a CMP bean instead of to a BMP bean, the session bean is the same. The CMP bean *ejbStore()* method would most likely be empty, and the container after calling it would persist the bean with generated code.
- If a stale connection exception occurs during persistence, it is wrapped with a remote exception and returned to the caller. The *causedByStaleConnection()* method would again look through the exception chain and find the root exception, which would be stale connection exception.

**Objects operating in a local transaction context**

When a database operation occurs outside of a global transaction context, a local transaction is implicitly begun by the container. This includes servlets or JSPs that do not begin transactions with the *UserTransaction* interface, as well as enterprise beans running in unspecified transaction contexts. As with global transactions, you must roll back the local transaction before the operation is retried. In these cases, the local transaction containment usually ends when the business method ends. The one exception is if you are using activity sessions. In this case the activity session must end before attempting to get a new connection.

When the local transaction occurs in an enterprise bean running in an unspecified transaction context, the enterprise bean client object, outside of the local transaction containment, could use the method described in the previous bullet to retry the transaction. However, when the local transaction containment takes place as part of a servlet or JSP file, there is no client object available to retry the operation. For this reason, it is recommended to avoid database operations in servlets and JSP files unless they are a part of a user transaction.

## Stale Connection on Linux systems

You might must set a loopback to access DB2 databases from the application server on a Linux platform.

A Linux semaphore issue can interfere with JDBC access to your DB2 database in either of these configurations:

- Using the DB2 Universal JDBC Type 2 driver to connect to a local DB2 database
- Using the DB2 Universal JDBC Type 2 driver to access DB2 for z/OS through a DB2 Connect™ installation on the same machine as the application server. The problem occurs only if DB2 Connect restricts local clients from running within an agent. (That is, if the DB2_IN_APP_PROCESS setting is not the default value, or if the setting is Yes. Set the value to No to fix the problem and avoid performing the following procedure.)

The issue often triggers the JVM logs to display the DB2 stale connection exception **SQL1224**. Because the SQL exception code can vary, however, check the DB2 trace log when you encounter a stale connection. If you see the following error data, the Linux semaphore behavior is the problem:

```
'71' -SQLCC_ERR_CONN_CLOSED_BY_PARTNER and SQLCODE -XXXX
```

To work around the problem, set the loopback for your database. For example, if your database name is *WAS*, host name is *LHOST*, and database service port number is *50000*, issue the following commands from the DB2 command-line window:

```
db2 catalog TCPIP node RHOST remote LHOST server 50000
db2 uncatalog db WAS
db2 catalog db WAS as WASAlias at node loop authentication server
//If you connect to WASAlias, it is connect through loopback;
//If you connect to WAS, it is "normal" connect.
db2 catalog db WASAlias as WAS at node RHOST
```

## Example: Handling servlet JDBC connection exceptions

The following code sample demonstrates how to set transaction management and connection management properties, such as operation retries, to address stale connection exceptions within a servlet JDBC transaction.

This example code performs the following actions:

- initializes a servlet
- looks up a data source
- specifies error messages, connection retries, and transaction rollback requirements

## Example: Handling connection exceptions for BMP beans in container-managed database transactions

The following code sample demonstrates how to roll back transactions and issue exceptions to the bean client in cases of stale connection exceptions.

```

## Example: Handling data access exception - ConnectionWaitTimeoutException (for the JDBC API)

This code sample demonstrates how you specify the conditions under which the application server issues the ConnectionWaitTimeoutException for a JDBC application.

In all cases in which the ConnectionWaitTimeoutException is caught, there is little that can be done to recover.

```
public void test1() {
      java.sql.Connection conn = null;
      java.sql.Statement stmt = null;
```

```
     java.sql.ResultSet rs = null;

     try {
        // Look for datasource
        java.util.Properties props = new java.util.Properties();
        props.put(
           javax.naming.Context.INITIAL_CONTEXT_FACTORY,
           "com.ibm.websphere.naming.WsnInitialContextFactory");
        ic = new javax.naming.InitialContext(props);
        javax.sql.DataSource ds1 = (javax.sql.DataSource) ic.lookup(jndiString);

        // Get Connection.
        conn = ds1.getConnection();
        stmt = conn.createStatement();
        rs = stmt.executeQuery("select * from mytable where this = 54");
     }
     catch (java.sql.SQLException sqlX) {
    if (sqlX instanceof com.ibm.websphere.ce.cm.ConnectionWaitTimeoutException
     || sqlX instanceof java.sql.SQLTransientConnectionException
        && sqlX.getCause() instanceof com.ibm.websphere.ce.cm.ConnectionWaitTimeoutException)
    {
        //notify the user that the system could not provide a
        //connection to the database.  This usually happens when the
        //connection pool is full and there is no connection
        //available for to share.
     }
    else
    {
        // handle other database problems.
    }
     }
     finally {
        if (rs != null)
           try {
              rs.close();
           }
           catch (java.sql.SQLException sqle1) {
           }
        if (stmt != null)
           try {
              stmt.close();
           }
           catch (java.sql.SQLException sqle1) {
           }
        if (conn != null)
           try {
              conn.close();
           }
           catch (java.sql.SQLException sqle1) {
           }
     }
  }
```

## Example: Handling data access exception - ConnectionWaitTimeoutException for Java EE Connector Architecture

This code sample demonstrates how you specify the conditions under which WebSphere Application Server issues the ConnectionWaitTimeout exception for a JCA application.

In all cases in which the `ConnectionWaitTimeout` exception is caught, there is little to do for recovery.

The following code fragment shows how to use this exception in Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA):

```
/**
 * This method does a simple Connection test.
 */
public void testConnection()
   throws javax.naming.NamingException, javax.resource.ResourceException,
```

```
       com.ibm.websphere.ce.j2c.ConnectionWaitTimeoutException {
   javax.resource.cci.ConnectionFactory factory = null;
   javax.resource.cci.Connection conn = null;
   javax.resource.cci.ConnectionMetaData metaData = null;
   try {
      // lookup the connection factory
      if (verbose) System.out.println("Look up the connection factory...");
try {
factory =
  (javax.resource.cci.ConnectionFactory) (new InitialContext()).lookup("java:comp/env/eis/Sample");
  }
   catch (javax.naming.NamingException ne) {
      // Connection factory cannot be looked up.
      throw ne;
   }
    // Get connection
      if (verbose) System.out.println("Get the connection...");
      conn = factory.getConnection();
      // Get ConnectionMetaData
      metaData = conn.getMetaData();
      // Print out the metadata Information.
      System.out.println("EISProductName is " + metaData.getEISProductName());
   }
   catch (com.ibm.websphere.ce.j2c.ConnectionWaitTimeoutException cwtoe) {
      // Connection Wait Timeout
      throw cwtoe;
   }
   catch (javax.resource.ResourceException re) {
      // Something wrong with connections.
      throw re;
   }
   finally {
      if (conn != null) {
         try {
            conn.close();
         }
         catch (javax.resource.ResourceException re) {
         }
      }
   }
}
```

## Example: Handling data access exception - error mapping in DataStoreHelper

The application server provides a DataStoreHelper interface for mapping different database SQL error codes to the appropriate exceptions in the application server.

Error mapping is necessary because various database vendors can provide different SQL errors and codes that represent that same issue. For example, the stale connection exception has different codes in different databases. The **DB2** SQLCODEs of *1015, 1034, 1036* , and so on indicate that the connection is no longer available because of a temporary database problem. The **Oracle** SQLCODEs of *28, 3113, 3114*, and so on, indicate the same situation.

Mapping these error codes to standard exceptions provides the consistency that makes applications portable across different installations of the application server. The following code segment illustrates how to add two error codes into the error map:

```
public class NewDSHelper extends GenericDataStoreHelper
{
  public NewDSHelper(java.util.Properties dataStoreHelperProperties)
  {
    super(dataStoreHelperProperties);
    java.util.Hashtable myErrorMap = null;
    myErrorMap = new java.util.Hashtable();
    myErrorMap.put(new Integer(-803), myDuplicateKeyException.class);
    myErrorMap.put(new Integer(-1015), myStaleConnectionException.class);
    myErrorMap.put("S1000", MyTableNotFoundException.class);
```

```
    setUserDefinedMap(myErrorMap);
    ...
  }
}
```

**Note:** The userDefinedErrorMap custom property overlays existing entries in the error map by starting the DataStoreHelper.setUserDefinedMap method. You can use the custom property to add, change, or remove entries from the error map.

- Entries are delimited by a ; (semicolon).
- Each entry consists of a key and value, where the key is an error code (numeric value) or SQLState, which is text enclosed in quotation marks.
- Keys and values are separated by the = (equals sign).

For example, to remove the mapping of SQLState S1000, add a mapping of error code 1062 to duplicate key, and add a mapping of SQLState 08004 to stale connection, you can specify the following value for userDefinedErrorMap:

```
"S1000"=;1062=com.ibm.websphere.ce.cm.DuplicateKeyException;"08004"=
com.ibm.websphere.ce.cm.StaleConnectionException
```

userDefinedErrorMap can be located in the administrative console by selecting the data source and configuring the custom properties.

A configuration option known as the Error Detection Model controls how the error map is used. At V6 and earlier, Exception Mapping was the only option available for the Error Detection Model. At V7 and later, another option called Exception Checking is also available. Under the Exception Mapping model, the application server consults the error map and replaces exceptions with the corresponding exception type listed in the error map. Under the Exception Checking model, the application server still consults the error map for its own purposes but does not replace exceptions. If you want to continue to use Exception Mapping, you do not need to change anything. Exception Mapping is the default Error Detection Model. If you want to use the Exception Checking Model, see the topic "Changing the Error Detection Model to use the Exception Checking Model" in the related links.

## Database deadlock and foreign key conflicts

Repetition of certain SQL error messages indicates problems, such as database referential integrity violations, that you can prevent by using the container managed persistence (CMP) sequence grouping feature.

### Exceptions resulting from foreign key conflicts due to violations of database referential integrity

A database *referential integrity* (RI) policy prescribes rules for how data is written to and deleted from the database tables to maintain relational consistency. Runtime requirements for managing bean persistence, however, can cause an enterprise JavaBeans (EJB) application to violate RI rules, which can cause database exceptions.

Your EJB application is violating database RI if you see an exception message in your WebSphere Application Server trace or log file that is similar to one of the following messages (which were produced in an environment running DB2):

```
The insert or update value of the FOREIGN KEY table1.name_of_foreign_key_constraint
is not equal to any value of the parent key of the parent table.
```

or

```
A parent row cannot be deleted because the relationship table1.name_of_foreign_key_constraint
is not equal to any value of the parent key of the parent table.
```

To prevent these exceptions, you must designate the order in which entity beans update relational database tables by defining sequence groups for the beans.

### Exceptions resulting from deadlock caused by optimistic concurrency control schemes

Additionally, sequence grouping can minimize transaction rollback exceptions for entity beans that are configured for optimistic concurrency control. Optimistic concurrency control dictates that database locks be held for minimal amounts of time, so that a maximum number of transactions consistently have access to the data. In such a highly available database, concurrent transactions can attempt to lock the same table row and create deadlock. The resulting exceptions can generate messages similar to the following (which was produced in an environment running DB2):

```
Unsuccessful execution caused by deadlock or timeout.
```

Use the sequence grouping feature to order bean persistence so that database deadlock is less likely to occur.

## Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

### Default product locations (distributed)

The following file paths are default locations. You can install the product and other components or create profiles in any directory where you have write access. Multiple installations of WebSphere Application Server - Express products or components require multiple locations. Default values for installation actions by root and nonroot users are given. If no nonroot values are specified, then the default directory values are applicable to both root and nonroot users.

*app_client_root*

*Table 50. Default installation root directories for the Application Client for IBM WebSphere Application Server.*

*This table shows the default installation root directories for the Application Client for IBM WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppClient` (Java EE Application client only)<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\Program Files\IBM\WebSphere\AppClient` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\IBM\WebSphere\AppClient` |

*app_server_root*

*Table 51. Default installation directories for WebSphere Application Server.*

*This table shows the default installation directories for WebSphere Application Server - Express.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppServer`<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppServer`<br>Windows `C:\Program Files\IBM\WebSphere\AppServer` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppServer`<br>Windows *user_home*`\IBM\WebSphere\AppServer` |

*component_root*

The component installation root directory is any installation root directory described in this topic. Some programs are for use across multiple components—in particular, the Web Server Plug-ins, the Application Client, and the IBM HTTP Server. All of these components are part of the product package.

*gskit_root*

IBM Global Security Kit (GSKit) can now be installed by any user. GSKit is installed locally inside the installing product's directory structure and is no longer installed in a global location on the target system. The following list shows the default installation root directory for Version 8 of the GSKit, where *product_root* is the root directory of the product that is installing GSKit, for example IBM HTTP Server or the web server plug-in.

AIX HP-UX Linux Solaris

*product_root*/gsk8

Windows

*product_root*\gsk8

*profile_root*

*Table 52. Default profile directories.*

*This table shows the default directories for a profile named profile_name on each distributed operating system.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/AppServer/profiles/*profile_name*<br>HP-UX Linux Solaris /opt/IBM/WebSphere/AppServer/profiles/*profile_name*<br>Windows C:\Program Files\IBM\WebSphere\AppServer\profiles*profile_name* |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/AppServer/profiles<br>Windows *user_home*\IBM\WebSphere\AppServer\profiles |

*plugins_root*

*Table 53. Default installation root directories for the Web Server Plug-ins.*

*This table shows the default installation root directories for the Web Server Plug-ins for WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/Plugins<br>HP-UX Linux Solaris /opt/IBM/WebSphere/Plugins<br>Windows C:\Program Files\IBM\WebSphere\Plugins |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/Plugins<br>Windows C:\IBM\WebSphere\Plugins |

*wct_root*

*Table 54. Default installation root directories for the WebSphere Customization Toolbox.*

*This table shows the default installation root directories for the WebSphere Customization Toolbox.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/Toolbox<br>HP-UX Linux Solaris /opt/IBM/WebSphere/Toolbox<br>Windows C:\Program Files\IBM\WebSphere\Toolbox |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/Toolbox<br>Windows C:\IBM\WebSphere\Toolbox |

*web_server_root*

*Table 55. Default installation root directories for the IBM HTTP Server.*

*This table shows the default installation root directories for the IBM HTTP Server.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/HTTPServer<br>HP-UX Linux Solaris /opt/IBM/HTTPServer<br>Windows C:\Program Files\IBM\HTTPServer |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/HTTPServer<br>Windows C:\IBM\HTTPServer |

# Assembling data access applications

When you assemble enterprise bean code into files that can be deployed onto an application server, you configure properties that define how the application accesses an enterprise information system (EIS), such as a database.

## Before you begin

This topic assumes that you have created an enterprise application containing an EJB module that must transact with a database.

## About this task

A data access application uses resources, such as data sources or connection factories, to connect with a database.

An application component uses a *connection factory* to access a connection instance, which the component then uses to connect to the underlying enterprise information system (EIS). Examples of connections include database connections, Java Message Service connections, and SAP R/3 connections.

During application assembly you perform activities that enable the application to use these resources. The process typically requires an assembly tool.

## Procedure

1. Identify the logical names that are used by the EJB module to reference application resources. These logical names are called *resource references*.

For further explanation, read the topic, The benefits of using resource references.

2. Start an assembly tool.
3. If you have not done so already, configure the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules. Ensure that **Java EE** capability is enabled.
4. Define mapping and security properties for the resource references. This process includes the following activities:
   a. Bind the resource references to the application resources that provide database connectivity.

      See the topic, Data source lookups for enterprise beans and web modules, for more information on the concept of binding. At deployment time you can alter your bindings if necessary.
   b. For each resource define an authentication type, which is the security configuration through which database connections are granted. There are two authentication types:

      **Component-managed**
      The enterprise bean code performs EIS signon for data source or connection factory connections.

      **Container-managed**
      The product performs EIS signon.

      See the topic, J2EE connector security, for detailed reference on resource authentication.
5. Configure access intent policy settings for your enterprise beans.
   a. Right-click your EJB module in a Project Explorer view and click **Open With > Deployment Descriptor Editor**.
   b. In an EJB Deployment Descriptor editor, select the **Access** tab.
   c. Under **Isolation Level**, click **Add**.
   d. Select the isolation level, enterprise beans, and method elements. For information on isolation levels, press **F1**.
   e. Click **Finish**.
6. Map enterprise beans to database tables.

### Results

Files for the updated application are shown in the Project Explorer view.

### What to do next

After testing your application, you are ready to deploy your application to an application server.

## Creating or changing a resource reference

A resource reference supports application access to a resource (such as a data source, URL, or mail provider) using a logical name rather than the actual name in the runtime environment. This capability eliminates the necessity to alter application code when you change the resource runtime configurations.

### Before you begin

This topic guides you through updating the resource references of an enterprise application that you assembled previously. The topic, Assembling applications, details the assembly procedure.

### About this task

Resource references are declared in the deployment descriptor by the application provider. At some point in the application deployment process, you must bind the resource reference to the actual name of the resource in the run time environment. When you create a connection factory or data source in the

application server, the application server provides a JNDI name that a component can use to access that connection factory or data source. The application server uses an indirect name with the java:comp/env prefix. For example:

- When you create a data source, the default JNDI name is set to jdbc/*data_source_name*.
- When you create a connection factory, its default name is eis/*j2c_connection_factory_name*.

If you override these values by specifying your own, retain the java:comp/env prefix. An indirect JNDI name allows the connection management infrastructure to access to any data from the resource reference that is associated with the application. This allows you to better manage resources based on the settings for authentication, isolation level, sharing scope, and resolution control.

This topic describes how to update the resource references of an enterprise application using an assembly tool. After you define the resource reference, you can perform an indirect JNDI lookup using the java:comp/env context.

## Procedure

1. Start an assembly tool.
2. If you have not done so already, configure the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules.
3. Import the enterprise application (EAR file) that you want to change into the EJB project.
4. Display the resource references for the type of module:
   - If an enterprise bean uses the resource reference:
     a. Expand the name of the EAR file.
     b. Expand **EJB Modules**.
     c. Expand the EJB module wanted.
     d. Expand the section for the appropriate type of enterprise bean (**Session Beans** or **Entity Beans**).
     e. Expand the enterprise bean.
   - If a servlet uses the resource reference:
     a. Expand the name of the EAR file.
     b. Expand **Web Modules**.
     c. Expand the web module wanted.
   - If an application client uses the resource reference:
     a. Expand the name of the EAR file.
     b. Expand **Application Clients**.
     c. Expand the application client module wanted.
5. Right-click the module whose resource references you want to change and click **Open With > Deployment Descriptor Editor**.
6. For servlets and application clients, click **Add**. For EJB modules, select the particular bean and click **Add**.
7. Select the resource reference option and click **Next**.
8. Specify the settings for the resource reference, and click **Finish**.
9. Optional: Select the **References** tab and, under **WebSphere Extensions**, select an isolation level. If you choose to forego this step, the isolation level defaults to TRANSACTION_NONE.
10. Optional: Under **WebSphere Bindings**, specify a JNDI name. If you choose to forego this step you can set (or override) the binding when the application is deployed.
11. Close the deployment descriptor editor and save your changes.

## Results

Files for the updated module are shown in the Project Explorer view.

### What to do next

Verify the contents of the updated enterprise application in the Project Explorer view. Then, deploy your enterprise application.

You can generate EJB deployment code and deploy an EJB module to a target server in one step. In the Project Explorer view, right-click on the EJB project and click **Deploy**. See also the topic, Deploying EJB modules.

## Assembling resource adapter (connector) modules

A resource adapter archive (RAR) file contains code that implements a library for connecting with a backend Enterprise Information System (EIS).

### Before you begin

This topic assumes that you have created and unit tested a resource adapter RAR file that you want to assemble in an enterprise application and deploy onto an application server.

A Resource Adapter Archive (RAR) file is a Java archive (JAR) file used to package a resource adapter for the Java 2 Connector (J2C) Architecture for the product.

A RAR file can contain the following:
- Enterprise information system (EIS) supplied resource adapter implementation code in the form of JAR files or other runnable components, such as dynamic link lists.
- Utility classes.
- Static documents, such as HTML files, images, and sound files.

The standard file extension of a RAR file is *.rar*.

### About this task

In an assembly tool, RAR files are called *connectors* and assembled resource adapters are called *connector modules*.

A *connector* is a Java Platform, Enterprise Edition (Java EE) component that provides access to Enterprise Information Systems (EIS), and must comply with the Java EE Connector Architecture (JCA). An example of an EIS is a transaction manager such as the Customer Information Control System (CICS®).

You might see the terms resource adapter *modules*, resource adapter *connectors* and resource adapter *archive files* used interchangeably.

Use an assembly tool to assemble a *connector* in either of the following ways:
- Import an existing RAR file.
- Create a new connector module.

For information on assembling connectors, refer to the online documentation or the information center for your assembly tool.

### Procedure

1. Start an assembly tool.
2. If you have not done so already, configure the assembly tool for work on J2EE modules. Ensure that **Java EE** and **EJB** capabilities are enabled.
3. Migrate RAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an assembly tool. To migrate files, import your RAR files to the assembly tool.

4. Create a new connector module.

### Results

A connector project is migrated or created. Files for the connector project are shown in the Project Explorer view under **Enterprise Applications** and **Connector Projects**.

### What to do next

After creating a connector project, you can edit the connector deployment descriptor if default properties are not sufficient. In the Connector Deployment Descriptor editor, you can view and edit source code.

After assembling the connector project, deploy the module or its application onto a server. After deployment, to ensure that the connector module finds the classes and resources that it needs, check the **Classpath** setting for the RAR on the console Resource adapter settings page.

## Deploying data access applications

Deploying a data access application includes more than installing your web application archive (WAR) or enterprise archive (EAR) file onto a server. Deployment can include tasks for configuring your application to use the data access resources of the server and overall runtime environment.

### Before you begin

You can deploy only application code that is assembled into the appropriate modules. See the topic, Assembling data access applications for guidelines, for this process.

### About this task

Perform the following steps if your application requires access to a relational database (RDB). When your application requires access to a different type of enterprise information system (EIS), such as an object-oriented database or the Customer Information Control System (CICS), consult the topics, Relational resource adapters and JCA, and Accessing data using Java EE Connector Architecture connectors.

### Procedure

1. If your RDB configuration does not exist, do the following steps:
   a. Create a database to hold the data.
   b. Create tables required by your application.
      **If your application uses container managed persistence (CMP) entity beans to access the data** You can create the tables using the data definition language (DDL) generated from the enterprise bean configuration. For more information, see the topic, Recreating database tables from the exported table data definition language.
      **If your application uses bean managed persistence (BMP) entity beans, or** *does not* **use entity beans**
      You must use your database server interfaces to create the tables.

      The Enterprise JavaBeans (EJB) to RDB Mapping wizard of an assembly tool is also used to create your database tables for either type of entity bean. Select the top-down mapping option in the wizard. However, this option does not give you direct control in naming the RDB elements or choosing column types. Additionally, because the top-down process is automatic, it might not provide mappings to reflect the precise relationships that you intend.

      If you use Rational Application Developer, consult the information center about the mapping wizard. To learn about all of your assembly tool options, see the assembly tools topic in this information center.

c. Check the data source minimum required settings by vendor to see any database vendor requirements for connecting to an application server. See the topic, Data source minimum required settings, by vendor, for instructions.

2. Optional: Map your entity beans to the database tables through the meet-in-the-middle mapping option of an assembly tool. Complete this step only if you did not create your database schema through the top-down mapping option, did not generate your mapping relationships through bottom-up mapping, or did not generate mappings during the application assembly process. For information about the top-down mapping option see the information center for Rational Application Developer.
3. Install your application onto the application server. See the topic, Installing enterprise application files. When you install the application, you can alter data access settings that were made during application assembly, or, if they were omitted from the assembly process, set them for the first time. These settings include resource bindings and resource authentication aliases, which are addressed in the following substeps:
   a. Bind application resource references to the data sources, or other resource objects, that provide database connectivity. For details on the concept of binding, see the topic, Data source lookups for enterprise beans and web modules.

      **Tip:** After deployment, you can use the WebSphere Application Server administrative console to alter resource bindings. Click **Applications** > **Application Types** > **Webphere enterprise applications** > ***application_name***, and select the link to the appropriate mapping page. For example, if you want to alter the binding of an EJB module resource, you might click **Map data sources for all 2.x CMP beans**. For a web module resource, click **Resource references**.

   b. Define authentication alias data for resources that must be authenticated with the backend through *container-managed* authorization. In this security configuration, WebSphere Application Server performs EIS signon for data source or connection factory connections. Consult the topic, J2EE connector security for detailed reference on resource authentication.
4. Start the deployed application files using the administrative console, the wsadmin scripting tool startApplication command, or your own Java program.
5. Save the changes to your administrative configuration.
6. Test the application. For example, point a web browser at the URL for a deployed application and examine the performance of the application.

## Results

When you deploy an application that uses a DB2 UDB for IBM i back-end database, you might find the following exception in the SystemOut.log file:

```
PMGR6022E: Error using adapter to create or execute an Interaction
```

This type of error indicates that you deployed an application with container-managed persistence (CMP) enterprise beans that were originally configured to access a DB2 database on Windows, Linux, or a supported UNIX system. Using the administrative console, uninstall the affected CMP applications, then reinstall the applications with the new database setting. Remember to select **Deploy enterprise beans**; on the **EJB deploy** panel, select the appropriate version of your DB2 UDB for IBM i database.

**Note:** This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

### What to do next

If the application does not perform as wanted, update the application, then save and test it again.

## Available resources

Use this page to select configured resources that you want to bind to the resource references of the enterprise beans or web modules in your application.

To view this administrative console page:

1. Click **Applications** > **Application Types** > **Websphere enterprise applications** > ***application_name***.
2. Click the link for any of these resource configuration pages:
   - **Resource references**
   - **Map data sources for all 2.x CMP beans**
   - **Provide default data source mapping for modules containing 2.x entity beans**
3. Locate the table row of the EJB or web module that you want to map to a different resource.
4. Within the row, locate the JNDI name of the resource that is currently bound to the EJB or web module.
5. Click **Browse**.

   You now see **Available resources**.

Each table row corresponds to a resource that you can bind to your enterprise bean or web module.

### Select

Select the resource that you want to bind to the resource reference of your module.

### JNDI name

The Java Naming and Directory Interface (JNDI) name of the resource that you want to bind to the resource reference of your module.

**Data type** String

### Scope

The scope of the resource. Note that this administrative console page displays only resources that are configured for a scope at which your application operates.

### Description

The text description of the resource.

## Map data sources for all 1.x CMP beans

Use this page to designate how the container-managed persistence (CMP) 1.x beans of an application map to data sources that are available to the application.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Map data sources for all 1.x CMP beans**.

**Guidelines for using this administrative console page:**

- The table depicts the 1.x CMP bean contents of your application.
- Each table row corresponds to a CMP bean within a specific EJB module. A row shows the JNDI name of the data source mapping target of the bean *only* if you bound them together during application assembly or installation. For every data source that is displayed, you see the corresponding security configuration.
- To set your mappings:

1. Select a row. Be aware that if you check multiple rows on this page, the data source mapping target that you select in step 2 applies to all of those CMP beans.
2. Click **Browse** to select a data source from the new page that is displayed, the Available Resources page. The Available Resources page shows all data sources that are available mapping targets for your CMP beans.
3. Click **Apply**. The console displays the 1.x CMP bean data sources page again. In the rows that you previously selected, you now see the JNDI name of the new resource mapping target.
4. *Before* you click **OK** to save your new configuration, set the security parameters for the data source. Use the following steps.

- To specify data source security settings:
  1. Select one or more rows in the table.
  2. Type in a user name and password that comprise the authentication alias for signing on to the data source. If these entries are not listed in the application Java Platform, Enterprise Edition (Java EE) Connector (J2C) authentication data list, you must input them into the list after saving your settings on this page. Read the information center topic on managing Java EE Connector Architecture authentication data entries for more information.
  3. Click **Apply** that immediately follows the user name and password input fields.
- Repeat all of the previous steps as necessary.
- Click **OK** to save your settings.

### Select
Select the check boxes of the rows that you want to edit.

### EJB
The name of an enterprise bean in the application.

### EJB Module
The name of the module that contains the enterprise bean.

### URI
Specifies location of the module relative to the root of the application EAR file.

### JNDI name
The Java Naming and Directory Interface (JNDI) name of the data source that is configured for the enterprise bean.

**Data type** String

### User name
The user name and password that comprise the authentication alias for securing the data source.

## Map default data sources for modules containing 1.x entity beans
Use this page to set the default data source mapping for EJB modules that contain 1.x container-managed persistence (CMP) beans. Unless you configure individual data sources for your 1.x CMP beans, this default mapping applies to all beans within the module.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Map default data sources for modules containing 1.x entity beans**.

**Guidelines for using this administrative console page:**

- The page displays a table that depicts the EJB modules in your application that contain 1.x CMP beans.

- Each table row corresponds to a module. A row shows the JNDI name of the data source mapping target of the EJB module *only* if you bound them together during application assembly. For every data source that is displayed, you see the corresponding security configuration.
- To set your default data source mappings:
  1. Select a row. Be aware that if you check multiple rows on this page, the data source mapping target that you select in step 2 applies to all of those EJB modules.
  2. Click **Browse** to select a data source from the new page that is displayed, the Available Resources page. The Available Resources page shows all data sources that are available mapping targets for your EJB modules.
  3. Click **Apply**. The console displays the 1.x entity bean data sources page again. In the rows that you previously selected, you now see the JNDI name of the new resource mapping target.
  4. *Before* you click **OK** to save your new configuration, set the security parameters for the data source. Use the following steps.
- To specify security settings for the default data source:
  1. Select a row. Be aware that if you check multiple rows on this page, the security settings that you select later apply to all of those data sources.
  2. Type in a user name and password that comprise the authentication alias for signing on to the data source. If these entries are not listed in the application Java Platform, Enterprise Edition (Java EE) Connector (J2C) authentication data list, you must input them into the list after saving your settings on this page. Read the information center topic on managing Java EE Connector Architecture authentication data entries for more information.
  3. Click **Apply** that immediately follows the user name and password input fields.
- Repeat all of the previous steps as necessary.
- Click **OK** to save your work.

### Select
Select the check boxes of the rows that you want to edit.

### EJB Module
The name of the module that contains the 1.x enterprise beans.

### URI
Specifies location of the module relative to the root of the application EAR file.

### JNDI name
The Java Naming and Directory Interface (JNDI) name of the default data source for the EJB module.

**Data type** String

### User name
The user name and password that comprise the authentication alias for securing the data source.

## Map data sources for all 2.x CMP beans settings
Use this page to map container-managed persistence (CMP) 2.x beans of an application to data sources that are available to the application.

To view this administrative console page, click **Applications** > **Application Types** > **Websphere enterprise applications** > ***application_name*** > **Map data sources for all 2.x CMP beans**.

Each table row corresponds to a CMP bean within a specific EJB module. A row shows the JNDI name of the data source mapping target of the bean only if you bound them together during application assembly. For every data source that is displayed, you see the corresponding security configuration.

## Set Multiple JNDI names

Specify the Java Naming and Directory Interface (JNDI) name for multiple EJB modules. Select one or more EJB modules from the table, and select a JNDI name from this list to configure the EJB modules with that JNDI name.

**Data type** Drop-down list

## Set Authorization Type

Specify the authorization type for securing the data source. Select one or more EJB modules from the table to set the authorization type.

Select either **Container** or **Application** from the displayed list. Container-managed authorization indicates that WebSphere Application Server performs signon to the data source. Application-managed authorization indicates that the enterprise bean code performs signon.

## Modify Resource Authentication Method

Specify the authorization type and the authentication method for securing the data source. Select one or more EJB modules from the table to modify the resource authentication method.

You can choose between the following authentication methods:

- **None**:
  1. Determine which data source configurations to designate with no authentication method.
  2. Select the appropriate table rows.
  3. Select **None** from the list of authentication method options that precede the table.
  4. Click **Apply**.
- **Use default method (many-to-one mapping)**:
  1. Determine which data source configurations to designate with the WebSphere Application Server DefaultPrincipalMapping login configuration. Apply this option to each data source individually if you want to designate different authentication data aliases. See the information center topic on J2EE Connector security for more information on the default mapping configuration.
  2. Select the appropriate table rows.
  3. Select **Use default method (many-to-one mapping)** from the list of authentication method options that precede the table.
  4. Select an authentication data entry or alias from the list.
  5. Click **Apply**.
- **Use Kerberos authentication**: Specifies to use the Kerberos authentication method.
  1. Ensure that you have configured the Kerberos authentication mechanism in the application server.
  2. Select the appropriate table row.
  3. Select **Use Kerberos authentication** from the list of authentication method options that precede the table.
  4. Select an application login configuration from the list.
  5. Click **Apply**.
  6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

  The application server will attempt to verify that you are connecting to the correct type of database when you select this option.
- **Use trusted connections (one-to-one mapping)**:
  1. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the information center topic on J2EE Connector security for more information on custom JAAS login configurations.
  2. Select the appropriate table row.

3. Ensure that the database to which the modules will connect is configured for trusted connections.
4. Select **Use trusted connections (one-to-one mapping)** from the list of authentication method options that precede the table.
5. Select an application login configuration from the list.
6. Click **Apply**.

The application server will attempt to verify that you are connecting to the correct type of database when you select this option.

- **Custom login configuration**:
  1. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the information center topic on J2EE Connector security for more information on custom JAAS login configurations.
  2. Select the appropriate table row.
  3. Select **Use custom login configuration** from the list of authentication method options that precede the table.
  4. Select an application login configuration from the list.
  5. Click **Apply**.
  6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

### Select
Select the check boxes of the rows that you want to edit.

### EJB
The name of an enterprise bean in the application.

### EJB Module
The name of the module that contains the enterprise bean.

### URI
Specifies location of the module relative to the root of the application EAR file.

### Target resource JNDI name
Specifies the resource to which the CMP bean is bound.

### Resource authorization
Specifies the current setting for the resource authorization type.

Modify this setting with **Set authorization type**.

## Map data sources for all 2.x CMP beans
Use this page to set the default data source mapping for EJB modules that contain 2.x container-managed persistence (CMP) beans. Unless you configure individual data sources for your 2.x CMP beans, this default mapping applies to all beans within the module.

To view this administrative console panel, click **Applications** > **Application Types** > **Websphere enterprise applications** > ***application_name*** > **Map data sources for all 2.x CMP beans** .

This panel displays a table that depicts the EJB modules in your application that contain 2.x CMP beans. Each table row corresponds to a module. A row shows the JNDI name of the data source mapping target of the EJB module only if you bound them together during application assembly. For every data source that is displayed, you see the corresponding security configuration.

## Set Multiple JNDI Names

Specifies the JNDI name to bind to one or more modules. Select one or more modules, click **Set Multiple JNDI Names**, and select the JNDI name for the resource to which you would like to bind the module.

## Set Authorization Type

Specifies the authorization type that you to use for the modules. Select one or more modules, click **Set Authorization Type**, and select the authorization type.

You can choose:

- Per application - indicates that the enterprise bean code performs signon.
- Container - indicates that the application server performs signon to the data source.

## Modify Resource Authentication Method

Specifies the resource authentication method for the modules that you have configured with container-managed authorization. Select one or more modules, click **Modify Resource Authentication Method**, and select the authentication method.

You can choose between the following authentication methods:

- **None**:
  1. Determine which data source configurations to designate with no authentication method.
  2. Select the appropriate table rows.
  3. Select **None** from the list of authentication method options that precede the table.
  4. Click **Apply**.
- **Use default method (many-to-one mapping)**:
  1. Determine which data source configurations to designate with the WebSphere Application Server DefaultPrincipalMapping login configuration. Apply this option to each data source individually if you want to designate different authentication data aliases. See the information center topic on J2EE Connector security for more information on the default mapping configuration.
  2. Select the appropriate table rows.
  3. Select **Use default method (many-to-one mapping)** from the list of authentication method options that precede the table.
  4. Select an authentication data entry or alias from the list.
  5. Click **Apply**.
- **Use Kerberos authentication**: Specifies to use the Kerberos authentication method.
  1. Ensure that you have configured the Kerberos authentication mechanism in the application server.
  2. Select the appropriate table row.
  3. Select **Use Kerberos authentication** from the list of authentication method options that precede the table.
  4. Select an application login configuration from the list.
  5. Click **Apply**.
  6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

  The application server will attempt to verify that you are connecting to the correct type of database when you select this option.
- **Use trusted connections (one-to-one mapping)**:
  1. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the information center topic on J2EE Connector security for more information on custom JAAS login configurations.
  2. Select the appropriate table row.
  3. Ensure that the database to which the modules will connect is configured for trusted connections.

4. Select **Use trusted connections (one-to-one mapping)** from the list of authentication method options that precede the table.
5. Select an application login configuration from the list.
6. Click **Apply**.

The application server will attempt to verify that you are connecting to the correct type of database when you select this option.

- **Custom login configuration**:
  1. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the information center topic on J2EE Connector security for more information on custom JAAS login configurations.
  2. Select the appropriate table row.
  3. Select **Use custom login configuration** from the list of authentication method options that precede the table.
  4. Select an application login configuration from the list.
  5. Click **Apply**.
  6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

### Select
Select the check boxes of the rows you want to edit.

### EJB Module
Specifies the name of the module that contains the 2.x enterprise beans.

### URI
Specifies location of the module relative to the root of the application EAR file.

### JNDI name
Specifies the Java Naming and Directory Interface (JNDI) name of the default data source for the EJB module.

**Data type** String

### Resource authorization
Specifies the authorization type and the authentication method for securing the data source.

### Extended Datasource Properties
When selected, you will be directed to a panel on which you can specify extended properties that the module can use for the DB2 data source.

The application server will attempt to verify that you are connecting to the correct type of database when you select this option.

## Installing a resource adapter archive

The application server uses the classes and other code that comprise a resource adapter archive (RAR) to support the resource adapters that you configure.

### Before you begin

A RAR file, which is often called a Java EE Connector Architecture (JCA) connector, must comply with the JCA Specification. You can meet these requirements by using a supported assembly tool to assemble a collection of Java archive (JAR) files, other runnable components, and utility classes into a deployable resource adapter archive (RAR). You can then install the RAR file in the application server.

## About this task

A resource adapter archive provides the classes and other code to support a resource adapter for access to a specific EIS, such as the Customer Information Control System (CICS). Therefore, you can only configure resource adapters for an EIS after you install the appropriate RAR file.

**Important:** When you use the **Install RAR** dialog to install a RAR file, the scope you define on the Resource Adapters page has no effect on where the RAR file is installed. You can install RAR files only at the node level, which you specify on the Install RAR page. To set the scope of an RAR file to a specific cluster, or server, after you install the RAR file at each node level, create a copy of the RAR file with the appropriate cluster or server scope.

## Procedure

1. Navigate to the **Resource adapter** panel. Click **Resources** > **Resource Adapters** > **Resource adapters**.
2. Install a new resource adapter archive.
   a. Click **Install RAR**. A dialog opens for installing a RAR file and configuring the associated resource adapter. Only click **New** if you want to configure a new resource adapter for a previously installed RAR file.
   b. Browse to find the appropriate RAR file.
      - If your RAR file is located on your local workstation, select **Local path**, and browse to find the file.
      - If your RAR file is located on your server, select **Remote file system**, and specify the fully qualified path to the file.
   c. Click **Next**.
3. Configure the resource adapter name and any other properties needed under *General Properties*. For more details on the settings that you can configure, such as the J2C connection factories, see the topics Installing resource adapters within applications and Configuring resource adapters.
4. Click **OK**.
5. Optional: Create a copy of the RAR file with a different scope level. After you install the RAR file at each node level, you can create another copy of the file that has a specific server or cluster as the scope for that file.

   **Note:**
   - If you do not create a copy of your RAR at the cluster scope, then you must create identical factories (connection factories, admin object, and activation specifications) at the node level for each of your nodes in the cluster. By creating the copy of your RAR, you provide a placeholder for your factories and circumvent the need to create identical factories at the node level for each of your nodes in the cluster.
   - You must still install the RAR binaries (files, such as jars and xml deployment files) on each node for the RAR to operate successfully.

   a. Click **Resources**.
   b. Click **Resource Adapters**.
   c. Select the scope level and then click **NEW**.
   d. Choose the RAR file from the installed archive path.
   e. Click **OK**.

## Results

You have installed a resource adapter archive that provide access to the EIS when it is properly configured. If you must configure more settings, or change some settings that were configured during the

installation process, refer to the topic on configuring a resource adapter in the administrative console for more information.

## Installing resource adapters embedded within applications

Install resource adapters in your applications so they can access outside data sources.

### Before you begin

The JCA Version 1.6 specification adds support for Java annotations in RAR modules. For more information on annotation support see the topic, JCA 1.6 support for annotations in RAR modules.

### About this task

### Procedure

1. Assemble an application with RAR modules in it. See the topic Assembling applications for more information.
2. Install the application. Follow the steps in the topic Installing a new application.

   In the **Map modules to servers** step, specify target servers or clusters for each RAR file. Be sure to map all other modules that use the resource adapters defined in the RAR modules to the same targets. Also, specify the web servers as targets that serve as routers for requests to this application. The plug-in configuration file (`plugin-cfg.xml`) for each web server is generated based on the applications that are routed through it.

   In the **Metadata for modules** step of installing an application, you can set or unset the metadata-complete flag as discussed in the topic, JCA 1.6 support for annotations in RAR modules.

   **Note:** When installing a RAR file on a server, the application server looks for the manifest (MANIFEST.MF) for the connector module. The application server first looks for the RAR file's `connectorModule.jar` file and loads the manifest from the `connectorModule.jar` file. If the class path entry is in the manifest from the `connectorModule.jar`file, the RAR uses that class path.

   To ensure that the installed connector module finds the classes and resources that it needs, check the Class path setting for the RAR using the administrative console. For more information on how to check this setting, see the topics Resource adapter settings and WebSphere relational resource adapter settings.
3. Click **Finish** > **Save** to save the changes.
4. Create connection factories for the newly installed application.

   See the topic, Configuring connection factories for resource adapters within applications to view the steps to complete this step.

### Results

**Note:** A given native library can only be loaded one time for each instance of the Java virtual machine (JVM). Because each application has its own class loader, separate applications with embedded RAR files cannot both use the same native library. The second application receives an exception when it tries to load the library.

If any application deployed on the application server uses an embedded RAR file that includes native path elements, then you must always ensure that you shut down the application server cleanly, with no outstanding transactions. If the application server does not shut down cleanly it performs *recovery* upon server restart and loads any required RAR files and native libraries. On completion of recovery, do not attempt any application-related work. Shut down the server and restart it. No further recovery is attempted by the application server on this restart, and normal application processing can proceed.

## Install RAR

Use this page to install a resource archive (RAR) file in one of two ways. You can either upload a RAR file from the local file system, or specify an existing RAR file on a server. The RAR file must be installed at the node level, and you can select the node on this page.

To view this page in the administrative console click **Resources** > **Resource Adapters** > **Resource Adapters** > **Install RAR**.

For information about installing a resource adapter, see the topic, Installing a resource adapter archive (RAR) file.

### Scope

Specifies the scope of the resource adapter. Only applications that are installed within this scope can use this adapter.

### Local file system

Specifies the path of a RAR that resides on the same server as the console.

**Data type** String

### Remote file system

Specifies the path of a RAR that resides on one of the nodes of the cell.

**Data type** String

# Deploying SQLJ applications

Use Structured Query Language in Java (SQLJ) to develop data access applications that connect to DB2 databases. SQLJ is a set of programming extensions that enable you to use the Java programming language to embed statements that provide SQL (Structured Query Language) database requests.

## About this task

The advantages of developing applications with SQLJ include improved performance and a shorter, more efficient development cycle. You can achieve the following with SQL:

- Improve performance by using static SQL statements.
- Reduce the development cycle:
  - Write less code with the simpler SQLJ syntax, which reduces the number of lines of code that is required to execute statements, set parameters, and retrieve parameters.
  - Detect programming errors earlier in the development phase with the online check function, which performs data type validation and schema validation. See the DB2 documentation for a complete list of customization options.

Consider using SQLJ in situations where dynamic SQL is not needed, and where applications use DB2 as the database server.

The application server includes enhanced SQLJ support for applications that use container-managed persistence (CMP). The enhanced support includes the following items: include:

- Deploying CMP beans during the application installation in the application server.
- Customizing and binding SQLJ profiles with the administrative console or scripting.
- Customizing and binding SQLJ applications again without needing to reinstall the application.

These enhancements reduce the complexity of installing, deploying, and customizing SQLJ applications for both container-managed and bean-managed persistence.

## Procedure

1. Acquire the required drivers to deploy an SQLJ application in the application server. You need the following files, depending on the JDBC provider that you use:

| JDBC provider type | Required files |
|---|---|
| DB2 Using IBM JCC Driver<br><br>This driver is also known as:<br>• IBM Data Server Driver for JDBC and SQLJ<br>• IBM DB2 Driver for JDBC and SQLJ<br>• IBM DB2 Universal JDBC Driver. | db2jcc.jar or db2jcc4.jar |
| DB2 Universal JDBC driver (deprecated) | db2jcc.jar |

2. Deploy the SQLJ application.
   - Deploy applications that use container-managed persistence (CMP):
     - "Deploying SQLJ applications that use container-managed persistence (CMP)" with the DB2 Using IBM JCC Driver.
     - "Deploying SQLJ applications that use container-managed persistence (CMP) with the ejbdeploy tool" on page 512.
   - "Deploying SQLJ applications that use bean-managed persistence, servlets, or sessions beans" on page 514.
   - "Using embedded SQLJ with the DB2 for z/OS Legacy driver" on page 524 (deprecated).
3. Customize and bind the SQLJ profiles. Before the application server can use an SQLJ application, the SQLJ statements must be processed for the database server. By default, four DB2 packages are created in the database; one package is created for each isolation level. The customization process augments the profiles with information that is specific to the database. If you do not customize the SQLJ profiles, the SQLJ application uses dynamic SQL like a JDBC application.
   - "Customizing and binding profiles for Structured Query Language in Java (SQLJ) applications" on page 515.
   - Customize and bind SQLJ profiles with the wsadmin scripting tool. See the topic, Customizing and binding SQLJ profiles with the wsadmin tool.
   - "Customizing and binding SQLJ profiles with the db2sqljcustomize tool" on page 517.

# Deploying SQLJ applications that use container-managed persistence (CMP)

Embed Structured Query Language in Java (SQLJ) statements in your applications to maximize the efficiency of transactions with your databases. Before your applications can take advantage of SQLJ, you must deploy the application and customize the SQLJ profiles that are created. The application server provides functionality to use SQLJ as the persistence mechanism for enterprise beans that use container-managed persistence. Deploy the CMP beans in the application server to enable SQLJ support.

## Before you begin

You need an application that uses SQLJ and container-managed persistence. Develop this application in Rational Application Developer or another development tool.

## About this task

Deploy SQLJ applications in the application server to simplify the process of SQLJ translation and bean deployment. The application server includes these new features for SQLJ support:

- Deploying CMP beans during the application installation in the application server.

- Customizing and binding SQLJ profiles with the administrative console or scripting.
- Customizing and binding SQLJ applications again without needing to reinstall the application.

You can also deploy the SQLJ application using the ejbdeploytool. Read the topic on deploying SQLJ applications that use container-managed persistence (CMP) with the ejbdeploy tool for more information.

## Procedure

1. Create a top-down mapping to a DB2 database.
2. From your DB2 installation, copy the `sqlj.zip` file to a directory on your workstation.
3. Deploy the EAR file in the administrative console.
   a. Click **Applications** > **Install New application**.
   b. Select **Local file system** or **Remote file system**, and browse to the EAR file.
   c. Select **Detailed - Show all installation options and parameters**. Click **Next**.
   d. In **Step 1: Select installation options**, select **Deploy enterprise beans**. Configure any other options, and click **Next**.
   e. In **Step 3: Provide options to perform the EJB deploy**, select **SQLJ** for **Deploy EJB option - Database access type**.
   f. Enter the location of the `sqlj.zip` file in the **SQLj class path** field.
   g. Complete the installation process for the application.

## What to do next

After the enterprise application is deployed, customize the SQLJ profiles using the administrative console, scripting, or the db2sqljcustomize tool:

- For administrative console support, read the topic on customizing and binding profiles for Structured Query Language in Java (SQLJ) applications.
- For scripting support, read the topic on the application management command group for the AdminTask object.
- For use of the db2sqljcustomize tool, read the topic on customizing and binding SQLJ profiles with the db2sqljcustomize tool.

# Deploying SQLJ applications that use container-managed persistence (CMP) with the ejbdeploy tool

Embed Structured Query Language in Java (SQLJ) statements in your applications to maximize the efficiency of transactions with your databases. Before your applications can take advantage of SQLJ, you must deploy the application and customize the SQLJ profiles that are created. The application server provides functionality to use SQLJ as the persistence mechanism for enterprise beans that use container-managed persistence. Use the ejbdeploy tool to deploy the application.

## About this task

You can deploy SQLJ applications with the ejbdeploy tool to deploy the enterprise application in a stand-alone environment.

Alternatively, the application server includes enhanced SQLJ support for applications that use container-managed persistence (CMP). The new features include:

- Deploying CMP beans during the application installation in the application server.
- Customizing and binding SQLJ profiles with the administrative console or scripting.
- Customizing and binding SQLJ applications again without needing to reinstall the application.

These enhancements reduce the complexity of installing, deploying, and customizing SQLJ applications for both container-managed and bean-managed persistence.Read the topic on deploying SQLJ applications

that use container-managed persistence (CMP) for more information.

### Procedure

1. Create a top-down mapping to a DB2 database.
2. From your DB2 installation, copy the `sqlj.zip` file to a directory on your workstation.
3. Modify the Java build path of your enterprise bean JAR project to include the `sqlj.zip` file.
4. Use Rational Application Developer or the DB2 SQLJ translator to automatically translate SQLJ.
   - Use Rational Application Developer:
     a. From the Project Navigator, click ***EJB_JAR_PROJECT_NAME*** > ***SOURCE_FOLDER*** > **META-INF** > **backends** > ***database_version***.
     b. Open Map.mapxmi in the Mapping editor.
     c. On the **Overview** panel, highlight the name of your JAR project in the Enterprise Beans column. You must highlight the name of the JAR project, not the name of one of the enterprise beans that is listed.
     d. On the **Properties** panel, expand **SQLJ**.
     e. Set **Is using SQLJ?** to `True`.
     f. Set **Translator Module** to the fully qualified path of the sqlj.zip file on your workstation.
     g. Save the Map.mapxmi file.
     h. Export the enterprise archive (EAR) file.
   - Use the DB2 SQLJ translator. This tool creates a .java version of your .sqlj file and a serialized profile, with a .ser extension, that is used later in processing. Refer to the DB2 documentation for more information on the SQLJ translator tool.
5. Deploy the EAR file with the ejbdeploy tool.
   a. Verify that the app_server_root/bin directory is in your class path.
   b. Run the ejbdeploy command utility with the `-sqlj` option. The ejbdeploy command will generate an EAR file with the name you specify and an Ant script with the name *application_name*.ear.xml.

      For example: :

      ```
      ejbdeploy d:\application_name.ear
                working d:\deployed_application_name.ear
                -sqlj
                -dbvendor DB2UDB_V81
                -cp "C:\PROGRA~1\IBM\SQLLIB\java\sqlj.zip"
      ```

      **Note:** Supply the location of the SQLJ translator sqlj.zip file with -cp, which is the class path option The ejbdeploy command does not access `sqlj.zip` from your system class path.
6. Choose the option for customization.
   - Use the application server's SQLJ support. Install the deployed application to customize the SQLJ profiles with the application server or scripting.
     a. Install the enterprise application in the application server.

        **Note:** Do not select **Deploy enterprise beans** during the application installation process in the administrative console. If you redeploy the enterprise beans from the administrative console, you will lose the customization changes that you have made.
     b. Customize the SQLJ profiles.
        – For administrative console support, read the topic on customizing and binding profiles for Structured Query Language in Java (SQLJ) applications.
        – For scripting support, read the topic on the application management command group for the AdminTask object.
   - Customize and bind the SQLJ profiles with the db2sqljcustomize tool. Read the topic on customizing and binding SQLJ profiles with the db2sqljcustomize tool.

# Deploying SQLJ applications that use bean-managed persistence, servlets, or sessions beans

You can embed Structured Query Language in Java (SQLJ) statements in your applications to maximize the efficiency of transactions with your databases. Before your applications can take advantage of SQLJ, deploy the application and customize the created SQLJ profiles. You can use Rational Application Developer or the DB2 SQLJ translator to translate the application before deploying it on the application server.

## Before you begin

Create an SQLJ application using Rational Application Developer or another development tool.

## About this task

To deploy SQLJ applications that do not use container-managed persistence, translate the SQLJ application first to configure it for the application server environment. After translation, customize the SQLJ profiles in the application server, with scripting, or with the db2sqljcustomizer tool.

SQLJ support for applications that use bean-managed persistence include these features:

- Customizing and binding SQLJ profiles with the administrative console or scripting.
- Customizing and binding SQLJ applications again without reinstalling the application.

## Procedure

1. Optional: Create a backup copy of your .java file. For example if your file is called `MyServlet.java`, copy `MyServlet.java` to `MyServlet.java.bkup`.
2. Optional: Rename your .java file to a file name with an `.sqlj` extension. For example, if your application is a servlet named `MyServlet.java`, rename `MyServlet.java` to `MyServlet.sqlj`
3. Optional: Edit the SQLJ file to convert the JDBC syntax to SQLJ syntax. When using SQLJ, if you want connection management for the application server to function properly, specify correct connection contexts.

   For example, convert the following JDBC operation:

   ```
   Connection con = dataSource.getConnection();
   Statement stmt = con.createStatement();
   stmt.execute("INSERT INTO users VALUES (1, 'user1')");
   con.commit();
   ```

   to the following SQLJ:

   ```
   // At the top of the file and just below the import statements, define Connection_Context
   #sql context Connection_context;
   .
   .
   Connection con = dataSource.getConnection();
   .
   .
   Connection_context ctx1 = new Connection_context(con);
   .
   .
   #sql [ctx1] {INSERT INTO users VALUES (1, 'user1')};
   .
   .
   con.commit(); ctx1.close();
   ```

   When you run the SQLJ translator, the `.java` file that is created has the same name as your old `.java` file. This provides you with a seamless transition to the SQLJ technology.
4. From your DB2 installation, copy the `sqlj.zip` file to a directory on your workstation. Modify the Java build path of your enterprise bean Java archive (JAR) file project to include the `sqlj.zip` file.

5. Use Rational Application Developer or the DB2 SQLJ translator to automatically translate SQLJ.
   - Use Rational Application Developer:
     a. In the Project Navigator, right-click your JAR project, and select **Add SQLJ Support...**.
     b. Select the check boxes for the applications for which you want SQLJ support.
     c. In the **SQLJ JAR file** field, type the fully qualified path to the `sqlj.zip` file that you previously copied to your workstation.
     d. Click **Finish**.
     e. Export the enterprise archive (EAR) file.
   - Use the DB2 SQLJ translator. This tool creates a `.java` version of the `.sqlj` file and a serialized profile, with an `.ser` extension, that is used later in processing. Refer to the DB2 documentation for more information about the SQLJ translator tool.
6. Package your JAR file for the enterprise application.
7. Install the application onto the application server, or customize the profiles with the db2sqljcustomize tool.
   - Customize the profiles with the application server.
     a. Package the JAR file for your enterprise beans, servlets, and any `.ser` files into an enterprise archive.
     b. Install the application in the application server, and customize SQLJ profiles with the administrative console or the wsadmin tool.

        **Note:** Do not select **Deploy enterprise beans** during the application installation process in the administrative console. If you redeploy the enterprise beans from the administrative console, you lose the customization changes that you have made.

        The application server provides enhanced support for SQLJ applications. Install the SQLJ application in the application server, and you can customize and bind SQLJ profiles through the administrative console or scripting:
        - To customize the SQLJ profiles with the administrative console, read the topic about customizing and binding profiles for Structured Query Language in Java (SQLJ) applications.
        - To customize SQLJ profiles with scripting, read the topic about the application management command group for the AdminTask object.
   - To use the db2sqljcustomize tool, read the topic about customizing and binding SQLJ profiles with the db2sqljcustomize tool for more information.

# Customizing and binding profiles for Structured Query Language in Java (SQLJ) applications

Simplify the process of customizing and binding SQLJ profiles for your applications by performing these functions in the administrative console or with scripting. SQLJ profiles must be customized and bound before the enterprise application can use the application's embedded SQL.

## Before you begin

You must have an SQLJ application that has already been deployed and installed in the application server.

For SQLJ applications that use container-managed persistence, you can deploy the application in two ways:

- Deploy the SQLJ application in the application server. See the topic on deploying SQLJ applications that use container-managed persistence (CMP) for more information.
- Deploy SQLJ applications with the ejbdeploy tool. See the topic on deploying SQLJ applications that use container-managed persistence (CMP) with the ejbdeploy tool.

For SQLJ application that use bean-managed persistence, see the topic on deploying SQLJ applications that use bean-managed persistence, servlets, or session beans.

## About this task

To take advantage of SQLJ applications in the application server, you need to customizing the SQLJ profiles that contain the embedded SQL statements. By default, four DB2 packages are created in the database; one for each isolation level. The customization process augments the profiles with information that is specific to the DB2 database. The database uses this information at run time.

In addition to profile customization, you need to bind the customized profiles to the DB2 database. Profile binding should only take place after the SQLJ profiles are customized.

You can also customize and bind profiles with scripting or the db2sqljcustomize tool:

- For scripting support, read the topic on the application management command group for the AdminTask object.
- For information on the db2sqljcustomize tool, read the topic on customizing and binding SQLJ profiles with the db2sqljcustomize tool for more information. If you customize profiles with the db2sqljcustomize tool, you will need to reinstall the application.

## Procedure

1. Make sure the necessary database tables exist, as described in the topic on deploying data access applications.
2. Navigate to the SQLJ application that is installed in the application server. Click **Applications** > **Websphere enterprise applications** > ***app_name***.

   **Note:** Do not run multiple sessions of the administrative console to customize and bind profiles that are in the same EAR file.
3. Navigate to the SQLJ profiles section. Click **SQLj profiles**. When you click this link, the application server expands the EAR file for the application into a temporary directory; there might be a delay before the panel for SQLJ profiles is displayed.
4. Select **Customize and bind profiles** or **Bind packages**. Choose your option based on the profiles with which you are working:
   - If your profiles have not been customized, or you want to customize the profiles again, choose **Customize and bind profiles**.
   - If the profiles are already customized, choose **Bind packages**.
5. Choose to select profiles or a profile group to customize and bind.
   - Select profiles from the list that is provided.
     a. Select the profiles from the list and click **Add**. The list displays the SQLJ profiles that are present in the enterprise application.

        **Note:**
        – Select more than one profile by holding CTRL.
        – Select a contiguous list of profiles by selecting the first profile name, holding SHIFT, and selecting the last profile. You will select the first profile, last profile, and any profiles in the middle.

     b. Select **Customize/bind the selected SQLj profiles as a group** This option specifies that the application server will create a .grp file that contains the SQLj profiles that are processed. You can use the .grp file for other binding operations in the future. After you have completed this panel and click **OK**, you will be given an option to download the .grp file.
   - Select **Use a profile group file to specify profiles to customize/bind**. Select this to specify a profile group to process. Click **Browse...** to locate the file on the system.

6. Complete the necessary information to connect to the database. You need to complete the following fields:

   **Database URL**
   Specifies the URL of the database to which the profile/s will be bound. The typical syntax is:
   `jdbc:db2://<host name="">:<port>/<database name="">.</database></port></host> or`

   or
   *fully_qualified_host_name*:*port*

   **User** Specifies the user ID for the database administrator on the server where the database is located.

   **Password**
   Specifies the password for the database administrator on the server where the database is located.

   **Additional options**
   Specifies additional options to use during the customization and bind processes. See the DB2 documentation for a complete list of customization options.

   **Class path**
   Specifies the class path where sqlj.zip, and db2jcc.jar or db2jcc4.jar are located.
7. Click **OK**.

   **Note:** If you are processing a large enterprise application, or you are processing many SQLJ profiles, the process might take longer than the default timeout for the administrative console. The default connection timeout for the application server's administrative console is set to 30 minutes. If the default timeout is reached and you lose the connection to the server, you can check the system output log for the final results of the customization and bind process.

   To prevent this disconnection, configure the console session timeout to a longer period of time. After a successful customization and binding process, check the system output log for the total processing time. Use that time period as a basis for the new timeout value. For information about how to configure the console timeout, see the topic on changing the console session expiration.

## Results

After the application server finishes processing the SQLJ profiles, you will see the results from the customization and binding. The results panel displays messages from the database server, as well as summary results from the application server.

If the operation completed successfully, the following message will be printed to the system log:

```
ADMA0507I=ADMA0507I: The SQLJ operation on application {0} completed successfully.  Exit code: {1}
ADMA0507I.explanation=This informational message indicates the program status.
ADMA0507I.useraction=No user action is required.
```

If the operation did not complete successfully, the following message will be printed to the system out log:

```
ADMA0506I=ADMA0506I: The SQLJ operation on application {0} did not complete successfully.  Exit code: {1}
ADMA0506I.explanation=The SQLJ operation encountered a problem.  This informational message indicates
the program status. Prior messages in the command output give details of the problem.
ADMA0506I.useraction=Check the command output for the cause of the problem.
```

## Customizing and binding SQLJ profiles with the db2sqljcustomize tool

Customize and bind SQLJ profiles with the db2sqljcustomize tool before you install the SQLJ application in the application server.

## Before you begin

To perform this task, you must have SQLJ application that has been deployed, but the application should not be installed in the application server. If the application is already installed in the application server, you will need to reinstall the application after you customize the profiles. You also need serialized profiles for the SQLJ application.

For SQLJ applications that use container-managed persistence, you can deploy the application in two ways:

- Deploy the SQLJ application in the application server. See the topic on deploying SQLJ applications that use container-managed persistence (CMP) for more information.
- Deploy SQLJ applications with the ejbdeploy tool. See the topic on deploying SQLJ applications that use container-managed persistence (CMP) with the ejbdeploy tool.

For SQLJ application that use bean-managed persistence, see the topic on deploying SQLJ applications that use bean-managed persistence, servlets, or sessions beans.

## About this task

To take advantage of SQLJ applications in the application server, you need to customize the SQLJ profiles. The customization process augments the profiles with information that is specific to the DB2 database. The database uses this information at run time. By default, four DB2 packages are created in the database; one package is created for each isolation level.

The application server supports customizing and binding the SQLJ profiles in the administrative console or with scripting:

- For administrative console support, read the topic on customizing and binding profiles for Structured Query Language in Java (SQLJ) applications.
- For scripting support, see the topic on the application management command group for the AdminTask object.

## Procedure

1. Make sure the necessary database tables exist, as described in the topic on deploying data access applications.
2. Transfer the serialized profiles to the environment on which you installed your application. Alternatively, use the Java `jar` command to extract the serialized profiles from the JAR file in your installed EAR directory.
3. Add the location for the SQLJ profiles and the application's JAR file to your environment's class path.
4. Make sure the necessary database tables exist, as described in the topic on deploying data access applications.
5. Optional: If your application is not running in a clustered environment, you can use the Ant script to make customization easier. If you run a batch SQLJ customization against an EAR file with the ejbdeploy tool, the tool produces an Ant script that is named *application_name*.ear.xml. You can use this script file to run the DB2 customizer program against the serialized profiles in all of the enterprise bean JAR files for the associated EAR file. The script updates each enterprise bean's JAR file with a serialized profile and replaces the JAR files in the existing EAR file with the modified versions.

   The tool is:

   - AIX HP-UX Solaris Linux ws_ant
   - Windows ws_ant.bat

   a. Change the values of the database URL, and the database user and password properties in ejbdeploy.sqlj.properties. This file is a common file to all Ant scripts that are generated by the ejbdeploy command. The ejbdeploy.sqlj.properties script defines the global properties for:
      - Database URL - db.url

- User - db.user
- Password - db.password

The Ant script uses the URL, user, and password properties in the serialized profile to customize the profile. By default, the properties for the serialized profile are created from the global properties.

b. Run the Ant script, specifying the `properties` target. For example:

```
ws_ant -buildfile application_name.ear.xml properties
```

This script creates the properties file, *application_name*.ear.properties. The *application_name*.ear.properties file contains properties that specify the default names for the packages corresponding to each serialized profile in the EAR file. This is a sample properties file:

```
url.MyEJB1.jar.DB2UDBNT_V8_1=jdbc:db2://localhost:50000/MyDB1
user.MyEJB1.jar.DB2UDBNT_V8_1=dbuser
password.MyEJB1.jar.DB2UDBNT_V8_1=dbpassword
pkg.MyEJB1.jar.DB2UDBNT_V8_1=TEST
url.MyEJB2.jar.DB2UDBNT_V8_1=jdbc:db2://localhost:50000/MyDB2
user.MyEJB2.jar.DB2UDBNT_V8_1=dbuser
password.MyEJB2.jar.DB2UDBNT_V8_1=dbpassword
pkg.MyEJB2.jar.DB2UDBNT_V8_1=WORK
```

c. Use the DB2 Control Center to identify the packages that are installed in the database. The DB2 SQLJ customizer requires a type 4 database URL in the form of:

```
jdbc:db2://host-name:port/database-name
```

It also requires a user and password. The value of the port is 50000, unless you change it when you install DB2.

d. Change the names that are used by the script file to ensure that the names for each customization profile do not conflict with existing package names that are in the database. Ant scripts that are generated for different EAR files use the same package names by default, and the script will overwrite existing packages unless you change the names. Overwritten packages can cause errors at run time.

DB2 uses the first seven characters of the package name. The DB2 customizer uses this name to create four packages in the database. For example, if you specify the name TEST, the DB2 customizer will create packages called TEST1, TEST2, TEST3, and TEST4.

e. Run the Ant script. The Ant script updates the original EAR file with the modified serialized profiles.

**Note:** Verify that you have db2jcc.jar in the class path. This file should have been added to the class path environment variable when DB2 V8 FixPak1 was installed.

A sample Ant command looks like this:

```
ws_ant -Dwork.dir=tmp
       -Dscript.property.file=other.properties
       -buildfile application_name.ear.xml
```

where:

- `-buildfile` specifies the XML file to create.
- `-Dscript.property.file` specifies a different properties file. This parameter is optional. If you want your Ant script to use a another file instead of *application_name*.ear.properties, specify the Dscript.property.file property when you run the script.
- `-Dwork.dir` specifies a temporary working directory for the script. The script will create and delete files and subdirectories in this directory. If the working directory contains existing files and directories with the same name as the files and directories used by the script, the script will erase or overwrite the files and directories. This script creates and uses a directory called `tmp` as its working directory.

f. Proceed to installing the application in the application server..

6. Run the db2sqljcustomize tool to customize the SQLJ profiles that correspond to each enterprise bean's JAR file. When you generate your deployment code, serialized profiles (files with a .ser extension) that are specific to your application are created. These profiles exist in the same directory as your SQLJ files, and the files must be customized to the environment before they can be used. When you run the DB2 SQLJ customizer against the serialized profiles, you create static SQL in the database that DB2 will use at run time. The customization phase creates four database packages that contain static SQL, one for each isolation level.
   a. Optional: Consider using the SQLJ customizer tool to enable context caching for your application's data source connections. DB2 V8.1 fix pack 6 provides the new caching option with the db2sqljcustomize tool called db2optimize. You can run this option if your application uses the explicit connection context instead of the default context.

      **Note:**

      - SQLJ context caching support requires the DB2 with IBM JCC driver or Version 2.2 or later of the DB2 Universal JDBC Driver with APAR PQ87786 applied.
      - If you want to enable context caching for an application or BMP bean that caches connections across transaction boundaries, you cannot use shareable connections. Use the get/use/close pattern of connection usage when you invoke the db2optimize option, or an object closed exception occurs. The following code gives an example of incorrect connection usage for context caching:

        ```
        utx.begin();
             cons =ds.getConnection(
             request.getParameter("db.user"),
             request.getParameter("db.password"));
                 cmctx1 = new CM_context(cons);
                 #sql [cmctx1] {DELETE FROM cmtest WHERE id=1};
         utx.commit();
               //The next statement verifies the result:
                 #sql [cmctx1] cursor1 = {SELECT id, name FROM cmtest WHERE id=1};
        ```

        In this case, the `Select` statement elicits an object closed exception. To prevent the exception from occurring, close the connection before committing the transaction. Then get a new connection and a new context before running the `Select` statement.

      The following example code demonstrates proper syntax for running the option on the serialized profile:

      ```
      sqlj -db2optimize SQLJTransactionTest.sqlj
      db2sqljcustomize -url jdbc:db2://localhost:50000/dbname -user USER_NAME -password PASSWORD
      SQLJTransactionTest_SJProfile0.ser
      ```

   b. Run the db2sqljcustomize tool to customize the SQLJ profiles. After you successfully run the db2sqljcustomize command, customized profiles exist in the directory from which you issued the command. If you run the db2sqljcustomize command from the directory that contains the serialized profiles that were not customized, the customized versions will overwrite previous versions that have the same file names.

      The recommended syntax for running the db2sqljcustomize command is:

      ```
      db2sqljcustomize -url JDBC_URL -user USER_NAME  -password PASSWORD
      [-rootpkgname PACKAGE_NAME] SERIALIZED_PROFILE1 SERIALIZED_PROFILE2 ...
      ```

      where:

      - *JDBC_URL* is the JDBC URL that is used to access the DB2 system where your tables reside.
      - *USER_NAME* is a valid user name for the DB2 system where your tables reside.
      - *PASSWORD* is the password for the specified user name.
      - *PACKAGE_NAME* is a valid partitioned data set (PDS) member name, up to seven characters long. Each of the four packages that are created by the profile customizer begin with this name and are appended with a number from 1 to 4. If you customize only one serialized profile, this value defaults to a shortened version of the serialized profile name and the -rootpkgname

parameter is not required. If you customize more than one serialized profile with the same command, there is no default value and the -rootpkgname parameter is required.

- *SERIALIZED_PROFILE#* is the name of the serialized profile that you are customizing.
  - To customize more than one serialized profile with the same command, list multiple files, separated by spaces.
  - Alternatively, you can specify the `-rootpkgname` parameter to customize more than one serialized profile with the same command.

**Note:** The following options provide more control over the customization process:

- `-automaticbind yes` specifies to run the DB2 SQLJ customizer against the serialized profiles to create static SQL in the database that the database will use at run time. The customization phase creates four database packages that contain static SQL, one for each isolation level.
- `-onlinecheck NO and -bindoptions "VALIDATE RUN"` specifies settings to bypass errors during a profile customization and ensure a successful customization.

7. Update the JAR file for the enterprise beans with the serialized profiles.
8. Use the `jar` command to replace the serialized profiles in your JAR file with the customized profiles.

   **Note:** The customized files must be placed in a location that is part of the application class path, and they must exist ahead of the serialized profiles that are not customized in your JAR file. If you decide to replace the serialized profiles in your JAR file, maintain the directory structure in which the profiles exist.
9. Package the JAR file for the enterprise bean, servlets, and serialized profiles into an enterprise archive (EAR) file.
10. Install the application in the application server.

    **Note:** Do not select **Deploy enterprise beans** during the application installation process in the administrative console. If you redeploy the enterprise beans from the administrative console, you will lose the customization changes that you have made.

## SQLJ profiles and pureQuery bind files settings

Use this panel to do customization and binding for the Structured Query Language in Java (SQLJ) profiles for DB2 that are included in this application. You can also use this panel to do binding for pureQuery bind files in the application. You can view SQLJ profiles for other database types, but you cannot change these profiles. PureQuery bind files are only valid for DB2. Use SQLJ or pureQuery to develop data access applications that connect to DB2 databases. SQLJ is a set of programming extensions that enable a programmer to use the Java programming language to embed statements that provide SQL database requests. PureQuery provides an alternate set of APIs that can be used instead of JDBC to access the DB2 database.

To view this administrative console page, click **Applications** > **Websphere enterprise applications** > ***app_name*** > **SQLJ profiles and pureQuery bind files**.

Advantages of developing applications with SQLJ include improved performance and a shorter, more efficient development cycle. With SQLJ, you can:

- Improve performance by using static SQL statements.
- Reduce the development cycle by:
  - Writing less code with the simpler SQLJ syntax, which reduces the amount of code that is required to execute statements, and set and retrieve parameters.
  - Detecting programming errors earlier in the development phase with the online check function, which performs data type and schema validation. Activate this function by running it as an option with the **db2sqljcustomize** command. See the DB2 documentation for a complete description of the SQLJ customize command.

DB2 pureQuery run time is an alternative set of APIs to JDBC or SQLJ. Advantages of developing applications with pureQuery include allowing SQL execution to be either dynamic or static. In addition to improved performance by using static SQL statements, pureQuery has better problem determination and diagnosis because it allows for errors at the DB2 server to be related back to application artifacts rather than to SQL that was generated by an application generator.

***Customize and bind profiles:***

Specifies that the application server processes the SQLJ profiles that you select from this application.

**Note:** This selection does not apply to pureQuery. If selected, this option is ignored when processing pureQuery bind files.

By default, one DB2 package is created in the database for each isolation level. The customization process augments the profile or profiles with information that is specific for the DB2 database for use at run time. Typically, the customization process should run after the SQLJ application has been translated and before the application is started. If you do not run the customization step, the SQLJ application uses dynamic SQL like a JDBC application.

Binding DB2 SQLJ profiles involves the process of binding the customized SQLJ profiles to the DB2 database.

***Bind packages:***

Specifies that the application server binds the SQLJ profiles that you select to the DB2 database server.

**Note:** This selection does not apply to pureQuery. If selected, this option is ignored when processing pureQuery bind files.

Bind packages from the SQLJ application that have already been customized.

***Select and order the profiles to customize/bind:***

Specifies the profiles to process from the list that is provided.

- Select a profile or group of profiles from the **Available profiles**, and click **Add** to add the profile that is selected to **Selected Profiles**.
- Select a profile or group of profiles from the **Selected Profiles**, and click **Remove** to add the profile that is selected to **Available profiles**.

When SQLJ or pureQuery profiles have been added to **Selected Profiles**, select profiles from that list and use **Move Up** or **Move Down** to change the order in which the profiles are processed.

***Customize/bind the selected SQLJ profiles as a group:***

Specifies that the application server creates a .grp file that contains the SQLJ profiles that you selected.

**Note:** This selection does not apply to pureQuery. If selected, this option is ignored when processing pureQuery bind files.

When you click **OK**, there is an option on the next panel to download the .grp file.

***Use a profile group file to specify profiles to customize/bind:***

Specifies a profile group file from the local file system to customize or bind.

***Database URL:***

Specifies the URL of the database to which the profile or profiles are bound.

The typical syntax is:
`jdbc:db2://host_name:port_name/database_name`

***User:***

Specifies the user ID for the database administrator on the server where the database is located.

***Password:***

Specifies the password for the database administrator on the server where the database is located.

***Additional options:***

Specifies additional options to use during the customization and bind processes.

Options for pureQuery binding uses the following syntax:
`-bindoptions "BLOCKING NO"`

For more information about pureQuery bind options, refer to the DB2 pureQuery Bind Utility topic.

***Class path:***

Specifies the class path where the sqlj.zip, and db2jcc.jar or db2jcc4.jar files for SQLJ are located. Specifies the class path where the pdq.jar, pdqmgt.jar, db2jcc.jar, db2jcc_license_cisuz.jar files for pureQuery are located.

## Download SQLJ profile group

Use this panel to download the group file for the Structured Query Language in Java (SQLJ) profiles that are bound together as a single package on the DB2 database server. You can use the file when performing future customization or binding work on the application. Click the link that is provided to download the profile group to your local file system. The group file has a filename extension of .grp and a HTTP Content-Type of text/plain.. Your web browser settings might cause the browser to display the file contents rather than prompting you for a download destination. If this happens, you can manually copy and paste the contents into your own .grp file.

**Note:** This topic does not apply to IBM Optim PureQuery Runtime. IBM Optim PureQuery Runtime does not support binding pureQuery bind files as a group.

Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***app_name*** > **SQLJ profiles and pureQuery bind files**. When you are selecting the profiles to customize and bind, select **Customize/bind the selected SQLJ profiles as a group** to view this console panel.

## Review results

Use this panel to review the results from the customization and binding process for the Structured Query Language in Java (SQLJ) profiles or pureQuery bind files. Use SQLJ or IBM Optim PureQuery Runtime to develop data access applications that connect to DB2 databases. SQLJ is a set of programming extensions that enable a programmer to use the Java programming language to embed statements that provide SQL (Structured Query Language) database requests. IBM Optim PureQuery Runtime provides an alternate set of APIs that can be used instead of JDBC to access the DB2 database.

Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **SQLj profiles and pureQuery bind**. Select profiles to customize and bind, complete the necessary fields, and click **OK** to view this console panel.

***Review results:***

Displays the results of the customization and bind process. The field shows information that is received from the database and summary statements from the application server.

# Using embedded SQLJ with the DB2 for z/OS Legacy driver

Structured Query Language in Java (SQLJ) is a set of programming extensions that enable a programmer, using the Java programming language, to embed statements that provide Structured Query Language (SQL) database requests. You can use the DB2 for z/OS Legacy driver with your data access applications.

## About this task

**Notes:**

1. To use SQLJ with WebSphere Application Server for z/OS and the DB2 for z/OS Legacy Driver, install DB2 APAR PQ76442.
2. Container Managed Persistence (CMP) beans generated using SQLJ are not supported by the DB2 for z/OS Legacy Driver. Use the DB2 Universal Driver for CMPs that are generated using SQLJ.

Following are the steps required to develop applications with SQLJ that run on WebSphere Application Server for z/OS v6.0 using the DB2 for z/OS Legacy driver.

## Procedure

1. Design your application in Rational Application Developer according to your requirements, using SQLJ when necessary. For example, if you develop a bean called Test that uses BMP, code TestBean.sqlj (instead of TestBean.java).
   a. From your DB2 for z/OS installation, copy the `db2sqljclasses.zip` file to a directory on your workstation, then modify the Java Build Path of your EJB Java archive (JAR) project to include the `db2sqljclasses.zip` file.
   b. Translate your SQLJ code according to the following steps:
      1) Locate your SQLJ file, then use ASCII mode transfer to FTP it to an HFS in your z/OS environment.
      2) Use the sqlj command to translate your SQLJ code into Java code. Two files are produced, one with a `.java` extension and the other with an `.ser` extension.

         ```
         sqlj -compile=false SQLJ_FILE_NAME
         ```

      3) Use ASCII mode transfer for the `.java` file and BINARY mode transfer for the `.ser` file to move these files back to the directory on your workstation where the SQLJ file resides.
      4) Refresh the project.
   c. Generate deployment code for your application.
   d. Export your EAR file.
2. Install your application
   a. Create a data source with the DB2 for zOS Local JDBC Provider (RRS). When you define your JDBC Provider and data source, the default values are sufficient for providing SQLJ support.
   b. Install your application into WebSphere Application Server.

      Use the data source you created in Step 1 to resolve your resource references.
3. Customize your serialized profiles When you generate your deployment code, serialized profiles, or files with an `.ser` extension, that are specific to your application, are created. These profiles must be customized in a z/OS environment before they can be used.
   a. Use binary transfer to transfer the serialized profiles to the z/OS environment on which you installed your application. Alternatively, use the Java jar command to extract the serialized profiles from the EJB JAR file in your installed EAR directory.

b. Use the db2profc command to customize your serialized profiles. You can get information about the various options associated with this command from the DB2 documentation; however, here are the minimum requirements to customize your profile:

   ```
   db2profc -pgmname=PROGRAM_NAME PROFILE_NAME
   ```

   - Where:
     - *PROGRAM_NAME* must be a valid MVS™ PDS member name, and can be up to seven characters.
     - *PROFILE_NAME* is the name of the serialized profile that you want to customize. You must run db2profc one time for each profile.
   - The profile customizer creates four DBRM data sets in the PDS *USERNAME*.DBRMLIB.DATA. The member names of the DBRMs begin with what you specified as *PROGRAM_NAME*.
   - Ensure that your CLASSPATH environment variable includes:
     - The location of the serialized profile
     - The EJB JAR file in your installed EAR directory
   - Allocate a PDS to contain the DBRMs that are created. Name this PDS *USERNAME*.DBRMLIB.DATA, where *USERNAME* is the user who implements the db2profc command.

     The following fields are an example:

     ```
     Space units=TRACK
     Primary quantity=15
     Secondary quantity=5
     Directory blocks=10
     Record format=FB
     Record length=80
     Block size=27920
     Data set name type=PDS
     ```

c. Place the existing serialized profiles, which are now customized, into a location that is part of the application classpath and that is ahead of the serialized profiles that exist in your EJB JAR file.

   The output of the DB2 profile customizer and the input file have the same name. Move the output file ahead of the original serialized profile in the classpath. Alternatively, you can move the customized profile into the EJB JAR file, replacing the original. It is recommended that you replace the original file.

   **IMPORTANT:** If you run the db2profc command from the directory where the serialized profile exists, the profile customizer overwrites the serialized profile. Because you need only the customized version after the profile customizer has run, this is not a problem.

d. Bind your DBRMs into a package.

   **Note:** You must create your database tables before binding your DBRMs. If you do not, the bind job fails.

   The db2profc customization command creates a series of DBRMs that must be bound into packages. For each customized profile, four DBRMs are created.

   These DBRMs:

   - Are located in *USERNAME*.DBRMLIB.DATA
   - All have names that begin with what you specified as *PROGRAM_NAME*
   - Are numbered from 1-through-4

     For example, if you log in as IBMUSER, and you specify -pgmname=TESTBMP, then run the db2profc command, the four data sets, TESTBMP1, TESTBMP2, TESTBMP3, AND TESTBMP4 are created and placed in the PDS IBMUSER.DBRMLIB.DATA.

     These data sets must be bound into packages with isolation of UR, CS, RS, and RR. You must run a bind for each serialized profile that you customize.

e. After you bind all of the DBRMs into packages, bind the packages into a plan. Name the plan whatever you like.

**IMPORTANT:** You must also include the JDBC packages in the package list (PKLIST) of your new plan. The default names for the JDBC packages to include are DSNJDBC.DSNJDBC1, ..., DSNJDBC.DSNJDBC4. If your installation did not use the default names for the JDBC packages, contact your DB2 administrator to determine the names of the JDBC packages that you need to include.

Following is a sample job used to bind a new plan.

- One serialized profile was created while logged on as IBMUSER.
- **-pgmname=TESTBMP** was specified to run db2profc.
- The new plan is named SQLJPLAN.

```
//BBOOLS  JOB (516B,1025),'IBMUSER',MSGCLASS=H,CLASS=A,PRTY=14,
//         NOTIFY=&SYSUID,TIME=1440,USER=IBMUSER,PASSWORD=IBMUSER,
//         MSGLEVEL=(1,1)
//*******************************************************************
//BINDOLS  EXEC PGM=IKJEFT01,DYNAMNBR=20
//DBRMLIB  DD  DSN=IBMUSER.DBRMLIB.DATA,DISP=SHR
//*        DD  DSN=MVSDSOM.DB2710.SDSNDBRM,DISP=SHR
//SYSTSPRT DD  SYSOUT=*
//SYSPRINT DD  SYSOUT=*
//SYSUDUMP DD  SYSOUT=*
//SYSTSIN  DD  *

 DSN SYSTEM(DB2)

 BIND -
     PACKAGE(TESTBMP) -
     QUALIFIER(IBMUSER) -
     MEMBER(TESTBMP1) -
     VALIDATE(BIND) -
     ISOLATION(UR) -
     SQLERROR(NOPACKAGE) -

 BIND -
     PACKAGE(TESTBMP) -
     QUALIFIER(IBMUSER) -
     MEMBER(TESTBMP2) -
     VALIDATE(BIND) -

  QUALIFIER(IBMUSER)                -
  PKLIST(TESTBMP.*                  -
         DSNJDBC.*                ) -
  ACTION(REPLACE) RETAIN            -
```

```
  VALIDATE(BIND)

END
/*
```

f. Grant the appropriate authority to your new plan. Use an interface to DB2, such as SPUFI, to grant the authority. Issue this command:

```
GRANT EXECUTE ON PLAN PLANNAME TO APPSERVERID
```

Where:

- *PLANNAME* is the name of the plan that you bound.
- *APPSERVERID* is the ID under which WebSphere Application Server runs; for example, CBSYMSR1.

4. Configure your data source to use your new plan
   a. From the WebSphere Application Server for z/OS Administrative Console, navigate to your Data Source and select Custom Properties.
   b. Select the Custom Property **planName**.
   c. Update the value of **planName** with what you named your plan when it was bound.
   d. Set **enableSQLJ** to **true**.
5. Stop and restart your server.
6. Run your application.

# Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

## Default product locations (distributed)

The following file paths are default locations. You can install the product and other components or create profiles in any directory where you have write access. Multiple installations of WebSphere Application Server - Express products or components require multiple locations. Default values for installation actions by root and nonroot users are given. If no nonroot values are specified, then the default directory values are applicable to both root and nonroot users.

*app_client_root*

*Table 56. Default installation root directories for the Application Client for IBM WebSphere Application Server.*

*This table shows the default installation root directories for the Application Client for IBM WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppClient` (Java EE Application client only)<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\Program Files\IBM\WebSphere\AppClient` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\IBM\WebSphere\AppClient` |

*app_server_root*

*Table 57. Default installation directories for WebSphere Application Server.*

*This table shows the default installation directories for WebSphere Application Server - Express.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/AppServer<br>HP-UX Linux Solaris /opt/IBM/WebSphere/AppServer<br>Windows C:\Program Files\IBM\WebSphere\AppServer |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/AppServer<br>Windows *user_home*\IBM\WebSphere\AppServer |

*component_root*

The component installation root directory is any installation root directory described in this topic. Some programs are for use across multiple components—in particular, the Web Server Plug-ins, the Application Client, and the IBM HTTP Server. All of these components are part of the product package.

*gskit_root*

IBM Global Security Kit (GSKit) can now be installed by any user. GSKit is installed locally inside the installing product's directory structure and is no longer installed in a global location on the target system. The following list shows the default installation root directory for Version 8 of the GSKit, where *product_root* is the root directory of the product that is installing GSKit, for example IBM HTTP Server or the web server plug-in.

AIX HP-UX Linux Solaris

*product_root*/gsk8

Windows

*product_root*\gsk8

*profile_root*

*Table 58. Default profile directories.*

*This table shows the default directories for a profile named profile_name on each distributed operating system.*

| User | Directory |
|---|---|

# Chapter 10. Developing Dynamic caching

This page provides a starting point for finding information about the dynamic cache service, which improves performance by caching the output of servlets, commands, web services, and JavaServer Pages (JSP) files.

Dynamic caching features include replication of cache entries, cache disk offload, Edge-Side Include caching, web services, and external caching. Use external caching to control caches outside of the application server.

## Configuring cacheable objects with the cachespec.xml file

Use this task to define cacheable objects inside the `cachespec.xml`, found inside the web module `WEB-INF` or enterprise bean `META-INF` directory.

### Before you begin

Enable the dynamic cache. Refer to the Using the dynamic cache service article for more information.

### About this task

You can save a global `cachespec.xml` in the application server properties directory, but the recommended method is to place the cache configuration file with the deployment module. The root element of the `cachespec.xml` file is <cache>, which contains <cache-entry> elements.

**gotcha:** In situations where there is a global `cachespec.xml` file in the application server properties directory, and a `cachespec.xml` file in an application, the entries in the two cachespec.xml files are merged. If there are conflicting entries in the two files, the entries in the in the `cachespec.xml` file that is in the application override the entries in the global `cachespec.xml` file for that application.

The <cache-entry> element can be nested within the <cache> element or a <cache-instance> element. The <cache-entry> elements that are nested within the <cache> element are cached in the default cache instance. Any <cache-entry> elements that are in the <cache-instance> element are cached in the instance that is specified in the **name** attribute on the <cache-instance> element.

Within a <cache-entry> element are parameters that allow you to complete the following tasks to enable the dynamic cache with the `cachespec.xml` file:

### Procedure

1. Develop a `cachespec.xml` file.
   a. Create a caching configuration file.

      In the *<app_server_root>*`/properties` directory, locate the `cachespec.sample.xml` file.
   b. Copy the `cachespec.sample.xml` file to `cachespec.xml` in web module `WEB-INF` or enterprise bean `META-INF` directory.
2. Define the cache-entry elements necessary to identify the cacheable objects. See the cachespec.xml file topic for a list of elements.
3. Develop cache ID rules.

   To cache an object, WebSphere Application Server must know how to generate unique IDs for different invocations of that object. The *<cache-id>* element performs that task. Each cache entry can have multiple cache-ID rules that run in order until either a rule returns cache-ID that is not empty or no more rules remain to run. If no cache-ID generation rules produce a valid cache ID, then the object is not cached. Develop the cache IDs in one of two ways:

© Copyright IBM Corp. 2011

- Use the *<component>* element defined in the cache policy of a cache entry (recommended). Refer to the cachespec_xml file topic for more information about the *<component>* element.
- Write custom Java code to build the ID from input variables and system state. To configure the cache entry to use the ID generator, specify your IdGenerator in the XML file by using the *<idgenerator>* tag, for example:

```
<cache-entry>
     <class>servlet</class>
     <name>/servlet/CommandProcessor</name>
  <cache-id>
      <idgenerator>com.mycompany.SampleIdGeneratorImpl</idgenerator>
      <timeout>60</timeout>
  </cache-id>
</cache-entry>
```

4. Specify dependency ID rules. Use dependency ID elements to specify additional cache group identifiers that associate multiple cache entries to the same group identifier.

   The dependency ID is generated by concatenating the dependency ID base string with the values returned by its component elements. If a required component returns a null value, then the entire dependency ID does not generate and is not used. You can validate the dependency IDs explicitly through the dynamic cache API, or use another cache-entry *<invalidation>* element. Multiple dependency ID rules can exist per cache entry. All dependency ID rules run separately. See cachespec.xml file topic for a list of *<component>* elements.
5. Invalidate other cache entries as a side effect of this object start, if relevant. You can define invalidation rules in exactly the same manner as dependency IDs. However, the IDs that are generated by invalidation rules are used to invalidate cache entries that have those same dependency IDs.

   The invalidation ID is generated by concatenating the invalidation ID base string with the values returned by its component element. If a required component returns a null value, then the entire invalidation ID is not generated and no invalidation occurs. Multiple invalidation rules can exist per cache-entry. All invalidation rules run separately.
6. Ensure your cache policy is working correctly. You can modify the policies within the `cachespec.xml` file while your application is running. The dynamic cache reloads the updated file automatically. If you are caching static content and you are adding the cache policy to an application for the first time, you must restart the application. You do not need to restart the application server to activate the new cache policy. Refer to the Verifying the cacheable page topic for more information.

### What to do next

Typically you declare several *<cache-entry>* elements inside a `cachespec.xml` file.

When new versions of the `cachespec.xml` are detected, the old policies are replaced. Objects that cached through the old policy file are not automatically invalidated from the cache; they are either reused with the new policy or eliminated from the cache through its replacement algorithm.

For each of the three IDs (cache, dependency, invalidation) generated by cache entries, a `<cache-entry>` can contain multiple elements. The dynamic cache runs the *<cache-id>* rules in order, and the first one that successfully generates an ID is used to cache that output. If the object is to be cached, each one of the *<dependency-id>* elements is run to build a set of dependency IDs for that cache entry. Finally, each of the *<invalidation>* elements are run, building a list of IDs that the dynamic cache invalidates, whether or not this object is cached.

## Verifying the cacheable page

Use this task to verify that the dynamic cache service has its cache policies configured correctly and is serving cached content.

## Before you begin

The dynamic cache service should be enabled. You should have a cache policy developed for your application. Refer to the Configuring cacheable objects with the cachespec.xml file article for more information. You must have servlet caching enabled in the web container. Refer to the Configuring servlet caching article for more information.

## About this task

You can verify the cacheable page by invoking the snoop servlet in the default application. If the dynamic cache is working correctly, refreshing the servlet repeatedly results in viewing cached content.

## Procedure

1. View the Snoop servlet in the default application by accessing the URI: `/snoop` The Snoop servlet is a part of the default application. Refer to the Default application article for more information.
2. Invoke and reload the URI several times using a different web browser or using different parameters. This action returns the same output for the snoop servlet. The snoop servlet is now operating incorrectly, because it displays the request information from its first invocation rather than from the current request.
3. Inspect the entry in the cache with the dynamic cache monitor. Refer to the Displaying cache information article for more information.

---

# cachespec.xml file

The cache parses the `cachespec.xml` file when the server starts, and extracts a set of configuration parameters from each cache-entry element. Every time a new servlet or other cacheable object initializes, the cache attempts to match each of the cache-entry elements to find the configuration information for that object.

The cache-entry elements can be inside the root cache element or inside a cache-instance element. Cache entries that are in the root element are cached with the default cache instance. Cache entries that are in the <cache-instance> element are cached in that particular cache instance. Different cacheable objects have different class elements. You can define the specific object that a cache policy refers to using the name element.

## Location

Place the `cachespec.xml` file with the deployment module. Use an assembly tool to define the cacheable objects. See topics about assembling applications. You can also place a global `cachespec.xml` file in the application server properties directory. In situations where there is a global `cachespec.xml` file in the application server properties directory, and a `cachespec.xml` file in an application, the entries in the two cachespec.xml files are merged. If there are conflicting entries in the two files, the entries in the in the `cachespec.xml` file that is in the application override the entries in the global `cachespec.xml` file for that application.

The `cachespec.dtd` file is available in the application server properties directory. The `cachespec.dtd` file defines the legal structure and the elements that can be in your `cachespec.xml` file.

## Usage notes

**Cachespec.xml elements**

The root element of the `cachespec.xml` file is cache and contains cache-instance and cache-entry elements. The cache-entry elements can also be placed inside of cache-instance elements to make that cache entry part of a cache instance that is different from the default.

**cache-instance**

```
<cache-instance name="cache_instance_name"></cache-instance>
```

The name attribute is the Java Naming and Directory Interface (JNDI) name of the cache instance that is set in the administrative console.

Each cache-instance element must contain at least one cache-entry element. A cache entry that is matched within a cache-instance element is cached in the servlet cache instance that is specified by the name attribute. If identical cache-entry elements exist across cache-instance elements, the first cache-entry element that is matched is used.

**cache-entry**

Each cache entry must specify certain basic information that the dynamic cache uses to process that entry. This section explains the function of each cache entry element of the `cachespec.xml` file including:

- class
- name
- sharing-policy
- skip-cache
- property
- cache-id

With the current version of WebSphere Application Server, you can define multiple cache policies for a single servlet. For example, if you define multiple mappings for a servlet in the `web.xml` file, you can create a cache entry for each one of the mappings.

**class**

```
<class>command | servlet | webservice | JAXRPCClient | static | portlet </class>
```

This element is required and specifies how the application server interprets the remaining cache policy definition. The value `servlet` refers to servlets and JavaServer Pages (JSP) files that are deployed in the WebSphere Application Server servlet engine. The `webservice` class extends the servlet with special component types for web services requests. The `JAXRPCClient` is used to define a cache entry for the web services client cache. The value, `command`, refers to classes using the WebSphere Application Server command programming model. The value, `static`, refers to files that contain static content. The following examples illustrate the class element:

```
<class>command</class>
<class>servlet</class>
<class>webservice</class>
<class>JAXRPCClient</class>
<class>static</class>
<class>portlet</class>
```

**name**

```
<name>name</name>
```

Use the following guidelines for the name element to specify a cacheable object:

- For commands, this required element must include the package name, if any, and class name, including a trailing `.\class`, of the configured object.

  **Important:** If you specify command caching in the cachespec.xml file, and servlet caching is not enabled for the application server on which the application runs, you will get an error. The application server still attempts to obtain a cache instance; therefore, enabling servlet caching will eliminate the error.
- For servlets and JSP files, if the `cachespec.xml` file is in the WebSphere Application Server properties directory, this required element must include the full URI of the JSP file or servlet to cache. For servlets and JSP files, if the `cachespec.xml` file is in the web application, this required element can be relative to the specific web application context root.
- For web services, include the Universal Resource Identifier (URI) of the Simple Object Access Protocol (SOAP) router that is associated with the web service that you want to cache.

- For web services client cache, the name is the target end point of the cacheable web service or the URI of the SOAP router that is associated with the cacheable web service. You can use the SOAP address location in the Web Services Description Language (WSDL) file to define the name for the web services client cache.
- For static files, if the `cachespec.xml` file is in the WebSphere Application Server properties directory, this required element must include the full URI of the file to cache. If the `cachespecm.xml` file is in the web application, this required element can be relative to the specific web application context root. For a web application with a context root, the cache policy for files using the static class must be specified in the web application, and not in the properties directory.
- For portlets, if the `cachespec.xml` file is in the WebSphere Application Server properties directory, this required element must include the full context path and name of the portlet to cache. If the `cachespec.xml` file is in the web application, this required element is the portlet name that is relative to the specific web application context root.

**Tip:** The preferred location of the `cachespec.xml` file is in the web application, not the properties directory.

You can specify multiple name elements within a cache-entry if you have different mappings that refer to the same servlet.

The following examples illustrate the name element:

```
<name>com.mycompany.MyCommand.class</name>
<name>default_host:/servlet/snoop</name>
<name>com.mycompany.beans.MyJavaBean</name>
<name>mywebapp/myjsp.jsp</name>
<name>/soap/servlet/soaprouter</name>
<name>http://remotecompany.com:9080/service/getquote</name>
<name>mywebapp/myLogo.gif</name>
```

### sharing-policy

```
<sharing-policy> not-shared | shared-push | shared-pull | shared-push-pull</sharing-policy>
```

When working within a cluster with a distributed cache, these values determine the sharing characteristics of entries that are created from this object. If this element is not present, a not-shared value is assumed. In single server environments, not-shared is the only valid value. When enabling a replication, the default value is `not-shared` . This property does not affect distribution to Edge Side Include processors through the Edge fragment caching property.

*Table 62. Sharing-policy values. Values and description for the sharing-policy.*

| Value | Description |
|---|---|
| not-shared | Cache entries for this object are not shared among different application servers. These entries can contain non-serializable data. For example, a cached servlet can place non-serializable objects into the request attributes, if the <class> type supports it. |
| shared-push | Cache entries for this object are automatically distributed to the dynamic caches in other application servers or cooperating Java virtual machines (JVMs). Each cache has a copy of the entry at the time it is created. These entries cannot store non-serializable data. |
| shared-pull | Cache entries for this object are shared between application servers on demand. If an application server gets a cache miss for this object, it queries the cooperating application servers to see if they have the object. If no application server has a cached copy of the object, the original application server runs the request and generates the object. These entries cannot store non-serializable data. This mode of sharing is not recommended. |
| shared-push-pull | Cache entries for this object are shared between application servers on demand. When an application server generates a cache entry, it broadcasts the cache ID of the created entry to all cooperating application servers. Each server then knows whether an entry exists for any given cache ID. On a given request for that entry, the application server knows whether to generate the entry or pull it from somewhere else. These entries cannot store non-serializable data. |

The following example shows a sharing policy:

```
<sharing-policy>not-shared</sharing-policy>
```

### skip-cache

Takes the name of a request attribute, which if present in the request context, dictates that the

response cannot be retrieved from the cache instance that is specified. This property is useful for previewing content in production systems and verifying that the application is working and performing as expected.

```
<cache>
 <skip-cache-attribute>att1</skip-cache-attribute> <!—Applies only to the base cache- ->
...
<cache-instance name="instance1">
<skip-cache-attribute>att2</skip-cache-attribute> <!-Applies only to this instance- ->
...
</cache-instance>
</cache>
```

### property

```
<property name="key">value</property>
```

where *key* is the name of the property for this cache entry element, and *value* is the corresponding value.

You can set optional properties on a cacheable object, such as a description of the configured servlet. The class determines valid properties of the cache entry. At this time, the following properties are defined:

*Table 63. Property values. Property values and valid classes.*

| Property | Valid classes | Value |
|---|---|---|
| ApplicationName | All | Overrides the JavaEEName application ID so that multiple applications can share a common cache ID namespace. |
| EdgeCacheable | Servlet | True or false. The default is `false`. If the property is `true`, then the given servlet or JSP file is externally requested from an Edge Side Include processor. Whether or not the servlet or JSP file is cacheable depends on the rest of the cache specification.<br><br>The permissible components for general edgecacheable cache entries are PARAMETER, HEADER, COOKIE, and PATH_INFOSERVLET_PATH |
| ExternalCache | Servlet and portlet | Specifies the external cache name. The external cache name needs to match the external cache group name. |
| consume-subfragments | Servlet, web service, or portlet | True or false. The default is `false`. When a servlet is cached, only the content of that servlet is stored, and includes placeholders for any other fragments to which it includes or forwards. Consume-subfragments (CSF) tells the cache not to stop saving content when it includes a child servlet. The parent entry, the one marked CSF, includes all the content from all fragments in its cache entry, resulting in one big cache entry that has no includes or forwards, but the content from the whole tree of entries. Consume-subfragments can save a significant amount of application server processing, but is typically only useful when the external HTTP request contains all the information needed to determine the entire tree of included fragments.<br><br>Use the <exclude> element to tell the cache to stop consuming for the excluded fragment and instead, create a placeholder for the include or forward. For example, exclude `A.jsp` from the consume-subfragment, as follows:<br>`<property name=`<br>`"consume-sbufragments">true`<br>`<exclude>/A.jsp<exclude>`<br>`</property>` |
| do-not-consume | Servlet, web service, or portlet | True or false. The default is `false`. When a fragment parent has the consume-subfragment property set to true the child fragment content is saved in the cache entry of the parent. Do-not-consume (DNC) tells the cache to stop saving the content for this fragment in the parent cache-entry and create a placeholder instead for the include or forward. |
| alternate_url | Servlet | Specifies the alternate URL that is used to invoke the servlet or JSP file. The property is valid only if the EdgeCacheable property also is set for the cache entry. |
| persist-to-disk | All | True or false. The default is `true`. When this property is set to `false`, the cache entry is not written to the disk when overflow or server stopping occurs. |

*Table 63. Property values (continued). Property values and valid classes.*

| Property | Valid classes | Value |
|---|---|---|
| save-attributes | Servlet and portlet | True or false. The default is `true`. When this property is set to `false`, the request attributes are not saved with the cache entry.<br><br>Use the <exclude> element to specify the request attributes that do not apply to the save-attributes property. For example, to save only the attr1 attribute with the cache entry:<br>`<property name=`<br>`"save-attributes">false`<br>`<exclude>attr1</exclude>`<br>`</property>`<br><br>To save all attributes except the `attr1` attribute in the cache entry, set the property to true in the preceding sample. If you do not use the <exclude> element, either all or no request attributes are saved with the cache entry. |
| delay-invalidations | Command | True or false. When this property is set to `true`, the commands that are invalidating cached objects based on the invalidation rules in this cache entry invalidate the cache entries after running. By default, the invalidation occurs before the command runs. |
| store-cookies | Servlet and portlet | On or off. The default is `On`. This property takes one or more cookie name as its argument which is saved along with the cache object and restored by the servlet cache in the response with a set-cookie header.<br><br>Save all cookies except cookie1 as part of the cache-entry as follows:<br>`<property name=`<br>` "store-cookies">true`<br>`<exclude>cookie</exclude>`<br>`</property>`<br><br>Save only cookie1 as part of the cache-entry, as follows:<br>`<property name=`<br>` "store-cookies">false`<br>`<exclude><cookie1</exclude>`<br>`</property>` |
| ignore-get-post | Servlet and portlet | True or false. The default is `false`. When the property is set to `true` the request type is not appended to the cache-id for GET and POST requests unless the requestType component requestType component subelement is defined. By default the request type is automatically appended to the cache-id for GET and POST requests. |
| ignore-char-encoding | Servlet and portlet | True or false. The default value is `false`. When the property is set to `true`, UTF-8 character encoding is not appended to the cache ID. Appending UTF-8 character encoding to the cache ID might lead to multiple copies of fragments, which unnecessarily increases the size of the cache. |
| do-not-cache | Servlet and portlet | Defines a fragment that is neither cached nor consumed by its parent.<br>`<cache-entry>`<br>`...`<br>`<property name="do-not-cache">`<br>` true</property>`<br><br>or<br>`<cache-id>`<br>`<property name="do-not-cache">`<br>` true</property>`<br>`</cache-id>`<br>`</cache-entry>` |

**cache-id**

To cache an object, the application server must know how to generate a unique ID for different invocations of that object. These IDs are built either from user-written custom Java code or from rules that are defined in the cache policy of each cache entry. Each cache entry can have multiple cache ID rules that run in order until either:

- A rule returns a non-empty cache ID, or
- No more rules are left to run.

If none of the cache ID generation rules produce a valid cache ID, the object is not cached.

Each cache-id element defines a rule for caching an object and is composed of the sub-elements component, timeout, inactivity, priority, property, idgenerator, and metadatagenerator. The following example illustrates a cache-id element:

```
<cache-id>
   component*| timeout? | inactivity? | priority? | property* | idgenerator? | metadatagenerator?
</cache-id>
```

**component subelement**

Use the component subelement to generate a portion of the cache ID. The component subelement consists of the attributes id, type, and ignore-value, and the elements index, method, field, required, value, and not-value.

- Use the id attribute to identify the component.
- Use the type attribute to identify the type of component. The following table lists the values for the type.

**gotcha:** When the parameter component subelement is specified in the cachespec.xml file, the web container sets character encoding based on the encoding setting obtained from the request object. If a servlet subsequently invokes the setCharacterEncoding method, the method has not effect because character encoding cannot be changed after it has already been set.

| Type | Valid classes | Meaning |
|---|---|---|
| method | Command | Calls the indicated method on the command or object |
| field | Command | Retrieves the named field in the command or object |
| parameter | Servlet and portlet | Retrieves the named parameter value from the request object |
| parameter-list | Servlet and portlet | Retrieves a list of values for the named parameter **gotcha:** The cache grabs the values for all of the parameters with this name and uses all of these values, in the order they are grabbed, to create the cache ID |
| session | Servlet and portlet | Retrieves the named value from the HTTP session |
| cookie | Servlet | Retrieves the named cookie value |
| attribute | Servlet and portlet | Retrieves the named request attribute |
| header | Servlet, web service, and portlet | Retrieves the named request header |
| pathInfo | Servlet | Retrieves the pathInfo element from the request |
| servletpath | Servlet | Retrieves the servlet path |
| locale | Servlet and portlet | Retrieves the request locale<br><br>**Attention:** The locale component is permissible for edgecacheable entries only, when using RRD. The locale component is not valid for all other ESI versions. |
| requestType | Servlet and portlet | Retrieves the HTTP request method from the request.<br><br>**Attention:** The requestType component is permissible for edgecacheable entries only, when using RRD. The requestType component is not valid for all other ESI versions. |
| tiles_attribute | Servlet and portlet | Retrieves the value of an attribute from a tile. |
| SOAPEnvelope | Web service and web services client cache | Retrieves the SOAPEnvelope element from a web services request. An ID attribute of Hash uses a Hash of the SOAPEnvelope element, while Literal uses the SOAPEnvelope element as received. |

| Type | Valid classes | Meaning |
|---|---|---|
| SOAPAction | Web service | Retrieves the SOAPAction header, if available, for a web services request. |
| serviceOperation | Web service | Retrieves the service operation for a web services request |
| serviceOperationParameter | Web service | Retrieves the specified parameter from a web services request |
| operation | Web services client cache | Indicates an operation type in the Web Services Description Language (WSDL) file. The id attribute is ignored and the value is the operation or method name. If the namespace of the operation is specified, format the value as<br>`namespaceOfOperation:nameOfOperation` |
| part | Web services client cache | Indicates an input message part in the WSDL file or a request parameter. Its id attribute is the part or parameter name, and the value is the part or parameter value. |
| SOAPHeaderEntry | Web services client cache | Retrieves special information in the Simple Object Access Protocol (SOAP) header of the web services request. The id attribute specifies the name of the entry. In addition, the entry of the SOAP header in the SOAP request must have the actor attribute, which contains com.ibm.websphere.cache. For example:<br>`<soapenv:Header>`<br>`<getQuote soapenv:actor=`<br>`"com.ibm.websphere.cache">IBM`<br>`</getQuote>`<br>`</soapenv:Header>` |
| portletSession | Portlet | Retrieves the named value from the portlet session |
| portletWindowId | Portlet | Retrieves the portlet window ID from the portlet request object |
| portletMode | Portlet | Retrieves the portlet mode from the portlet request object |
| portletWindowsState | Portlet | Retrieves the portlet window state from the portlet request object |
| sessionID | Servlet and portlet | Retrieves the HTTP session ID |

- Use the ignore-value attribute to specify whether or not to use the value that is returned by this component in cache ID formation. This attribute is optional with a default value of `false`. If the value is `true`, only the ID of the component is used when creating a cache ID, or no output is used when creating a dependency or invalidation ID.
- Use the method element to call a void method on a returned object. You can infinitely nest method and field objects in any combination. The method must be public and is not valid for edge-cacheable components. For example:

  ```
  <component id="getUser" type="method"><method>getUserInfo
  <method>getName</method></method></component>
  ```

  This method is equivalent to getUser().getUserInfo().getName()

  For component types attribute, method, or field that can return an object, when the object returned is a collection or array, the ID is created with a comma separated list of the elements in the collection or array. For example, if the request attribute users returns an array [a, b] and the cache entry is defined like the following example:

  ```
  <cache-entry>
   <class>servlet</class>
   <name>xxx.jsp</name>
   <cache-id>
    .
  ```

```
  .
  <component id="users" type="attribute">
   <required>true</required>
  </component>
  .
  .
 </cache-id>
 <dependency-id>dep
  <component id="users" type="attribute">
   <required>true</required>
  </component>
 </dependency-id>
</cache-entry>
```

The cache id contains the string `users: a,b`. The dependency id is `dep: a,b`.

Use the multipleIDs attribute with the component types to specify and generate multiple dependency IDs (or invalidation IDs), based on the items in the collection or array. For example:

```
<cache-entry>
 <class>servlet</class>
 <name>xxx.jsp</name>
 <cache-id>
  .
  .
   <component id="users" type="attribute">
    <required>true</required>
   </component>
  .
  .
 </cache-id>
 <dependency-id>dep
  <component id="users" type="attribute" multipleIDs="true">
   <required>true</required>
  </component>
 </dependency-id>
</cache-entry>
```

The cache policy will generates the following dependency IDs:

- `dep:a,b`
- `dep:a`
- `dep:b`

Use the index element with the previous component type to add only the value of the element at the specified index position in the collection or array, to the ID that is being created.

```
<cache-entry>
 <class>servlet</class>
 <name>xxx.jsp</name>
 <cache-id>
  .
  .
   <component id="users" type="attribute">
    <required>true</required>
    <index>1</index>
   </component>
  .
  .
 </cache-id>
 <dependency-id>dep
  <component id="users" type="attribute" multipleIDs="true">
   <required>true</required>
  </component>
 </dependency-id>
</cache-entry>
```

The previous cache policy generates the following component to use in the cache ID: `users: b`.
Use the <method> element to call a void method on a returned object.

- Use the field element to access a field in a returned object. You can infinitely nest method and field objects in any combination. The field must be public. This field is not valid for edge-cacheable components. For example:

```
<component id="getUser" type="method"><method>getUserInfo
<field>name</field></method></component>
```

This method is equivalent to the getUser().getUserInfo().name method.

- Use the required element to specify whether or not this component must return a non-null value for this cache ID to represent a valid cache. If set to `true`, this component must return a non-null value for this cache ID to represent a valid cache ID. If set to `false`, the default, a non-null value is used in the formation of the cache ID and a null value means that this component is not used at all in the ID formation. For example:

  ```
  <required>true</required>
  ```
- Use the value element to specify values that must match to use this component in cache ID formation. For example:

  ```
  <component id="getUser" type="method"><value>blue</value>
  <value>red</value> </component>
  ```
- Use the not-value element to specify values that must not match to use this component in cache ID formation. This method is similar to value element, but instead prescribes the defined values from caching. You can use multiple not-value elements when more than one value that is not valid exists. For example:

  ```
  <component id="getUser" type="method">
  <required>true</required>
  <not-value>blue</not-value>
  <not-value>red</not-value></component>
  ```

The component subelement can have either a method and a field element, a value element, or a not-value element. The method and field elements apply to commands only. The following example illustrates the attributes of a component sub-element:

```
<component id="isValid" type="method" ignore-value="true"><component>
```

**timeout subelement**

The timeout subelement is used to specify an absolute time-to-live (TTL) value for the cache entry. For example,

```
<timeout>value</timeout>
```

where *value* is the amount of time, in seconds, to keep the cache entry. Cache entries that are in memory are kept indefinitely, as long as the entries remain in memory. Cache entries that are stored on disk are evicted if they are not accessed for 24 hours.

**inactivity subelement**

The inactivity subelement is used to specify a time-to-live (TTL) value for the cache entry based on the last time that the cache entry was accessed. It is a subelement of the cache-id element.

```
<inactivity>value</inactivity>
```

where *value* is the amount of time, in seconds, to keep the cache entry in the cache after the last cache hit.

**priority subelement**

Use the priority subelement to specify the priority of a cache entry in a cache. The priority weighting is used by the least recently used (LRU) algorithm of the cache to decide which entries to remove from the cache if the cache runs out of storage space. For example,

```
<priority>value</priority>
```

where *value* is a positive integer between 1 and 16 inclusive.

**Samples**

The following sample keeps the cache entry in the cache for a minimum of 35 seconds and a maximum of 180 seconds. If the cache entry is accessed within each 35 second inactivity period, the inactivity period is extended for another 35 seconds. However, because the timeout element is also configured, the cache entry is always invalidated after 180 seconds. If the cache entry is not accessed within the 35 second period, the entry is removed from the cache.

```
<cache-id>
 <component id="timeout" type="parameter">
  <required>true</required>
 </component>
```

```
 <timeout>180</timeout>
 <inactivity>35</inactivity>
 <priority>1</priority>
</cache-id>
```

The following sample keeps the cache entry in the cache for a minimum of 600 seconds. If the cache entry is accessed within each 600 second period, the inactivity period is extended for another 600 seconds. If the cache entry is not accessed within the 600 second period, the cache entry is removed from the cache.

```
<cache-id>
 <component id="timeout" type="parameter">
  <required>true</required>
 </component>
 <inactivity>600</inactivity>
 <priority>1</priority>
</cache-id>
```

In the following sample, the value for inactivity has no meaning because the timeout period is less than the inactivity period. The cache entry is always invalidated after 180 seconds, no matter how often the cache entry is accessed.

```
<cache-id>
 <component id="timeout" type="parameter">
  <required>true</required>
 </component>
 <timeout>180</timeout>
 <inactivity>600</inactivity>
 <priority>1</priority>
</cache-id>
```

**property subelement**

Use the property subelement to specify generic properties for the cache entry. For example,

```
<property name="key">value</property>
```

where *key* is the name of the property to define, and *value* is the corresponding value.

For example:

```
<property name="description">The Snoop Servlet</property>
```

*Table 64. Property subelement values.. Property valid classes and meaning.*

| Property | Valid classes | Meaning |
|---|---|---|
| sharing-policy/timeout/priority | All | Overrides the settings for the containing cache entry when the request matches this cache ID. |
| EdgeCacheable | Servlet | Overrides the settings for the containing cache entry when the request matches this cache ID. |

## idgenerator and metadatagenerator sub-elements

Use the idgenerator element to specify the class name that is loaded for the generation of the cache ID. The IdGenerator element must implement the com.ibm.websphere.servlet.cache.IdGenerator interface for a servlet or the com.ibm.websphere.webservices.IdGenerator interface for the web services client cache. An example of the idgenerator element follows:

```
<idgenerator> class name </idgenerator>
```

Where *class name* is the fully-qualified name of the class to use. Define this generator class in a shared library.

Use the metadatagenerator element inside the cache-id element to specify the class name loaded for the metadata generation. The MetadataGenerator class must implement the com.ibm.websphere.servlet.cache.MetaDataGenerator interface for a servlet or the

com.ibm.websphere.cache.webservices.MetaDataGenerator interface for a web services client cache. The MetadataGenerator class defines properties like timeout, inactivity, external caching properties or dependencies. An example of the `metadatagenerator` element follows:

```
<metadatagenerator> classname </metadatagenerator>
```

In this example, class name is the fully-qualified name of the class to use. Define this generator class in a shared library.

### dependency-id element

Use the dependency-id element to specify additional cache identifiers that associate multiple cache entries to the same group identifier.

The value of the dependency-id element is generated by concatenating the dependency ID base string with the values that are returned by its component elements. If a required component returns a null value, the entire dependency does not generate and is not used. Validate the dependency IDs explicitly through the dynamic cache API, or use the invalidation element. Multiple dependency ID rules can exist in one cache-entry element. All dependency rules run separately.

### invalidation element

To invalidate cached objects, the application server must generate unique invalidation IDs. Build invalidation IDs by writing custom Java code or through rules that are defined in the cache policy of each cache entry. The following example illustrates an invalidation in the cache policy:

```
<invalidation>component* | invalidationgenerator? </invalidation>
```

### invalidationgenerator subelement

The invalidationgenerator element is used with the web services client cache only. Use the invalidationgenerator element to specify the class name to load for generating invalidation IDs. The InvalidationGenerator class must implement the com.ibm.websphere.cache.webservices.InvalidationGenerator interface. An example of the invalidationgenerator element follows:

```
<invalidationgenerator>class name</invalidationgenerator>
```

In this example, classname is the fully qualified name of the class that implements the com.ibm.websphere.cache.webservices.InvalidationGenerator interface. Define this generator class in a shared library.

## Example: Configuring the dynamic cache service

This example puts all of the steps together for configuring the dynamic cache service with the `cachespec.xml` file, showing the use of the cache ID generation rules, dependency IDs, and invalidation rules.

Suppose that a servlet manages a simple news site. This servlet uses the query parameter "action" to determine if the request views (query parameter "view") news or updates (query parameter "update") news (used by the administrator). Another query parameter "category" selects the news category. Suppose that this site supports an optional customized layout that is stored in the user's session using the attribute name "layout". Here are example URL requests to this servlet:

http://*yourhost/yourwebapp*/newscontroller?action=view&category=sports (Returns a news page for the sports category )

http://*yourhost/yourwebapp*/newscontroller?action=view&category=money (Returns a news page for the money category)

http://*yourhost/yourwebapp*/newscontroller?action=update&category=fashion (Allows the administrator to update news in the fashion category)

Here are the steps for configuring the dynamic cache service for this example with the `cachespec.xml` file:

1. Define the <cache-entry> elements that are necessary to identify the servlet. In this case, the URI for the servlet is "newscontroller", so this is the cache-entry <name> element. Because this example caches a servlet or JavaServer Pages (JSP) file, the cache entry class is "servlet".

```
<cache-entry>
<name> /newscontroller </name>
<class>servlet  </class>
 </cache-entry>
```

2. Define cache ID generation rules. This servlet caches only when action=view, so one component of the cache ID is the parameter "action" when the value equals "view". The news category is also an essential part of the cache ID. The optional session attribute for the user's layout is included in the cache ID. The cache entry is now:

```
<cache-entry>
 <name> /newscontroller </name>
 <class>servlet  </class>
  <cache-id>
  <component id="action" type="parameter">
   <value>view</value>
   <required>true</required>
  </component>
  <component id="category" type="parameter">
   <required>true</required>
  </component>
  <component id="layout" type="session">
   <required>false</required>
  </component>
 </cache-id>
</cache-entry>
```

3. Define dependency ID rules. For this servlet, a dependency ID is added for the category. Later, when the category is invalidated due to an update event, all views of that news category are invalidated. Following is an example of the cache entry after adding the dependency ID:

```
<cache-entry>
 <name>newscontroller </name>
 <class>servlet  </class>
  <cache-id>
  <component id="action" type="parameter">
   <value>view</value>
   <required>true</required>
  </component>
  <component id="category" type="parameter">
   <required>true</required>
  </component>
  <component id="layout" type="session">
   <required>false</required>
  </component>
 </cache-id>
 <dependency-id>category
  <component id="category" type="parameter">
   <required>true</required>
  </component>
 </dependency-id>
</cache-entry>
```

4. Define invalidation rules. Because a category dependency ID is already defined, define an invalidation rule to invalidate the category when action=update. To incorporate the conditional logic, add

"ignore-value" components into the invalidation rule. These components do not add to the output of the invalidation ID, but only determine whether or not the invalidation ID creates and runs. The final cache-entry now looks like the following:

```
<cache-entry>
 <name>newscontroller </name>
 <class>servlet  </class>
  <cache-id>
  <component id="action" type="parameter">
   <value>view</value>
   <required>true</required>
  </component>
  <component id="category" type="parameter">
   <required>true</required>
  </component>
  <component id="layout" type="session">
   <required>false</required>
  </component>
 </cache-id>
 <dependency-id>category
  <component id="category" type="parameter">
   <required>true</required>
  </component>
 </dependency-id>
 <invalidation>category
  <component id="action" type="parameter" ignore-value="true">
   <value>update</value>
   <required>true</required>
  </component>
  <component id="category" type="parameter">
   <required>true</required>
     </component>
 </invalidation>
</cache-entry>
```

## cacheinstances.properties file

Use the information in this document as a reference of the names, values, and explanations that you can use in the cacheinstances.properties file.

The following list provides the property names, associated values, and explanations for the cacheinstance.properties file.

| **Property name - *x* is the instance number, which starts with 0** | **Version** | **Scope** | **Possible value** | **Description** |
|---|---|---|---|---|
| | | | | |
| *Cache core properties* | | | | |
| `cache.instance.x` | 5.1.x and later | Per cache instance | any string (no default set) | Specifies cache instance name or JNDI name. |
| `cache.instance.x. cacheSize` | 5.1.x and later | Per cache instance | > 0 (default=2000) | Specifies the maximum number of entries that are held in memory cache. |
| `cache.instance.x. disableDependencyId` | 6.0.2.x and later | Per cache instance | True or false (default=false) | Specifies that the dynamic cache service supports cache entry dependency IDs. Disable this option if you do not need to use dependency IDs. Dependency IDs specify additional cache group identifiers that associate multiple cache entries to the same group identifier in your cache policy. |

| **Property name - *x* is the instance number, which starts with 0** | **Version** | **Scope** | **Possible value** | **Description** |
|---|---|---|---|---|
| cache.instance.x. disableTemplates Support | 6.0.2.x and later | Per cache instance | True or false (default=false) | Specifies whether template support feature is enabled. |
| cache.instance.x. useListenerContext | 5.1.x and later | Per cache instance | True or false (default=false) | Set this value to true to have invalidation events sent to registered invalidation listeners, using the Java Platform, Enterprise Edition (Java EE) context of the listener. If you want to use listener Java EE context for callback, set this value to true. If you want to use the caller thread context for callback, set this value to false. |
| cache.instance.x. enableNioSupport | 6.0.2.x and later | Per cache instance | True or false (default=false) | Specifies whether DistributedMap or DistributedNioMap is used. |
| cache.instance.x. memoryCacheSizeInMB | 7.0 | Per cache instance | > 0 (default: -1 limit does not exist) | Specifies a value for the maximum memory cache size in megabytes (MB) |
| cache.instance.x. memoryCacheHigh Threshold | 7.0 | Per cache instance | > 0 % (default=95) | Specifies when the eviction policy runs. The threshold is expressed in terms of the percentage of the memory cache size in MB. The higher value is used when limit memory cache size in MB is specified. |
| cache.instance.x. memoryCacheLow Threshold | 7.0 | Per cache instance | > 0 % (default=80) | Specifies when the eviction policy runs. The threshold is expressed in terms of the percentage of the memory cache size in MB. The lower value is used when limit memory cache size in MB is specified. |
| cache.instance.x. createCacheAt ServerStartup | 7.0 | Per cache instance | True or false (default=false) | Specifies whether the configured cache instance is created during the server startup. This is useful when cache replication feature is used. However, the time for server startup will take long. |
| | | | | |
| *Cache servlet/JavaServer Pages (JSP) caching properties* | | | | |
| cache.instance.x. cascadeCachespec Properties | 6.0.2.19, 6.1.0.9 and later | Per cache instance | True or false (default=false) | A configurable change in the behavior of the cache so that the child pages and fragments inherit the cache specification properties of their parent pages and fragments. If the request for a fragment does not match a defined cache policy, the fragment will inherit the save-attributes and the store-cookies properties from its parent fragment. Enable this cascade of save-attributes and store-cookies properties by setting the value to true. |

| Property name - *x* is the instance number, which starts with 0 | Version | Scope | Possible value | Description |
|---|---|---|---|---|
| cache.instance.x. disableStoreCookies | 6.0.2.9, 6.1.x and later | Per cache instance | "none", "ALL","All", cache instance name, comma delineated list of cookie names, (default="none") | Specifies whether disable store cookies is NONE or ALL. Stores cookies as part of the response by default unless configured otherwise on a per request basis in cachespec.xml file. There is a risk of sharing cookies between users, which violates security. |
| cache.instance.x. enableServlet Support | 6.0.2.x and later | Per cache instance | True or false (default=false) | Specifies whether the cache instance is servlet cache or object cache. |
| | | | | |
| *Cache disk offload properties* | | | | |
| cache.instance.x. enableDiskOffload | 5.1.x and later | Per cache instance | True or false (default=false) | Specifies whether disk offload is enabled. |
| cache.instance.x. diskOffload Location | 5.1.x and later | Per cache instance | String – For example: . $(app_server_root) /diskOffload | Specifies the location on the disk to save cache entries when disk offload is enabled. |
| cache.instance.x. diskCacheSize | 5.1.1.13, 6.0.2.17, 6.1.x and later | Per cache instance | >= 0 (0=limit does not exist) | Specifies a value for the maximum disk cache size in number of entries. |
| cache.instance.x. diskCacheSizeInGB | 5.1.1.13, 6.0.2.17, 6.1.x and later | Per cache instance | 0 or > 2 in GB (0=limit does not exist) | Specifies a value for the maximum disk cache size in gigabytes (GB). |
| cache.instance.x. diskCacheEntrySize InMB | 5.1.1.13, 6.0.2.17, 6.1.x and later | Per cache instance | >= 0 in MB (0=limit does not exist) | Specifies a value for the maximum size of an individual cache entry in megabytes (MB). Any cache entry that is larger than this, when evicted from memory, will not be offloaded to disk. |
| cache.instance.x. flushToDiskOnStop | 5.1.x and later | Per cache instance | True or false (default = false) | Specifies if in-memory cached objects are saved to disk when the server stops. |
| cache.instance.x. diskCache PerformanceLevel | 5.1.1.13, 6.0.2.17, 6.1.x and later | Per cache instance | 0=low 1=balance 2=custom 3=high (default=1) | Specifies the performance level to tune the performance of the disk cache. |
| cache.instance.x. htodCleanup Frequency | 5.1.1.2 and later | Per cache instance | 0 <= x <= 1440 in minutes (0=cleanup at midnight) | Specifies a value for the disk cache cleanup frequency, in minutes. If this value is set to 0, the cleanup runs only at midnight. This setting applies only when the Disk Offload Performance Level is low, balanced, or custom. The high performance level does not require disk cleanup, and this value is ignored. |
| cache.instance.x. htodDelayOffload DepIdBuckets | 5.1.1.13, 6.0.2.17, 6.1.x and later | Per cache instance | > 0 (default=1000) | Specifies a value for the maximum number of dependency identifier buckets in the disk cache metadata in memory. If this limit is exceeded, the information is offloaded to the disk. This setting applies only when the disk cache performance level is custom. |

| Property name - *x* is the instance number, which starts with 0 | Version | Scope | Possible value | Description |
|---|---|---|---|---|
| cache.instance.x.<br>htodDelayOffload<br>TemplateBuckets | 5.1.1.13, 6.0.2.17, 6.1.x and later | Per cache instance | > 0 (default=100) | Specifies a value for the maximum number of template buckets that are in the disk cache metadata in memory. If this limit is exceeded, the information is offloaded to the disk. This setting applies only when the disk cache performance level is custom. |
| cache.instance.x<br>htodDelayOffload<br>EntriesLimit | 5.1.1.2 and later | Per cache instance | > 0 (default=1000) | Specifies a value for the maximum number of cache identifiers that are stored for an individual dependency ID or template in the disk cache metadata in memory. If this limit is exceeded, the information is offloaded to the disk. This setting applies only when the disk offload performance level is custom. |
| cache.instance.x.<br>diskCacheEviction<br>Policy | 5.1.1.13, 6.0.2.17, 6.1.x and later | Per cache instance | 0=disable 1=random 2:size (default=0) | Specifies the eviction algorithm that the disk cache will use to evict entries once the high threshold is reached. |
| cache.instance.x.<br>diskCacheHigh<br>Threshold | 5.1.1.13, 6.0.2.17, 6.1.x and later | Per cache instance | > 0 % (default=80) | Specifies when the eviction policy runs. The threshold is expressed in terms of the percentage of the disk cache size in GB or entries. The high value is used when limit disk cache size in GB and limit disk cache size in entries are specified. |
| cache.instance.x.<br>diskCacheLow<br>Threshold | 5.1.1.13, 6.0.2.17, 6.1.x and later | Per cache instance | > 0 % (default=70) | Specifies when the eviction policy runs. The threshold is expressed in terms of the percentage of the disk cache size in GB or entries. The lower value is used when limit disk cache size in GB and limit disk cache size in entries are specified. |
| | | | | |
| *Cache replication properties* | | | | |
| cache.instance.x.<br>enableCache<br>Replication | 6.0.2.x and later | Per cache instance | True or false (default=false) | Specifies whether cache replication is enabled. Use cache replication to have cache entries copied to multiple application servers configured in the same replication domain. |
| cache.instance.x.<br>replicationType | 5.1.x and later | Per cache instance | 1 (Not shared, 2 (Push), 4 (Push and pull) | Specifies the global sharing policy for this application server. |
| cache.instance.x.<br>replicationDomain | 6.0.2.x and later | Per cache instance | String – For example: DynamicCacheDomain | Specifies a replication domain from which your data is replicated. |
| cache.instance.x.<br>useServer<br>ClassLoader | 5.1.1.9, 6.0.2.9, 6.1.x and later | Per cache instance | True or false (default=false) | Specifies whether using server class loader is enabled. Setting this value to true, deserializes the InvalidationEvent using system classloader first and then using application classloader, if that fails. This improves performance. |

| Property name - *x* is the instance number, which starts with 0 | Version | Scope | Possible value | Description |
|---|---|---|---|---|
| cache.instance.x. cacheEntryWindow | 5.1.1.13, 6.0.2.17, 6.1.0.7 and later | Per cache instance | > 0 (default=50) | Specifies a limit on the total number of cache entries that are sent by the data replication service (DRS) in terms of number of entries. |
| cache.instance.x. cachePercentage Window | 5.1.1.13, 6.0.2.17, 6.1.0.7 and later | Per cache instance | > 0 % (default=2) | Specifies a limit on the number of cache entries that are sent by DRS in terms of the percentage of total cache in memory. |
| cache.instance.x. cacheInvalidate EntryWindow | 5.1.1.14, 6.0.2.19, 6.1.0.7 and later | Per cache instance | > 0 (default=50) | Specifies a limit on the total number of invalidation events that are sent by DRS in terms of number of entries. |
| cache.instance.x. cacheInvalidate PercentWindow | 5.1.1.14, 6.0.2.19, 6.1.0.7 and later | Per cache instance | > 0 % (default=2) | Specifies a limit on the number of invalidation events that are sent by DRS in terms of the percentage of total cache in memory. |
| cache.instance.x. filterTimeOut Invalidation | 6.0.2.13, 6.1.x and later | Per cache instance | True or false (default=false) | Specifies whether sending invalidations that are based on timeout eviction is enabled. |
| cache.instance.x. filterLRU Invalidation | 6.0.2.13, 6.1.x and later | Per cache instance | True or false (default=false) | Specifies whether sending invalidations that are based on LRU eviction is enabled. |
| cache.instance.x. ignoreValueIn InvalidationEvent | 5.1.1.13, 6.0.2.17, 6.1.x or later | Per cache instance | True or false (default=false) | Specifies whether the cache value of Invalidation event is ignored. If it is true, the cache value of Invalidation event is set to NULL when the code is returned to the caller. |

# Chapter 11. Developing Dynamic and EJB query

This page provides a starting point for finding information about dynamic query, a WebSphere programming extension for unprecedented application flexibility. This information also includes Enterprise JavaBeans (EJB) query, the Java feature upon which the WebSphere extension is built.

Dynamic query lets you dynamically build and submit queries that select, sort, join, and perform calculations on application data at run time.

Dynamic query service provides the ability to pass in and process EJB query language queries at run time, eliminating the need to hard-code required queries into deployment descriptors during application development.

## Developing applications that use EJB query

## EJB query language

EJB query language enables you to write queries based on entity beans without knowing the underlying relational schema.

An EJB query is a string that contains the following elements:
- a SELECT clause that specifies the enterprise beans or values to return;
- a FROM clause that names the bean collections;
- an optional WHERE clause that contains search predicates over the collections;
- an optional GROUP BY and HAVING clause; see the topic Aggregation functions.
- an optional ORDER BY clause that specifies the ordering of the result collection.

Collections of entity beans are identified in EJB queries through the use of their abstract schema name in the query FROM clause.

The elements of EJB query language are discussed in more detail in the following related topics.

### FROM clause

The FROM clause specifies the collections of objects to which the query is to be applied. Each collection is specified either by an abstract schema name (ASN) or by a path expression identifying a relationship. An identification variable is defined for each collection.

Conceptually, the semantics of the query is to form a temporary collection of tuples, **R**, with elements consisting of all possible combinations of objects from the collections. This collection is subject to the constraints imposed by any path relationships and by the JOIN operation. The JOIN can be either an *inner* or *outer* join.

The identification variables are bound to elements of the tuple. After forming the temporary collection, the search conditions of the WHERE clause are applied to R, and yield a new temporary collection, **R1**. The ORDER BY, GROUP BY, HAVING, and SELECT clauses are applied to R1 to yield the final result.

```
from_clause::=FROM identification_variable_declaration [, {identification_variable_declaration |
                          collection_member_declaration } ]*

identification_variable_declaration::= range_variable_declaration [join]*

join :=  [ { LEFT [OUTER] | INNER  }]  JOIN  {collection_valued_path_expression | single_valued_path_expression}
 [AS] identifier
```

#### Examples: Joining collections

`DeptBean` contains records 10, 20, and 30. `EmpBean` contains records 1, 2, and 3 that are related to department 10, and records 4 and 5 that are related to department 20. Department 30 has no employees.

© Copyright IBM Corp. 2011

```
SELECT d FROM  DeptBean AS d, EmpBean AS e
WHERE d.name = e.name
```

The comma syntax performs an inner join resulting in all possible combinations. In this example, R would consist of 15 tuples (3 departments x 5 employees). If any collection is empty, then R is also empty. The keyword *AS* is optional.

This example shows that a collection can be joined with itself.

```
SELECT d FROM DeptBean AS d, DeptBean AS d1
```

R would consist of 9 tuples (3 departments x 3 departments).

### Examples: Relationship joins

A collection can be a relationship based on a previously declared identifier as in

```
SELECT e FROM DeptBean AS d , IN (d.emps) AS e
```

R would contain 5 tuples. Department 30 would not appear in R because it contains no employees. Department 10 would appear in 3 tuples and department 20 would appear in 2 tuples. IN can only refer to multi-valued relationships. The following is not valid

```
SELECT m FROM EmpBean e,  IN( e.dept.mgr) as m   INVALID
```

When joining with a relationship the alternate syntax INNER JOIN ( keyword INNER is optional) can also be used, as shown here.

```
SELECT e FROM DeptBean AS d INNER JOIN d.emps AS e
```

An ASN declaration (**d** in the above query) can be followed by one or more join clauses. The relationship following the JOIN keyword must be related (directly or indirectly) to the ASN declaration. Unlike the case with the IN clause, relationships used in a join clause can be single- or multi-valued. This query has the same semantics as the query

```
SELECT e FROM DeptBean AS d , IN (d.emps) AS e
```

You can use multiple joins together.

```
SELECT m FROM EmpBean e JOIN e.dept d JOIN d.mgr m
```

This is equivalent to

```
SELECT m FROM EmpBean e JOIN e.dept.mgr m
```

### Examples: OUTER JOIN

An OUTER JOIN results in a temporary collection that contains combinations of the *left* and *right* operands, subject to the relationship constraints and such that the left operand always appears in R. In the example an outer join results in a temporary collection R that contains department 30, even though the collection **d.emps** is empty. The tuple contains Department 30 along with a NULL value. References to **e** in the query yields a null value.

```
SELECT e FROM DeptBean AS d LEFT OUTER JOIN d.emps AS e
```

The keyword OUTER is optional, as shown here.

```
SELECT e FROM DeptBean AS d LEFT JOIN d.emps AS e
```

You can also use combinations of INNER and OUTER JOIN.

```
SELECT m FROM EmpBean e JOIN e.dept d LEFT JOIN d.mgr m
```

## Inheritance in EJB query

If an Enterprise JavaBeans (EJB) inheritance hierarchy has been defined for an abstract schema, using the abstract schema name in a query statement implies the collection of objects for that abstract schema as well as all subtypes.

### Example: Inheritance

Suppose that bean `ManagerBean` is defined as a subtype of `EmpBean` and `ExecutiveBean` is a subtype of `ManagerBean` in an EJB inheritance hierarchy. The following query returns employees as well as managers and executives:

```
SELECT OBJECT(e) FROM EmpBean e
```

## Path expressions

A path expression is an identification variable followed by the navigation operator ( . ) and a container managed persistence (CMP) or relationship name.

A path expression that leads to a cmr field can be further navigated if the cmr field is single-valued. If the path expression leads to a multi-valued relationship, then the path expression is terminal and cannot be further navigated. If the path expression leads to a CMP field whose type is a value object, it is possible to navigate to attributes of the value object.

### Example: Value object

Assume that `address` is a CMP field for `EmpBean`, which is a value object.

```
SELECT  object(e)  FROM EmpBean e
WHERE  e.address.distance('San Jose') < 10  and e.address.zip = 95037
```

It is best to use the composer pattern to map value object attributes to relational columns if you intend to search on value attributes. If you store value objects in serialized format, then each value object must be retrieved from the database and deserialized. Value object methods can only be done in dynamic queries.

A path expression can also navigate to a bean method. The method must be defined on either the remote or local bean interface. Methods can only be used in dynamic queries. You cannot mix both remote and local methods in a single query statement.

If the query contains remote methods, the dynamic query must be executed using the query remote interface. Using the query remote interface causes the query service to activate beans and create instances of the remote bean interface

Likewise, a query statement with local bean methods must be executed with the query local interface. This causes the query service to activate beans and local interface instances.

Do not use get methods to access CMP and cmr fields of a bean.

If a method has overloaded definitions, the overloaded methods must have different number of parameters.

Methods must have non-void return types and method arguments and return types must be either primitive types byte, short, int, long, float, double, boolean, char or wrapper types from the following list:

Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Character, java.util.Calendar, java.sql.Date, java.sql.Time, java.sql.Timestamp, java.util.Date

If any input argument to a method is NULL, it is assumed the method returns a NULL value and the method is not invoked.

A collection valued path expression can be used in the FROM clause as a collection member declaration, and with the IS EMPTY, MEMBER OF, and EXISTS predicates in the WHERE clause.

*Table 65. FROM clause usage. The following table lists three valid From clause usage and one invalid usage.*

| | |
|---|---|
| `FROM EmpBean e WHERE e.dept.mgr.name='Bob'` | OK |
| `FROM EmpBean e WHERE e.dept.emps.name='BOB'` | INVALID -- cannot navigate through emps because it is multivalued |
| `FROM EmpBean e, IN (e.dept.emps) e1 WHERE e1.name='BOB'` | OK |
| `FROM EmpBean e WHERE e.dept.emps IS EMPTY` | OK |

## WHERE clause

The WHERE clause lists search conditions for items to add to a result set.

The WHERE clause contains search conditions composed of the following:
- literal values
- input parameters
- expressions
- basic predicates
- quantified predicates
- BETWEEN predicate
- IN predicate
- LIKE predicate
- NULL predicate
- EMPTY collection predicate
- MEMBER OF predicate
- EXISTS predicate
- IS OF TYPE predicate

If the search condition evaluates to TRUE, the tuple is added to the result set.

***Literals:***

Literals can be considered constants that do not change in value.

A string literal is enclosed in single quotes. A single quote that occurs within a string literal is represented by two single quotes. For example: 'Tom''s'. A string literal cannot exceed the maximum length that is supported by the underlying persistent datastore.

A numeric literal can be any of the following:
- an exact value such as 57, -957, +66
- any value supported by Java long
- a decimal literal such as 57.5, -47.02
- an approximate numeric value such as 7E3, -57.4E-2

A decimal or approximate numeric value must be in the range supported by the underlying persistent datastore.

A boolean literal can be the keyword TRUE or FALSE and is case insensitive.

***Input parameters:***

Input parameters are designated by the question mark followed by a number; for example: `?2`. Input parameters are numbered starting at 1 and correspond to the arguments of the finder or select method; therefore, a query must not contain an input parameter that exceeds the number of input arguments.

An input parameter can be a primitive type of byte, short, int, long, float, double, boolean, char or wrapper types of Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Char, java.util.Calendar, java.util.Date, java.sql.Date, java.sql.Time, java.sql.Timestamp, an EJBObject, or a binary data string in the form of Java byte[].

An input parameter must not have a NULL value. To search for the occurrence of a NULL value the NULL predicate should be used.

***WebSphere Application Server, Expressions:***

An expression specifies a value.

Conditional expressions can consist of comparison operators and logical operators (AND, OR, NOT).

Arithmetic expressions can be used in comparison expressions and can be composed of arithmetic operations and functions, path expressions that evaluate to a numeric value and numeric literals and numeric input parameters.

String expressions can be used in comparison expressions and can be composed of string functions, path expressions that evaluate to a string value and string literals and string input parameters. A CMP field of type char is handled as if it were a string of length 1.

Binary expressions can be used in comparison expressions and can be composed of path expressions that evaluate to the Java byte[] type as well as input parameters of type byte[].

Boolean expressions can be used with = and <> comparison and can be composed of path expressions that evaluate to a boolean value and TRUE and FALSE keywords and boolean input parameters.

Reference expressions can be used with = and <> comparison and can be composed of path expressions that evaluate to a cmr field, an identification variable and an input parameter whose type is an EJB reference

Four different expression types are supported for working with date-time types. For portability the java.util.Calendar type should be used. DB2 style date, time and timestamp expressions are supported if the datastore is DB2 and the CMP field is of type java.util.Date, java.sql.Date, java.sql.Time or java.sql.Timestamp. If you use DB2 UDB, you might obtain a syntax error when using the java.sql.Timestamp.ojbect. You must use the syntax TIMESTAMP 'yyyy-mm-dd hh:mm:ss.nnnn'.

A Calendar type can be compared to another Calendar type, an exact numeric literal or input parameter of type long whose value is the standard Java long millisecond value.

The following query finds all employees born before Jan 1, 1990:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e.birthDate <  631180800232
```

Date expressions can be used in comparison expressions and can be composed of operators + - , date duration expressions and date functions, path expressions that evaluate to a date value, string representation of a date and date input parameters.

Time expressions can be used in comparison expressions and can be composed of operators + - , time duration expressions and time functions, path expressions that evaluate to a time value, string representation of time and time input parameters.

Timestamp expressions can be used in comparison expressions and can be composed of operators + - , timestamp duration expressions and timestamp functions, path expressions that evaluate to a timestamp value, string representation of a timestamp and timestamp input parameters.

Standard bracketing ( ) for ordering expression evaluation is supported.

The operators and their precedence order from highest to lowest are:
- Navigation operator ( . )
- Arithmetic operators in precedence order:
  - + - unary
  - * / multiply, divide
  - + - add, subtract
- Comparison operators: =, >, <, >=, <=, <>(not equal)
- Logical operator NOT
- Logical operator AND
- Logical operator OR

*Null value semantics:*

The following describe the semantics of NULL values.
- Comparison or arithmetic operations with an unknown (NULL) value yield an unknown value
- In a Java 2 platform, Enterprise Edition (J2EE) version 1.3 application, a path expression uses an outer-join semantic where a NULL field or cmr value evaluates to NULL. In J2EE version 1.4, the path expression uses an inner-join semantic.
- The IS NULL and IS NOT NULL operators can be applied to path expressions and return TRUE or FALSE. Boolean operators AND, OR and NOT use three valued logic.

*Table 66. Null value semantics. The following table describes the semantics of NULL values.*

| **AND** | **True** | **False** | **Unknown** |
|---|---|---|---|
| **True** | True | False | Unknown |
| **False** | False | False | False |
| **Unknown** | Unknown | False | Unknown |

*Table 67. Null value semantics. The following table describes the semantics of NULL values.*

| **OR** | **True** | **False** | **Unknown** |
|---|---|---|---|
| **True** | True | True | True |
| **False** | True | False | Unknown |
| **Unknown** | True | Unknown | Unknown |

*Table 68. Null value semantics. The following table describes the semantics of NULL values.*

| | **NOT** |
|---|---|
| **True** | False |
| **False** | True |
| **Unknown** | Unknown |

### Example: Null value semantics

```
select object(e) from EmpBean where e.salary > 10  and e.dept.budget > 100
```

If salary is NULL the evaluation of `e.salary > 10` returns unknown and the employee object is not returned. If the cmr field dept or budget is NULL evaluation of `e.dept.budget > 100` returns unknown and the employee object is not returned.

```
select object(e) from EmpBean where e.dept.budget is null
```

In J2EE 1.3 if dept or budget is NULL evaluation of `e.dept.budget` is null returns TRUE and the employee object is returned. In J2EE 1.4 the employee object is returned only if budget is NULL.

```
select object(e) from EmpBean e ,  in (e.dept.emps) e1 where e1.salary > 10
```

If dept is NULL, then the multivalued path expression `e.dept.emps` results in an empty collection (not a collection that contains a NULL value). An employee with a null dept value will not be returned.

```
select object(e) from EmpBean e where  e.dept.emps is empty
```

If dept is NULL the evaluation of the predicate in unknown and the employee object is not returned.

```
select object(e) from EmpBean e , EmpBean e1  where e member of  e1.dept.emps
```

If dept is NULL evaluation of the member of predicate returns unknown and the employee is not returned.

*Date time arithmetic and comparisons:*

DATE, TIME and TIMESTAMP values can be compared with another value of the same type. Comparisons are chronological. Date time values can also be incremented, decremented, and subtracted.

If the datastore is DB2, then DB2 string representation of DATE, TIME and TIMESTAMP types can also be used.

*Table 69. Date, time and timestap formats. A string representation of a date or time can use ISO, USA, EUR or JIS format. A string representation of a timestamp uses ISO format.*

| Format | Date format | Date examples | Time format | Time examples |
|---|---|---|---|---|
| ISO | yyyy-mm-dd | 1987-02-24 1987-2-24 | hh.mm.ss | 13.50.00 13.50 |
| USA | mm/dd/yyyy | 2/24/1987 | hh:mm AM or PM | 1:50 pm 02:10 AM |
| EUR | dd.mm.yyyy | 24.02.1987 24.2.1987 | hh.mm.ss | 13.50.00 13.55 |
| JIS | yyyy-mm-dd | 1987-02-24 | hh:mm:ss | 13:50 13:50:05 |

**Example 1: Date time arithmetic comparisons**

```
e.hiredate > '1990-02-24'
```

The timestamp of February 24th, 1990 1:50 pm can be represented as follows:

```
'1990-02-24-13.50.00.000000'  or
'1990-02-24-13.50.00'
```

If the datastore is DB2, DB2 decimal durations can be used in expressions and comparisons. A date duration is a decimal(8,0) number that represents the difference between two dates in the format YYYYMMDD. A time duration is a decimal(6,0) number that represents the difference between two time values as HHMMSS. A timestamp duration is a decimal(20,6) number representing the differences between two timestamp values as YYYYMMDDHHMMSS.ZZZZZZ (ZZZZZZ is the number of microseconds and is to the right of the decimal point ) .

Two date values (or time values or timestamp values) can be subtracted to yield a duration. If the second operand is greater than the first the duration is a negative decimal number. A duration can be added or subtracted from a datetime value to yield a new datetime value.

**Example 2: Date time arithmetic comparisons**

`DATE('3/15/2000') - '12/31/1999'` results in a decimal number 215 which is a duration of 0 years, 2 months and 15 days.

Durations are really decimal numbers and can be used in arithmetic expressions and comparisons.

`( DATE('3/15/2000') - '12/31/1999' ) + 14 > 215` evaluates to TRUE.

`DATE('12/31/1999') + DECIMAL(215,8,0)` results in a date value 3/15/2000.

`TIME('11:02:26') - '00:32:56'` results in a decimal number 102930 which is a time duration of 10 hours, 29 minutes and 30 seconds.

`TIME('00:32:56') + DECIMAL(102930,6,0)` results in a time value of 11:02:26.

`TIME('00:00:59') + DECIMAL(240000,6,0)` results in a time value of 00:00:59.

`e.hiredate + DECIMAL(500,8,0) > '2000-10-01'` means compare the hiredate plus 5 months to the date 10/01/2000.

***Basic predicates:***

A basic predicate compares two values.

Basic predicates can be of two forms, for example:

```
expression-1  comparison-operator  expression-2
expression-3  comparison-operator ( subselect )
```

The subselect must not return more than one value and the subselect cannot return a type of an Enterprise JavaBeans (EJB) reference. Boolean types and reference types only support = and <> comparisons.

**Example: Basic predicates**

```
d.name='Java Development'
e.salary > 20000
e.salary > ( select avg(e.salary) from EmpBean e)
```

***Quantified predicates:***

A quantified predicate compares a value with a set of values produced by a subselect.

Use the syntax:

```
expression   comparison-operator   SOME | ANY |   ALL    ( subselect )
```

The expression must not evaluate to a reference type.

When SOME or ANY is specified the result of the predicate is as follows:
- TRUE if the comparison is true for at least one value returned by the subselect.
- FALSE if the subselect is empty or if the comparison is false for every value returned by the subselect.
- UNKNOWN if the comparison is not true for all of the values returned by the subselect and at least one of the comparisons is unknown because of a null value.

When ALL is specified the result of the predicate is as follows:
- TRUE if the subselect returns empty or if the comparison is true to every value returned by the subselect.
- FALSE if the comparison is false for at least one value returned by the subselect.
- UNKNOWN if the comparison is not false for all values returned by the subselect and at least one comparison is unknown because of a null value.

***BETWEEN predicate:***

The BETWEEN predicate determines whether a given value lies between two other given values.

The syntax for the predicate is:

```
expression  [NOT]  BETWEEN expression-2  AND expression-3
```

The expression must not evaluate to a boolean or reference type.

**Example: BETWEEN predicate**

```
e.salary BETWEEN 50000 AND 60000
```

is equivalent to:

```
e.salary >= 50000  AND e.salary <= 60000
e.name NOT BETWEEN 'A' AND 'B'
```

is equivalent to:

```
e.name < 'A'  OR e.name > 'B'
```

***IN predicate:***

The IN predicate compares a value to a set of values.

It can have one of two forms:

```
expression [NOT] IN  ( subselect )
expression [NOT] IN  ( value1, value2,  .... )
```

ValueN can either be a literal value or an input parameter. The expression cannot evaluate to a reference type.

**Example: IN predicate**

```
e.salary IN ( 10000, 15000 )
```

is equivalent to

```
( e.salary = 10000  OR  e.salary = 15000 )
e.salary IN ( select  e1.salary from EmpBean e1 where e1.dept.deptno = 10)
```

is equivalent to

```
e.salary = ANY   ( select  e1.salary from EmpBean e1 where e1.dept.deptno = 10)
e.salary NOT IN ( select  e1.salary from EmpBean e1 where e1.dept.deptno = 10)
```

is equivalent to

```
e.salary <> ALL    ( select  e1.salary from EmpBean e1 where e1.dept.deptno = 10)
```

***LIKE predicate:***

The LIKE predicate searches a string value for a certain pattern.

The syntax for this predicate is:

```
string-expression   [NOT]  LIKE  pattern    [ ESCAPE escape-character ]
```

The pattern value is a string literal or parameter marker of type string in which the underscore ( _ ) stands for any single character and percent ( % ) stands for any sequence of characters ( including empty sequence ). Any other character stands for itself. The escape character can be used to search for character _ and %. The escape character can be specified as a string literal or an input parameter.

If the string-expression is null, then the result is unknown.

If both string-expression and pattern are empty, then the result is true.

**Example: LIKE predicate**
- `'' LIKE ''` is true
- `'' LIKE '%'` is true
- `e.name LIKE '12%3'` is true for '123' '12993' and false for '1234'
- `e.name LIKE 's_me'` is true for 'some' and 'same', false for 'soome'
- `e.name LIKE '/_foo' escape '/'` is true for '_foo', false for 'afoo'
- `e.name LIKE '//_foo' escape '/'` is true for '/afoo' and for '/bfoo'
- `e.name LIKE '///_foo' escape '/'` is true for '/_foo' but false for '/afoo'

***NULL predicate:***

The NULL predicate tests for null values.

Use the syntax:

```
single-valued-path-expression IS [NOT] NULL
```

**Example: NULL predicate**

```
e.name IS NULL
e.dept.name IS NOT NULL
e.dept IS NOT NULL
```

***EMPTY collection predicate:***

You can use the EMPTY collection predicate to test if a multivalued relationship has no members.

Use the following syntax:

```
collection-valued-path-expression  IS [NOT]  EMPTY
```

**Example: Empty collection predicate**

To find all departments with no employees:

```
SELECT OBJECT(d) FROM DeptBean d  WHERE  d.emps IS EMPTY
```

***MEMBER OF predicate:***

This expression tests whether the object reference specified by the single valued path expression or input parameter is a member of the designated collection.

If the collection valued path expression designates an empty collection the value of the MEMBER OF expression is FALSE.

```
{ single-valued-path-expression | input_parameter } [ NOT ] MEMBER [ OF ] collection-valued-path-expression
```

**Example: MEMBER OF predicate**

Find employees that are not members of a given department number:

```
SELECT OBJECT(e) FROM EmpBean e , DeptBean d
WHERE e NOT MEMBER OF d.emps AND d.deptno = ?1
```

Find employees whose manager is a member of a given department number:

```
SELECT OBJECT(e) FROM EmpBean e, DeptBean d
WHERE e.dept.mgr MEMBER  OF d.emps  and d.deptno=?1
```

***EXISTS predicate:***

The exists predicate tests for the presence or absence of a condition specified by a subselect.

Use the syntax:

```
EXISTS ( subselect )
EXISTS collection-valued-path-expression
```

The result of EXISTS is true if the subselect returns at least one value or the path expression evaluates to a nonempty collection, otherwise the result is false.

To negate an EXISTS predicate, precede it with the logical operator NOT.

**Example: EXISTS predicate**

Return departments that have at least one employee earning more than 1000000:

```
SELECT  OBJECT(d) FROM  DeptBean d
WHERE EXISTS ( SELECT  1  FROM IN (d.emps) e WHERE  e.salary > 1000000 )
```

Return departments that have no employees:

```
SELECT OBJECT(d) FROM DeptBean d
WHERE NOT EXISTS  ( SELECT 1 FROM IN (d.emps) e)
```

The above query can also be written as follows:

```
SELECT OBJECT(d) FROM DeptBean d WHERE NOT EXISTS d.emps
```

***IS OF TYPE predicate:***

The IS OF TYPE predicate is used to test the type of an Enterprise JavaBeans (EJB) reference. It is similar in function to the Java instance of operator.

IS OF TYPE is used when several abstract beans have been grouped into an EJB inheritance hierarchy. The type names specified in the predicate are the bean abstract names. The ONLY option can be used to specify that the reference must be exactly this type and not a subtype.

```
identification-variable IS OF TYPE ( [ONLY] type-1, [ONLY] type-2, ..... )
```

**Example: IS OF TYPE predicate**

Suppose that bean `ManagerBean` is defined as a subtype of `EmpBean` and `ExecutiveBean` is a subtype of `ManagerBean` in an EJB inheritance hierarchy.

The following query returns employees as well as managers and executives:

```
SELECT  OBJECT(e) FROM EmpBean e
```

If you are interested in objects which are employees and not managers and not executives:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e IS OF TYPE( ONLY EmpBean )
```

If you are interested in object which are managers or executives:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e IS OF TYPE( ManagerBean)
```

The above query is equivalent to the following query:

```
SELECT  OBJECT(e) FROM ManagerBean e
```

If you are interested in managers only and not executives:

```
SELECT  OBJECT(e) FROM  EmpBean e WHERE e IS OF TYPE( ONLY ManagerBean)
```

or:

```
SELECT  OBJECT(e) FROM  ManagerBean e
WHERE  e IS OF TYPE (ONLY ManagerBean)
```

## Scalar functions

An Enterprise JavaBeans (EJB) query contains scalar functions for doing type conversions, string manipulation, and for manipulating date-time values.

The list of scalar functions is documented in the topic EJB query: Scalar functions.

### Example: Scalar functions

Find employees hired in 1999:

```
SELECT OBJECT(e) FROM EmpBean e where YEAR(e.hireDate) = 1999
```

The only scalar functions that are guaranteed to be portable across backend datastore vendors are the following:

- ABS
- MOD
- SQRT
- CONCAT
- LENGTH
- LOCATE
- SUBSTRING
- UCASE
- LCASE

The other scalar functions should be used only when DB2 is the backend datastore.

***EJB query: Scalar functions:***

Enterprise JavaBeans (EJB) query contains scalar built-in functions for doing type conversions, string manipulation, and for manipulating date-time values.

EJB query scalar built-in functions are listed below:

#### Numeric functions

```
ABS ( < any numeric datatype > ) -> < any numeric datatype >
MOD ( <int>, <int> ) -> int
SQRT ( < any numeric datatype > ) -> Double
```

#### Type conversion functions

```
CHAR ( < any  numeric datatype > ) ->  string
CHAR ( <  string  > ) ->  string
CHAR ( < any datetime  datatype >  [, Keyword k ]) ->  string
```

Datetime datatype is converted to its string representation in a format specified by the keyword k. The valid keywords values are ISO, USA, EUR or JIS. If k is not specified the default is ISO.

```
BIGINT ( < any numeric datatype > ) -> Long
BIGINT ( < string > ) -> Long
```

The function in the second line of the following code converts the argument to an integer n by truncation, and returns the date that is n-1 days after January 1, 0001:

```
DATE ( < date string > ) -> Date
DATE (  < any numeric datatype>) -> Date
```

The following function returns date portion of a timestamp:

```
DATE( timestamp ) -> Date
DATE ( < timestamp-string > ) -> Date
```

The following function converts number to decimal with optional precision p and scale s.

```
DECIMAL ( < any numeric datatype > [, p [ ,s ] ] ) -> Decimal
```

The following function converts string to decimal with optional precision p and scale s.

```
DECIMAL ( < string > [ , p [ , s ] ] ) -> Decimal

DOUBLE ( < any numeric datatype > ) -> Double
DOUBLE ( < string > ) -> Double

FLOAT ( < any numeric datatype > ) -> Double
FLOAT ( < string > ) -> Double
```

Float is a synonym for DOUBLE.

```
INTEGER ( < any numeric datatype > ) -> Integer
INTEGER ( < string > ) -> Integer

REAL ( < any numeric datatype > ) -> Float

SMALLINT ( < any numeric datatype ) -> Short
SMALLINT ( < string > ) -> Short

TIME ( < time > ) -> Time
TIME ( < time-string  > ) -> Time
TIME ( < timestamp > ) -> Time
TIME ( < timestamp-string  > ) -> Time

TIMESTAMP ( < timestamp > ) -> Timestamp
TIMESTAMP ( < timestamp-string > ) -> Timestamp
```

**String functions**

```
CONCAT ( <string>, <string>  ) -> String
```

The following function returns a character string representing absolute value of the argument not including its sign or decimal point. For example, `digits( -42.35)` is "4235".

```
DIGITS ( Decimal d  ) -> String
```

The following function returns the length of the argument in bytes. If the argument is a numeric or datetime type, it returns the length of internal representation.

```
LENGTH ( < string >  ) -> Integer
```

The following function returns a copy of the argument string where all upper case characters have been converted to lower case.

```
LCASE ( < string > ) -> String
```

The following function returns the starting position of the first occurrence of argument 1 inside argument 2 with optional start position. If not found, it returns 0.

```
LOCATE ( String s1 , String s2  [, Integer start ] ) -> Integer
```

The following function returns a substring of s beginning at character m and containing n characters. If n is omitted, the substring contains the remainder of string s. The result string is padded with blanks if needed to make a string of length n.

```
SUBSTRING ( String s ,  Integer m [ , Integer n ] ) -> String
```

The following function returns a copy of the argument string where all lower case characters have been converted to upper case.

```
UCASE ( < string > ) -> String
```

### Date - time functions

The following function returns the day portion of its argument. For a duration, the return value can be -99 to 99.

```
DAY (  Date ) ->  Integer
DAY ( < date-string > ) ->  Integer
DAY ( < date-duration > ) -> Integer
DAY ( Timestamp  ) ->  Integer
DAY ( < timestamp-string > ) ->  Integer
DAY ( < timestamp-duration > ) -> Integer
```

The following function returns one more than number of days from January 1, 0001 to its argument.

```
DAYS ( Date  ) ->  Integer
DAYS ( < Date-string > ) ->  Integer
DAYS ( Timestamp  ) ->  Integer
DAYS ( < timestamp-string > ) ->  Integer
```

The following function returns the hour part of its argument. For a duration, the return value can be -99 to 99.

```
HOUR ( Time ) -> Integer
HOUR ( < time-string > ) -> Integer
HOUR ( < time-duration > ) ->  Integer
HOUR ( Timestamp ) -> Integer
HOUR ( < timestamp-string > ) -> Integer
HOUR ( < timestamp-duration >  ) -> Integer
```

The following function returns the microsecond part of its argument.

```
MICROSECOND ( Timestamp ) -> Integer
MICROSECOND ( < timestamp-string > ) -> Integer
MICROSECOND ( < timestamp-duration >  ) -> Integer
```

The following function returns the minute part of its argument. For a duration, the return value can be -99 to 99.

```
MINUTE ( Time ) -> Integer
MINUTE ( < time-string > ) -> Integer
MINUTE ( < time-duration > ) ->  Integer
MINUTE ( Timestamp ) -> Integer
MINUTE ( < timestamp-string > ) -> Integer
MINUTE ( < timestamp-duration >  ) -> Integer
```

The following function returns the month portion of its argument. For a duration, the return value can be -99 to 99.

```
MONTH (  Date ) ->  Integer
MONTH ( < date-string > ) ->  Integer
MONTH ( < date-duration > ) -> Integer
MONTH ( Timestamp  ) ->  Integer
MONTH ( < timestamp-string > ) ->  Integer
MONTH ( < timestamp-duration > ) -> Integer
```

The following function returns the second part of its argument. For a duration, the return value can be -99 to 99.

```
SECOND ( Time ) -> Integer
SECOND ( < time-string > ) -> Integer
SECOND ( < time-duration > ) ->  Integer
SECOND ( Timestamp ) -> Integer
SECOND ( < timestamp-string > ) -> Integer
SECOND ( < timestamp-duration >  ) -> Integer
```

The following function returns the year portion of its argument. For a duration, the return value can be -9999 to 9999.

```
YEAR (  Date ) ->  Integer
YEAR ( < date-string > ) ->  Integer
YEAR ( < date-duration > ) -> Integer
YEAR ( Timestamp  ) ->  Integer
YEAR ( < timestamp-string > ) ->  Integer
YEAR ( < timestamp-duration > ) -> Integer
```

## Aggregation functions

Aggregation functions operate on a set of values to return a single scalar value. You can use these functions in the select and subselect methods.

The following example illustrates an aggregation:

```
SELECT  SUM (e.salary) FROM EmpBean e WHERE e.dept.deptno =20
```

This aggregation computes the total salary for department 20.

The aggregation functions are AVG, COUNT, MAX, MIN, and SUM. The syntax of an aggregation function is illustrated in the following example:

```
aggregation-function  (    [ ALL |  DISTINCT ]  expression )
```

or:

```
COUNT( [ ALL |  DISTINCT ] identification-variable )
```

or:

```
COUNT( * )
```

The DISTINCT option eliminates duplicate values before applying the function. ALL is the default option and does not eliminate duplicates. Null values are ignored in computing the aggregate function except in the cases of COUNT(*) and COUNT(identification-variable), which return a count of all the elements in the set.

If your datastore is Informix, you must limit the expression argument to a single valued path expression when using the COUNT function or the DISTINCT forms of the functions SUM, AVG, MIN, and MAX.

### Defining return type

For a select method using an aggregation function, you can define the return type as a primitive type or a wrapper type. The return type must be compatible with the return type from the datastore. The MAX and MIN functions can apply to any numeric, string or datetime datatype and return the corresponding datatype. The SUM and AVG functions take a numeric type as input, and return the same numeric type that is used in the datastore. The COUNT function can take any datatype, and returns an integer.

When applied to an empty set, the SUM, AVG, MAX, and MIN functions can return a null value. The COUNT function returns zero (0) when it is applied to an empty set. Use wrapper types if the return value might be NULL; otherwise, the container displays an ObjectNotFound exception.

### Using GROUP BY and HAVING

The set of values that is used for the aggregate function is determined by the collection that results from the FROM and WHERE clause of the query. You can divide the set into groups and apply the aggregation function to each group. To perform this action, use a GROUP BY clause in the query. The GROUP BY clause defines grouping members, which comprise a list of path expressions. Each path expression specifies a field that is a primitive type of byte, short, int, long, float, double, boolean, char, or a wrapper type of Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Character, java.util.Calendar, java.util.Date, java.sql.Date, java.sql.Time or java.sql.Timestamp.

The following example illustrates the use of the GROUP BY clause in a query that computes the average salary for each department:

```
SELECT e.dept.deptno,  AVG ( e.salary) FROM EmpBean e GROUP BY e.dept.deptno
```

In division of a set into groups, a NULL value is considered equal to another NULL value.

Just as the WHERE clause filters tuples (that is, records of the return collection values) from the FROM clause, the groups can be filtered using a HAVING clause that tests group properties involving aggregate functions or grouping members:

```
SELECT e.dept.deptno,  AVG ( e.salary) FROM EmpBean e
GROUP BY e.dept.deptno
HAVING  COUNT(*) > 3  AND  e.dept.deptno > 5
```

This query returns the average salary for departments that have more than three employees and the department number is greater than five.

It is possible to use a HAVING clause without a GROUP BY clause, in which case the entire set is treated as a single group, to which the HAVING clause is applied.

## SELECT clause

The SELECT clause consists of either a single identification variable that is defined in the FROM clause, or a single valued path expression that evaluates to an object reference or container managed persistence (CMP) value. You can use the DISTINCT keyword to eliminate duplicate references.

For finder and select queries, the syntax of the SELECT clause is illustrated in the following example:

```
SELECT  [  ALL | DISTINCT  ]
 { single-valued-path-expression  |  aggregation expression  |  OBJECT ( identification-variable )  }
```

For a query that defines a finder method, the query must return an object type consistent with the home that is associated with the finder method. For example, a finder method for a department home can not return employee objects.

### Example: SELECT clause

Find all employees that earn more than John:

```
SELECT OBJECT(e) FROM EmpBean ej, EmpBean e
WHERE  ej.name = 'John'  and e.salary > ej.salary
```

Find all departments that have one or more employees who earn less than 20000:

```
SELECT DISTINCT  e.dept  FROM EmpBean e where e.salary < 20000
```

A select method query can have a path expression that evaluates to an arbitrary value:

```
SELECT  e.dept.name  FROM EmpBean e where e.salary < 2000
```

The previous query returns a collection of name values for those departments having employees earning less than 20000.

A select method query can return an aggregate value:

```
SELECT  avg(e.salary)  FROM EmpBean e
```

### Example: Valid dynamic queries

For dynamic queries the syntax is as follows:

```
SELECT { ALL | DISTINCT }  [ selection , ]*  selection
selection  ::= { expression   |  scalar-subselect [[AS] id ] }
```

A scalar-subselect is a subselect that returns a single value.

The following are examples of dynamic queries:

```
SELECT e.name, e.salary+e.bonus as total_pay from EmpBean e
SELECT  SUM( e.salary+e.bonus) from EmpBean e where e.dept.deptno = ?1
```

## ORDER BY clause

The ORDER BY clause specifies an ordering of the objects in the result collection

Use the syntax:

```
ORDER BY  [ order_element ,]* order_element
order_element ::= { path-expression | integer } [ ASC | DESC ]
```

The path expression must specify a single valued field that is a primitive type of byte, short, int, long, float, double, char or a wrapper type of Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Character, java.util.Calendar, java.util.Date, java.sql.Date, java.sql.Time, java.sql.Timestamp.

ASC specifies ascending order and is the default. DESC specifies descending order.

Integer refers to a selection expression in the SELECT clause.

### Example: ORDER BY clause

Return department objects in decreasing deptno order:

```
SELECT  OBJECT(d) FROM  DeptBean d ORDER BY  d.deptno DESC
```

Return employee objects sorted by department number and name:

```
SELECT  OBJECT(e) FROM EmpBean e ORDER BY e.dept.deptno ASC,  e.name DESC
```

## UNION clause operation

The UNION clause specifies a combination of the output of two subqueries. The two queries must return the same number of elements and compatible types.

For the purposes of UNION, all Enterprise JavaBeans (EJB) types in the same inheritance hierarchy are considered compatible. UNION requires that equality be defined for the element types.

```
query_expression := query_term [UNION [ALL] query_term]*

query_term :=  {select_clause_dynamic  from_clause  [where_clause]
 [group_by_clause] [having_clause] } | (query_expression) }
```

You cannot use dependent value objects with UNION.

UNION ALL combines all results together in a single collection.

UNION combines results but eliminates duplicates.

If ORDER BY is used together with UNION, the ORDER BY must refer to selection expression using integer numbers.

### Examples: UNION operation

This example returns a collection of all employee objects of type EmpBean and all manager objects of type ManagerBean where ManagerBean is a subtype of EmpBean.

```
 select e from EmpBean e union all select m from DeptBean d, in(d.mgr) m
```

This example shows a query that is not valid, because EmpBean and DeptBean are not compatible.

```
select e from EmpBean e union all select d from DeptBean d
```

## Subqueries

A subquery can be used in quantified predicates, the EXISTS predicate, or the IN predicate. A subquery should only specify a single element in the SELECT clause.

When a path expression appears in a subquery, the identification variable of the path expression must be defined either in the subquery, in one of the containing subqueries, or in the outer query. A scalar subquery is a subquery that returns one value. A scalar subquery can be used in a basic predicate and in the SELECT clause of a dynamic query.

### Example: Subqueries

```
SELECT  OBJECT(e) FROM  EmpBean e
WHERE e.salary > ( SELECT  AVG(e1.salary) FROM  EmpBean e1)
```

The above query returns employees who earn more than average salary of all employees.

```
SELECT  OBJECT(e) FROM EmpBean e WHERE  e.salary >
( SELECT AVG(e1.salary) FROM  IN  (e.dept.emps) e1  )
```

The above query returns employees who earn more than average salary of their department.

```
SELECT  OBJECT(e) FROM EmpBean e WHERE e.salary =
( SELECT MAX(e1.salary) FROM IN (e.dept.emps) e1  )
```

The above query returns employees who earn the most in their department.

```
 SELECT OBJECT(e) FROM EmpBean e
WHERE e.salary > ( SELECT AVG(e.salary) FROM EmpBean e1
WHERE YEAR(e1.hireDate) =  YEAR(e.hireDate)  )
```

The above query returns employees who earn more than the average of employees hired in same year.

## EJB query language limitations and restrictions

When using the Enterprise JavaBeans (EJB) query language on the product, deviations can be seen in comparison to standard EJB query language. The limitations and restrictions you must be aware of are listed in the following section.

This topic outlines current known limitations and restrictions.

- EJB query language (QL) queries involving enterprise beans with keys made up of relationships to other enterprise beans appear as not valid and cause errors at deployment time. This is a known problem.
- The IBM EJB QL support extends the EJB 2.0 specification in various ways, including relaxing some restrictions, adding support for more DB2 functions, and so on. If portability across various vendor databases or EJB deployment tools is a concern, then care should be taken to write all EJB QL queries strictly according to Chapter 11 in the EJB 2.0 specification.
- Pre-loading across m:n relationships results in the generation of inaccurate structured query language (SQL). This is a known limitation that may be addressed in the future.
- Pre-loading across self referencing relationships causes inaccurate SQL to be generated.
- Avoid relationships between parent and children enterprise beans within the same inheritance hierarchy that are not well-defined.
- EJB Query Language validation for EJB 2.0 JAR files currently runs as a part of the EJB-RDB Mapping validation. If a mapping document (Map.mapxmi file) does not exist in the project, the EJB queries are not validated.

## EJB query compatibility issues with SQL

Because an Enterprise JavaBeans (EJB) query is compiled into structured query language (SQL), you must be aware of compatibility issues between the Java language and SQL.

The two languages differ along the following points that can be critical to correct EJB query formulation:

- The comparison semantics of SQL strings do not exactly match those of the Java language. For example: `'A'` (the letter A) and`'A '` (the letter A plus a blank space) are considered equal in SQL, but not in the Java language.
- Comparisons and collating order depend on the underlying database. For example, if you are using DB2 with an EBCDIC code page, the collating order is not the same as doing the sort in a Java program. Some databases sort the NULL value low while others sort the NULL value high.
- An arithmetic overflow causes an exception in SQL, but not in the Java language.
- SQL databases have differing minimum and maximum ranges for floating point values, which can differ from floating point value ranges in the Java language. Values near the range limits of Java Double may fail to translate into SQL.
- Java methods do not translate into SQL; therefore standard EJB queries cannot include Java methods.

  **Note:** Only with the dynamic EJB query service can you use functions that do not translate into SQL. Such functions include Java methods and converters or composers that are used in mapping enterprise beans to relational databases (RDBs). A standard finder or select query that uses any of these functions fails at deployment time with the message "Cannot push down query". (You can resolve this problem by changing either the query or the mapping.) The dynamic query run time, however, processes the query by performing the operation involving the function in the application server.

## Database restrictions for EJB query

The Enterprise JavaBeans (EJB) query functions must adhere to certain restrictions for databases.

### General database restriction

- All of the enterprise beans involved in a given query must map to the same data source. The EJB query does not support cross-data source join operations.
- It is possible that a structured query language (SQL) statement generated by the WebSphere Application Server deployment code generation utility for an *ejbSelect* EJB query language query returns rows in a result set that consist of null values in all columns.

  During run time persistence manager saves the set received as a result from this query. When your application retrieves the primary key of the result bean, persistence manager calls the extractor. The extractor is a method that is an EJB deploy generated class. This method returns a value of `0` for any null column entries. This value is passed back to the EJB container to forward to the application. The EJB container invokes the bean instance with the PK value of `0`. This could create a problem, as the end user cannot determine if this bean instance has a *null PK* or a *PK value of 0*.

  To avoid this, use the *IS NOT NULL* clause in the finder query to eliminate such null values from the result set.

### Specific database restrictions

Different database products place different restrictions on elements that can be included in EJB query statements. Following is a list of those restrictions; check with your database administrator to see if any apply in your environment:

- Certain functions are used in queries that run against DB2 only, because these functions are not supported by other databases. These functions include date and time arithmetic expressions, certain scalar functions including those *not* listed as portable across vendors, and implied scalar functions when used for mapping certain container managed persistence (CMP) fields. For example, consider mapping an int numeric type to a decimal (5,2) type field. When deployed against a database other than DB2, a finder or select query that contains a CMP field with this particular mapping fails, producing a `Cannot push down query` error message.
- A CMP of type String, when mapped to a character large object (CLOB) in the database, cannot be used in comparison operations because the database does not support CLOB comparisons.

- Databases can impose limits on the length of string values that are used either as literals or input parameters with comparison operators. These limits can hinder query performance. For example: For DB2 on the z/OS platform, the search "name = ?1" can fail if the value of ?1 at run time is greater than 255 in length.
- Mapping a numeric CMP type to a column that contains a dissimilar type can cause unexpected results. For example, consider the case of mapping the int numeric type to a column of type decimal (5,2). This scenario does not preserve an exact decimal value (for example, the value 12.25) over the course of transfer from the database to the enterprise bean CMP field, and back again to the database. This mapping causes replacement of the initial value with a whole number (in this case, 12). Consequently, you want to avoid using the CMP field in comparison operations when the CMP field uses a mapping of this nature.
- Some databases do not support a data type that corresponds to the semantics of java.sql.Time. For example: If a CMP field of type java.sql.Time is mapped to an Oracle DATE column, comparisons on time might not produce the expected result because the year-month-day portion of the column value is truncated in the mapping.
- Some databases treat a zero length string value ( '' ) as a null value; this approach can affect the query results. For the sake of portability, avoid the use of zero length string values.
- Some databases perform division between two integer values using integer arithmetic rules, while others use non-integer rules. This discrepancy might not be desirable in environments that use both kinds of databases. For the sake of portability, avoid the division of integer values in an EJB query.

## Rules for data type manipulation in EJB query

When using an Enterprise JavaBeans (EJB) query to work with data types, certain rules must be followed.

### Rules for container managed persistence (CMP) field type

You can use a CMP field of any type in a SELECT clause. You must, however, use fields of only the following types in search conditions and in grouping or ordering operations:

- Primitive types: byte, short, int, long, float, double, boolean, char
- Object types: Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Character, java.util.Calendar, java.util.Date
- JDBC types: java.sql.Date, java.sql.Time, java.sql.Timestamp
- Binary string: byte[]

### Converters and basic types

If ALL of the following conditions occur:
- a CMP field of one of the basic types listed previously is mapped to an SQL column using a converter
- the CMP field appears in the left hand side of a basic predicate
- the right hand side of the predicate is a literal or input parameter

then the toData() method of the converter is used to compute the SQL search value.

For example, given a converter that maps the integer value 10 to the string value "Ten," the following EJB query:

```
e.cmp = 10
```

is translated into the following SQL query:

```
column = 'Ten'
```

If you include a more complicated predicate, such as in the following example:

```
e.cmp * 10 >  e.salary
```

in a finder or select query, you receive the `Cannot push down query` error message. Use the dynamic EJB query service for such multi-function queries; the dynamic query run time processes the predicate in the application server.

Overall, converters preserve equality, collating sequence, and NULL values. If a converter does not meet these requirements, avoid using it for CMP field comparison operations.

**User types, converters, and composers**

A user type cannot be used in a comparison operation or expression. You can, however, use subfields of the user type in a path expression. For example, consider the CMP addr field with the type `com.exam.Address`, and street, city, and state subfields. The following syntax for a query on this CMP field is not valid:

```
e.addr =  ?1
```

However, a query that designates one of the subfields is valid:

```
e.addr.street = ?1
```

A CMP field can be mapped to an SQL column using Java serialization. Using the CMP field in predicates or expressions for deployment queries usually results in the `Cannot push down query` error message. The dynamic query run time processes the expression by reading and deserializing all instances of the user type in the application server.

However, this expensive process sacrifices performance. You can maintain performance by using a composer in a deployment EJB query. In the previous example, if you want to map the addr field to a binary type, you use a composer to map each subfield to a binary column in the database.

## EJB query: Reserved words

The following words are reserved in WebSphere Application Server Enterprise JavaBeans (EJB) queries.

all, as, distinct, empty, false, from, group, having, in, is, like, select, true, union, where

Avoid using identifiers that start with underscore (for example, _integer ) as these are also reserved.

## EJB query: BNF syntax

The Backus-Naur Form (BNF) is one of the most commonly used notations for specifying the syntax of programming languages or command sets. This article lists the syntax for Enterprise JavaBeans (EJB) query language.

```
EJB QL ::= [select_clause] from_clause [where_clause] [order_by_clause]

DYNAMIC EJB QL := query_expression  [order_by_clause]

query_expression := query_term [UNION [ALL] query_term]*

query_term :=  {select_clause_dynamic  from_clause  [where_clause]
 [group_by_clause] [having_clause] } | (query_expression) }  [order_by_clause]

from_clause::=FROM identification_variable_declaration
               [, {identification_variable_declaration | collection_member_declaration } ]*

identification_variable_declaration::=collection_member_declaration |
       range_variable_declaration [join]*

join :=  [ { LEFT [OUTER] | INNER  }]  JOIN  {collection_valued_path_expression | single_valued_path_expression}
 [AS] identifier

collection_member_declaration::=
       IN ( collection_valued_path_expression ) [AS] identifier
```

```
range_variable_declaration::=abstract_schema_name [AS] identifier

single_valued_path_expression ::=
       {single_valued_navigation | identification_variable}. ( cmp_field |
 method  |  cmp_field.value_object_attribute |  cmp_field.value_object_method )
          | single_valued_navigation

single_valued_navigation::=
       identification_variable.[  single_valued_cmr_field.  ]*
            single_valued_cmr_field

collection_valued_path_expression ::=
       identification_variable.[  single_valued_cmr_field.  ]*
           collection_valued_cmr_field

select_clause::= SELECT { ALL | DISTINCT }  {single_valued_path_expression |
                        identification_variable |  OBJECT ( identification_variable) |
        aggregate_functions }

select_clause_dynamic ::= SELECT { ALL | DISTINCT }  [ selection , ]*  selection

selection  ::= { expression  |  subselect }  [[AS] id ]

order_by_clause::= ORDER BY [ {single_valued_path_expression | integer}  [ASC|DESC],]*
      {single_valued_path_expression | integer}[ASC|DESC]

where_clause::= WHERE conditional_expression

conditional_expression ::= conditional_term |
                           conditional_expression OR conditional_term
conditional_term ::= conditional_factor |
                     conditional_term AND conditional_factor
conditional_factor ::= [NOT] conditional_primary
conditional_primary::=simple_cond_expression | (conditional_expression)

simple_cond_expression ::= comparison_expression | between_expression |
       like_expression | in_expression | null_comparison_expression |
       empty_collection_comparison_expression | quantified_expression |
       exists_expression | is_of_type_expression  |  collection_member_expression

between_expression ::= expression [NOT] BETWEEN expression AND expression

in_expression ::= single_valued_path_expression [NOT] IN
          { (subselect) |  ( [ atom ,]* atom )  }

atom = { string-literal | numeric-constant | input-parameter }

like_expression ::= expression [NOT] LIKE
                {string_literal | input_parameter}
                [ESCAPE {string_literal | input_parameter}]

null_comparison_expression ::=
       single_valued_path_expression IS [ NOT ] NULL

empty_collection_comparison_expression ::=
       collection_valued_path_expression IS [NOT] EMPTY

collection_member_expression  ::=
       { single_valued_path_expression |  input_paramter }  [ NOT ] MEMBER [ OF ]
         collection_valued_path_expression

quantified_expression ::=
       expression comparison_operator  {SOME | ANY | ALL} (subselect)

exists_expression ::= EXISTS {collection_valued_path_expression |  (subselect)}

subselect ::= SELECT [{ ALL | DISTINCT }]  expression  from_clause [where_clause]
       [group_by_clause] [having_clause]

group_by_clause::= GROUP BY [single_valued_path_expression,]*
                    single_valued_path_expression
```

```
having_clause ::= HAVING conditional_expression

is_of_type_expression ::= identifier  IS OF TYPE
            ([[ONLY] abstract_schema_name,]* [ONLY] abstract_schema_name)

comparison_expression ::=  expression   comparison_operator { expression |  ( subquery ) }

comparison_operator ::=    = | > | >= | < | <= | <>

        TIME( expression ) |
        TIMESTAMP( expression ) |
        UCASE ( expression) |
        YEAR( expression )

xrel := XREL identification_variable . { single_valued_cmr_field | collection_valued_cmr_field }
             [ , identification_variable . { single_valued_cmr_field | collection_valued_cmr_field } ]*
```

## EJB specification and WebSphere query language comparison

WebSphere Application Server extends the Enterprise JavaBeans (EJB) query language with elements of its own.

WebSphere Application Server supports the following extensions to the EJB query language.

*Table 70. Extensions supported for the EJB query language. The product supports the following extensions.*

| Item | |
|---|---|
| Delimited identifiers | |
| Dependent Value object attributes used in path expressions | |
| EJB Inheritance | |
| EXISTS predicate | |
| Java methods: EJB bean methods or value object methods | dynamic query only |
| Multiple element select clauses | dynamic query only |
| SQL Date/time expressions | |
| Subqueries, group by, and having clauses | |

# Using the dynamic query service

There are times in the development process when you might prefer to use the dynamic query service rather than the regular Enterprise JavaBeans (EJB) query service (which can be referred to as *deployment query*). During testing, for instance, the dynamic query service can be used at application run time, so you do not have to re-deploy your application.

## About this task

Following are common reasons for using the dynamic query service rather than the regular EJB query service:

- You need to programmatically define a query at application run time, rather than at deployment.
- You need to return multiple CMP or CMR fields from a query. (Deployment queries allow only a single element to be specified in the SELECT clause.) For more information, see the topic, Example: EJB queries.
- You want to return a computed expression in the query.
- You want to use value object methods or bean methods in the query statement. For more information, see the topic, Path expressions.
- You want to interactively test an EJB query during development, but do not want to repeatedly deploy your application each time you update a finder or select query.

The dynamic query API is a stateless session bean; using it is similar to using any other J2EE EJB application bean. It is included in the com.ibm.websphere.ejbquery in the API package.

The dynamic query bean has both a remote and a local interface. If you want to return remote EJB references from the query, or if the query statement contains remote methods, you must use the query remote interface:

remote interface = `com.ibm.websphere.ejbquery.Query`
remote home interface = `com.ibm.websphere.ejbquery.QueryHome`

If you want to return local EJB references from the query, or if the query statement contains local methods, you must use the query local interface:

local interface = `com.ibm.websphere.ejbquery.QueryLocal`
local home interface = `com.ibm.websphere.ejbquery.QueryLocalHome`

Because it uses less application server memory, the local interface ensures better overall EJB performance than the remote.

## Procedure

1. Verify that the query.ear application file is installed on the application server on which your application is to run, if that server is different from the default application server created during installation of the product.

   The `query.ear` file is located in the *app_server_root* directory, where `<WAS_HOME>` is the location of the WebSphere Application Server. The product installation program installs the `query.ear` file on the default application server using a JNDI name of

   ```
   com/ibm/websphere/ejbquery/Query
   ```

   (You or the system administrator can change this name.)
2. Set up authorization for the methods executeQuery(), prepareQuery(), and executePlan() in the remote and local dynamic query interfaces to control access to sensitive data. (This step is necessary only if your application requires security.)

   Because you cannot control which ASN names, CMP fields, or CMR fields can be used in a dynamic EJB query, you or your system administrator must place restrictions on use of the methods. If, for example, a user is permitted to run the executeQuery method, he or she can run any valid dynamic query. In a production environment, you certainly want to restrict access to the remote query interface methods.
3. Write the dynamic query as part of your application client code. You can refer to the example topics, Remote interface dynamic query example, and Local interface dynamic query example, as query models; they illustrate which import statements to use.
4. If the CMP you want to query is on a different module, you should:
   a. do a remote lookup on query.ear
   b. map the query.ear file to the server that the queried CMP bean is installed on.
5. Compile and run your client program with the file **qryclient.jar** in the classpath.

## Example

**Using the remote interface for Dynamic query.**

When you run a dynamic Enterprise JavaBeans (EJB) query using the remote interface, you are calling the executeQuery method on the Query interface. The executeQuery method has a transaction attribute of REQUIRED for this interface; therefore you do not need to explicitly establish a transaction context for the query to run.

When you run a dynamic Enterprise JavaBeans (EJB) query using the remote interface, you are calling the executeQuery method on the Query interface. The executeQuery method has a transaction attribute of REQUIRED for this interface; therefore you do not need to explicitly establish a transaction context for the query to run.

Begin with the following import statements:

```
import com.ibm.websphere.ejbquery.QueryHome;
import com.ibm.websphere.ejbquery.Query;
import com.ibm.websphere.ejbquery.QueryIterator;
import com.ibm.websphere.ejbquery.IQueryTuple;
import com.ibm.websphere.ejbquery.QueryException;
```

Next, write your query statement in the form of a string, as in the following example that retrieves the names and ejb-references for underpaid employees:

```
String query =
"select e.name as name , object(e) as emp from EmpBean e where e.salary < 50000";
```

Create a Query object by obtaining a reference from the QueryHome class. (This class defines the executeQuery method.) Note that for the sake of simplicity, the following example uses the dynamic query JNDI name for the Query object:

```
InitialContext ic =  new InitialContext();

Object obj =  ic.lookup("com/ibm/websphere/ejbquery/Query");

QueryHome  qh =
 ( QueryHome) javax.rmi.PortableRemoteObject.narrow( obj, QueryHome.class );
Query qb = qh.create();
```

You then must specify a maximum size for the query result set, which is defined in the QueryIterator object, which is included in the Class QueryIterator. This class is included in the You then must specify a maximum size for the query result set, which is defined in the QueryIterator object, which is included in the QueryIterator API package. This example sets the maximum size of the result set to 99:

```
QueryIterator it = qb.executeQuery(query, null, null ,0, 99 );
```

The iterator contains a collection of IQueryTuple objects, which are records of the return collection values. Corresponding to the criteria of our example query statement, each tuple in this scenario contains one value of *name* and one value of *object(e)*. To display the contents of this query result, use the following code:

```
while (it.hasNext() ) {
 IQueryTuple tuple = (IQueryTuple) it.next();
 System.out.print( it.getFieldName(1) );
 String s = (String) tuple.getObject(1);
 System.out.println( s);
 System.out.println( it.getFieldName(2) );
 Emp e = ( Emp) javax.rmi.PortableRemoteObject.narrow( tuple.getObject(2), Emp.class );
 System.out.println( e.getPrimaryKey().toString());
}
```

The output from the program might look something like the following:

```
name Bob
emp 1001
name Dave
emp 298003
...
```

Finally, catch and process any exceptions. An exception might occur because of a syntax error in the query statement or a run-time processing error. The following example catches and processes these exceptions:

```
} catch (QueryException qe) {
    System.out.println("Query Exception "+ qe.getMessage() );
}
```

**Handling large result collections for the remote interface query**

If you intend your query to return a large collection, you have the option of programming it to return results in multiple smaller, more manageable quantities. Use the skipRow and maxRow parameters on the remote executeQuery method to retrieve the answer in chunks. For example:

```
int skipRow=0;
int maxRow=100;
QueryIterator it = null;
do {
 it = qb.executeQuery(query, null, null ,skipRow, maxRow );
 while (it.hasNext() ) {
 // display result
 skipRow = skipRow + maxRow;
}
} while ( ! it.isComplete() ) ;
```

**Using the local interface for Dynamic query.**

When you run a dynamic Enterprise JavaBeans (EJB) query using the local interface, you are calling the executeQuery method on the QueryLocal interface. This interface does not initiate a transaction for the method; therefore you must explicitly establish a transaction context for the query to run.

**Note:** To establish a transaction context, the following example calls the begin() and commit() methods. An alternative to using these methods is simply embedding your query code within an EJB method that runs within a transaction context.

Begin your query code with the following import statements:

```
import com.ibm.websphere.ejbquery.QueryLocalHome;
import com.ibm.websphere.ejbquery.QueryLocal;
import com.ibm.websphere.ejbquery.QueryLocalIterator;
import com.ibm.websphere.ejbquery.IQueryTuple;
import com.ibm.websphere.ejbquery.QueryException;
```

Next, write your query statement in the form of a string, as in the following example that retrieves the names and ejb-references for underpaid employees:

```
String query =
"select e.name, object(e) from EmpBean e where e.salary < 50000 ";
```

Create a QueryLocal object by obtaining a reference from the QueryLocalHome class. (This class defines the executeQuery method.) Note that in the following example, `ejb/query` is used as a local EJB reference pointing to the dynamic query JNDI name (`com/ibm/websphere/ejbquery/Query`):

```
InitialContext ic =  new InitialContext();
   QueryLocalHome  qh =  ( LocalQueryHome) ic.lookup( "java:comp/env/ejb/query" );
QueryLocal qb = qh.create();
```

The last portion of code initiates a transaction, calls the executeQuery method, and displays the query results. The QueryLocalIterator class is instantiated because it defines the query result set. This class is included in the Class QueryIterator API package. Keep in mind that the iterator loses validity at the end of the transaction; you must use the iterator in the same transaction scope as the executeQuery call.

```
userTransaction.begin();
QueryLocalIterator it = qb.executeQuery(query, null, null);
while (it.hasNext() ) {
 IQueryTuple tuple = (IQueryTuple) it.next();
 System.out.print( it.getFieldName(1) );
 String s = (String) tuple.getObject(1);
 System.out.println( s);
 System.out.println( it.getFieldName(2) );
 EmpLocal e = ( EmpLocal ) tuple.getObject(2);
 System.out.println( e.getPrimaryKey().toString());
}
userTransaction.commit();
```

In most situations, the QueryLocalIterator object is *demand-driven*. That is, it causes data to be returned incrementally: for each record retrieval from the database, the next() method must be called on the iterator. (Situations can exist in which the iterator is not demand-driven. For more information, consult the "Local query interfaces" subsection of the Dynamic query performance considerations topic.)

Because the full query result set materializes incrementally in the application server memory, you can easily control its size. During a test run, for example, you may decide that return of only a few tuples of the query result is necessary. In that case you should use a call of the close() method on the QueryLocalIterator object to close the query loop. Doing so frees SQL resources that the iterator uses. Otherwise, these resources are not freed until the full result set accumulates in memory, or the transaction ends.

## Example: Using the remote interface for Dynamic query

When you run a dynamic Enterprise JavaBeans (EJB) query using the remote interface, you are calling the executeQuery method on the Query interface. The executeQuery method has a transaction attribute of REQUIRED for this interface; therefore you do not need to explicitly establish a transaction context for the query to run.

Begin with the following import statements:

```
import com.ibm.websphere.ejbquery.QueryHome;
import com.ibm.websphere.ejbquery.Query;
import com.ibm.websphere.ejbquery.QueryIterator;
import com.ibm.websphere.ejbquery.IQueryTuple;
import com.ibm.websphere.ejbquery.QueryException;
```

Next, write your query statement in the form of a string, as in the following example that retrieves the names and ejb-references for underpaid employees:

```
String query =
"select e.name as name , object(e) as emp from EmpBean e where e.salary < 50000";
```

Create a Query object by obtaining a reference from the QueryHome class. (This class defines the executeQuery method.) Note that for the sake of simplicity, the following example uses the dynamic query JNDI name for the Query object:

```
InitialContext ic =  new InitialContext();

Object obj =  ic.lookup("com/ibm/websphere/ejbquery/Query");

QueryHome  qh =
 ( QueryHome) javax.rmi.PortableRemoteObject.narrow( obj, QueryHome.class );
Query qb = qh.create();
```

You then must specify a maximum size for the query result set, which is defined in the QueryIterator object, which is included in the Class QueryIterator. This class is included in the You then must specify a maximum size for the query result set, which is defined in the QueryIterator object, which is included in the QueryIterator API package. This example sets the maximum size of the result set to 99:

```
QueryIterator it = qb.executeQuery(query, null, null ,0, 99 );
```

The iterator contains a collection of IQueryTuple objects, which are records of the return collection values. Corresponding to the criteria of our example query statement, each tuple in this scenario contains one value of *name* and one value of *object(e)*. To display the contents of this query result, use the following code:

```
while (it.hasNext() ) {
 IQueryTuple tuple = (IQueryTuple) it.next();
 System.out.print( it.getFieldName(1) );
 String s = (String) tuple.getObject(1);
 System.out.println( s);
 System.out.println( it.getFieldName(2) );
 Emp e = ( Emp) javax.rmi.PortableRemoteObject.narrow( tuple.getObject(2), Emp.class );
 System.out.println( e.getPrimaryKey().toString());
}
```

The output from the program might look something like the following:

```
name Bob
emp 1001
name Dave
emp 298003
...
```

Finally, catch and process any exceptions. An exception might occur because of a syntax error in the query statement or a run-time processing error. The following example catches and processes these exceptions:

```
} catch (QueryException qe) {
    System.out.println("Query Exception "+ qe.getMessage() );
}
```

### Handling large result collections for the remote interface query

If you intend your query to return a large collection, you have the option of programming it to return results in multiple smaller, more manageable quantities. Use the skipRow and maxRow parameters on the remote executeQuery method to retrieve the answer in chunks. For example:

```
int skipRow=0;
int maxRow=100;
QueryIterator it = null;
do {
 it = qb.executeQuery(query, null, null ,skipRow, maxRow );
 while (it.hasNext() ) {
 // display result
 skipRow = skipRow + maxRow;
}
} while ( ! it.isComplete() ) ;
```

## Example: Using the local interface for Dynamic query

When you run a dynamic Enterprise JavaBeans (EJB) query using the local interface, you are calling the executeQuery method on the QueryLocal interface. This interface does not initiate a transaction for the method; therefore you must explicitly establish a transaction context for the query to run.

**Note:** To establish a transaction context, the following example calls the begin() and commit() methods. An alternative to using these methods is simply embedding your query code within an EJB method that runs within a transaction context.

Begin your query code with the following import statements:

```
import com.ibm.websphere.ejbquery.QueryLocalHome;
import com.ibm.websphere.ejbquery.QueryLocal;
import com.ibm.websphere.ejbquery.QueryLocalIterator;
import com.ibm.websphere.ejbquery.IQueryTuple;
import com.ibm.websphere.ejbquery.QueryException;
```

Next, write your query statement in the form of a string, as in the following example that retrieves the names and ejb-references for underpaid employees:

```
String query =
"select e.name, object(e) from EmpBean e where e.salary < 50000 ";
```

Create a QueryLocal object by obtaining a reference from the QueryLocalHome class. (This class defines the executeQuery method.) Note that in the following example, `ejb/query` is used as a local EJB reference pointing to the dynamic query JNDI name (`com/ibm/websphere/ejbquery/Query`):

```
InitialContext ic =  new InitialContext();
   QueryLocalHome  qh =  ( LocalQueryHome) ic.lookup( "java:comp/env/ejb/query" );
QueryLocal qb = qh.create();
```

The last portion of code initiates a transaction, calls the executeQuery method, and displays the query results. The QueryLocalIterator class is instantiated because it defines the query result set. This class is included in the Class QueryIterator API package. Keep in mind that the iterator loses validity at the end of the transaction; you must use the iterator in the same transaction scope as the executeQuery call.

```
userTransaction.begin();
QueryLocalIterator it = qb.executeQuery(query, null, null);
while (it.hasNext() ) {
 IQueryTuple tuple = (IQueryTuple) it.next();
 System.out.print( it.getFieldName(1) );
 String s = (String) tuple.getObject(1);
 System.out.println( s);
```

```
 System.out.println( it.getFieldName(2) );
 EmpLocal e = ( EmpLocal ) tuple.getObject(2);
 System.out.println( e.getPrimaryKey().toString());
}
userTransaction.commit();
```

In most situations, the QueryLocalIterator object is *demand-driven*. That is, it causes data to be returned incrementally: for each record retrieval from the database, the next() method must be called on the iterator. (Situations can exist in which the iterator is not demand-driven. For more information, consult the "Local query interfaces" subsection of the Dynamic query performance considerations topic.)

Because the full query result set materializes incrementally in the application server memory, you can easily control its size. During a test run, for example, you may decide that return of only a few tuples of the query result is necessary. In that case you should use a call of the close() method on the QueryLocalIterator object to close the query loop. Doing so frees SQL resources that the iterator uses. Otherwise, these resources are not freed until the full result set accumulates in memory, or the transaction ends.

## Dynamic query performance considerations

While using a dynamic query can be convenient, there are times when it can have an impact on your application performance.

### General performance considerations

Use of the following elements in your dynamic query can diminish application performance somewhat:

- Datatype converters and Java methods

  Why: In general, query operations and predicates are translated into SQL so that the database server can perform them. If your query includes datatype converters (for EJB to RDB mapping, for example) or Java methods, however, the associated predicates and operations of your query must be performed in the memory of the application server.
- EJB methods and criteria that call for the return of EJB references

  Why: Queries that incorporate these elements trigger full activation of EJBs in the memory of the application server. (Returning a list of CMP fields from a query does not cause an EJB to be activated.)

When assessing application performance, you should also be aware that dynamic queries share connections with the persistence manager. Consequently, an application that includes a mixture of finder methods, CMR navigation, and dynamic queries relies on a single shared connection between the persistence manager and the dynamic query service to perform these tasks.

### Limiting the return collection size

- **Remote interface queries**: The QueryIterator class of the remote interface mandates that all of your query results materialize in application server memory over the course of one method call. The SQL cursor(s) used to run the EJB query are closed upon completion of that call. Because this requirement poses a high risk for creating bottlenecks within the database server, you need to limit the size of any potentially large result collections.
- **Local interface queries**: In most situations, the QueryLocalIterator object behaves as a wrapper around an SQL cursor. It is *demand-driven*; it causes data to be returned incrementally. For each record retrieval from the database, the next() method must be called on the iterator.

  Use of certain operations in local interface queries, however, overrides the demand-driven behavior. In these cases, the query results fully materialize in memory just as do the result collections of remote interface queries. An example of such a case is:

  ```
  select  e.myBusinessMethod( ) from EmpBean e
   where e.salary < 50000 order by 1 desc
  ```

  This query requires performance of an EJB method to produce the final result collection. Consequently, the full dataset from the database must be returned in one collection to application server memory,

where the EJB method can be run on the dataset in its entirety. For that reason, local interface query operations that invoke EJB methods are generally not demand-driven. You cannot control the return collection size for such queries.

Because they *are* demand-driven, all other local interface queries allow you to control the size of return collections. You can use a call of the close() method on the QueryLocalIterator object to close the query loop after the desired number of return values has been fetched from the datastore. Otherwise, the SQL cursor(s) used to run the EJB query are not closed until the full result set accumulates in memory, or the transaction ends.

## Access intent implications for dynamic query

WebSphere Application Server gives you the option to set access intent policies for your entity enterprise beans as a way of managing their transfer of data with the underlying data store. An access intent policy controls the isolation level used on the data source connection, as well as the database locks used during data retrieval. By manipulating these elements, you can maximize the efficiency of your application's data flow.

To learn more, begin with the topic, Access intent policies and the topic, Concurrency control.

When formulating dynamic queries, keep in mind the following considerations concerning their interaction with access intent policies:

- A dynamic query uses the first ASN name in the FROM clause to determine access intent.
- The collection increment attribute of an access intent policy is not used in processing a dynamic query.
- When performed on entity beans that have a pessimistic-Update access intent policy, your dynamic queries must return updateable collections. Therefore you need to formulate your query statements to return only collections of entity beans, *not* collections of CMP fields. For example, the statement `select object(c) from Customer` is valid for a dynamic query performed under the constraint of a pessimistic-Update policy. The statement `select c.name from Customer c`, however, is not a valid dynamic query under this constraint.
- Using pessimistic-Update policy places restrictions on the types of query expressions. The restrictions depend on the back end database type and release. Refer to the topic Access intent – isolation levels and update locks, for details.

## Dynamic query API: prepareQuery() and executePlan() methods

Use these methods to more efficiently allocate the overhead associated with dynamic query. They are equivalent in function to the prepareStatement() and executeQuery() methods of the JDBC API.

To perform a dynamic Enterprise JavaBeans (EJB) query, the application server must parse the query string into structured query language (SQL) at run time. You can, of course, eliminate run-time overhead by choosing to perform a standard EJB query instead of a dynamic query. Sometimes referred to as *deployment queries*, standard queries are parsed and built at deployment, then performed by a finder or select method.

Another option is to write code that redistributes dynamic query overhead for better application performance. Begin by calling the prepareQuery() method in place of the executeQuery() method. The prepareQuery() method parses and translates your query, and returns a string called a *query plan*. The plan contains the SQL statement produced by parsing and translation, as well as other information needed by the dynamic query API. Save this string in your application and call the executePlan() method with the string to run your query. (You also might want to use the prepareQuery() method simply to see the SQL translation product; just call the method and display the return value.)

Pass the parameters of your query as an array of type Object on the prepareQuery() and the executePlan() method calls. Ensure that you pass appropriate data types, because the application server validates your query according to parameter type (rather than actual values) when it processes the prepareQuery() method call.

**Example code**

**Note:** In the example code that follows, the first executePlan() method call substitutes `parms[0]` for `?1`. Hence the first query performed is functionally equivalent to the following query statement:

```
select e.name as name, object(e) as emp from EmpBean e where e.salary < 50000
```

The second call runs a query that is functionally equivalent to this statement:

```
select e.name as name, object(e) as emp from EmpBean e where e.salary < 60000
```

The example:

```
String query =
"select e.name as name , object(e) as emp from EmpBean e where e.salary < ?1";
QueryIterator it = null;
Integer[] parms = new Integer[1];
parms[0] = new Integer(0);
```

In the call to `prepareQuery()`, pass any Integer value. Doing so defines `?1` as an Integer type, as in the following:

```
String queryPlan= qb.prepareQuery(query, parms, null );

   parms[0] = new Integer(50000);
```

Next you run the query with a real value of `Integer(50000)` for `?1`:

```
select e.name as name, object(e) as emp from EmpBean e where e.salary < 50000it =
 qb.executePlan( queryPlan, parms, 0, 99);

parms[0] = new Integer(60000);
```

Run the query again with a different value of `Integer(60000)` for `?1`:

```
it = qb.executePlan( queryPlan, parms, 0, 99);
```

## Dynamic and deployment EJB query services comparison

You can use the dynamic query service to build and execute queries against entity beans constructed dynamically at run time, rather than defining them at deployment time. By using dynamic query you gain the flexibility of queries defined at run time and utilize the power of Enterprise JavaBeans (EJB)-Query Language (QL). Apart from supporting all of the capabilities of an EJB-QL query, dynamic query adds functionality not available to standard static query. Two examples are the ability to select multiple data fields directly from the bean itself (static queries currently only allow one) and executing business methods directly in the query.

You can effectively create more efficient and less resource intensive applications with dynamic query. For example, two data fields are required from the results of a query. Because a standard EJB-QL query can only select one data field, it is necessary to select the entire EJB object and extract the needed data from the returned results through data access methods, possibly traversing Container Managed Relationships (CMR) boundaries in the process. However, when using dynamic query, you can get both pieces of data directly from the query without additional CMR traversal or accessor methods. This principle is the key to evaluating whether or not dynamic query can be used for performance gain. You should review the amount of data that must be retrieved, in addition to the amount of business logic needed to retrieve it, for example, CMR traversal or accessor methods.

Using parameters in the query rather than literal values is another performance consideration. Under most circumstances, it is better to define conditional values as parameters in the query and then pass those parameters through the appropriate mechanisms. By using this method, you have a greater chance of matching a cached query plan, and you eliminate the need to parse and build the plan from scratch. For example, "SELECT Object(o) FROM schemaname AS o WHERE o.fieldname LIKE foo", is more appropriately expressed as "SELECT Object(o) FROM schemaname AS o WHERE o.fieldname LIKE ?1" with the value *foo* passed as a parameter to the executeQuery method. The result is that any subsequent

execution of a dynamic query structure that is the same, except for different string literal conditions, is registered as a plan cache hit (which delivers better "observed" performance).

When used as a direct replacement for an equivalent static query, dynamic query is approximately 25% slower than the static variation. This slowdown is due to the need for parsing and building a plan for the query, in addition to executing it. In the static variation, these costs are paid at deploy time. Despite this, the added functionality gained through the use of dynamic query, specifically the ability to select multiple data fields in a single query even across CMRs, creates opportunities to utilize dynamic query for the sake of performance improvement.

# Chapter 12. Developing EJB applications

This page provides a starting point for finding information about enterprise beans.

Based on the Enterprise JavaBeans (EJB) specification, enterprise beans are Java components that typically implement the business logic of Java 2 Platform, Enterprise Edition (J2EE) applications as well as access data.

## Developing EJB 2.x enterprise beans

## Partial column update feature for container managed persistence

The Container Managed Persistence (CMP) bean method `ejbStore` stored all of the persistent attributes of the CMP bean to the database, even if only a subset of persistent attribute fields were changed. This needless performance degradation is eliminated in this release of the product.

**Note:** Entity beans are not supported in EJB 3.0 modules.

For Enterprise JavaBeans (EJB) 2.x CMP entity beans, you can use the partial update feature to specify how you want to update the persistent attributes of the CMP bean to the database. This feature is provided as a bean level persistence option, called `PartialOperation`, in the access intent policy configured for the bean. PartialOperation has two possible values:

**NONE** Partial update is turned off. All of the persistent attributes of the CMP bean are stored to the database. This is the default value.

**UPDATE_ONLY**
Specifies that updates to the database occur only for the persistent attributes of the CMP bean that are changed.

For information on how to set partial update, see “Setting partial update for container-managed persistent beans” on page 587.

### Performance

Performing partial updates increases performance in several ways:

- by reducing query execution time, since only a subset of the columns are in the query. Improvement is higher for tables with many columns and indexes. When the table has many indexes only the indexes affected by the updated columns need to be updated by the backend database.
- by reducing network input and output since there is less data to be transmitted.
- by saving any processing time for non-trivially mapped columns. For example, if a column uses converters, composers, and transformations to partially inject the input record.
- by eliminating unnecessary firing of update triggers. If a CMP bean field is not changed, any trigger depending only on the corresponding column is not fired.

Although partial update improves performance, it can adversely affect performance as follows:

- If you enable partial update for a bean that your application modifies several different combinations of columns during the same time span, the prepared statement cache maximum for the connection is reached very quickly. As a result, statement handles are evicted from the cache based on least recent usage. This results in statements being prepared repeatedly, decreasing performance for all CMP functions, not just limited to the ejbStore method.
- Partial update query templates cached in the function set increase memory use. The increase is linear relative to the number of fields in the CMP bean for which the partial update access intent option is turned on.

© IBM Corporation 2009

- The PartialOperation persistent option, when used in combination with the Batch Update persistent option, affects the performance of the batch update because each partial query is different. There is an execution time cost incurred for generating a partial update query string dynamically. Since query fragments are stored for each column, the execution cost to assemble the query fragments is linear, based on the number of CMP bean fields dirtied.
- There are condition checks for each CMP field, for example, to inspect the dirty flags and to execute the preparedStatement setXXX method calls.

## Considerations for using partial update

The performance gains you hope to achieve should be weighed against the possible instances where degradation can occur. You can use the following guidelines to help you make the decision.

- Partial update might not benefit an application that only involves a small table with a few columns and simple data types and no update triggers. The cost to assemble the partial query dynamically outweighs the performance gain.
- Partial update is a benefit if there is a complex data type that is not updated often. An example of a complex data type is an employee bean with a “photo” CMP attribute mapped to a BLOB OR VARGRAPHIC, or similar complex backend type, that is typically stored in a different location in the database manager implementation.
- Partial Update might benefit if there are several VARCHAR type columns and only a very few of them are updated.
- It is better not to use the partial operation if the application can randomly be updating different combinations of columns and the number of assignable columns (non-key) is higher than five. This generates different partial queries and fills up the prepared statement cache quickly. But, if the bean does not have too many columns, for example, four or less, and it has complex data types, you might consider turning partial update on, with the option of increasing the statement cache size to ensure an increased number of queries. For information on increasing the statement cache size, refer to the data source settings help.
- Partial Update is beneficial when there are update triggers needed on a subset of columns.
- Partial Update is beneficial when the table has many columns and indexes, and only a few indexes are touched by a typical update.

## Restrictions

By default, batch update of update queries is disabled for all CMP beans for which partial update is enabled. In other words, partial update takes precedence over batch update. Batch update of delete and insert queries is not affected.

Batch update performance is affected when both batch update and partial update persistence options are used on the same bean, because each partial query is different. You can use the JVM property, `-Dcom.ibm.ws.pm.grouppartialupdate=true`, to group the similar partial update queries into a batch update. Grouping partial updates only helps when there are several partial queries with the same shape in a transaction. Otherwise, grouping partial updates has the opposite affect on performance. Because this setting is not on a bean level basis, you should be careful when turning it on. Because this affects all beans that have both partial update and batch update on, you must make sure that batch update of partial queries does increase performance when viewed across all the beans for which both updates are on.

To set the JVM property:

1. Open the `server.xml` file.
2. Change the value of `-Dcom.ibm.ws.pm.grouppartialupdate=true` to `-Dcom.ibm.ws.pm.grouppartialupdate=false`.

## Setting partial update for container-managed persistent beans

For Enterprise JavaBeans (EJB) 2.x CMP entity beans, you can use the *partial update* feature to specify how you want to update the persistent attributes of the CMP bean to the database. This feature is provided as a bean-level persistence option, called *PartialOperation*, in the access intent policy configured for the bean.

### About this task

See the topic Partial operation for container managed persistence in the assembly tool information center to learn how to complete this task with the assembly tool.

---

# Developing EJB 3.x enterprise beans

## Enterprise JavaBeans (EJB) 3.1 specification

This topic describes the Enterprise JavaBeans (EJB) 3.1 specification that is the foundation of the development and application programming model for EJB 3.1 applications. Read this topic for a brief overview of the EJB 3.1 specification.

The EJB 3.1 specification focuses on simplification and ease of use. In addition, it adds many new features to the programming model.

- *Singleton session beans* are a new type of session bean. As the name implies, only one instance of the bean exists. A Singleton is useful for storing data that is shared by different parts of an application. Data concurrency might be controlled by either the container or the application itself.
- *Non-persistent EJB Timers* are similar to the persistent EJB Timers that existed before EJB 3.1, except that they exist only in memory and are not stored in a database. Non-persistent timers are useful for scenarios where it is not desirable to retry missed events.
- *Automatically created EJB Timers* are created automatically when the application starts, and they are removed automatically when the application is uninstalled. Automatically created timers might be either persistent or non-persistent. Automatically created timers are useful because they remove the need for the application or an administrator to explicitly create and remove the timers.
- *Calendar based timer expressions* allow developers to specify a timeout schedule using a calendar-based syntax that closely resembles the UNIX Cron functionality. Calendar-based expressions are useful because they make it much easier to specify and understand the timeout schedule for a timer.
- *Asynchronous method invocation* allows applications to run multiple chunks of work in parallel. Asynchronous methods are useful from a performance perspective because work loads are not single threaded, and they are also useful from a simplification perspective because the application programmer is shielded from the complexities associated with multithreaded programming.
- The *No-Interface Local View* further simplifies the plain old Java objects (POJO) programming model. With the No-Interface Local View, EJBs are no longer required to have a bean interface.
- The *embeddable EJB container* allows developers to unit test their EJB function in a Java SE environment. The embeddable EJB container is useful because it allows developers to test EJB function quickly and easily in their personal sandbox environment, and it removes the need to install the EJBs into an application server.

- *Packaging EJB content in WAR modules* allows both web and EJB content to be physically combined into the same module. This packaging option is useful because it might simplify the assembly and installation of the application, and simplifying the interaction between the web and EJB components that are collocated in the same module.

## Enterprise JavaBeans (EJB) 3.0 specification

This topic describes the Enterprise JavaBeans (EJB) 3.0 specification that is the foundation of the development and application programming model for the EJB 3.0 applications. Read this topic for a brief overview of the EJB 3.0 specification.

The EJB 3.0 specification has justifiably been called the most important upgrade to the Java Platform, Enterprise Edition 5 (Java EE 5) programming model. The EJB 3.0 specification represents simplification and streamlining of the business logic and persistence programming models used in Java EE. The ultimate source of information is the specification, which is available on the Oracle website.

While the Java Persistence API (JPA) replacement is called an entity class, it should not be confused with entity enterprise beans. A JPA entity is not an enterprise bean and is not required to run in an EJB container.

The EJB 3.0 specification is organized into three areas:

- EJB core contracts and requirements
- EJB 3.0 simplified application programming interface (API)
- JPA

The EJB core contracts and requirements define the service provider interfaces (SPIs) between the enterprise bean instance and the enterprise bean container. This part of the specification also includes the APIs between the enterprise bean provider and the enterprise bean container, protocols, component and container contracts, system level issues, infrastructure services that are provided by the container to the bean and other information about development packaging and deployment for session, message-driven, and entity beans.

The EJB 3.0 simplified API provides information about simplifying EJB APIs and SPIs that exist from previous EJB specification versions.

The JPA document introduces the Plain Old Java Object (POJO)-style persistent entity development guidelines.

Another good source for EJB 3.0 information is Mastering Enterprise JavaBeans 3.0, Fourth Edition. This edition features chapters on session beans and message-driven beans, EJB, and Java EE integration and advanced persistence concepts. Also included is coverage of the JPA and POJO using entities with the EJB programming model.

## Application exceptions

Application exceptions alert the client of application specific or business logic issues; they do not report system level exceptions. This topic includes a brief overview of how application exceptions are defined and examples of the `@ApplicationException` annotation and corresponding `application-exception` deployment descriptor element.

### Definition of Application Exception

Bean providers define application exceptions along with the business logic of an application. Unlike system exceptions, application exceptions are not used to report system-level errors. Instead, business methods

use application exceptions to notify the client of application-level activity that might cause errors; for example, invalid input argument values to a business method. In most cases, clients can return to normal processing after experiencing application exceptions

You can define application exceptions in the throws clause of a method. The method that you use to define the application exception can be that of a business interface, no-interface view, home interface, component interface, message listener interface, or web service endpoint of the enterprise bean. When you define the exception, remember that application exceptions can be:

- A subclass, either direct or indirect, of the java.lang.Exception exception, which renders a *checked exception*
- A subclass of the java.lang.RuntimeException exception, which renders an *unchecked exception*

**Attention:** You cannot define an application exception as a subclass of java.rmi.RemoteException because this exception and its subclasses are for system-level problems.

The following standard application exceptions and their subclasses are used to report errors to the client:

- javax.ejb.CreateException
- javax.ejb.RemoveException
- javax.ejb.FinderException

The previous application exceptions are defined in the create, remove, and finder methods of the EJBHome interface, the EJBLocalHome interface, or both. These interfaces come from components that are written to the EJB 2.1 client view.

In the Enterprise Java beans 3.0 specification, the @ApplicationException annotation had only one optional parameter of rollback. The corresponding application-exception element had only one optional subelement, rollback, that you set to true or false. The rollback parameter/subelement is used to specify whether the transaction is marked for rollback. By default this value is false. Inheritance of an application exception could not be specified and was not given an explicit default value in the EJB 3.0 specification. The product implementation of the EJB 3.0 specification did not provide application exception inheritance, unless an application exception was defined on the `throws` clause of a business method of a bean. In contrast, the EJB 3.1 specification has introduced the optional `inherited` parameter to the @ApplicationException annotation and the optional `inherited` subelement to the corresponding application-exception deployment descriptor element. By default, marking an exception as an application exception causes all subclasses of that exception to also be application exceptions (that is, `inherited=true`). You can disable the inheriting behavior by setting the `inherited` parameter of the @ApplicationException to false. Likewise, you can disable the inheriting behavior by setting the `inherited` subelement of the application-exception element in the deployment descriptor to false. For more information about application exceptions, refer to section 14.1.1 of the EJB 3.1 specification.

**Inherited application exceptions using annotations:**

```
import javax.ejb.ApplicationException;

@ApplicationException(inherited=true, rollback=true)
public class RTExceptionA extends RuntimeException{

   //RTExceptionA

}
public class RTExceptionB extends RTExceptionA{

   //RTExceptionB

}
import javax.ejb.ApplicationException;

@ApplicationException(inherited=false, rollback=false)
```

```
public class RTExceptionC extends RTExceptionB{

   //RTExceptionC

}
public class RTExceptionD extends RTExceptionC{

   //RTExceptionD

}
```

The previous example yields the following results:

RTExceptionA is an application exception with transaction rollback.

RTExceptionB is an application exception with transaction rollback.

RTExceptionC is an application exception without transaction rollback.

RTExceptionD is not an application exception.

### Inherited application exceptions using XML:

```
public class RTExceptionA extends RuntimeException{

   //RTExceptionA

}
public class RTExceptionB extends RTExceptionA{

   //RTExceptionB

}
public class RTExceptionC extends RTExceptionB{

   //RTExceptionC

}
public class RTExceptionD extends RTExceptionC{

   //RTExceptionD

}
```

```
<!-- Example ejb-jar.xml -->
<?xml version="1.0" encoding="UTF-8"?>
<ejb-jar id="ejb-jar_ID" xmlns="http://java.sun.com/xml/ns/javaee"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_1.xsd"
    metadata-complete="true" version="3.1">
    <assembly-descriptor>
        <application-exception>
            <exception-class>myXML.example.package.RTExceptionA</exception-class>
            <rollback>true</rollback>
            <inherited>true</inherited>
        </application-exception>
        <application-exception>
            <exception-class>myXML.example.package.RTExceptionC</exception-class>
            <rollback>false</rollback>
            <inherited>false</inherited>
        </application-exception>
    </assembly-descriptor>
</ejb-jar>
```

As in the annotation version, the previous example yields the following results:

RTExceptionA is an application exception with transaction rollback.

RTExceptionB is an application exception with transaction rollback.

RTExceptionC is an application exception without transaction rollback.

RTExceptionD is not an application exception.

**Remember:** You can use the `rollback` and `inherited` subelements of the `application-exception` to explicitly override the `rollback` and `inherited` attribute values that were specified or implicitly set by the `@ApplicationException` annotation.

When you specify an exception on the throws clause of a business method of a bean, the resulting checked exception is an application exception. All subclasses of this application exception are also application exceptions. No option is available to disable this inheriting behavior of checked application exceptions. You can use the `inherited` element to determine the rollback value of the checked application exception subclasses. If the `inherited` element of the checked application exception is set to `true` and its `rollback` element is set to `true`, then the subclasses of that checked application exception inherit the `rollback = true` value.

## Getting EJB 3.0 application exception inheritance behavior:

You have the following options if you have an existing EJB 3.0 application and you want to continue having the application exception inheritance behavior be false, which means that the subclasses of an application exception are not application exceptions themselves.

- You can modify the exception's `@ApplicationException` annotation of the exception by adding the `inherited` attribute and setting it to `false`.
- You can add a version 3.1 deployment descriptor and explicitly set the `inherited` subelement of the `application-exception` element to `false`. If you have an existing version 3.0 deployment descriptor you must migrate to a version 3.1 deployment descriptor and XSD schema and set the `inherited subelement of the application-exception` element to `false`.

### How to get EJB 3.0 application exception inheritance behavior with annotations:

Suppose that you previously had the following code:

```
import javax.ejb.ApplicationException;

@ApplicationException()
public class EJB30_RTException extends RuntimeException{

   //EJB30_RTException, in EJB 3.0 subclasses were not application exceptions

}
```

You must modify the `@ApplicationException` annotation to include the `inherited=false` attribute:

```
import javax.ejb.ApplicationException;

@ApplicationException(inherited=false)
public class EJB30_RTException extends RuntimeException{

   //EJB30_RTException,  now you must explicitly set inherited to false to disable inheritance

}
```

### How to get EJB 3.0 application exception inheritance behavior using XML:

Suppose that you previously had the following code:

```
<!-- Example ejb-jar.xml -->

<?xml version="1.0" encoding="UTF-8"?>
  <ejb-jar id="ejb-jar_ID" xmlns="http://java.sun.com/xml/ns/javaee"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_0.xsd"
      metadata-complete="true" version="3.0">
    <assembly-descriptor>
        <application-exception>
```

```
            <exception-class>myXML.example.package.EJB30_RTException</exception-class>
        </application-exception>
    </assembly-descriptor>
</ejb-jar>
```

You must modify your code to include the `inherited` element set to `false` as well as migrate to a version 3.1 deployment descriptor and XSD schema:

```
<!-- Example ejb-jar.xml -->
<?xml version="1.0" encoding="UTF-8"?>
<ejb-jar id="ejb-jar_ID" xmlns="http://java.sun.com/xml/ns/javaee"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_1.xsd"
    metadata-complete="true" version="3.1">
    <assembly-descriptor>
        <application-exception>
            <exception-class>myXML.example.package.EJB30_RTException</exception-class>
            <rollback>false</rollback>
            <inherited>false</inherited>
        </application-exception>
    </assembly-descriptor>
</ejb-jar>
```

# EJB 3.x module considerations

When using Enterprise JavaBeans (EJB) 3.x modules, keep in mind the following considerations.

## Version 8.0 does not support 1.x and 2.x entity beans in EJB 3.x-level modules

IBMWebSphere Application Server Version 8.0 does not support the use of 1.x and 2.x bean managed persistence (BMP) and container managed persistence (CMP) entity beans in EJB 3.x-level modules. EJB entity beans can be used on V8.0, but they must be packaged in an EJB 2.1 or earlier-level module.

Java Platform, Enterprise Edition (Java EE) applications that are packaged with EJB entity beans in EJB 3.x-level modules fail to install on Version 8.0.

An EJB Java archive (JAR) file is considered to be an EJB 3.x module when either of the following are true:

- The EJB JAR file contains configuration data in an `ejb-jar.xml` file with an EJB 3.0 or EJB 3.1 header specification. For example:

  ```
  <ejb-jar id="ejb-jar_ID" version="3.0"
        xmlns="http://java.sun.com/xml/ns/javaee"
        xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://java.sun.com/xml/ns/javaee
  http://java.sun.com/xml/ns/javaee/ejb-jar_3_0.xsd">
  ```

- The EJB JAR file contains beans with EJB 3.x-style source annotations that provide configuration data and does not contain an `ejb-jar.xml` deployment descriptor file.

You need to repackage your EJB 3.x modules using EJB 2.x and earlier modules. Otherwise, the installation of any applications that contain entity beans fail.

## Annotations

Consider using annotations versus deployment descriptors, or both. See the topic EJB 3.x metadata annotations for more information about annotations.

## EJB module

WebSphere Application Server Version 8.0 supports EJB module Java archive (JAR) files with an `ejb-jar.xml` deployment descriptor declared at the 1.1, 2.0, 2.1, 3.0, or 3.1 level, or with no `ejb-jar.xml` deployment descriptor present. If no deployment descriptor is present, the EJB module is assumed to be at the 3.0 level or greater.

EJB modules that contain EJB 3.x beans must be declared to be at the EJB 3.0 or EJB 3.1 level. This can be accomplished either by setting the `ejb-jar.xml` deployment descriptor level to 3.0 or 3.1, or ensuring that the module does not contain an `ejb-jar.xml` deployment descriptor. If the module level is 2.1 or earlier, no EJB 3.x-specific functions such as annotation scanning or resource injection is performed.

Entity beans are not supported in EJB 3.x level modules. You must place any entity beans in EJB modules at the 2.1 or earlier level.

If you want to package an EJB 3.x module with a deployment descriptor, there are several ways to do it. Package an EJB 3.x module with an EJB 3.x style session and message-driven beans exclusively; with an EJB 2.1 style session and message-driven beans exclusively, or a combination of 2.1 and 3.x style beans. The XML deployment descriptor must be a Version 3.0 or 3.1 deployment descriptor. It is required that 2.1 entity beans are packaged in modules with 2.1 deployment descriptors. EJB modules that contain EJB 3.x beans must be at the EJB 3.0 or EJB 3.1 specification level when running on the product. Prepare the EJB module to support EJB 3.x beans, by setting the `ejb-jar.xml` deployment descriptor level to 3.0 or 3.1, or you can make sure that the module does not contain an `ejb-jar.xml` deployment descriptor. If the module level is EJB 2.1 or earlier, no EJB 3.x functions, including annotation scanning or resource injection is performed at run time.

## Java EE application client module

The product provides support for Java EE application client modules. Additionally, it supports injection of EJB references into client components if the injection is defined through the @EJB annotation.

**Attention:** EJB 3.x does not support the injection of an enterprise bean that creates an enterprise bean of itself. Do not inject an enterprise bean that creates an enterprise bean of itself.

### Defining an ejb-ref reference to an EJB 3.x business interface from a Java EE client component descriptor

It is possible to define an ejb-ref from an `application-client.xml` descriptor that points to an EJB 3.x business interface. EJB 3.x business interfaces are accessed directly without the use of a home, yet the ejb-ref element in Java EE requires that a home interface type is specified. Therefore, you must include the <home></home> stanza in the ejb-ref definition, but specify a null value as shown in the example. For the value of the <remote> stanza, specify the EJB 3.x business interface class name. Finally, when you set the binding value, either during application installation or through tooling, specify the location where the EJB 3.x business interface was bound.

For example, the ejb-ref in your client component `application-client.xml` file looks like the following code sample:

```
<ejb-ref id="EJBRef_1">
 <ejb-ref-name>java_comp-env_name_of_ref</ejb-ref-name>
 <ejb-ref-type>Session</ejb-ref-type>
 <home></home>
 <remote>com.ejbs.business.interface.class.name</remote>
</ejb-ref>
```

The corresponding section of the `ibm-application-client-bnd.xmi` file looks like the following code sample. A default EJB binding pattern is used here; the default EJB binding conventions are described in the topic, EJB 3.x applications binding support.

```
<ejbRefBindings xmi:id="EjbRefBinding_1"
         jndiName=EJB3App/EJB3Mod.jar/MyBean##com.ejbs.business.interface.class.name">
 <bindingEjbRef href="application-client.xml#EjbRef_1"/>
</ejbRefBindings>
```

## EJB metadata annotations

Annotations enable you to write metadata for Enterprise JavaBeans (EJB) inside your source code. You can use them instead of extensible markup language (XML) deployment descriptor files. Annotations can also be used *with* descriptor files.

If you installed the Feature Pack for EJB 3.0, the default was to scan annotations during the installation of an EJB 3.0 module. For WebSphere Application Server, Version 7.0 and later, the default is not to scan pre-Java EE 5 modules during the application installation or at server startup

To preserve backward compatibility with both the Feature Pack for EJB 3.0 and the Feature Pack for Web Services, you have a choice whether to scan legacy web modules for additional metadata. A server level switch is defined for each feature pack scan behavior. If the default is not appropriate, the switch must be set on each server and administrative server that requires a change in the default. The switches are server custom properties com.ibm.websphere.webservices.UseWSFEP61ScanPolicy={true|false} and com.ibm.websphere.ejb.UseEJB61FEPScanPolicy={true|false}. To define these properties in the administrative console click **Application servers** > **server name** > **Process definition** > **Java Virtual Machine** > **Custom properties**.

The product also provides default values for most of the EJB annotations it uses. In many cases, omitting an annotation implies that you want to use the default value.

Usually, annotations are found in the *javax.ejb* and *javax.persistence* packages.

## EJB 3.x interceptors

An interceptor is a method that is automatically called when the business methods of an Enterprise JavaBeans (EJB) are invoked or lifecycle events of an EJB occur.

There are three kinds of interceptor methods: business method interceptors, timeout method interceptors (which are new in EJB3.1), and lifecycle callback interceptors. Business method interceptors are invoked around the call to a business method. Timeout method interceptors are invoked around the call to an EJB timeout method. Lifecycle callback interceptors are called around one of the PostConstruct, PreDestroy, PrePassivate, or PostActivate lifecycle events. For each interceptor type, an individual class can only declare one interceptor method. However, each class in a class hierarchy can declare an interceptor method for each interceptor type. If an interceptor method in a subclass overrides the same method in a super-class, only the method in the subclass might be invoked.

Interceptor methods are permitted to access and call all resources and components that the associated method is allowed to call. Additionally, interceptor methods execute with the same transaction and security context as the associated method. Except for singleton session beans, lifecycle interceptor methods are executed with local transaction containment (LTC).

You can declare interceptor methods directly in the EJB class or in a separate interceptor class. To declare interceptor methods in a separate class, you must bind the interceptor class to the EJB using either an annotation or XML. Use the following example to declare interceptors using the annotation:

```
@Interceptors({ClassInterceptor1.class, ClassInterceptor2.class})
public class TestBean { /* ... */ }

@Interceptors({ClassInterceptor1.class})
public class TestBean2 {
 @Interceptors({MethodInterceptor1.class, MethodInterceptor2.class})
 public void businessMethod() { /* ... */ }
}
```

Use the following example to declare interceptors using the deployment descriptor:

```
  <assembly-descriptor>
    <interceptor-binding>
      <ejb-name>TestBean</ejb-name>
      <interceptor-class>ClassInterceptor1</interceptor-class>
      <interceptor-class>ClassInterceptor2</interceptor-class>
    </interceptor-binding>

    <interceptor-binding>
      <ejb-name>TestBean2</ejb-name>
      <interceptor-class>ClassInterceptor1</interceptor-class>
    </interceptor-binding>

    <interceptor-binding>
      <ejb-name>TestBean2</ejb-name>
      <interceptor-class>MethodInterceptor1</interceptor-class>
      <interceptor-class>MethodInterceptor2</interceptor-class>
      <method>
        <method-name>businessMethod</method-name>
      </method>
    </interceptor-binding>
  </assembly-descriptor>
```

You can exclude class-level interceptors from a method by using either the ExcludeClassInterceptors annotation or the exclude-class-interceptors element in the deployment descriptor. Use the following example to exclude the interceptor, ClassInterceptor, from the method, businessMethod.

```
@Interceptors({ClassInterceptor1.class})
public class TestBean2 {
 @ExcludeClassInterceptors
 public void businessMethod() { /* ... */ }

 public void businessMethodWithClassInterceptor1() { /* ... */
}
```

Use the following example to exclude the interceptor from the method using the deployment descriptor:

```
  <assembly-descriptor>
    <interceptor-binding>
      <ejb-name>TestBean2</ejb-name>
      <exclude-class-interceptors>true</exclude-class-interceptors>
      <method>
        <method-name>businessMethod</method-name>
      </method>
    </interceptor-binding>
  </assembly-descriptor>
```

Interceptor methods can have public, protected, package private, or private visibility. Interceptor methods must not be final or static. Business method interceptors and timeout method interceptors must have a return type of java.lang.Object, a single parameter of javax.interceptor.InvocationContext, and a single throws clause type of java.lang.Exception. All lifecycle interceptors must have a return type of void and must not have a throws clause. Lifecycle interceptors declared directly on the EJB class must not have parameters; lifecycle interceptors declared on an EJB superclass or on an interceptor class must have a single parameter of javax.interceptor.InvocationContext. Timeout interceptor methods and lifecycle interceptor methods must not throw application exceptions.

You can use the InvocationContext parameter of an interceptor method to get information about the method being invoked. The getTarget method returns the bean instance being invoked. The getTimer method is applicable to timeout method interceptors only, and it returns the timer being executed. The getMethod method returns the business interface method that is being invoked. The getParameters method returns the parameters being passed to the business method, and the setParameters method allows the parameters to be modified. The getContextData method returns the data association with the method being invoked. Finally, the proceed method invokes either the next interceptor or the target method.

You can declare interceptor methods using either annotations or XML. To declare an interceptor method using an annotation, place the appropriate AroundInvoke, AroundTimeout, PostConstruct, PreDestroy, PrePassivate, or PostActivate annotation on the interceptor method. Use the following example to declare a business method interceptor, a timeout method interceptor, and a PostConstruct lifecycle interceptor method on an EJB class using annotations.

```
@Interceptors({ClassInterceptor.class})
public class TestBean {
 @PostConstruct
 private void beanPostConstruct() { /* ... */ }

 @AroundInvoke
 protected Object beanAroundInvoke(InvocationContext ic) throws Exception {
  return ic.proceed();
 }

        @AroundTimeout
        protected Object beanAroundTimeout(InvocationContext ic) throws Exception {
  return ic.proceed();
        }
}
```

Use the following example to declare the same interceptor methods on an interceptor class.

```
public class ClassInterceptor {
 @PostConstruct
 private void interceptorPostConstruct(InvocationContext ic) {
  try {
   ic.proceed();
  } catch (Exception ex) { /* ... */ }
 }

 @AroundInvoke
 protected Object interceptorAroundInvoke(InvocationContext ic) throws Exception {
  return ic.proceed();
 }

 @AroundTimeout
 protected Object interceptorAroundTimeout(InvocationContext ic) throws Exception {
  return ic.proceed();
 }
}
```

Alternatively, you can declare an interceptor method in the deployment descriptor with the around-invoke, around-timeout, post-construct, pre-destroy, pre-passivate, and post-activate elements. Use the following example to declare a business method interceptor, a timeout method interceptor, and a PostConstruct lifecycle interceptor method on an EJB class and an interceptor class using the deployment descriptor.

```
  <enterprise-beans>
    <session>
      <ejb-name>TestBean</ejb-name>
      <around-invoke>
        <method-name>beanAroundInvoke</method-name>
      </around-invoke>
      <around-timeout>
        <method-name>beanAroundTimeout</method-name>
```

```
      </around-timeout>
      <post-construct>
        <lifecycle-callback-method>beanPostConstruct</lifecycle-callback-method>
      </post-construct>
    </session>
  </enterprise-beans>

  <interceptors>
    <interceptor>
      <interceptor-class>ClassInterceptor</interceptor-class>
      <around-invoke>
        <method-name>interceptorAroundInvoke</method-name>
      </around-invoke>
      <around-timeout>
        <method-name>interceptorAroundTimeout</method-name>
      </around-timeout>
      <post-construct>
        <lifecycle-callback-method>interceptorPostConstruct</lifecycle-callback-method>
      </post-construct>
    </interceptor>
  </interceptors>

  <assembly-descriptor>
    <interceptor-binding>
      <ejb-name>TestBean</ejb-name>
      <interceptor-class>ClassInterceptor</interceptor-class>
    </interceptor-binding>
  </assembly-descriptor>
```

You can also declare interceptor methods on super-classes. Use the following example to declare a PostActivate interceptor on a bean super-class using annotations:

```
public class TestBean extends BeanSuperClass { /* ... */ }

public class BeanSuperClass {
 @PostActivate
 private void beanSuperClassPostActivate(InterceptorContext ic) {
  try {
   ic.proceed();
  } catch (Exception ex) { /* ... */ }
 }
}
```

Use the following example to declare the same interceptor method on a superclass of an interceptor class using annotations:

```
public class ClassInterceptor extends InterceptorSuperClass { /* ... */ }

public class InterceptorSuperClass {
 @PostActivate
 private void interceptorSuperClassPostActivate(InterceptorContext ic) {
  try {
   ic.proceed();
  } catch (Exception ex) { /* ... */ }
 }
}
```

You can also declare the same interceptor methods using the deployment descriptor. Use the following example to declare an interceptor method on the superclasses of a bean and interceptor class:

```
<enterprise-beans>
  <session>
    <ejb-name>TestBean</ejb-name>
    <post-activate>
      <class>BeanSuperClass</class>
  <lifecycle-callback-method>beanSuperClassPostActivate</lifecycle-callback-method>
    </post-activate>
```

```
 </session>
</enterprise-beans>

<interceptors>
  <interceptor>
   <interceptor-class>ClassInterceptor</interceptor-class>
   <post-activate>
     <class>InterceptorSuperClass</class>
 <lifecycle-callback-method>interceptorSuperClassPostActivate</lifecycle-callback-method>
   </post-activate>
  </interceptor>
</interceptors>

<assembly-descriptor>
  <interceptor-binding>
    <ejb-name>TestBean</ejb-name>
    <interceptor-class>ClassInterceptor</interceptor-class>
  </interceptor-binding>
</assembly-descriptor>
```

You can declare default interceptors that apply to all session and message-driven beans in a module. Default interceptors can only be declared in the deployment descriptor, and they are specified using an ejb-name of "*". Use the following example to declare a default interceptor.

```
 <assembly-descriptor>
   <interceptor-binding>
     <ejb-name>*</ejb-name>
     <interceptor-class>DefaultInterceptor</interceptor-class>
   </interceptor-binding>
 </assembly-descriptor>
```

You can exclude default interceptors from a specific class or method by using either the ExcludeDefaultInterceptors annotation or the exclude-default-interceptors element in XML. Use the following examples to exclude default interceptors using the annotation:

```
@ExcludeDefaultInterceptors
public class TestBean { /* ... */ }

public class TestBean2 {
 @ExcludeDefaultInterceptors
 public void businessMethod() { /* ... */ }
}
```

Use the following example to excludes default interceptors using the deployment descriptor:

```
 <assembly-descriptor>
   <interceptor-binding>
     <ejb-name>TestBean</ejb-name>
     <exclude-default-interceptors>true</exclude-default-interceptors>
   </interceptor-binding>

   <interceptor-binding>
     <ejb-name>TestBean2</ejb-name>
     <exclude-default-interceptors>true</exclude-default-interceptors>
     <method>
       <method-name>businessMethod</method-name>
     </method>
   </interceptor-binding>
 </assembly-descriptor>
```

When interceptors are invoked for a method, default interceptor classes are invoked first, class-level interceptors are invoked next, and interceptors methods from the EJB class are invoked last. For a single interceptor class hierarchy, interceptor methods are always invoked on the most general super-class first. The default and class-level interceptor classes are invoked in the order specified in the deployment descriptor or the Interceptors annotation. You can override this ordering by specifying the complete list of default and class-level interceptors in the interceptor-order element in the deployment descriptor.

```
 <assembly-descriptor>
   <interceptor-binding>
     <ejb-name>TestBean</ejb-name>
     <!--
       The default ordering would be:
  1. DefaultInterceptor
  2. ClassInterceptor1
  3. ClassInterceptor2

The following stanza overrides the default ordering.
     -->
     <interceptor-order>
       <interceptor-class>ClassInterceptor2</interceptor-class>
<interceptor-class>DefaultInterceptor</interceptor-class>
<interceptor-class>ClassInterceptor1</interceptor-class>
     </interceptor-order>
   </interceptor-binding>
 </assembly-descriptor>
```

## Create stubs command

The createEJBStubs command creates stub classes for remote interfaces of Enterprise JavaBeans (EJB) Version 3.x beans packaged in Java archive (JAR), web application archive (WAR), or enterprise archive (EAR) files. It also provides an option to create a single stub class from an interface class located in a directory or a JAR file. Several command options are provided to package the generated stub classes in different ways. See the following syntax and example sections for more details.

This command is found in the *<WAS_HOME>*/bin directory as:
- createEJBStubs.bat - Windows platforms
- createEJBStubs.sh - UNIX based platforms
- createEjbStubs - iSeries platform

The command searches the input JAR, WAR, or EAR file, looking for EJB version 3.x modules that contain beans with remote interfaces. When remote interfaces are found, the corresponding stub classes are generated and packaged according to the command options specified. In the case where the input specified is a single interface class, the tool assumes that this class is an EJB version 3.x remote interface class and generates a remote stub class.

For many client-side scenarios, the WebSphere Application Server Just-In-Time (JIT) deployment feature dynamically generates the RMI-IIOP stub classes that are required for invocation of remote EJB 3.x business interfaces. However, there are some scenarios where the JIT deploy environment is not available to dynamically generate these classes. In these scenarios, the createEJBStubs command must be used instead to generate and embed the client-side stub class files in your client application. If your client environment is one of the following, use the createEJBStubs command:
- "Bare" Java Standard Edition (SE) clients, where a Java SE Java Virtual Machine (JVM) is the client environment.
- A WebSphere Application Server container (web container, EJB container, or application client container) from a version earlier than version 7, or without the Feature Pack for EJB 3.0 applied.
- Non-WebSphere Application Server environments.

The JVM running the createEJBStubs command must have the java.io.tmpdir system property defined. The property must point to a readable and writable directory that exists.

In addition to creating stubs for bean content packaged in EAR and JAR files, the command also creates stubs for bean content that is packaged in a WAR file. If an EAR file is specified as the input file, and that EAR file contains a WAR file with remote interfaces, then stubs are generated for those interfaces.

Stubs are placed into the WAR file in the same location as the remote interface or bean class that they correspond to. If the remote interface or bean class that they correspond to is placed loosely in the

WEB-INF/classes directory structure, then the stub is placed there as well. If the remote interface or bean class is packaged inside of a JAR file in the WEB-INF/lib directory, then the stub is inserted into that same JAR file. If a stub is generated for a remote interface that is not packaged inside the WAR file, then it is placed loosely in the WEB-INF/classes directory structure.

The createEJBStubs command is not supported for use with a 2.x or 1.x EJB module packaged inside a stand-alone JAR file. The stubs for a 2.x or 1.x EJB module packaged inside a stand-alone JAR file must be generated using the EJBDeploy tool instead. If the createEJBStubs command is run against a 2.x or 1.x EJB module packaged inside a stand-alone JAR file, then the command issues a CNTR9241I message, and does not generate any stubs.

However, the createEJBStubs command is supported for use with 2.x or 1.x EJB modules packaged inside a WAR file. In this case, the createEJBStubs command must be used instead of the EJBDeploy tool.

A client component uses these stubs to communicate with the EJB components running inside the server. The client component must use stub instances that were created by the correct tool. If the client component is communicating with a 2.x or 1.x EJB module packaged inside a stand-alone JAR, then the stubs must come from the EJBDeploy tool. However, if the client component is communicating with a 2.x or 1.x EJB module packaged inside a WAR, then the stubs must come from the createEJBStubs command. A single stub instance cannot be used to communicate with both a 2.x/1.x EJB module packaged inside a stand-alone JAR, and that same 2.x/1.x EJB module packaged inside a WAR.

## Syntax

**createEJBStubs***input_ class_ name* | *input_JAR_name* | *input_WAR_name* | *input_EAR_name* [**-help**] [**-newfile[new_file]**] [**-updatefile[update_file]**] [**-quiet**] [**-verbose**] [**-logfile log_file**] [**-appendlog**] [**-cp class_path**] [**-trace**]

**createEJBStubs**

This is the command to create EJB stub classes for a single interface class file, a JAR file, a WAR file, or an EAR file. When invoked without any arguments, or only –help, the createEJBStubs command displays a list of options that can be specified, and a list of example invocations with detailed explanations.

*input_class_name* **or** *input_EAR_name* **or** *input_JAR_name* **or** *input_WAR_name*

The first parameter is a required element for the command. It must contain the source class, JAR, WAR, or EAR file to process.

This parameter may be the fully qualified name of a single interface class (e.g. com.ibm.myRemoteInterface). Note that the package name segments are separated by "." characters, no path name proceeds the class name, and the ".class" extension is not included. For this interface class input, you must use the class path option (e.g. –cp my_path, or –cp my_path/my_interfaces.jar) to specify where the interface class is found. The generated stub class is placed in the package-defined directory structure, starting with the current directory where the command is invoked.

This parameter may also be a JAR, WAR, or EAR file. In this case the path must be specified (e.g. my_path/my_Server_App.ear). The generated stub classes are placed in the same module or modules with the beans, or in the same module or modules with the remote interface classes, depending on whether the –updatefile option is specified. See the following sections for more details.

**-help** Provides the command syntax, including a list of options that can be specified, and example invocations with detailed explanations.

**-newfile [new_file]**

Requests that a new file is generated containing the original files in the input JAR, WAR, or EAR plus the stub classes. When this option is not specified, the stubs are written back into the original

JAR, WAR, or EAR file. If this option is specified, but the new_file name is not provided, a new file name is constructed by appending the input JAR, WAR, or EAR file name with "_withStubs". This option is not allowed when the first input parameter is an interface class.

**-updatefile [update_file]**
Requests that a second file (e.g. in addition to the input file) is updated with stub classes. This option also provides a different packaging behavior. The stub classes are packaged in the same module or modules as the remote interface classes. By contrast, when this option is not specified, the stub classes are packaged in the same module or modules with the bean classes. If this option is specified, but the update_file name is not provided only the original JAR, WAR, or EAR file is updated with stub classes. This option is not allowed when the first input parameter is an interface class.

**-quiet** Requests the suppression of messages. The -quiet option cannot be specified with either the –verbose or the –trace options. Error messages are still displayed.

**-verbose**
Requests that additional informational messages be output. The -verbose option cannot be specified with either the -quiet or the –trace options.

**-logfile log_file**
Requests that messages be printed to a log file in addition to the console. If this option is specified, the log_file name must also be provided.

**-appendlog**
Requests that messages be appended to an existing log file. If this option is specified, the -logfile option must also be specified.

**-cp class_path**
Requests that the class loader includes the specified the class path where additional class or jar files are located, which are necessary for the remote interface classes to be loaded. The class path might include multiple segments where each path is separated from a previous path by the default path separator character of the operating system. Each path can specify either a JAR file, or a directory. If this option is specified, the class_path name must also be provided.

**-trace** Request that detailed trace output be generated. This is intended to collect information for use by IBM service to resolve problems. The trace output is English-only. This option cannot be specified with either the –quiet or the –verbose options.

## Examples

**createEJBStubs com.ibm.myRemoteInterface -cp my_path**

Generate the stub class for one remote interface class and place it in the package-defined directory structure, starting at the current directory. The my_path directory is used as the class path. If the remote interface class to process is in a JAR file, the –cp my_path/my_interfaces.jar syntax must be used for the class path specification.

**createEJBStubs my_path/my_beans.jar -newfile –quiet**

Generate the stub classes for all level 3.0 enterprise beans in the my_beans.jar file that have remote interfaces. Both the generated stub classes and the original JAR file contents are packaged into a new JAR file named “my_beans_withStubs.jar” because the optional new_file name parameter is not specified along with the –newfile option. Output messages are suppressed except for error notifications.

**createEJBStubs my_path/my_Server_App.ear -logfile myLog.out**

Generate the stub classes for all level 3.0 enterprise beans in the my_Server_App.ear file that have remote interfaces. The generated stub classes are placed into the original EAR file because the –newfile

option is not specified. The stub classes are packaged into the same module or modules as the bean classes because the –updatefile option is not specified. Messages are written to both the myLog.out log file and the command window.

**createEJBStubs my_path/my_Server_App.ear -updatefile my_path/my_Client_interfaces.jar**

Generate the stub classes for all level 3.0 enterprise beans in the my_Server_App.ear file that have remote interfaces. The generated stub classes are placed into both the original EAR file and the my_Client_interfaces.jar file. The stub classes are packaged into the same module or modules as the remote interface classes because the –updatefile option is specified.

**createEJBStubs my_path/my_Server_App.ear –updatefile**

Generate the stub classes for all level 3.0 enterprise beans in the my_Server_App.ear file that have remote interfaces. The generated stub classes are only placed into the original EAR file because the optional update_file name parameter is not provided with the –updatefile option. The stub classes are packaged into the same module or modules as the remote interface classes because the -updatefile option is specified.

**createEJBStubs my_path/my_beans.war**

Generate the stub classes for all 3.x beans that are packaged in the WAR file and have remote interfaces. The Bean1 class is packaged loosely inside the WEB-INF/classes directory structure, and therefore, the corresponding stub is placed there as well. Likewise, the Bean2 class is packaged inside of the myEJB.jar file in the WEB-INF/lib directory, and therefore, the corresponding stub is inserted into that JAR file.

# Developing entity beans

## Defining data sources for entity beans

An application that is installed on an application server must have bindings defined before you can start the application. The Enterprise JavaBeans (EJB) references and resource references that are defined in the application must be bound to the actual enterprise beans or resources that are defined in the application server.

### Before you begin

Create a data source or JDBC resource and give it a Java Naming and Directory Interface (JNDI) name.

### About this task

For more information, see the topic Application bindings.

Before you do this task, it is assumed that the entity beans in your application are container-managed persistence (CMP) enterprise beans.

**Note:**
The EJB container handles the persistence of the bean attributes in the underlying persistent store. Specify which data store is used by binding an EJB module or individual EJB to a data source.

If you bind an EJB *module* to a data source, all beans in that module use the same data source for persistence. If you specify the data source at the bean level, then that data source is used instead.

See the assembly tool information center for the steps on how to complete this task.

# Lightweight local operational mode for entity beans

WebSphere Application Server provides a special operational mode called *lightweight local* mode, which can improve the performance of entity bean methods. You can decide which entity beans in your application to run in this mode.

In lightweight local mode, the container streamlines the processing that it performs before and after every method on the local home interface and local business interface of the bean. This streamlining can result in improved performance when entity bean operations are called locally from within an application. Because some processing is skipped when running in lightweight local mode, this mode can be used in certain scenarios only.

Lightweight local mode is patterned somewhat after the Plain Old Java Object (POJO) entity model introduced in the Enterprise JavaBeans (EJB) 3.0 specification. Using lightweight local mode, you can obtain some of the performance advantages of the POJO entity model without having to convert your existing EJB 2.x application code to the new POJO model. You can apply lightweight local mode to both container-managed persistence (CMP) and bean-managed persistence (BMP) entity types that meet the specific criteria.

**Attention:** Entity beans are not supported in EJB 3.x modules.

## When to use the lightweight local mode

Lightweight local mode is designed for entity beans that are created, found, and called using the *Session Facade* pattern. Under this pattern, entity bean local home and local business methods are called from within methods of a stateless session bean or stateful session bean. The session bean methods, which can be called remotely or locally, provide security control and transaction demarcation for the entity beans that are accessed by the session bean.

You can apply lightweight local mode only to an entity bean that meets the following criteria:
- The bean implements an EJB local interface.
- No security authorization is defined on the entity bean local home or local business interface methods.
- No *run-as* security attribute is defined on the local home or local business methods.
- The classes for the calling bean and the called entity bean are loaded by the same Java class loader.
- The entity bean methods do not call the WebSphere Application Server-specific Internationalization Service or Work Area Service.

The first criterion prevents CMP 1.x beans from supporting lightweight local mode, because the 1.x beans cannot have local interfaces.

In addition, lightweight local mode provides its fullest performance benefits only to entity bean methods that do not need to start a global transaction. This condition is true if you ensure that your entity bean also meets the following criteria:
- A global transaction is already in effect when the entity bean home or business method is called. Typically, this transaction is started by the calling session bean.
- The local business interface methods and the local home methods of the entity bean use the following transaction attributes only: REQUIRED, SUPPORTS, or MANDATORY.

If an entity bean method that is running in lightweight local mode must start a global transaction, the bean still functions normally but only a partial performance benefit is realized.

You can mark an entity bean that defines a remote interface or a TimedObject interface, in addition to the local interface, for lightweight local mode. However, the performance benefit is apparent only when the bean is called through its local interface.

# Applying lightweight local mode to an entity bean

WebSphere Application Server provides a special operation mode called *lightweight local* mode, which can improve the performance of entity bean methods. You can decide which entity beans in your application to run in this mode.

## About this task

You can apply lightweight local mode to specific EntityBean types within your application with the Marker interface technique.

### Marker interface technique

#### About this task

Use the marker interface technique when a group of beans within the application is related through a common inheritance hierarchy, and all the beans in the hierarchy are to be marked. For an application with a large number of beans in a hierarchy, this technique is the most efficient.

To use a marker interface, code your bean implementation class to implement the **com.ibm.websphere.ejbcontainer.LightweightLocal** interface. The bean implementation class does not need to directly implement the interface; any parent class or interface can also implement it. For details, see the **com.ibm.websphere.ejbcontainer** package in the API section of the information center.

# Developing read-only entity beans

In addition to the existing Enterprise JavaBeans (EJB) caching options, you can develop read-only entity beans.

## About this task

You are most likely to want to use it under the following conditions:

- Your application uses data that change relatively infrequently. An example might be a retailing application that uses pricing data that only changes once a week or month.
- Your application can tolerate data that might be stale. The degree of *staleness* allowed by the EJB container is configurable by the user.
- The bean is coded in a thread-safe manner, so it can safely be invoked by multiple threads at once.

To use this function, declare the bean type as *read-only*. Declaring a bean type is done the same way that bean caching options are selected - through a selection list within an assembly tool.

To complete this task see the topic, Defining bean cache settings for a bean in the assembly tool information center.

### Example: Using a read-only entity bean

A usage scenario and example for writing an Enterprise JavaBeans (EJB) application that uses a read-only entity bean.

#### Usage scenario

A customer has a database of catalog pricing and shipping rate information that is updated daily no later than 10:00 PM local time (22:00 in 24-hour format). They want to write an EJB application that has read-only access to this data. That is, this application never updates the pricing database. Updating is done through some other application.

#### Example

The customer's entity bean local interface might be:

```
public interface ItemCatalogData extends EJBLocalObject {

  public int getItemPrice();

  public int getShippingCost(int destinationCode);

}
```

The code in the stateless SessionBean method (assume it is a TxRequired) that invokes this EntityBean to figure out the total cost including shipping, would look like:

```
.....
// Some transactional steps occur prior to this point, such as removing the item from
 // inventory, etc.
 // Now obtain the price of this item and start to calculate the total cost to the purchaser

 ItemCatalogData theItemData =
    (ItemCatalogData) ItemCatalogDataHome.findByPrimaryKey(theCatalogNumber);

int totalcost = theItemData.getItemPrice();

// ...     some other processing, etc. in the interim
// ...
// ...

// Add the shipping costs
totalcost = totalcost + theItemData.getShippingCost(theDestinationPostalCode);
```

At application assembly time, the customer sets the EJB caching parameters for this bean as follows:
- ActivateAt = ONCE
- LoadAt = DAILY
- ReloadInterval = 2200

**Note:** The reloadInterval and reloadingEnabled attributes of the IBM deployment descriptor extensions, including both the WAR file extension (WEB-INF/ibm-web-ext.xmi) and the application extension (META-INF/ibm-application-ext.xmi) were deprecated in V6.0.

On the first call to the getItemPrice() method after 22:00 each night, the EJB container reloads the pricing information from the database. If the clock strikes 22:00 between the call to getItemPrice() and getShippingCost(), the getShippingCost() method still returns the value it had prior to any changes to the database that might have occurred at 22:00, since the first method invocation in this transaction occurred prior to 22:00. Thus, the item price and shipping cost used remain in sync with each other.

## Creating timers using the EJB timer service for enterprise beans

You can use enterprise beans to take advantage of the EJB timer service to schedule time-based events.

### About this task

**Note:** In support of the EJB 3.1 specification, you can now create non-persistent EJB timers. This product also supports the expanded TimerService API for programmatic timer creation. In addition, you can configure the EJB container to automatically create a timer when the application starts.

WebSphere Application Server implements the Enterprise JavaBeans(EJB) timer service. Based on your business needs, you can use persistent timers or non-persistent timers. Persistent timers are helpful if you are creating a timer for a time-based event that requires assurance of timer existence beyond the life cycle of the server. Previously started persistent timers automatically start when your server starts and persist through server shutdowns and restarts. For example, you can use persistent timers to start a system

application or send a status notification on the expiration of a timer. Non-persistent timers are helpful in non-critical situations where the timer actions are skipped or redone without negative business impacts, such as polling a temperature.

You can create timers programmatically. You can also create timers automatically by using the @Schedule annotation in the bean class, or by using the timer element in the ejb-jar.xml deployment descriptor. By automatically creating timers, you can schedule a timer without relying on your enterprise bean invocation to programmatically start an EJB timer service creation method.

**Persistent timers**

Persistent timers are implemented as a scheduler service task. By default, an internal or pre-configured scheduler instance is used to manage those tasks, and they persist in an Apache Derby database associated with the server process.

You can perform basic customizations to the internal scheduler instance. For information about customizing the scheduler instance, see the configuring a timer service information.

The creation and cancellation of Timers is transactional and persistent. If a Timer is created within a transaction and that transaction is later rolled back, the creation of the Timer is rolled back as well. Similar rules apply to the cancellation of a Timer. Previously started Timers are maintained across application server shutdowns and restarts.

**Non-persistent timers**

EJB 3.1 augments the EJB timer service to enable non-persistent EJB timers in addition to the persistent timers. Non-persistent timers have many of the same semantics and behavior as persistent timers, but without the overhead of a data store. Non-persistent timers have a different life cycle than persistent timers. Where persistent timers are maintained across application server shutdowns and restarts, non-persistent timers are active only while the application server is active. Unlike persistent timers, there are no commands to find or cancel non-persistent timers. Non-persistent timers are canceled when the application server is stopped or fails to remain in an active state.

As with persistent timers, the creation and cancellation of non-persistent timers is transactional. If a timer is created within a transaction and that transaction is later rolled back, the creation of the timer is rolled back as well. Similar rules apply to the cancellation of a timer.

You can configure non-persistent timers to share a thread pool with persistent timers, or to have a unique thread pool that is not shared with persistent timers.

**Programmatically created timers**

A programmatically created persistent timer is maintained across application server shutdowns and restarts, unless it is canceled. It is the responsibility of application code or system administrator to delete a programmatically created timer which is no longer wanted.

To programmatically create a timer that is associated with your enterprise bean, the bean calls the getTimerService() method on the applicable context instance to get a reference to the TimerService object. The bean also calls one of the TimerService methods, such as createTimer, to specify the timer for the bean. This Timer instance is now associated with your bean. The TimerService methods are described in the EJB 3.1 specification. You can now pass the Timer instance to other Java code as a local object. After the Java code obtains the Timer instance, the code can use any of the methods defined by the javax.ejb.Timer interface, such as the cancel() or getTimeRemaining() methods.

In a clustered environment, a programmatically created persistent timer can run in any cluster member, but a programmatically created non-persistent timer runs only in the same JVM in which it was created.

**Automatically created timers**

The EJB 3.1 specification augments the EJB timer service to enable the automatic creation of a timer when your application starts without relying on a bean invocation to programmatically start one of the timer service timer creation methods. Use the @Schedule annotation or the timeout-method deployment descriptor element to automatically create timers. Automatically created timers are created by the container as a result of application deployment.

**Note:** The CancelEJBTimers command also cancels automatically created timers. When automatically created timers are canceled, the only way to recreate them is to uninstall the application and reinstall it again.

**Timers in a clustered environment**

In a clustered environment, a persistent timer runs only in one cluster member which might not necessarily be the same cluster member it was created in. A non-persistent timer runs in each cluster member that it was created in - automatic non-persistent timers run in each cluster member that contains the EJB.

Automatic persistent timers are removed from their persistent store when their containing module or application is uninstalled. Therefore, do not update applications that use automatic persistent timers with the Rollout Update feature. Doing so uninstalls and reinstalls the application while the cluster is still operational, which might cause failure in the following cases:

- If a timer running in another cluster member activates after the database entry is removed and before the database entry is recreated, then the timer fails. In this case, a com.ibm.websphere.scheduler.TaskPending exception is written to the First Failure Data Capture (FFDC), along with the SCHD0057W message, indicating that the task information in the database has been changed or canceled.
- If the timer activates on a cluster member that has not been updated after the timer data in the database has been updated, then the timer might fail or cause other failures if the new timer information is not compatible with the old application code still running in the cluster member.

When you use the proxy server in the product, do not define a scheduler at the cell level if that scheduler is configured as the one to use for the EJB timer service. Doing so prevents persistent timers from running. This can happen if the proxy server gets the scheduler lease. Since no applications run in the proxy server, there is no application code to handle the timer events that are sent by the scheduler.

**Retries and missed timeouts**

If you use EJB timers, you must understand the concepts of failure, retry, and missed timeouts.

- A failure is a timeout execution that is attempted, but does not succeed.
- A retry is an additional attempt to successfully execute a timeout that was previously attempted, but failed.
- A missed execution is a timeout that must have been attempted, but was not, because the server was unavailable or busy retrying a previously failed timeout.

The retry behavior reflects:

- Number of additional times that the server retries the failed timeout
- Interval between these server retries

The missed timeout behavior reflects:

- Whether the server eventually attempts missed timeouts, or not
- If missed timeouts are eventually attempted, when those attempts occur
- Interval between the missed timeout attempts

*Table 72. Retry and missed timeout behavior. Retry and missed timeout behavior for both persistent and non-persistent timers.*

| Characteristic | Default behavior | Configurable |
|---|---|---|
| Number of retry attempts | As many as it takes to succeed.<br><br>Persistent timers are temporarily deactivated if their scheduler failure threshold is reached in a server. For more information, see the topic about stopping tasks that are failing. | Yes, for non-persistent timers |
| Interval between retry attempts | First retry attempt is immediate.<br><br>Subsequent retry attempts occur on the configured scheduler poll interval for persistent timers, and on the configured retry interval for non-persistent timers. | Yes |
| Missed timeout recovery | All missed timeouts are recovered. | No |
| When missed timeouts are recovered | Both persistent and non-persistent timers recover missed timeouts when the blocking retry attempts stop. Additionally, persistent timers recover timeouts when an unavailable server restarts. | No |
| Next timeout, after retry attempts are successful and missed timeouts are recovered | At the next originally scheduled time. | No |

The configurable characteristics are configured on the scheduler instance for persistent timers and on the non-persistent timer configuration for non-persistent timers.

The following scenarios illustrate how the retry and missed timeout behavior influences the timeouts for both persistent and non-persistent timers.

Persistent timer scenario:

A persistent timer is created and configured to run for the first time at 10:00 am, and then run every hour after that. The scheduler supporting the timer is configured with a 30 second poll interval.

The timer runs at 10:00 am and fails because a database is unavailable. The timer is immediately retried, and retried again every 30 seconds when the scheduler is polled, and keeps failing, until 12:30 pm. At that moment, a retry attempt succeeds because the database is now back online, and therefore the server stops retrying the previously failed attempt.

Now, the server begins to work through the missed timeouts. First, it attempts the timeout that must have run at 11:00 am, which succeeds at 12:31 pm. When the scheduler is polled again 30 seconds later, it attempts the timeout that must have run at 12:00 pm, which succeeds at 12:32 pm. The server is now current, and the next timeout occurs at its originally scheduled time of 1:00 pm, as opposed to an hour after the last success, which would have been 1:32 pm. Going forward, the original schedule is maintained. The schedule is not updated based on the time of the last successful timeout.

Non-persistent timer scenario:

A non-persistent timer is created and configured to run for the first time at 10:00 am, and then run every hour after that. This non-persistent timer is configured to have a retry count of 5, and a retry interval of 30 minutes.

The timer runs at 10:00 am and fails because a database is not available. The timer is immediately retried, and fails again. Now, having executed the initial immediate retry, the server waits for the configured retry interval of 30 minutes between the next retry attempt. Retry attempts

occur at 10:30 am and 11:00 am, and both fail. Finally, the fourth retry occurs at 11:30 am, and succeeds because the database is now back online.

Now, the server begins to work through the missed timeouts. The timeout that was originally scheduled for 11:00 am is immediately run, and succeeds at 11:31 am. The server is now current, and the next timeout occurs at its originally scheduled time of 12:00 pm (as opposed to an hour after the last success, which would be 12:32 pm).

**Behavior of the getNextTimeout and getTimeRemaining methods**

For both persistent and non-persistent timers, the Timer.getNextTimeout method returns a java.util.Date object that indicates the next time the timer is scheduled to execute. When you call the getNextTimeout method from a timeout callback method for an interval or calendar-based timer, the method returns the next scheduled time; for calendar-based timers with no future timeouts, the method throws the NoMoreTimeoutsException exception as required by the EJB 3.1 specification. When you call the getNextTimeout method from a timeout callback method for a single-action timer, the method returns the originally scheduled time. If a timeout callback method fails and retries are being attempted, the getNextTimeout method continues to return the originally scheduled time as if the failed execution had not occurred. In all cases, the Timer.getTimeRemaining method returns the difference in milliseconds between the getNextTimeout returned value and the current system time, which could result in a negative number, if the scheduled execution time was in the past.

**Inheritance behavior of automatically created timers**

Automatic timer methods in a hierarchy of bean classes cause multiple timers to be created. The number of timers associated with a timer method is not determined by the number of occurrences of the method in the source code. Instead, the number of timers associated with a timer method is determined by the number of beans with visibility to that method. For example:

```
@Stateless
public class Abean {

   @Schedule(hour="1")
   public void timerMethod1()

@Stateless
public class Bbean extends Abean {

   @Schedule(hour="2")
   public void timerMethod2()

@Stateless
public class Cbean extends Bbean {

   @Schedule(hour="2")
   public void timerMethod2()
```

In the previous bean class hierarchy, three automatic timers with callback method Abean.timerMethod1 are created, one for each bean instance with visibility to that method. One timer with callback method Bbean.timerMethod2 is created, and since that method is overridden by bean Cbean, only one timer with callback method Cbean.timerMethod2 is created.

In the previous example, when bean Abean is processed by the container, a single automatic timer is created, with callback method Abean.timerMethod1.

When the bean Bbean is processed by the container, an automatic timer is created with callback method Bbean.timerMethod2, and another automatic timer is created with callback method Abean.timerMethod1.

When the bean Cbean is processed by the container, an automatic timer is created with callback method CBean.timerMethod2. Another automatic timer is created with callback method

Abean.timerMethod1. A timer for Bbean.timerMethod2 is not created when processing the bean Cbean. Bbean.timerMethod2 is not visible in the class hierarchy of Cbean because it is overridden by method Cbean.timerMethod2.

Consider another example like the previous one, if the @Stateless annotation were removed from classes Abean and Bbean, so that class Cbean is the only EJB. In that case, the only automatic timers created would be those visible to Cbean - one with callback method Abean.timerMethod1, one with callback method Cbean.timerMethod2.

Although beans can share identical code in an inherited bean callback method, the runtime behavior might be polymorphic. For example:

```
public class Employee {

   @Schedule(hour="1", dayOfMonth="-1", info = "payroll timer")
   public void getSalaryIncrease() {
      printChecks(salary * rate());
   }

   protected float rate() {
      return (float)1.01;
   }

}

public class Manager extends Employee {

   protected float rate() {
      return (float)1.15;
   }

}

public class Executive extends Manager {

   protected float rate() {
      return (float)1.30;
   }

}
```

In the previous example, each bean instance has an automatic timer with callback method getSalaryIncrease(). Although the same callback code is shared by each timer, note that the rate used in calculating the salary increase by each bean is different, due to polymorphism. That is, timer callback methods might be polymorphic in the same way that any Java methods might be.

## Procedure

- To create timers programmatically, define the timeout method using the @Timeout annotation, the timeout-method deployment descriptor element, or by implementing the javax.ejb.TimedObject interface.

  A bean can have at most one timeout method for timers that are created programmatically. The timeout method is identified by the @Timeout annotation in the source code, or by the timeout-method deployment descriptor element contained in the ejb-jar.xml file. The timeout method must accept no parameters or a single parameter of type javax.ejb.Timer.

  – Define the timeout method by using the @Timeout annotation to create timers programmatically. The following code is an example of using the @Timeout annotation within the MyBeanImpl class:

    ```
    class MyBeanImpl implements MyBean{
    @Timeout
    void myTimeOutMethod()
    ```

  – Define the timeout method by using the timeout method deployment descriptor element.

You can write your enterprise bean to implement the javax.ejb.TimedObject interface, including the ejbTimeout() method. If the bean implements the TimedObject interface, there is no need to annotate a timeout method, and it is not valid unless that method is the ejbTimeout() method.

The following code snippet illustrates using the timeout method deployment descriptor element within the `ejb-jar.xml` file:

```
<timeout-method>
<method-name>myTimeoutMethod</method-name>
<method-params>
<method-param>javax.ejb.Timer</method-param>
</method-params>
</timeout-method>
```

In this case, the container starts the myTimeoutMethod method on a bean instance when a timer for that instance has expired. The instance is notified by the myTimeoutMethod method of the defined time-based event so the instance can run the associated business logic, based on the timer expiration notification.

Now, you can pass the timer instance to other Java code as a local object. After the Java code obtains the timer instance, the code can use any of the methods defined by the javax.ejb.Timer interface, such as the cancel() or getTimeRemaining() methods.

**Note:** ForWebSphereApplication Server Version 6, no assembly tool supports the EJB timedObject object. To set the ejbTimeout method transaction attribute, you must manually enter the attributes in the deployment descriptor.

– Define the timeout method by using the javax.ejb.TimedObject interface.
  - Write your enterprise bean to implement the javax.ejb.TimedObject interface, including the ejbTimeout() method. The bean calls the EJBContext.getTimerService() method to get an instance of the TimerService object. The bean calls the TimerService method to create a timer. This Timer is now associated with that bean.
  - After you create the timer, you can pass the timer instance to other Java code as a local object.

  The ejbTimeout method can contain any code that is typically placed in a business method of the bean. Method-level attributes such as *transaction* or *runAs* can be associated with this method by the application assembler. An instance of the timer that causes the method to run is passed in as an argument to ejbTimeout method. The following code snippet illustrates using the javax.ejb.TimedObject interface:

```
import javax.ejb.Timer;
import javax.ejb.TimedObject;
import javax.ejb.TimerService;

public class MyBean implements EntityBean, TimedObject {

  // This method is called by the container when the timer expires.
  public void ejbTimeout(Timer theTimer) {

    //You can place code that is typically placed in an EJB method.

     String whyWasICalled = (String) theTimer.getInfo():
     System.out.println("I was called because of"+ whyWasICalled);
  } // end of method ejbTimeout
```

  A timer is created that starts the ejbTimeout method in 30 seconds. A simple string object is passed in at timer creation to identify the timer; for example:

```
// Instance variable to hold the EJB context.
private EntityContext theEJBContext;

// This method is called by the EJB container upon bean creation.
public void setEntityContext(EntityContext theContext) {

// Save the entity context passed in upon bean creation.
  theEJBContext = theContext;
```

```
}

// This business method causes the ejbTimeout method to begin in 30 seconds.
public void fireInThirtySeconds() throws EJBException  {

  TimerService theTimerService = theEJBContext.getTimerService();
  String aLabel = "30SecondTimeout";
  Timer theTimer = theTimerService.createTimer(30000, aLabel);

} // end of method fireInThirtySeconds

} // end of class MyBean
```

**Note:** The EJB 3.x programming model provides additional strategic ways to define persistent and non-persistent timers within your business environments. Although defining persistent timers using the ejbTimeout method with the TimedObject interface is still supported, take advantage of the easy-to-implement EJB annotations to create persistent and non-persistent timers to meet your business needs.

- Determine whether your timer must be single-action, interval, or calendar-based.
  –

  A single-action timer is scheduled to run once on a specific date or after a specified duration. To specify a single-action timer, use the TimerService.createSingleActionTime or TimerService.createTimer(Date, Serializable) APIs.

  –

  An interval timer is scheduled to begin on a specific date or after a specified duration and continues to run at a fixed rate until it is canceled. To specify an interval timer, use the TimerService.createIntervalTimer, TimerService.createTimer(long, long, Serializable), or TimerService.createTimer(Date, long, Serializable) APIs.

  –

  A calendar-based timer is scheduled to run at specific dates and times. To specify a calendar-based timer, either use an automatically created timer or use the TimerService.createCalendarTimer APIs, which accept a javax.ejb.ScheduleExpression argument.

  **Note:** When the EJB container stores a serialized calendar-based timer in the database, the serialized format is incompatible with the format used in WebSphere Application Server Version 7 and lower. If you use calendar-based timers, you must not configure the scheduler for the EJB container to use database tables that are shared with an older version of WebSphere Application Server.

  When using the TimerService.createCalendarTimer API, several attributes are specified to form an expression like the *cron* job scheduling daemon. The first set of attributes is used to control how date calculations are performed:

*Table 73. Attributes that control how dates are calculated.. Attributes that control how dates are calculated*

| | |
|---|---|
| start | Specifies a date value that is the inclusive starting point for calculating timeouts. The default value is null, which means the timer can start at any time. |
| end | Specifies a date value that is the inclusive ending point for calculating timeouts. The default value is null, which means the timer continues to run indefinitely. |
| timezone | Specifies a valid time zone according to the java.util.TimeZone API. The default value is null, which corresponds to the default time zone of the host server. |

  The second set of attributes determines when the timer runs. All attributes have a set of allowable values in addition to a special wild-card value *, which represents all possible values for that attribute.

*Table 74. Attributes that determine when the timer runs.. Attributes that determine when the timer runs*

| | |
|---|---|
| second | Specifies an integer in the range 0 to 59; default 0. |
| minute | Specifies an integer in the range 0 to 59; default 0. |
| hour | Specifies an integer in the range 0 to 23; default 0. |
| dayOfMonth | Specifies an integer in the range 1 to 31; default *. Alternatively, the value can be:<br>• The keyword **Last**, which corresponds to the last day of the month.<br>• An integer in the range -1 to -7, which corresponds to a day before the last day of the month. For example, in a month with 31 days, the value -3 would correspond to the 28 day of the month.<br>• The keyword **1st**, **2nd**, **3rd**, **4th**, **5th**, or **Last** followed by a day of the week keyword **Sun**, **Mon**, **Tue**, **Wed**, **Thu**, **Fri**, or **Sat**. For example, you might use **3rd Sun** and **Last Wed**. You must use the abbreviated English ordinals and keywords. |
| dayOfWeek | Specifies an integer in the range 0 to 7; default *. These values correspond to the keywords **Sun**, **Mon**, **Tue**, **Wed**, **Thu**, **Fri**, and **Sat**, which can be used instead. The values 0 and 7 both correspond to the keyword **Sun**. When both dayOfMonth and dayOfWeek are a value other than *, only one of the attributes needs to match a given day. |
| month | Specifies an integer in the range 1 to 12; default *. These values correspond to the keywords **Jan**, **Feb**, **Mar**, **Apr**, **May**, **Jun**, **Jul**, **Aug**, **Sep**, **Oct**, **Nov**, and **Dec**, which can be used instead. |
| year | Specifies any four-digit calendar year; default *. |

You can specify each of these attributes using an **x-y** range notation. For example, **0-3** is a valid range for the hour attribute and **Jun-Aug** is a valid range for the month attribute. Additionally, the second, minute, and hour attributes can be specified using an **x/y** increment notation. For example, **30/10** is a valid increment for the minute attribute, which includes the values 30, 40, and 50.

All attributes can also be specified as comma-delimited lists of single values or ranges of values. For example, the value **4,10-12** is valid for the hour attribute, and it corresponds to the times 4 AM, 10 AM, 11 AM, and 12 PM.

The following example uses the America/New_York time zone value for its calendar operations. The timer runs on the last Friday of the months January, February, March, and June. On those days, it runs every two hours starting at 1:30 AM:

```
TimerService theTimerService = theEJBContext.getTimerService();
Timer theTimer = theTimerService.createCalendarTimer(new ScheduleExpression()
 .timezone("America/New_York")
 .month("Jan-Mar, Jun")
 .dayOfMonth("Last Fri")
 .hour("1/2")
 .minute(30))
```

- To create timers automatically, define the timeout callback method using the @Schedule or @Schedules annotation or using the timer deployment descriptor element. Use annotations to write metadata for EJBs inside your source code. For more details, see the information about EJB 3.x metadata annotations.

  A bean can have multiple timeout callback methods for timers that are created automatically. The timeout callback method and automatic timers are identified by the @Schedule or @Schedules annotation in the source code or by using the timer deployment descriptor element in the ejb-jar.xml file. If you specify both annotations for the same method or if you specify an annotation and the timer deployment descriptor element for the same method, the metadata is combined and multiple automatic timers are created. The timeout callback methods must have a void return type and must accept either no parameters or a single parameter of type javax.ejb.Timer. All automatic timers are calendar-based. See information about scheduling calendar-based timers for additional information.

  The server creates automatic timers when the application starts for the first time. Subsequent application start operations detect that timers have already been created for this application, and the timers are not recreated even if they were subsequently canceled. For persistent automatic timers, the

server stores this data in the scheduler tables. If your application is installed on a server cluster, then you must configure the EJB container on each server to use a shared cluster-scoped scheduler. If your application is installed on independent servers, then you must ensure that each server is configured with a unique database or unique database table prefix. See information about clustered environment considerations for timer service.

The application server automatically removes persistent automatic timers from the database when you uninstall the application while the server is running. If the application server is not running, you must manually delete the automatic timers from the database. Additionally, if you add, remove, or change the metadata for automatic timers while the server is not running, you must manually delete the automatic timers.

– Define the automatic timer by using the @Schedule annotation. The following example uses @Schedule annotation:

```
class MyBeanImpl implements MyBean {
    @Schedule(hour="20", info="single timer", persistent=false)
    public void automatic(Timer t) {
        // ...
    }
}
```

The @Schedule annotation has second, minute, hour, dayOfMonth, dayOfWeek, month, year, and timezone elements that correspond to the same attributes of javax.ejb.ScheduleExpression. The annotation also has a persistent element that you can use to specify whether the server uses the EJB timer service scheduler to persist the timer. By default, automatic timers are persistent. Finally, the annotation also has an info element that you can use to specify application information that is delivered as a java.lang.String object with the javax.ejb.Timer object when the timeout callback method runs.

– Define multiple automatic timers for the same method by using the @Schedules annotation. The following example uses the @Schedules annotation:

```
class MyBeanImpl implements MyBean {
    @Schedules(
        @Schedule(hour="1" info="1AM timer", persistent=false),
        @Schedule(minute="0/30" info="30 minute timer")
    )
    public void automaticMultiple(Timer t) {
        // ...
    }
}
```

– Define timers using the deployment descriptor element. You can use the following subelements of the timer element:

*Table 75. Subelements of the timer element. Subelements of the timer element*

| Element | Required or Optional | Description |
|---|---|---|
| schedule | Required | Includes optional second, minute, hour, day-of-month, day-of-week, month, and year subelements that correspond to the same attributes of javax.ejb.ScheduleExpression. |
| start and end | Optional | Specify the inclusive starting and ending points for calculating timeouts. |
| timeout-method | Required | Specifies the timeout callback method. |
| persistent | Optional | Specifies whether the server uses the EJB timer service scheduler to persist the timer. By default, automatic timers are persistent. |
| timezone | Optional | Corresponds to the same attribute of javax.ejb.ScheduleExpression. |
| info | Optional | Specifies application information that is delivered as a java.lang.String object with the javax.ejb.Timer object when the timeout callback method runs. |

The following example uses the timer deployment descriptor element:

```
<session>
  <ejb-name>MyBeanImpl</ejb-name>
  <timer>
    <schedule>
      <hour>20</hour>
    </schedule>
    <start>2000-01-01T13:00:00</start>
    <timeout-method>
      <method-name>automatic</method-name>
    </timeout-method>
    <persistent>false</persistent>
    <timezone>America/New_York</timezone>
    <info>single timer</info>
  </timer>
</session>
```

- Determine whether your timer is persistent or non-persistent.
  - Create a persistent timer.
  - Create a non-persistent timer.
- Deploy your EJB application. After you deploy your EJB application, the enterprise bean must run so that the createTimer methods are called before the timer is created programmatically. If the timer is automatically created, the timer starts when the EJB application is started.

### Results

You have programmatically or automatically configured an EJB timer that is either persistent or non-persistent.

## Clustered environment considerations for timer service

In a single server environment, it is clear which server instance should invoke the timeout method of the bean on a given bean. In a multi-server clustered environment there are other considerations governing the behavior.

WebSphere Application Server implements the Enterprise JavaBeans (EJB) Timer Service. Based on your business needs, you can use persistent timers or non-persistent timers. Persistent timers are helpful if you are creating a timer for a time-based event that requires assurance of timer existence beyond the life cycle of the server to survive server shutdowns and restarts. Previously started persistent timers automatically start when your server starts and they require a database instance. Non-persistent timers do not use a data store and are canceled when the application server is stopped or fails to remain in an active state. Non-persistent timers exist only on the server where they are created. In a clustered environment, if your EJB application automatically creates a non-persistent timer and this application is mirrored on multiple servers, each server has its own non-persistent timer that runs within that server environment. A programmatically created non-persistent timer only runs in the cluster member that it was created in.

When configuring a persistent timer in a multi-server clustered server environment, consider the following possibilities for the server instance to invoke the timeout method on a given bean:

- Separate timer service database per server process or cluster member. This is the default configuration. Only the server instance or cluster member that created the Timer can access the Timer and run the timeout method of the bean. If the server instance is unavailable, the Timer does not run at the specified time, and does not run until the server is restarted. Also, if an enterprise bean calls the *getTimers()* method, only those timers created on the server instance are found. This can cause unexpected behavior if the enterprise bean attempts to cancel all timers associated with it; for example, when the enterprise bean is removed. This configuration is NOT recommended for production level systems.
- Shared or common timer service database for the cluster. Timers can be created and accessed on any server process or cluster member. Timers created in one server process are found by the *getTimers()* method on other server processes in the cluster. When an entity bean is removed, all timers, no matter

where created, are cancelled. However, all timers are executed on a single server in the cluster, that is, the timeout method of the bean is run for all timers on a single server. Which server executes the timers varies depending on which server process obtains a lock on the common database tables. If the server executing timers becomes unavailable, then another server or cluster member takes over and begins executing all timers at their scheduled time. This is the recommended configuration for all production level systems.

- **Note:** When using the EJB Timer service in an application using multi-threaded database access, application flow can introduce deadlock problems.
  To avoid this, use the wsPessimisticUpdate access intent. This access intent causes the finder method in your application to run a *select for update* statement instead of a generic select. This in turn prevents the lock escalation deadlock when multiple threads try to escalate their locks to perform an update.

See the information on using the EJB timer service for enterprise beans to learn how to configure the data source (database) to be used for each server process timer service.

**Note:** Once the data source for the timer service is changed to point to a different database, the server process automatically attempts to create the required tables in that database on the next server start.

If the user ID associated with the start of the server process is not authorized to create database tables in the configured timer service database, then the tables must be created manually.

**Note:** When you use the proxy server in the product, do not define a scheduler at the cell level if that scheduler is configured as the one to use for the EJB timer service. Doing so prevents persistent timers from running. This can happen if the proxy server gets the scheduler lease. Since no applications run in the proxy server, there is no application code to handle the timer events that are sent by the scheduler.

## Timer service commands

Information about Enterprise JavaBeans (EJB) timers is specific to the application that the timers are created for, and the timers are not visible outside of that application. Therefore, when you manage EJB timers, use the application that contains the enterprise bean and creates the EJB timer.

You can use the following commands during application development to provide basic EJB timer management functions. These commands are not available on *client only* installations.

### findEJBTimers

This command displays information about existing persistent EJB timers, based on specified filter criteria.

This command displays information about existing persistent EJB timers, based on specified filter criteria. The syntax for this command is:

```
findEJBTimers server filter [options]
   filter: -all | -timer | -app [-mod [-bean ]]
           -all
           -timer timer id
           -app   application name
           -mod   module name
           -bean  bean name

  options: -host  host name
           -port  portnumber
           -conntype connector type
           -user  userid
           -password password
           -quiet
```

```
          -logfile filename
          -replacelog
          -trace
          -help
```

The following options exist:

**server** Specifies the name of the server process where the EJB timers are located

**-all** Specifies to find all EJB timers associated with the server process

**timer id**
Specifies the EJB Timer ID that uniquely identifies the timer

**application name**
Specifies to find all EJB timers associated with the application

**module name**
Specifies to find all EJB timers associated with the module

**bean name**
Specifies to find all EJB timers associated with the enterprise bean

**host name**
Specifies the host name of the server process

**portnumber**
Specifies the port of the server process

**connector type**
Specifies the type of connection. For example, SOAP, RMI, or NONE.

**userid** Specifies the user to use when connecting to the server process

**password**
Specifies the password to use when connecting to the server process

**quiet** Specifies to disable output

**logfile** Specifies to direct output to a file

**replacelog**
Specifies to clear the existing log before executing the command

**trace** Specifies to enable trace

**help** Specifies to provide command-specific help

**Note:** If the server you specify is configured to use a scheduler instance that is shared by multiple servers, then EJB timers that are created in any of the server processes might be found.

See the information about locating EJB timers using the findEJBTimers command.

### cancelEJBTimers

This command cancels and removes from persistent storage EJB persistent timers based on the specified filter criteria.

The syntax for this command is:

```
cancelEJBTimers server filter [options]
   filter: -all | -timer | -app [-mod [-bean ]]
           -all
           -timer timer id
           -app   application name
           -mod   module name
```

```
          -bean  bean name

  options: -host  host name
           -port  portnumber
           -conntype connector type
           -user  userid
           -password password
           -quiet
           -logfile filename
           -replacelog
           -trace
           -help
```

the following options exist:

**server** Specifies the name of the server process where the EJB timers are located

**-all** Specifies to find all EJB timers associated with the server process

**timer id**
Specifies the EJB Timer ID that uniquely identifies the timer

**application name**
Specifies to find all EJB timers associated with the application

**module name**
Specifies to find all EJB timers associated with the module

**bean name**
Specifies to find all EJB timers associated with the enterprise bean

**host name**
Specifies the host name of the server process

**portnumber**
Specifies the port of the server process

**connector type**
Specifies the type of connection. For example, SOAP, RMI, or NONE.

**userid** Specifies the user to use when connecting to the server process

**password**
Specifies the password to use when connecting to the server process

**quiet** Specifies to disable output

**logfile** Specifies to direct output to a file

**replacelog**
Specifies to clear the existing log before executing the command

**trace** Specifies to enable trace

**help** Specifies to provide command-specific help

**Note:** If the server you specify is configured to use a scheduler instance that is shared by multiple servers, then EJB timers that are created in any of the server processes might be canceled.

For an example of the cancelEJBTimers command, see the topic CancelEJBTimers command example.

***findEJBTimers command:***

The following examples illustrate how to use the `findEJBTimers` command to find Enterprise JavaBeans (EJB) timers and explain the output statement. For relevant parameters and syntax information, read about the timer service commands.

To find *all* EJB timers on a server called **server1**, enter the following command in the `<install-root>\profiles\<profile>\bin` directory:

```
findEJBTimers server1 -all
```

To find all EJB timers on **server1**, associated with the *Increment* bean in the **DefaultApplication**, enter the following command in the `<install-root>\profiles\<profile>\bin` directory:

```
findEJBTimers server1 -app DefaultApplication.ear
                      -mod Increment.jar -bean Increment
```

When EJB timers matching the filter criteria are found, the output appears similar to the following:

```
EJB Timer : 252     Expiration: 5/25/10 10:53 AM     Single
   EJB    : TimerPtestApp, TimerPtestEJB.jar, NoMoreTimeoutsBean
   Info   : Single
   Programmatic timer
EJB Timer : 253     Expiration: 5/25/10 11:47 AM     Calendar
   EJB    : TimerPtestApp, TimerPtestEJB.jar, NoMoreTimeoutsBean
   Automatic timer
Calendar expression: [start=null, end=null, timezone=null, seconds="52",
           minutes="47", hours="11", dayOfMonth="25", month="5", dayOfWeek="*",
           year="2010"]
2 EJB Timer tasks found
```

In this output, the following elements exist:

- `EJB Timer` is the unique identifier of the timer.
- `Expiration` is the next time the timer is expected to execute.
- *Calendar expression* is the calendar expression that defines the timer expiration intervals and frequencies, if the timer expirations were defined by a ScheduleExpression. All automatic timers have expirations defined by a ScheduleExpression.
- `EJB Key` is the *toString()* method output of the primary key for and entity bean. For other EJB types, `Not Available` will be output.
- `Info` is the *toString()* method output of the object passed by the application when the EJB timer was created.

Only the first forty bytes of *toString()* output are displayed for the primary key and timer information. This information is only useful if the application overrides the *toString()* method for these objects.

***CancelEJBTimers command example:***

The following examples illustrate how to use the command to cancel Enterprise JavaBeans (EJB) timers.

To use the cancelEJBTimer command to cancel all EJB timers on a server called **server1**:

```
cancelEJBTimers server1 -all
```

To cancel all EJB timers on **server1**, associated with the *Increment* bean in the **DefaultApplication**:

```
cancelEJBTimers server1 -app DefaultApplication.ear -mod Increment.jar -bean Increment
```

To cancel a specific EJB timer identified through the FindEJBTimers command or from a system log entry indicating a problem or failure:

```
cancelEJBTimers server1 -id 25
```

*Increment* in the *DefaultApplication* does not implement the *TimedObject* interface, and so could not actually have associated EJB Timers. Increment is used merely for illustrative purposes in this example.

**Note:** The CancelEJBTimers command also cancels automatically created persistent timers. When automatically created persistent timers are cancelled, the only way to recreate them is to uninstall the application and reinstall it again.

***EJB command group:***

The EJB command group for the AdminTask object provides commands that you can use to manipulate enterprise beans.

**removeAutomaticEJBTimers**

Applications or modules use annotations or XML to instruct the application server to automatically create EJB timers.

Automatically created timers are persisted in the scheduler instance associated with the server that the application or module is running on at the moment the automatic EJB timer is created. Schedules are configured on a per server basis, and thus it is possible for each server in your topology to use a unique scheduler instance. In this case, the scheduler instance specific to each server supports the EJB timers running in that server.

Each scheduler instance is associated with a set of database tables. If you have multiple scheduler instances, configure each scheduler instance with a unique prefix to ensure the instance maps to a unique set of database tables.

When the application or module that requested the automatic EJB timers are removed from a server, the automatic EJB timers must be removed from the corresponding scheduler instance. If the application or module was installed on multiple servers, and each of those servers used a unique scheduler instance, then the timers must be removed from each of those scheduler instances. In other words, automatically created EJB timers are removed on a per server basis.

In some cases, the removal or update of the application or module results in the removal of the automatically created EJB timers from the scheduler instance. In this scenario, no user action is required.

However, in other cases, the removal, or update of the application or module does not result in the removal of the automatically created EJB timers from the scheduler instance. In this case, you must manually remove the EJB timers using the removeAutomaticEJBTimers command.

The command is only supported in a connected mode. In a network deployment topology, the deployment manager, NodeAgent, and the managed server that contains the scheduler instance must all be running. In a base topology, the stand-alone server must be running.

In a Rational Application Developer loose configuration scenario, you must manually remove your automatically created EJB timers. Also, programmatically created EJB timers, which are not the same as automatically created EJB timers, are not automatically removed or removed by this command.

In a network deployment topology, when a single module is only installed on a subset of the servers in the topology, the automatically created timers associated with that module must be removed from the scheduler instance(s) associated with that subset of servers only. A scheduler instance corresponding to a server that does not have the module installed on it does not need to be cleaned up.

**Target Object: None**

**Required parameters**

**-appName**
The name of the application that requested the automatically created EJB timers you want to remove. (String, required)

**-serverName**
The name of the server that runs the application or module that contains the automatically created EJB timers you want to remove. This parameter represents the logical name of an application server, not a host name. (String, required)

### Optional parameters

**-schedulerJNDIName**
This parameter represents the JNDI name of the scheduler instance that persists the automatically created EJB timers you want to remove.

A server instance is always configured to use a particular scheduler instance to support automatically created EJB timers. You can explicitly configure which scheduler instance is used, or you can choose to not explicitly configure a scheduler instance. In the latter case a default scheduler instance is used.

If the scheduler instance that contains the automatically created EJB timers you want to remove is the same scheduler instance that is currently configured for the server, then you can omit this parameter. In this case, the command examines the configuration, discovers the scheduler instance that is currently configured, and uses that.

However, if the scheduler instance that is currently configured is *not* the one that contains the EJB timers you want to remove, then specify the JNDI name of the scheduler instance that does contain these timers. (String, optional)

**-nodeName**
The name of the node that contains the server. (String, required)

**-moduleName**
The name of the module that requested the automatically created EJB timers you want to remove. If you want to remove all automatically created timers in the application, regardless of which module they are defined in, then this parameter is omitted. This parameter is only specified when you want to remove the automatically created timers requested by one module in the application, but not the timers requested by another module in the same application. (String, optional)

### Return value: None

The following information helps to determine when this command is needed:

- WebSphere Application Server attempts to remove automatically created EJB timers when all the following conditions are met:
  - One of the following actions is performed:
    - Application uninstallation
    - Application update
    - Module uninstallation
    - Module update
  - The action was performed in a connected mode (not wsadmin -conntype none).
  - The needed servers were running at the time of the action.
    - For a network deployment topology, the deployment manager, node agent, and managed server containing the automatically created EJB timers were all running.
    - For a base topology, the stand-alone server was running.
  - The correct follow-up action was performed.
    - For a network deployment topology, you save your changes and synchronize them to the node agent. If you save your changes but do not synchronize them, then the automatically created EJB timers are *not* removed. The automatically created EJB timers are only removed during the sync processing.
    - For a base topology, you save your changes.

  - The database supporting the scheduler instance was running.
- WebSphere Application Server does *not* remove automatically created EJB timers when *any* of the following conditions occur:
  - Any action is performed other than an update or uninstallation of an application or module.
  - The action (even if it is an application/module uninstallation/update) was performed in disconnected mode.
  - The needed servers were not running.
    - For a network deployment topology, the deployment manager, node agent, or managed server was not running.
    - For a base topology, the stand-alone server was not running
  - The correct follow-up action was not performed.
    - For a network deployment topology, either the save or synchronize was not performed.
    - For a base topology, the save was not performed.
  - The database supporting the scheduler instance was not running.

If WebSphere Application Server encounters an error when attempting to remove automatically created EJB timers from a server, then a warning is written to log file.

If an error occurs, or if the application server did not attempt to remove automatically created EJB timers, or if you are not sure if the automatically created EJB timers were removed, manually issue the removeAutomaticEJBTimers command to ensure that the automatically created EJB timers are removed. If the automatically created timers were actually removed from the scheduler instance, running the command is unnecessary, but does no harm.

If you are running in a clustered environment, and your cluster contains multiple nodes, and each of those nodes contains a server that maps to the same cluster level scheduler instance, then the automatically created timers only must be removed from one of the servers. This is because the shared scheduler instance is updated, and all servers using that shared scheduler instance see the change.

As a result, if a server in one node is not running and you receive a log warning that the automatic timers could not be removed from it, but you know that server shares a cluster-level scheduler instance with a server in a different node that was successfully cleared, then no user action is required because the shared scheduler instance has already been updated.

The same is true when there are multiple servers in a cluster, and they are all part of the same node, and share a single cluster-level scheduler instance, and one or more of those cluster members are not running. In this case, the application server issues a log warning that the automatic timers could not be removed from those servers. However if you know that they share a common scheduler instance, and one of the cluster members was successfully cleared, then no user action is required because the shared scheduler instance has already been updated.

If you are running in a network deployment topology and have multiple servers, the type of scheduler used (default versus custom configured) has an impact on performance in regards to scheduler cleanup. The default EJBContainer scheduler is unique per server. If you are using the default EJBContainer scheduler instance, and you have five servers, this means you have five unique scheduler instances, and the automatic timers must be removed from all five of them when the application is updated or removed. However, if you are using a single shared, custom configured scheduler instance, then the automatic timers must only be removed once, from that one scheduler instance.

**Example 1**

**Topology**:

- Deployment manager running on workstation A.

- NodeAgent running on workstation B. The node is called Node01.
- Managed server server1 running on workstation C.
- Managed server server2 running on workstation D.
- Security is enabled.
- server2 is currently configured to use the same scheduler instance that contains the timers.

**Background**:

The testApp application was uninstalled in a connected mode from the administrative console. You want to remove all the automatically created timers in the application, regardless of which module requested them.

The deployment manager, node agent, and server1 servers were running, and the automatic EJB timers were removed from server1. However, server2 was not running, and so the automatic EJB timers were not removed from server2.

Now, you must manually remove the automatic EJB timers from server2.

**Action**

- Using Jacl, from a connected wsadmin session in the deployment manager enter the following line of code:

  ```
  $AdminTask removeAutomaticEJBTimers "-appName testApp -serverName server2 -nodeName Node01"
  ```

- Using Jython, from a connected wsadmin session in the deployment manager enter the following line of code:

  ```
  AdminTask.removeAutomaticEJBTimers('-appName testApp -serverName server2 -nodeName Node01')
  ```

**Example 2**

**Topology**:

- Stand-alone server1 running on workstation A. The node is called Node01.
- Administrative security is disabled.
- server1 was configured to use scheduler instance `jndi/sched_1` when the automatic EJB timers were created. However, server1 is currently configured to use scheduler instance `jndi/sched_2`.

**Background**

The module, mod1, from application, testApp, was uninstalled, but because server1 was configured to use the `jndi/sched_2` instance at the moment of uninstallation, the automatic EJB timers were not removed from scheduler instance `jndi/sched_1`.

Now, you must manually remove the automatic EJB timers from the `jndi/sched_1` scheduler instance on server1.

The application contains modules, mod1 and mod2. Both of these modules requested automatically created EJB timers. The mod2 module is still installed, and you still need the automatically created EJB timers it requested. You only want to remove the automatically created EJB timers requested by mod1.

**Action**

- Using Jacl, from a connected wsadmin session in the stand-alone server enter the following line of code:

```
$AdminTask removeAutomaticEJBTimers "-appName testApp -moduleName mod1 -serverName server1 -nodeName Node01 -schedulerJNDIName jndi/sched_1"
```

- Using Jython, from a connected wsadmin session in the stand-alone server enter the following line of code:

```
AdminTask.removeAutomaticEJBTimers('-appName testApp -moduleName mod1 -serverName server1 -nodeName Node01 -schedulerJNDIName jndi/sched_1')
```

***Example: Using the Timer Service with the TimedObject interface:***

This example shows the implementation of the *ejbTimeout()* method that is called when the scheduled event occurs.

**Note:** The EJB 3.x programming model provides additional strategic ways to define persistent and non-persistent timers within your business environments. Although defining persistent timers using the ejbTimeout method with the TimedObject interface is still supported, take advantage of the easy-to-implement EJB annotations to create persistent and non-persistent timers to meet your business needs. See the using the EJB timer service for enterprise beans information to learn more about creating persistent and non-persistent timers using annotations or defining your own timeout methods within a deployment descriptor.

The ejbTimeout method can contain any code that is typically placed in a business method of the bean. Method-level attributes such as *transaction* or *runAs* can be associated with this method by the application assembler. An instance of the Timer object that causes the method to fire is passed in as an argument to the ejbTimeout method.

```
import javax.ejb.Timer;
import javax.ejb.TimedObject;
import javax.ejb.TimerService;

public class MyBean implements EntityBean, TimedObject {

  // This method is called by the EJB container upon Timer expiration.
  public void ejbTimeout(Timer theTimer) {

    // Any code typically placed in an EJB method can be placed here.

     String whyWasICalled = (String) theTimer.getInfo():
     System.out.println("I was called because of"+ whyWasICalled);
  } // end of method ejbTimeout
```

A Timer is created that starts the ejbTimeout method in 30 seconds. A simple string object is passed in at Timer creation to identify the Timer.

```
// Instance variable to hold the EJB context.
private EntityContext theEJBContext;

// This method is called by the EJB container upon bean creation.
public void setEntityContext(EntityContext theContext) {

// Save the entity context passed in upon bean creation.
  theEJBContext = theContext;

}

// This business method causes the ejbTimeout method to begin in 30 seconds.
public void fireInThirtySeconds() throws EJBException  {

  TimerService theTimerService = theEJBContext.getTimerService();
  String aLabel = "30SecondTimeout";
  Timer theTimer = theTimerService.createTimer(30000, aLabel);

} // end of method fireInThirtySeconds

} // end of class MyBean
```

## Developing enterprise beans

One of two enterprise bean development scenarios is typically used with the product. The first is command-line using Ant, Make, Maven or similar tools. The second is an IDE-based development and build environment. The steps in this article focus on development without an IDE.

## Before you begin

**Enterprise JavaBeans (EJB) 2.x beans only:** Design a J2EE application and the enterprise beans that it needs.

- Before developing entity beans with container-managed persistence (CMP), read the topic Concurrency control.

**EJB 3.x beans only:** Design a Java EE application and the enterprise beans that it needs.

- Before developing entity beans with CMP, read the topic, Concurrency control. Keep in mind that EJB 3.x modules do not support entity beans. You must continue to place entity beans in your EJB 2.x-level modules.

## About this task

The two basic approaches to select tools for developing enterprise beans are as follows:

- You can use one of the available IDE tools that automatically generate significant parts of the enterprise bean code and contain integrated tools for packaging and testing enterprise beans. The Rational Application Developer product is the recommended IDE.

  Add install_root/dev/JavaEE/j2ee.jar to the IDE project build path to resolve compilation dependencies on the new EJB 3.x API classes. Code assist works when this JAR file is added to the project build path. If you define a server (see J2EE Perspective), point the server to the product installation directory. When you create a Java EE related project in Rational Application Developer, the project automatically adds install_root/dev/JavaEE/j2ee.jar. to the project build path.
- If you have decided to develop enterprise beans without an IDE, you need at least an ASCII text editor. You can also use a Java development tool that does not support enterprise bean development. You can then use tools available in the Java Software Development Kit (SDK) and in this product to assemble, test, and deploy the beans.

  Like the assembly tool, a standard Java EE command-line build environment requires some change to use the EJB 3.x modules. As with previous Java EE application development patterns, you must include the `j2ee.jar` file located in the install_root/dev/JavaEE directory on the compiler class path. An example of a command-line build environment using Ant is located in the install_root/samples/src/TechSamp directory.

The following steps primarily support the second approach, development without an IDE.

## Procedure

1. If necessary, migrate any pre-existing code to the required version of the EJB specification.

   Applications written to the EJB specification versions 1.1, 2.0, and 2.1 can run unchanged in the EJB 3.x container. See the topic Migrating enterprise bean code to the supported specification.
2. Write and compile the components of the enterprise bean.
   - At a minimum, a session bean developed with the EJB 3.x specifications requires a bean class.
   - At a minimum, an EJB 1.1 session bean requires a bean class, a home interface, and a remote interface. An EJB 1.1 entity bean requires a bean class, a primary-key class, a home interface, and a remote interface.
   - At a minimum, an EJB 2.x session bean requires a bean class, a home or local home interface, and a remote or local interface. An EJB 2.x entity bean requires a bean class, a primary-key class, a remote home or local home interface, and a remote or local interface. The types of interfaces go together: If you implement a local interface, you must also define a local home interface.

     **Attention:** The primary-key class can be *unknown*. See the topic Unknown primary-key class for more information.
   - A message-driven bean requires only a bean class.
3. For each entity bean, complete work to handle persistence operations.

For EJB 3.x modules, consider using the Java Persistence API (JPA) specification to develop plain old Java Object (POJO) persistent entities. Review the topic Java Persistence API for more information. If you choose to develop entity beans to earlier EJB specifications, follow these steps:

- Create a database schema for the entity bean persistent data.
  - For entity beans with CMP, you must store the bean persistent data in one of the supported databases. The assembly tool automatically generates SQL code for creating database tables for CMP entity beans. If your CMP beans require complex database mappings, it is recommended that you use Rational Application Developer to generate code for the database tables. For more information about using the assembly tools, see the assembly tool information center.
  - For entity beans with bean-managed persistence (BMP), you can create the database and database table by using the database tools or use an existing database and database table.

  For more information about creating databases and database tables, review your database documentation.
- **(CMP entity beans for EJB 2.x only)**

  Define finder queries with EJB Query Language (EJB QL).

  With EJB QL, you define finders in terms of CMP fields and container-managed relationships, as follows:
  - *Public* finders are visible in the bean home interface. Implemented in the bean class, they return only remote interfaces and collection types.
  - *Private* finders, expressed as SELECT statements, are used only within the bean class. They can return both local and remote interfaces, dependent values, other CMP field types, and collection types.
- **(CMP entity beans for EJB 1.1 only: an IBM extension)** Create a finder helper interface for each CMP entity bean that contains specialized finder methods (other than the findByPrimaryKey method).

  Logic other than the findByPrimaryKey method is required for each finder method that is contained in the home interface of an entity bean with CMP:
  - The logic must be defined in a public interface named *Name*`BeanFinderHelper`, where *Name* is the name of the enterprise bean, for example, AccountBeanFinderHelper.
  - The logic must be contained in a String constant named *findMethodName* `WhereClause`, where *findMethodName* is the name of the finder method. The String constant can contain zero or more question marks (?) that are replaced from left to right with the value of the finder method arguments when that method is called.

## Example: Using a read-only entity bean

This usage scenario and example shows how to write an Enterprise JavaBeans (EJB) application that uses a read-only entity bean.

### Usage scenario

A customer has a database of catalog pricing and shipping rate information that is updated daily no later than 10:00 PM local time (22:00 in 24-hour format). They want to write an EJB application that has read-only access to this data. That is, this application never updates the pricing database. Updating is done through some other application.

### Example

The customer's entity bean local interface might be:

```
public interface ItemCatalogData extends EJBLocalObject {

  public int getItemPrice();

  public int getShippingCost(int destinationCode);

}
```

The code in the stateless SessionBean method (assume it is a TxRequired) that invokes this EntityBean to figure out the total cost including shipping, would look like:

```
.....
// Some transactional steps occur prior to this point, such as removing the item from
 // inventory, etc.
 // Now obtain the price of this item and start to calculate the total cost to the purchaser

 ItemCatalogData theItemData =
    (ItemCatalogData) ItemCatalogDataHome.findByPrimaryKey(theCatalogNumber);

int totalcost = theItemData.getItemPrice();

// ...     some other processing, etc. in the interim
// ...
// ...

// Add the shipping costs
totalcost = totalcost + theItemData.getShippingCost(theDestinationPostalCode);
```

At application assembly time, the customer sets the EJB caching parameters for this bean as follows:

- ActivateAt = ONCE
- LoadAt = DAILY
- ReloadInterval = 2200

**Note:** The reloadInterval and reloadingEnabled attributes of the IBM deployment descriptor extensions, including both the WAR file extension (WEB-INF/ibm-web-ext.xmi) and the application extension (META-INF/ibm-application-ext.xmi) were deprecated in V6.0.

On the first call to the getItemPrice() method after 22:00 each night, the EJB container reloads the pricing information from the database. If the clock strikes 22:00 between the call to getItemPrice() and getShippingCost(), the getShippingCost() method still returns the value it had before any changes to the database that might have occurred at 22:00, since the first method invocation in this transaction occurred before 22:00. Thus, the item price and shipping cost used remain in sync with each other.

### What to do next

Assemble the beans in one or more EJB modules. See the topic Assembling EJB modules, or Assembling EJB 3.x modules if you are using EJB 3.x beans.

## Developing message-driven beans

You can develop a bean implementation class for a message-driven bean as introduced by the Enterprise JavaBeans specification. A message-driven bean (MDB) is a message consumer that implements business logic and runs on the server.

### Before you begin

Determine the messaging model you want for your application regarding use of topics, queues, producers and consumers, publish or subscribe, and so on. You can refer to the message-driven bean component contract that is described in the Enterprise JavaBeans™ specification.

### About this task

A message-driven bean (MDB) is a consumer of messages from a Java Message Service (JMS) provider. An MDB is invoked on arrival of a message at the destination or endpoint that the MDB services. MDB

instances are anonymous, and therefore, all instances are equivalent when not actively servicing a client message. The container controls the life cycle of bean instances, which hold no state that is visible to a client.

The following example is a basic message-driven bean:

```
@MessageDriven(activationConfig={
                @ActivationConfigProperty(propertyName="destination",     propertyValue="myDestination"),
                @ActivationConfigProperty(propertyName="destinationType", propertyValue="javax.jms.Queue")
})
public class MsgBean implements javax.jms.MessageListener {

  public void onMessage(javax.jms.Message msg) {

      String receivedMsg = ((TextMessage) msg).getText();
      System.out.println("Received message: " + receivedMsg);

   }

}
```

As with other enterprise bean types, you can also declare metadata for message-driven beans in the deployment descriptor rather than using annotations, for example:

```
<?xml version="1.0" encoding="UTF-8"?>

<ejb-jar id="EJBJar_1060639024453" version="3.0"
      xmlns="http://java.sun.com/xml/ns/javaee"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_0.xsd"
      metadata-complete="false">
  <enterprise-beans>

    <message-driven>

      <ejb-name>MsgBean</ejb-name>
      <ejb-class>com.acme.ejb.MsgBean</ejb-class>
      <activation-config>
         <activation-config-property>
            <activation-config-property-name>destination</activation-config-property-name>
            <activation-config-property-value>myDestination</activation-config-property-value>
         </activation-config-property>
         <activation-config-property>
           <activation-config-property-name>destinationType</activation-config-property-name>
           <activation-config-property-value>javax.jms.Queue</activation-config-property-value>
        </activation-config-property>
      </activation-config>

    </message-driven>

  </enterprise-beans>
</ejb-jar>
```

## Procedure

- Code the business logic of the message-driven bean, which must implement the appropriate message listener interface defined by the messaging type; for example, javax.jms.MessageListener. The business logic is invoked when the message listener method of the MDB is called to service a message; for example, `MessageListener.onMessage()`. If the MDB implements more than one interface, denote the message listener interface by coding the `messageListenerInterface` attribute of the `MessageDriven` annotation, or by coding the `<messaging-type>` element of the `message-driven` deployment descriptor element. You do not have to specify which is the message listener interface, as long as there is only one interface other than `java.io.Serializable`, `java.io.Externalizable`, or any of the `javax.ejb` package interfaces.
- You can optionally define message destination references on any type of enterprise bean. A message destination reference is a logical name by which an enterprise bean can refer to a message destination. The `Resource` annotation is used to inject a message destination reference, for example:

```
@Resource (name="jms/Outlet", type=javax.jms.Queue) Queue salesOutlet;
```

Alternatively, you can use the <message-destination-ref> element in the deployment descriptor to specify the message destination reference; for example:

```
<message-destination-ref>
   <message-destination-ref-name>jms/Outlet</message-destination-ref-name>
   <message-destination-type>javax.jms.Queue</message-destination-type>
   <injection-target>
     <injection-target-class>com.acme.ejb.MsgBean</injection-target-class>
     <injection-target-name>salesOutlet</injection-target-name>
  </injection-target>
</message-destination-ref>
```

The message-destination-ref element is similar to the resource-env-ref element, but also has subelements, message-destination-usage with possible values Produces, Consumes or ProducesConsumes, and message-destination-link. You can use the message-destination-link element to tie two or more message-destination-ref references in the deployment descriptor together, which allows the deployer to bind the destination for several enterprise beans all at once, to the same destination. The message-destination-link value must match the message-destination-name value in the message-destination element; for example:

```
<ejb-jar>

  <enterprise-beans>

    <session>
      <ejb-name>OutletBean</display-name>
      ...
      <message-destination-ref>
        <message-destination-ref-name>jms/target</message-destination-ref-name>
        <message-destination-type>javax.jms.Queue</message-destination-type>
        <message-destination-usage>Produces</message-destination-usage>
        <message-destination-link>destination</message-destination-link>
      </message-destination-ref>
      ...
    </session>

    <session>
      <ejb-name>InletBean</display-name>
      ...
      <message-destination-ref>
        <message-destination-ref-name>jms/source</message-destination-ref-name>
        <message-destination-type>javax.jms.Queue</message-destination-type>
        <message-destination-usage>Consumes</message-destination-usage>
        <message-destination-link>destination</message-destination-link>
      </message-destination-ref>
      ...
    </session>

    <message-driven>
      <ejb-name>InletBean</display-name>
      ...

      <ejb-name>MsgBean</ejb-name>
      <ejb-class>com.acme.MsgBean</ejb-class>
      <messaging-type>javax.jms.MessageListener</messaging-type>
      <message-destination-type>javax.jms.Queue</message-destination-type>
      <message-destination-link>destination</message-destination-link>

      ...
    </message-driven>

  </enterprise-beans>
      ...
  <assembly-descriptor>
    ...
    <message-destination>
      <message-destination-name>destination</message-destination-name>
    </message-destination>
```

```
    ...
  </assembly-descriptor>

</ejb-jar>
```

The `message-destination-link` element can refer to a destination that is defined in a different Java archive (JAR) file within the same application, as with an `ejb-link` element. For example, to link to the destination, `ProduceQueue`, defined in the `grocery.jar` file, enter the following line in the deployment descriptor:

```
<message-destination-link>grocery.jar#ProduceQueue</message-destination-link>
```

- As with any enterprise bean, you can package a message-driven bean in a JAR file, or in a web application archive (WAR) file.

### Results

You developed a simple message-driven bean, along with some deployment and packaging options.

### What to do next

Read related information about designing an enterprise application that uses message-driven beans.

## Enterprise bean development best practices

Use the following guidelines when designing and developing enterprise beans.

- Use a stateless session bean to act as the entry point for business logic.
- Entity beans should use container-managed persistence.
- In an Enterprise JavaBeans (EJB) Version 2.x and later version environments, use local interfaces to improve communication between enterprise beans in the same Java virtual machine.

  Local calls avoid the overhead of RMI/IIOP and use pass-by-reference semantics instead of pass-by-value. For each call, the caller and callee beans share the state of arguments. EJB 2.x and later beans can have both a local and remote interface, but more typically, have one or the other.
- For communicating with remote clients, provide remote and remote home interfaces. For communicating with local clients like servlets, entity beans, and message-driven beans, provide local and local home interfaces.

### Batched commands for container managed persistence

From JDBC 2.0 on, *PreparedStatement* objects can maintain a list of commands that can be submitted together as a batch. Instead of multiple database round trips, there is only one database round trip for all the batched persistence requests.

You can enable the use of this feature for EJB container managed persistence (CMP). When you do, the run time defers *ejbStore/ejbCreate/ejbRemove* or the equivalent database persistence requests (insert/update/delete) until they are needed. This can be at the end of the transaction, or when a flush is needed for finders related to this EJB type. When the persistence operation finally happens, run time accumulates the database requests and uses JDBC *PreparedStatement* batch operation to make a single JDBC call for multiple rows of the same operation.

The product enables you to make the same settings using assembly tools.

### Deferred Create for container managed persistence

For CMP during the *ejbCreate*, the container can create the representation of the entity in the database immediately, or defer it to a later time.

You can turn this option on from the EJB CMP side. When you choose this option, the runtime defers *ejbCreate*, or the equivalent database persistence request, until it is needed. This can be at the end of the

transaction, or when a flush is needed for finders related to this EJB type. By doing this you can reduce two round trips for the newly created entity (insert and update) to one (insert).

The product enables you to make the same settings using assembly tools. Review the assembly tools information center at http://publib.boulder.ibm.com/infocenter/radhelp/v7r5mbeta/topic/com.ibm.jee5.doc/topics/cejb3.html

# WebSphere extensions to the Enterprise JavaBeans specification

This topic outlines extensions to the Enterprise JavaBeans (EJB) specification provided with the product.

## Inheritance in enterprise beans

In the Java language, *inheritance* is the creation of a new class from an existing class or a new interface from an existing interface. This product supports two forms of inheritance: standard class inheritance and EJB inheritance.

In standard class inheritance, the home interface, remote interface, or enterprise bean class inherits properties and methods from base classes that are not themselves enterprise bean classes or interfaces.

By contrast in enterprise bean inheritance, an enterprise bean inherits properties, such as container-managed persistence (CMP) fields and container-managed relationship (CMR) fields, methods, and method-level control descriptor attributes from another enterprise bean.

For more information, see the documentation for the assembly tools.

## Optimistic concurrency control for container-managed persistence

This product supports optimistic concurrency control of data access. For more information, see the topic about concurrency control.

## Access intents for EJB persistence

This product supports the application of named data-access policies.

## Sequence grouping for container-managed persistence

By designating CMP sequence groups for entity beans, you can prevent certain types of database-related exceptions from occurring during the run time of your EJB application. Within each group you specify the order in which the beans update your relational database tables. For instructions, see the topic about setting the run time for CMP sequence groups.

## Performance enhancements

Through the lifetime-in-cache settings, this product provides a way for you to improve performance for beans that are only occasionally updated. For more information, see the topic about entity bean assembly settings in the assembly tool documentation.

Some enterprise beans created with the assembly tools can utilize *read-ahead* for loading a bean and its related beans in a single database operation. An entire object graph or any part of the graph can be preloaded by configuring a finder method to use read-ahead.

## Assembly and deployment extensions

This product supports IBM extensions of assembly and deployment options.

## Setting the run time for batched commands with JVM arguments

This article explains how to set the run time for batched commands with JVM arguments.

### Procedure

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. In the Additional Properties area, select **Process Definition**.
6. In the Additional Properties area, select **Java Virtual Machine**.
7. Update the **Generic JVM arguments** with *-Dcom.ibm.ws.pm.batch=true*.

## Setting the run time for deferred create with JVM arguments

For Container Managed Persistence (CMP) to happen during the ejbCreate, the Enterprise JavaBeans (EJB) container can create the representation of the entity in the database immediately, or defer it to a later time.

### About this task

When you choose the defer option, the run time defers ejbCreate, or the equivalent database persistence request, until it is needed. This can be at the end of the transaction, or when a flush is needed for finders related to this EJB type. By doing this you can reduce two round trips for the newly created entity (insert and update) to one (insert).

### Procedure

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. In the Additional Properties area, select **Process Definition**.
6. In the Additional Properties area, select **Java Virtual Machine**.
7. Update the **Generic JVM arguments** with *-Dcom.ibm.ws.pm.deferredcreate=true*.

## Setting persistence manager cache invalidation

To set persistence manager cache invalidation, follow these steps.

### Procedure

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. In the Server Infrastructure area, select **Java and Process Management**.
6. Select **Process Definition**.
7. In the Additional Properties area, select **Java Virtual Machine**.
8. Update the **Generic JVM arguments** with *-Dcom.ibm.ws.ejbpersistence.cacheinvalidation=true*.

## Setting the system property to enable remote EJB clients to receive nested or root-cause exceptions

You might want to code your application to perform a given action if a certain kind of exception is the root-cause of a failure and is nested within the exception that you receive. The default behavior in the product might mask a nested or root-cause exception in your application.

### About this task

The Enterprise JavaBeans (EJB) container creates a TransactionRolledbackException exception for a remote client when it can create a RemoteException exception instead. With the RemoteException exception, the container does not lose the ability to have root-cause information nested inside the exception.

You can set the following Java virtual machine (JVM) system property to **true** through the administrative console for the product: com.ibm.websphere.ejbcontainer.includeRootExceptionOnRollback This change enables the remote client to receive nested exceptions when a rollback occurs.

**Note:** This property is applicable only for scenarios where the transaction in which the bean method is running was started by the container for this specific method invocation. All of the other scenarios must result in a TransactionRollBackException exception according to the EJB specification.

### Procedure

1. Open the administrative console.
2. Select **Servers**.
3. Select **Servers > Application servers > server_name**.
4. Under Server infrastructure, select **Java and Process Management > Process Definition**.
5. Under Additional properties, select **Java virtual machine > Custom properties > New**.
6. In the **Name** entry field, type **com.ibm.websphere.ejbcontainer.includeRootExceptionOnRollback**.
7. In the **Value** entry field, type **true**.
8. Select **OK**.

## Unknown primary-key class

When writing an entity bean, the minimum requirements usually include a primary-key class. However, in some cases you might choose not to specify the primary-key class for an entity bean with container-managed persistence (CMP).

Perhaps there is no obvious primary key, or you want to allow the deployer to select the primary key fields at deployment time. The primary key type is usually derived from the type used by the database system that stores the entity objects, and you might not know what this key is.

So, the *unknown key type* is actually a type chosen at deployment time, making it changeable each time the bean is deployed. Your client code must deal with this key as type *Object*.

Currently, WebSphere Application Server supports top-down mapping and enables the deployer to choose *String* keys generated at the application server.

# Developing applications using the embeddable EJB container

Use this task to develop applications using the embeddable Enterprise JavaBeans (EJB) container. Applications running in the embeddable container start faster and require a smaller footprint than when running in the full application server. It is an optimal environment for quickly developing and testing applications that might eventually run on the application server.

## Before you begin

To create an embeddable EJB container application, you must set your development environment to use Version 6.0 of Java Development Kit (JDK) Version 1.6. Your development environment must also include the WebSphere embeddable container Java archive (JAR) file in the class path. The `com.ibm.ws.ejb.embeddableContainer_8.0.0.jar` file is located in the `\runtimes` directory under the installation directory of WebSphere Application Server.

**Restriction:** The EJB thin client, `com.ibm.ws.ejb.thinclient_8.0.0.jar`, and the EJB embeddable JAR file, `com.ibm.ws.ejb.embeddableContainer_8.0.0.jar`, cannot coexist in the same class path.

If your beans use the javax.annotation.Resource annotation with the lookup attribute, which is new in EJB 3.1, you must also use the Java Endorsed Standards Override Mechanism to override the javax.annotation.Resource API that is available in the JDK on your system. Copy the `app_server_root\runtimes\endorsed\endorsed_apis_8.0.0.jar` file into a target directory of your choice. Use the java.endorsed.dirs property on the Java command to specify your directory that contains the copied JAR file.

## Procedure

1. Create an EJB 3.X module. When creating this module, you must ensure that it only contains features that are supported by WebSphere embeddable container. For a full list of supported functions, see the “Embeddable EJB container functions” on page 641 topic. Ensure that the EJB modules are on the class path of the embeddable container. You can package the EJB module as directories of classes or as EJB JAR files.
2. Create the main class that launches the embeddable container and starts methods on the enterprise beans. Use the javax.ejb.EJBContainer class to create an instance of the embeddable container (optionally passing container configuration parameters), get the container naming context, and close the embeddable container.

   The following sample code illustrates usage of the embeddable container:

```
//EmbeddableContainerSample.java
import java.util.HashMap;
import java.util.Map;
import javax.ejb.embeddable.EJBContainer;
import my.pkg.MyBeanIface; // this is the local business interface of the
                           // enterprise bean

public class EmbeddableContainerSample {

   public static void main(String[] args) throws Throwable {

      // Create a properties map to pass to the embeddable container:
      Map<String,Object> properties = new HashMap<String,Object>();

      // Specify that you want to use the WebSphere embeddable container:
      properties.put(EJBContainer.PROVIDER,
          "com.ibm.websphere.ejbcontainer.EmbeddableContainerProvider");

      // Create the container instance, passing it the properties map:
      EJBContainer ec = EJBContainer.createEJBContainer(properties);

      // Use the container context to look up a bean:
      MyBeanIface bean = ec.getContext().lookup(
          "java:global/MyEJBModule/MyBean!my.pkg.MyBeanIface");

      // Invoke a method on the bean instance:
      bean.doStuff();

      ...
```

```
      // Close the embeddable container:
      ec.close();

   }
}
```

In this sample code, you created an instance of an embeddable container by specifying the EJBContainer.PROVIDER property to the com.ibm.websphere.ejbcontainer.EmbeddableContainerProvider class, and passing that property to the EJBContainer.createEJBContainer method. You used the container naming context to look up a local enterprise bean, for example, MyBean. The lookup uses the portable global naming syntax.

This sample code relies on the embeddable container to automatically scan the class path to find the EJB module, MyEJBModule. Alternatively, you could have specified the modules you wanted to start using the EJBContainer.MODULES property. Use this property to specify a string or string array of module names that must exist in the JVM class path.

You can also specify a file or file array of modules that do not exist in the class path. This file or file array approach might require you to modify the context class loader on the current thread, if these modules require additional libraries that are also not on the JVM class path.

The following code sample illustrates how to start the embeddable container using a file array.

```
...
// Create the properties object to pass to the embeddable container:
Map<String,Object> props = new HashMap<String,Object>();

// Specify the EJB modules to start when creating the container:
File[] ejbModules = new File[2];
ejbModules[0] = new File("/home/myusername/ejbs/ShoppingCartEJB.jar");
ejbModules[1] = new File("/home/myusername/ejbs/OnlineCatalogEJB.jar");
props.put(EJBContainer.MODULES, ejbModules);

// In this example, both of these modules rely on code in a shared library.
// In order for the embeddable container to load the shared library, the
// context classloader must be able to load that shared library.

// Set up the context classloader so that it can load the shared library:
File sharedLibUtilityFile = new File("/home/myusername/ejbs/SharedLib.jar");
ClassLoader oldCL = Thread.currentThread().getContextClassLoader();
ClassLoader newCL = new URLClassLoader(new URL[]{
   sharedLibUtilityFile.toURI().toURL()}, oldCL);
Thread.currentThread().setContextClassLoader(newCL);

// Now, create the embeddable container, passing it the properties map:
EJBContainer ec = EJBContainer.createEJBContainer(props);

// Invoke an EJB loaded by the embeddable container:
...
```

After looking up the bean instance, start methods on it. When you finish the container-related tasks, close the container, which starts the bean methods marked as PreDestroy and closes the embeddable container. Close the embeddable container instance before creating a new one.

3. Customize the embeddable container. You can use properties to customize the embeddable EJB container run time. For a full list of supported properties, see the topic Embeddable EJB container custom properties.
4. If you want your application to use resources like data sources, then you can create and configure those resources in the properties map passed to the embeddable container or in a properties file.

   One common usage of the embeddable EJB container is to test applications that eventually run in the application server. Many of these applications rely on JDBC data sources that are configured in the server using the administrative console or wsadmin scripting tool. Since these tools do not exist in the embeddable container, you can configure the WebSphere embeddable container to provide these resources by passing properties to it.

The data source configuration properties can also be stored in a properties file. The embeddable container automatically loads properties stored in a file called embeddable.properties in the current working directory. You can override this file location by specifying the new file location as the value of the com.ibm.websphere.embeddable.configFileName system property.

The data source configuration properties all start with `DataSource`, and are followed by a term that identifies which data source is being configured. For example, `DataSource.myDataSource.someProperty` applies to a different data source than one named `DataSource.anotherDS.someOtherProperty`. The list of data source properties are located in the embeddable EJB container custom properties information.

Here is an example of how your application can use data sources:

```
...
InitialContext context = new InitialContext();
DataSource ds = (DataSource) context.lookup("env/jdbc/AcctsPayableDS");
Connection conn = ds.getConnection();
// Use the connection to access the AcctsPayableDS database
...
```

In the server, a systems administrator has created a data source and bound it in the JNDI name space to `env/jdbc/AcctsPayableDS`. Alternatively the code might have looked up the data source in a java:comp namespace, which is mapped to `env/jdbc/AcctsPayableDS` or specified an EJB field to be injected with the data source. In all cases, a data source must be bound in the namespace. Use the following code to complete this action programmatically when creating the embeddable container instance:

```
...
// Create a properties map to store embeddable container config properties
Map<String,Object> props = new HashMap<String,Object>();

// Set the JNDI name to bind this data source:
props.put("DataSource.ds1.jndiName", "env/jdbc/AcctsPayableDS");

// Set the data source class name ; this is a required property
// This example uses a Derby JDBC driver
props.put("DataSource.ds1.dataSourceClass",
   "org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource");

// Set the database name
props.put("DataSource.ds1.databaseName", "AcctsPayableTestDB");

// Create the embeddable container instance with our custom properties
EJBContainer ec = EJBContainer.createEJBContainer(props);

// Now invoke an EJB in the embeddable container...
...
```

The preceding code creates a simple data source to an Apache Derby database called AcctsPayableTestDB and binds it at `env/jdbc/AcctsPayableDS`. You can complete this same task declaratively by putting the following text into a file called `embeddable.properties` in the current working directory of the JVM. You can also put this text in any text file, and specify that text file in the com.ibm.websphere.embeddable.configFileName system property.

```
DataSource.ds1.jndiName=env/jdbc/AcctsPayableDS
DataSource.ds1.dataSourceClass=org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource
DataSource.ds1.databaseName=AcctsPayableTestDB
```

Use resource references when developing the EJB rather than looking up data sources directly.

5. Your application can use Java EE role-based security, both declarative and programmatic, to verify your EJB role-based security. You can complete the following actions to verify EJB role-based security:
   - Define a user to be used for authorization purposes.
   - Assign users to roles that are declared in your EJB.
   - Test the use of the EJBContext methods, isCallerInRole() and getCallerPrincipal(), in your EJB.

   Here is an example of how your application can use declarative and programmatic security:

```
import java.util.HashMap;
import java.util.Map;
import javax.ejb.EJBContainer;
import my.pkg.MyBeanIface; // this is the local business interface of the
                           // enterprise bean
public class EmbeddableContainerSample {

   public static void main(String[] args) throws Throwable {
      // Create a properties map to pass to the embeddable container:
      Map<String,Object> properties = new HashMap<String,Object>();
      // Specify that you want to use the WebSphere embeddable container:
      properties.put(EJBContainer.PROVIDER,
          "com.ibm.websphere.ejbcontainer.EmbeddableContainerProvider");

      // Specify that you want security checking enabled:
      properties.put("com.ibm.websphere.securityEnabled", "true");

      // Assign the users bob, fred, and mary to the role employee:
      props.put("role.employee", "bob, fred, mary");
      // Assign the user fred to the role manager:
      props.put("role.manager", "fred");
      // The user fred will be used for the runAs role manager:
      props.put("role.runAs.manager", "fred");
      // The user fred will be used for role authorization when invoking
      // methods on the EJB:
      props.put("user.invocation", "fred");
      // Create the container instance, passing it the properties map:
      EJBContainer ec = EJBContainer.createEJBContainer(properties);
      // Use the container context to look up a bean:
      MyBeanIface bean = ec.getContext().lookup(
          "java:global/MyEJBModule/MyBean!my.pkg.MyBeanIface");
      // Invoke a method on the bean instance:
      bean.doStuff();
      ...
      // Close the embeddable container:
      ec.close();
   }
}
```

The preceding code enables security and then creates two roles, `employee` and `manager`, and three users, `bob`, `mary`, and `fred`. It then specifies that the `fred` user is used when running as the `manager` role. Before creating the embeddable container, it sets the invocation user as `fred`. This means that when EJB methods are started, they are started by `fred`, which means that if those methods require the role of `employee` or `manager`, `fred` is able to access those methods.

6. Your application can specify Local Transaction Containment (LTC) behavior per bean. For an explanation of LTC, read about local transaction containment.

   Here is an example of how your application can specify the LTC resolver and unresolved action:

```
import java.util.HashMap;
import java.util.Map;
import javax.ejb.EJBContainer;
import my.pkg.MyBeanIface; // this is the local business interface
                           // of the enterprise bean

 public class EmbeddableContainerSample {

   public static void main(String[] args) throws Throwable {

      // Create a properties map to pass to the embeddable container:
      Map<String,Object> properties = new HashMap<String,Object>();
      // Specify that you want to use the WebSphere embeddable container:
      properties.put(EJBContainer.PROVIDER,
          "com.ibm.websphere.ejbcontainer.EmbeddableContainerProvider");

      // Specify that you want the LTC resolver container-at-boundary:
      properties.put("Bean.myApp1#moduleA#bean101.LocalTransaction.Resolver",
```

```
                                                    "ContainerAtBoundary");

        // Specify that you want the LTC unresolved action commit:
        properties.put("Bean.myApp1#moduleA#bean101.LocalTransaction.UnresolvedAction",
                                                    "Commit");

        // Create the container instance, passing it the properties map:
        EJBContainer ec = EJBContainer.createEJBContainer(properties);
        // Use the container context to look up a bean:
        MyBeanIface bean = ec.getContext().lookup(
            "java:global/MyEJBModule/MyBean!my.pkg.MyBeanIface");
        // Invoke a method on the bean instance:
        bean.doStuff();
        ...
        // Close the embeddable container:
        ec.close();
    }
}
```

The preceding code sets the resolver action for the specified bean to its non-default value of container-at-boundary, and causes the unresolved action to be the non-default action that commits the transaction.

If an application name is not specified when launching the embeddable container, the *<application_name>* must be omitted. However, you must use the # delimiter. For example:

```
properties.put("Bean.#moduleA#bean101.LocalTransaction.UnresolvedAction", "Commit");
```

## Embeddable EJB container

The embeddable Enterprise JavaBeans (EJB) container is a container for enterprise beans that do not require a Java Platform, Enterprise Edition (Java EE).

TheWebSphere Application Server embeddable EJB container is a container for enterprise beans that does not require a Java EE server to run. The EJB programming model and the EJB container services are now available for Java Platform, Standard Edition (Java SE) server.

The following are embeddable container usage scenarios:

- EJB unit testing: developers can test their enterprise beans without needing a full server installation of WebSphere Application Server in their development environment.
- Embedding enterprise beans in Java SE applications: developers can use enterprise beans and the functionality that is provided with an EJB container, for example, dependency injection, transactions, and security in stand-alone desktop applications.

The following advantages exist when using the WebSphere embeddable EJB container:

- No server installation is necessary for EJB development, unit testing, and Java SE-based application deployment.
- The embeddable container is a much smaller footprint, in terms of disk space and main memory, than the server-based container.
- The embeddable container starts faster than the server-based container because it initializes only EJB-related components.

Be aware of the following limitations when using the embeddable container:

- Inbound RMI/IIOP calls are not supported, which means that all EJB clients must exist within the same Java virtual machine (JVM) as the embeddable container.
- Message driven beans (MDB) are not supported.
- The embeddable container cannot be clustered for high availability per workload management. For a complete list of supported functions in the WebSphere embeddable container, see the topic, Embeddable EJB container functions.

# Running an embeddable container

Use this task to run an embeddable container. Applications running in the embeddable container start faster and require a smaller footprint than when running in the full application server. It is an ideal environment for quickly developing and testing applications that might eventually run in the application server.

## Before you begin

Before running an embeddable container, you must have the following items ready:

- A copy of the *<app_server_root>*\runtimes\com.ibm.ws.ejb.embeddableContainer_8.0.0.jar

  **Restriction:** The Enterprise JavaBeans (EJB) thin client, com.ibm.ws.ejb.thinclient_8.0.0.jar, and the EJB embeddable Java archive (JAR) file, com.ibm.ws.ejb.embeddableContainer_8.0.0.jar, cannot coexist in the same class path.
- A copy of the *<app_server_root>*\runtimes\endorsed\endorsed_apis_8.0.0.jar file, if you are using the @Resource annotation with the lookup attribute
- One or more EJB modules in JAR files or class directories
- A main class that creates the embeddable container
- A Java SE Development Kit (JDK) or a Java Runtime Environment (JRE) Version 6.0 or later

**Note:** This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using SystemOut.log , SystemErr.log, trace.log, and activity.log files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

## About this task

The key to running the embeddable container is the class path. The class path must include all the artifacts previously listed. For example, if the main class is my.pkg.MyMainClass, and it uses enterprise beans that are stored in the MyEJBModule.jar file, the following line might run the main class that launches the embeddable container. This example assumes that all JAR files and class directories are in the current working directory.

- Windows:

```
C:\test> java -cp .;com.ibm.ws.ejb.embeddableContainer_8.0.0.jar my.pkg.MyMainClass
```

- UNIX:

```
[test]$ java -cp .:com.ibm.ws.ejb.embeddableContainer_8.0.0.jar:MyEJBModule.jar my.pkg.MyMainClass
```

It is possible to run the embeddable container without specifying all the modules on the class path. This requires the code to specify a File or File array for the MODULES property, and the context class loader for the thread creating the container instance must be able to load the specified files.

If you want to specify embeddable container properties in a text file other than embeddable.properties in the current working directory, then you must specify the com.ibm.websphere.embeddable.configFileName system property; for example:

- Windows:

```
C:\test> java -Dcom.ibm.websphere.embeddable.configFileName="C:\test\my-config.properties"
 -cp .;com.ibm.ws.ejb.embeddableContainer_8.0.0.jar;MyEJBModule.jar my.pkg.MyMainClass
```

- UNIX:

```
[test]$ java -Dcom.ibm.websphere.embeddable.configFileName="/home/myusername/test/my-config.properties"
 -cp .:com.ibm.ws.ejb.embeddableContainer_8.0.0.jar:MyEJBModule.jar my.pkg.MyMainClass
```

When developing an application using JPA in the embeddable EJB container, the class path must include the JPA thin client, com.ibm.ws.jpa.thinclient_*n*.0.0.jar, where *n* is the WebSphere Application Server release; for example, 8 for V8. The JPA thin client is located in \runtimes where the root directory of the installation image is located.

- Windows:

```
C:\test> java -cp .;com.ibm.ws.ejb.embeddableContainer_8.0.0.jar;%WAS_HOME%\runtimes
  \com.ibm.ws.jpa.thinclient_8.0.0.jar;MyEJBModule.jar my.pkg.MyMainClass
```

- UNIX:

```
[test]$ java -cp .:com.ibm.ws.ejb.embeddableContainer_8.0.0.jar:${WAS_HOME}/runtimes
  /com.ibm.ws.jpa.thinclient_8.0.0.jar:MyEJBModule.jar my.pkg.MyMainClass
```

**Note:** You can specify the Java agent mechanism to complete the dynamic enhancement at run time. For example, type the following line of code at the command prompt:

- Windows:

```
C:\test> java -javaagent:%WAS_HOME%\runtimes\com.ibm.ws.jpa.thinclient_8.0.0.jar
 -cp .;com.ibm.ws.ejb.embeddableContainer_8.0.0.jar;MyEJBModule.jar my.pkg.MyMainClass
```

- UNIX:

```
[test]$ java -javaagent:${WAS_HOME}/runtimes/com.ibm.ws.jpa.thinclient_8.0.0.jar
 -cp .:com.ibm.ws.ejb.embeddableContainer_8.0.0.jar:MyEJBModule.jar my.pkg.MyMainClass
```

To enable tracing in the embeddable container, you can specify the com.ibm.ejs.ras.lite.traceSpecification system property to a trace specification value as you would specify for the server. By default, the trace is printed to standard output, but you can redirect the output by specifying the com.ibm.ejs.ras.lite.traceFileName system property. The following example shows how you can use both system properties:

- Windows:

```
C:\test> java -Dcom.ibm.ejs.ras.lite.traceSpecification=EJBContainer=all:MetaData=all
 -Dcom.ibm.ejs.ras.lite.traceFileName=trace.log
 -cp .;com.ibm.ws.ejb.embeddableContainer_8.0.0.jar;MyEJBModule.jar my.pkg.MyMainClass
```

- UNIX:

```
[test]$ java -Dcom.ibm.ejs.ras.lite.traceSpecification=EJBContainer=all:MetaData=all
 -Dcom.ibm.ejs.ras.lite.traceFileName=trace.log
 -cp .:com.ibm.ws.ejb.embeddableContainer_8.0.0.jar:MyEJBModule.jar my.pkg.MyMainClass
```

If your beans use the javax.annotation.Resource annotation with the lookup attribute, you must also use the Java Endorsed Standards Override Mechanism to override the javax.annotation.Resource API that is available in the JDK on your system. Copy the *app_server_root*\runtimes\endorsed\endorsed_apis_8.0.0.jar file into a target directory of your choice. Use the java.endorsed.dirs property on the Java command to specify your directory that contains the copied JAR file. The following example shows how you can specify the java.endorsed.dirs property:

- Windows:

```
C:\test> java -Djava.endorsed.dirs="myTargetDirectory"
 -cp .;com.ibm.ws.ejb.embeddableContainer_8.0.0.jar;MyEJBModule.jar my.pkg.MyMainClass
```

- UNIX:

```
[test]$ java -Djava.endorsed.dirs="myTargetDirectory"
 -cp .:com.ibm.ws.ejb.embeddableContainer_8.0.0.jar:MyEJBModule.jar my.pkg.MyMainClass
```

## Embeddable EJB container functions

According to the Enterprise JavaBeans (EJB) 3.1 specification, all embeddable EJB containers that vendors use must at least implement the EJB Lite subset of EJB functionality. The application server also contains additional features that support the EJB Lite subset. Refer to the EJB 3.1 specification for more information.

**Attention:** Container-managed authentication is only supported with the default container-managed authentication alias. For data sources, the user ID and password fields of the Java EE data source resource, or the embeddable properties data source, are used as the default container-managed authentication alias.

### EJB Lite includes:

- Local (and no-interface) session beans with synchronous methods only, which include stateless, stateful, and singleton bean types.
- Declarative and programmatic security.
- Interceptors.
- Support for annotations or XML deployment descriptors, the `ejb-jar.xml` file.
- Java Persistence Architecture (JPA) 2.0.

### The WebSphere embeddable container provides the following additional functions:

- Java Database Connectivity (JDBC) data source configuration, usage, and dependency injection.
- Bean validation

  To use bean validation with the embeddable EJB container, the javax.validation classes must exist in the class path. That can be done in one of two ways:
  - Include the JPA thin client that is located in the directory `${WAS_INSTALL_ROOT}\runtimes\com.ibm.ws.jpa.thinclient_8.0.0.jar` in the class path. See the topic, Running an embeddable container, and the information about JPA, for more information.
  - Include a third party bean validation provider Java archive (JAR) file in the class path of the embeddable EJB container run time.

## Embeddable EJB container configuration properties

Use the following configuration properties for the embeddable Enterprise JavaBeans (EJB) container.

*Table 76. Embeddable EJB container configuration properties. Use the properties for embeddable EJB container configurations.*

| Property | Type | Default value | Description |
|---|---|---|---|
| com.ibm.websphere.ejbcontainer.cacheSize | java.lang.Long | 2 053 | Number of buckets for the EJB cache. |
| com.ibm.websphere.ejbcontainer.cacheSweepInterval | java.lang.Long | 3 000 | Time between sweeps of the EJB cache to determine whether to remove entries. |
| com.ibm.websphere.ejbcontainer.inactivePoolCleanupInterval | java.lang.Long | 30 000 | Time in milliseconds for the clean up thread to wait before cleaning the inactive pool. |
| com.ibm.websphere.ejbcontainer.passivationDir | java.lang.String | <TempDir> | Directory to passivate stateful beans in. The user must have read and write access to the specified directory. |
| com.ibm.websphere.embeddable.configFileName | java.lang.String | <CurrentWorkingDirectory> /embeddable.properties | File name of a properties file containing embeddable EJB container properties. When this file is processed, each property is passed to the newly created EJB container as if they were passed in programmatically. Any properties in the configuration file are overridden by properties passed in programmatically.<br><br>**Attention:** It is also possible to specify this property as a system property on the command line. |

The following table contains configuration properties for data sources. Each property is specific to an individual data source which allows you to configure multiple data sources with different settings. Replace *<data_source_id>* with a unique term that identifies the data source to be configured. Some properties are listed as required for each data source.

*Table 77. Embeddable EJB container configuration properties for Java Database Connectivity (JDBC) data sources. Use the embeddable EJB container configuration properties for JDBC data sources.*

| Property | Type | Description |
|---|---|---|
| DataSource.<*data_source_id*>.name | java.lang.String | **Required.** The Java Naming and Directory Interface (JNDI) string that the container uses to bind this data source in the global namespace of the embeddable container. This string must match the JNDI lookup string used in the application. |
| DataSource<*data_source_id*>.className | java.lang.String | **Required.** The Java class name of the data source class. For testing, Apache Derby can be used if *app_server_root*/derby/lib/derby.jar is on the Java Virtual Machine classpath. The supported data source classes for Apache Derby are org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource and org.apache.derby.jdbc.EmbeddedXADataSource. |
| DataSource.<*data_source_id*>.connectionSharing | java.lang.String | The policy for sharing connections. Valid values are MatchOriginalRequest (default), MatchCurrentState or None. MatchOriginalRequest means that a connection request might share if it matches the originally requested settings of an existing connection. MatchCurrentState means that a connection request might share if it matches the current settings of an existing connection. None means that multiple connection requests do not share the same connection. |
| DataSource.<*data_source_id*>.databaseName | java.lang.String | The name of the database that this data source connects to. |
| DataSource.<*data_source_id*>.isolationLevel | java.lang.Integer | The transaction isolation level for connections from this data source. If unspecified, the default is provided by the JDBC driver or database.<br><br>Valid values are 1 for Read Uncommitted, 2 for Read Committed, 4 for Repeatable Read, or 8 for Serializable. These values come from constants in java.sql.Connection and are subject to change. |
| DataSource.<*data_source_id*>.maxIdleTime | java.lang.Integer | The number of seconds after which the connection pool can close an unused connection. |
| DataSource.<*data_source_id*>.maxPoolSize | java.lang.Integer | The maximum number of connections that are created for this data source. After this number of simultaneous connections are in use, future requests to get a connection from this data source are blocked until one or more of the in-use connections have been returned to the pool. |
| DataSource.<*data_source_id*>.maxStatements | java.lang.Integer | The maximum number of statements cached by the connection pool. This value is divided by the *maxPoolSize* value to determine the number of statements that can be cached for each connection in the pool. A value of 0 disables statement caching. |
| DataSource.<*data_source_id*>.minPoolSize | java.lang.Integer | The minimum number of connections to keep in the connection pool for this data source. If no connections are in use, the connection pool might discard connections until the pool size reaches this setting. This setting must be non-negative. |
| DataSource.<*data_source_id*>.password | java.lang.String | Password for the given *user* when accessing the database. Like the preceding property, this property can be omitted if the database does not have security enabled or if the user name and password are provided programmatically when creating the connection. |
| DataSource.<*data_source_id*>.transactional | java.lang.Boolean | Whether this data source must be enlisted in Java Transaction API (JTA) transactions. Valid values are true (default) or false. |
| DataSource.<*data_source_id*>.user | java.lang.String | User name for accessing the database. This property can be omitted if the database does not have security enabled or if the user name and password are provided programmatically when creating the connection. |
| DataSource.<*data_source_id*>.<*vendor_property_name_or_connection_pool_property_name*> | java.lang.String | You can also configure other properties:<br>• Vendor-specific data source properties, such as *serverName* and *portNumber*<br>• WebSphere Application Server data source properties, such as *userDefinedErrorMap* and *validateNewConnection*<br>• WebSphere Application Server connection pooling properties, such as *connectionTimeout* and *purgePolicy* |
| DataSource.<*data_source_id*>.xaRecoveryPassword | java.lang.String | Applies to XA data sources only. Password for XA recovery. |
| DataSource.<*data_source_id*>.xaRecoveryUser | java.lang.String | Applies to XA data sources only. Some databases require a user with special privileges for XA recovery. Use this property to specify a user name for XA recovery instead of the default user. |

## Use the following properties to configure two data sources.

```
DataSource.ds1.name=env/jdbc/ds1
DataSource.ds1.className=org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource
DataSource.ds1.transactional=true
DataSource.ds1.createDatabase=create
DataSource.ds1.databaseName=jtest1
DataSource.ds1.user=dbuser1
DataSource.ds1.password=dbpwd1
DataSource.ds1.maxPoolSize=5

DataSource.ds2.name=env/jdbc/ds2
DataSource.ds2.className=org.apache.derby.jdbc.EmbeddedXADataSource
DataSource.ds2.connectionSharing=MatchOriginalRequest
DataSource.ds2.createDatabase=create
DataSource.ds2.databaseName=jtest2
DataSource.ds2.user=dbuser2
DataSource.ds2.password=dbpwd2
DataSource.ds2.maxPoolSize=10
DataSource.ds2.minPoolSize=1
```

The first data source, ds1, is bound in the namespace under the name, env/jdbc/ds1, and provides connection pooling for up to five connections to an Apache Derby database. The second data source, ds2, is bound in the namespace at env/jdbc/ds2 and provides XA-compliant connection pooling to an Apache Derby database.

The following table contains configuration properties for EJB bindings. For each property, replace *<app>* with the application name, *<module>* with the module name, *<ejb>* with the name of the EJB, *<interceptor>* with the name of an interceptor class, and *<ref>* with the name of the resource reference, EJB reference, or environment entry.

If an application name is not specified when launching the embeddable container, the *<app>* must be omitted. However, you must use the # delimiter. For example, `Bean.#<module>#<bean>.ResourceRef.BindingName.`

*Table 78. Embeddable EJB container configuration properties for reference bindings. Use the embeddable EJB container configuration properties for reference bindings.*

| Property | Type | Description |
|---|---|---|
| Bean.*<app>*#*<module>*#*<ejb>*.ResourceRef.BindingName.*<ref>* or Interceptor.*<app>*#*<module>*#*<interceptor>*.ResourceRef.BindingName.*<ref>* | java.lang.String | The JNDI string to use when the resource reference is looked up or injected. This must be the JNDI name of a configured data source. |
| Bean.*<app>*#*<module>*#*<ejb>*.EJBRef.BindingName.*<ref-name>* or Interceptor.*<app>*#*<module>*#*<interceptor>*.EJBRef.BindingName.*<ref>* | java.lang.String | The JNDI string to use when the EJB reference is looked up or injected. This must be the java:global, java:app, or java:module JNDI string of an EJB in the embeddable EJB container. |
| Bean.*<app>*#*<module>*#*<ejb>*.EnvEntry.Value.*<ref-name>* or Interceptor.*<app>*#*<module>*#*<interceptor>*.EnvEntry.Value.*<ref>* | java.lang.String | The value to use when the environment entry is looked up or injected. This property overrides the value specified by env-entry-value. The value must be valid for the type of the environment entry. |
| Bean.*<app>*#*<module>*#*<ejb>*.EnvEntry.BindingName.*<ref>* or Interceptor.*<app>*#*<module>*#*<interceptor>*.EnvEntry.BindingName.*<ref>* | java.lang.String | The JNDI string to use when the environment entry is looked up or injected. This must be the java:global, java:app, or java:module JNDI string of another environment entry in the same embeddable EJB container. |
| Bean.*<app>*#*<module>*#*<ejb>*.DataSource.BindingName.*<ref>* or Interceptor.*<app>*#*<module>*#*<interceptor>*.DataSource.BindingName.*<ref>* | java.lang.String | The JNDI string to use when the data source is looked up or injected. This must either be the JNDI name of a configured data source or the java:global, java:app, or java:module JNDI string of another data source in the same embeddable EJB container. Application developers should use resource references rather than looking up a data source directly. If an application is coded to look up data sources directly, you can use this property to override data source definitions included in the application. See the information center for more information about data source definitions. |

Use the following properties to configure the bindings for an EJB with two references and an interceptor with an environment entry:

```
Bean.#TestModule#TestBean.ResourceRef.BindingName.jdbc/dsref=env/jdbc/ds1
Bean.#TestModule#TestBean.EJBRef.BindingName.ejb/Cart=java:global/CartModule/CartBean
Interceptor.#TestModule#com.ibm.example.LoggerInterceptor.EnvEntry.Value.logFile=/tmp/output.log
```

**Note:** Use the following properties to override java:module/env/TestDataSource that is defined in an EJB named TestBean in an EJB module named TestModule, with jdbc/MyDataSource that is defined in embeddable properties:

```
Bean.#TestModule#TestBean.DataSource.BindingName.java\:module/env/TestDataSource=jdbc/MyDataSource
```

*Table 79. Embeddable EJB container configuration properties for security. Use the embeddable EJB container configuration properties for security.*

| Property | Type | Default value | Description |
|---|---|---|---|
| com.ibm.websphere.securityEnabled | java.lang.String | false | Determines whether security roles are checked. Valid values are false (default) or true. If true, then security roles are checked; if false, then security roles are not checked. |

*Table 79. Embeddable EJB container configuration properties for security (continued). Use the embeddable EJB container configuration properties for security.*

| Property | Type | Default value | Description |
|---|---|---|---|
| role.<role_name> | java.lang.String | | Maps an EJB role to one or more users. The <role_name> is a role assigned to a method, either through the annotation @RolesAllowed or through the deployment descriptor <method-permission>. The value is a string of comma-delimited user names, for example "bob, mary, john". The users in the list are allowed to run methods that require the <role_name>. |
| role.runAs.<role_name> | java.lang.String | | Maps one EJB role to one user. The <role_name> is a role assigned to a bean or method, either through the annotation @RunAs or through the deployment descriptor <run-as>. The value is a single user name. The user name is used for any authorization that is required by the bean while it is running. |
| user.invocation | java.lang.String | | Defines the user that might be used for authorization when the bean is invoked. The value is a single user name. The container checks that this user is mapped to a role that is allowed to run any executed method. |

The following table contains configuration properties for the Local Transaction Containment (LTC) behavior. For an explanation of LTC, read about local transaction containment. Each property is specific to a bean.

If an application name is not specified when launching the embeddable container, the *<application_name>* must be omitted. However, you must use the # delimiter. For example, `Bean.#<module_name>#<bean_name>LocalTransaction.Resolver`.

*Table 80. Embeddable EJB container configuration properties for Local Transaction Containment. Use the embeddable EJB container configuration properties for Local Transaction Containment.*

| Property | Type | Default value | Description |
|---|---|---|---|
| Bean.*<application_name>*#*<module_name>*#*<bean_name>*.LocalTransaction.Resolver | java.lang.String | Application | Determines the entity that is responsible for local transaction resolution. Valid values are Application (default) or ContainerAtBoundary. |
| Bean.*<application_name>*#*<module_name>*#*<bean_name>*.LocalTransaction.UnresolvedAction | java.lang.String | Rollback | Determines the action taken for unresolved local transactions. Valid values are Rollback (default) or Commit. |

The following table contains configuration properties for XA behavior.

*Table 81. Embeddable EJB configuration properties for XA. Use the embeddable EJB configuration properties for XA.*

| Property | Type | Default value | Description |
|---|---|---|---|
| com.ibm.websphere.tx.acceptHeuristicHazard | java.lang.String | false | Specifies whether last participant support is enabled for all modules. The default value is `false`. |
| com.ibm.websphere.tx.auditRecovery | java.lang.String | true | Specifies whether recovery processing outputs audit messages, which indicate XA resource and XID processing during recovery. When no audit recovery is specified, only a single recovery message is output along with the number of transactions that are recovered, unless an error occurs. |
| com.ibm.websphere.tx.clientInactivityTimeout | java.lang.String | 0 | Specifies the maximum duration, in seconds, between transactional requests. Any period of client inactivity that exceeds this timeout value results in the transaction being rolled back. The default setting, `0`, means that no limit exists. |
| com.ibm.websphere.tx.enableLoggingForHeuristicReporting | java.lang.String | false | This property enables logging for heuristic reporting. If last participant support is enabled, reporting of heuristic outcomes that might occur when the server becomes unavailable requires additional information to be written to the transaction log. If enabled, one additional log write is completed for any transaction that involves both one-phase and two-phase commit resources. No additional records are written for transactions that do not involve a one-phase commit resource. |
| com.ibm.websphere.tx.heuristicRetryLimit | java.lang.String | 0 | Specifies the number of times that the transaction service retries a completion signal such as commit or rollback. Retries occur after a transient exception from a resource manager. The default value, `0`, indicates no limit to the number of retries. |

*Table 81. Embeddable EJB configuration properties for XA (continued). Use the embeddable EJB configuration properties for XA.*

| Property | Type | Default value | Description |
|---|---|---|---|
| com.ibm.websphere.tx.heuristicRetryWait | java.lang.String | 0 | Specifies the number of seconds that the transaction service waits before retrying a completion signal, such as commit or rollback, after a transient exception from a resource manager. |
| com.ibm.websphere.tx.LPSHeuristicCompletion | java.lang.String | ROLLBACK<br><br>(case insensitive) | The heuristic completion action to be taken by the transaction service in a transaction with last participant support when the outcome of the one-phase commit resource is unknown. The values ROLLBACK or COMMIT cause the two-phase commit resources to be completed accordingly. The setting, MANUAL, means that the transaction service takes no action and leave the two-phase commit resources in-doubt. The default value is ROLLBACK. |
| com.ibm.websphere.tx.maximumTransactionTimeout | java.lang.String | 300 | Specifies, in seconds, the upper limit of the transaction timeout value. This timeout value constrains the upper limit of all other transaction timeout values. |
| com.ibm.websphere.tx.totalTranLifetimeTimeout | java.lang.String | 120 | Specifies the default maximum time, in seconds, allowed for a transaction before the transaction service initiates timeout. Any transaction that does not begin completion processing before this timeout occurs is rolled back. |
| com.ibm.websphere.tx.tranLogDirectory | java.lang.String | profiles*server name*\tranlog | Specifies the name of a directory for this server where the transaction service stores log files for recovery. |
| com.ibm.websphere.tx.tranLogSize | java.lang.String | 1024 | Specifies the size, in kilobytes, of transaction log files. The minimum file size is 64KB. The default value sets the file size to 1MB. |

# Configuring EJB 3.1 session bean methods to be asynchronous

Use this task to configure Enterprise JavaBeans (EJB) 3.1 session bean methods to run asynchronously. You can make some or all of your bean methods asynchronous.

## Before you begin

**Attention:** In EJB 3.1 modules, you can set one or more session bean methods to be asynchronous, broadening parallel processing in your application.

- If you are not already familiar with EJB 3.1 asynchronous methods, read about EJB 3.1 asynchronous methods, client programming model for EJB asynchronous methods, bean implementation programming model for EJB asynchronous methods, and EJB container work manager for asynchronous methods. The topics provide an overview of EJB 3.1 asynchronous methods, describe the client and bean implementation programming models, and discuss the work manager that the EJB container uses to dispatch asynchronous methods.
- Develop a new EJB 3.1 session bean for your application, or change an existing session bean so that it conforms to the EJB 3.1 programming model requirements for asynchronous methods. For general information, see information about developing enterprise beans.

## About this task

After you have developed a session bean, complete the following steps to make one or more of the bean methods asynchronous.

## Procedure

1. Specify one or more methods of the bean implementation class as asynchronous. This can be accomplished by adding @Asynchronous annotations in your bean source code, by adding <async-method> stanzas in your module deployment descriptor, or by adding a combination of both annotations and deployment descriptor stanzas. You can apply the @Asynchronous annotation or its superclasses only, to your bean implementation class. It cannot be applied to interface classes. Also, when the annotation is applied at the class level, all methods of that class are asynchronous. Likewise, all methods of a bean can be configured as asynchronous by applying "*" as the <method-name> in your deployment descriptor.

   See the following examples of applying the @Asynchronous annotation:

- Apply the @Asynchronous annotation to one method of a bean with a no-interface view. In this example, the m1 method is synchronous and the m2 method is asynchronous.

```
@Stateless @LocalBean
public class MyLocalBean {

   public void m1() {

      // method code
   }

   @Asynchronous
   public Future<String> m2() {

      // method code

      return new javax.ejb.AsyncResult("Hello, Async World!");
   }
}
```

  **Important:** The javax.ejb.AsyncResult<V> object is a convenience implementation of the Future<V> interface. See the API documentation for more details.

- Apply the @Asynchronous annotation to the class level of a bean class. In this example, both the m1 method and the m2 method are asynchronous on this no-interface view bean.

```
@Stateless @LocalBean @Asynchronouspublic class MyLocalBean {

   public void m1() {

      // method code
   }

   public Future<String> m2() {

      // method code

      return new javax.ejb.AsyncResult("Hello, Async World!");
   }

}
```

- Apply the @Asynchronous annotation to one method of a bean implementation class. In this example, the m1 method is synchronous and the m2 method is asynchronous. This example also demonstrates how the return types might differ between the business interface and the implementation class.

```
public interface MyIntf {

   public void m1();

   public Future<Integer> m2();

}
@Stateless @Local(MyIntf.class)
public class MyBean {

   public void m1() {

      // method code
   }

   @Asynchronous
   public Integer m2() {

      // method code
```

```
      return new Integer(3);
   }
}
```

- Apply the @Asynchronous annotation to the class level of a bean implementation class. In this example, both the m1 method and the m2 method are asynchronous.

```
@Stateless @Local(MyIntf.class) @Asynchronous
public class MyBean {

   public void m1() {

      // method code
   }

   public Integer m2() {

      // method code

      return new Integer(8);
   }
}
```

See the following examples of modifying the EJB module deployment descriptor, `ejb-jar.xml`:

- In this example all business methods of the FullAyncBean bean implementation class and its superclasses are configured as asynchronous with the wildcard (*) method-name element.

```
<session>
   <display-name>FullAsyncEJB</display-name>
   <ejb-name>FullAsyncBean</ejb-name>
   <business-local>com.ibm.sample.async.ejb.FullAsyncIntf</business-local>
   <ejb-class>com.ibm.sample.async.ejb.FullAsyncBean</ejb-class>
   <session-type>Stateless</session-type>   <async-method>
      <method-name>*</method-name>
   </async-method>
</session>
```

- In this example only the specified methods and signatures -- all methods named m1 and the method m2 with a single String parameter -- are configured as asynchronous on the PartiallyAsyncBean bean implementation class.

```
<session>
   <display-name>PartiallyAsyncEJB</display-name>
   <ejb-name>PartiallyAsyncEJB</ejb-name>
   <business-local>com.ibm.sample.async.ejb.PartiallyAsyncIntf</business-local>
   <ejb-class>com.ibm.sample.async.ejb.PartiallyAsyncBean</ejb-class>
   <session-type>Stateless</session-type>   <async-method>
      <method-name>m1</method-name>
   </async-method>
   <async-method>
      <method-name>m2</method-name>
      <method-params>
         <method-param>java.lang.String</method-param>
      </method-params>
   </async-method>
</session>
```

See the following examples of applying a combination of the @Asynchronous annotation in the bean source code and modifying the EJB module deployment descriptor, `ejb-jar.xml`:

- In this example the @Asynchronous annotation configures method m2 to be asynchronous, and the deployment descriptor configures method m1 to also be an asynchronous method.

```
@Stateless @LocalBean
public class MyLocalBean {

   public void m1() {

      // method code
   }
```

```
   @Asynchronous
   public Future<String> m2() {

      // method code

      return new javax.ejb.AsyncResult("Hello, Async World!");
   }
}

<session>
   <display-name>MyLocalEJB</display-name>
   <ejb-name>MyLocalEJB</ejb-name>
   <local-bean/>
   <ejb-class>com.ibm.sample.async.ejb.MyLocalBean</ejb-class>
   <session-type>Stateless</session-type>   <async-method>
      <method-name>m1</method-name>
   </async-method>
</session>
```

- In this example the @Asynchronous annotation for method m2 is ignored because the deployment descriptor header contains the metadata-complete="true" flag. This flag causes configuration information to only be taken from the deployment descriptor elements. The result is that only method m1 of the MyLocalBean implementation is configured to be asynchronous.

```
@Stateless @LocalBean
public class MyLocalBean {

   public void m1() {

      // method code
   }

   @Asynchronous
   public Future<String> m2() {

      // method code

      return new javax.ejb.AsyncResult("Hello, Async World!");
   }
}

<ejb-jar id="ejb-jar_ID" ...
metadata-complete="true" version="3.1">
...
<session>
   <display-name>MyLocalEJB</display-name>
   <ejb-name>MyLocalEJB</ejb-name>
   <local-bean/>
   <ejb-class>com.ibm.sample.async.ejb.MyLocalBean</ejb-class>
   <session-type>Stateless</session-type>   <async-method>
      <method-name>m1</method-name>
   </async-method>
</session>
...
</ejb-jar>
```

2. Verify that the transaction attribute applied to any asynchronous method is either REQUIRED, REQUIRES_NEW, or NOT_SUPPORTED. These transaction attribute types are the only transaction attribute types supported on asynchronous methods. You can complete this action by either applying @TransactionAttribute annotations in the bean source code, by adding <container-transaction> stanzas in the `ejb-jar.xml` file, or by adding a combination of both annotations and <container-transaction> stanzas in the deployment descriptor.

   See the following example of setting the transaction attribute of an asynchronous method using annotations:

```
@Singleton @LocalBean
public class FullAsyncBean {
 @Asynchronous
 @TransactionAttribute(REQUIRED) // the default; specified for illustration
 public void m1() {
  // ...
 }

 @Asynchronous
 @TransactionAttribute(NOT_SUPPORTED)
 public void m2() {
  // ...
 }

 @Asynchronous
 @TransactionAttribute(REQUIRES_NEW)
 public void m3() {
  // ...
 }

 // ...
}
```

See the following example of setting the transaction attribute of an asynchronous method using the XML deployment descriptor:

```
  <assembly-descriptor>
    <container-transaction>
      <method>
        <ejb-name>FullAsyncBean</ejb-name>
        <method-name>m1</method-name>
      </method>
      <trans-attribute>Required</trans-attribute>
    </container-transaction>

    <container-transaction>
      <method>
        <ejb-name>FullAsyncBean</ejb-name>
        <method-name>m2</method-name>
      </method>
      <trans-attribute>NotSupported</trans-attribute>
    </container-transaction>

    <container-transaction>
      <method>
        <ejb-name>FullAsyncBean</ejb-name>
        <method-name>m3</method-name>
      </method>
      <trans-attribute>RequiresNew</trans-attribute>
    </container-transaction>
  </assembly-descriptor>
```

See the following example of using a combination of both annotations and the XML deployment descriptor to configure the transaction attributes of a bean. In this example the deployment descriptor stanzas for method m3 override the class level annotation. The result is that method m3 is configured as REQUIRES_NEW, while methods m1 and m2 are configured as REQUIRED:

```
@Singleton @LocalBean
@Asynchronous
@TransactionAttribute(REQUIRED) // the default; specified for illustration
public class FullAsyncBean {

 public void m1() {
  // ...
 }

 public void m2() {
  // ...
 }
```

```
 public void m3() {
  // ...
 }

 // ...
}

<assembly-descriptor>

   <container-transaction>
      <method>
         <ejb-name>FullAsyncBean</ejb-name>
         <method-name>m3</method-name>
      </method>
      <trans-attribute>RequiresNew</trans-attribute>
   </container-transaction>

</assembly-descriptor>
```

### What to do next

Continue to develop additional components for your application, or if you have finished all components required by your application, assemble and deploy your application. See information about assembling EJB modules and deploying EJB modules.

When you run your application, if it fails when it first attempts to use a session bean that has an asynchronous method, a configuration error might exist. Check the system log file for configuration error messages.

Analyze the trace data or forward it to the appropriate organization for analysis. EJB asynchronous method scheduling and invocation are traced in the EJB container trace. For instructions on enabling this trace see the information about enabling trace on a running server. To analyze trace data, see information about trace output.

## Configuring remote asynchronous EJB method results

Use this task to set the maximum number of unclaimed results for a remote asynchronous Enterprise JavaBeans (EJB) method call.

### About this task

When a remote asynchronous EJB method is called, the server must save the results of the remote method invocation until the client claims the results using the Future.get method. If the client never claims the result, unclaimed results can accumulate in the server and use memory. To avoid using too much memory, the server limits the number of unclaimed results to 1000 by default. If the number of unclaimed results approaches or exceeds the limit, the server issues the `CNTR0328W` warning.

### Procedure

1. Optional: Open the administrative console.
2. Select **Servers**.
3. Select **Server Types**.
4. Select **WebSphere application servers**.
5. Select the server that you want to configure.
6. From Server Infrastructure, select **Java and Process Management Process definition.**
7. From Additional Properties, select **Java Virtual Machine** .
8. In the Additional Properties area, select **Custom Properties** .

9. On the Application servers page, click **New** to specify an arbitrary name and value pair for your server.
10. In the **Name** entry field, type: `com.ibm.websphere.ejbcontainer.maxUnclaimedAsyncResults`
11. In the **Value** entry field, enter the wanted maximum number of unclaimed results. The special value `0` is interpreted as unlimited. The default value is `1000`.
12. Click **OK**.
13. Save the configuration.
14. Restart the server.

### Results

The maximum number of unclaimed asynchronous EJB method results for all EJBs is set.

## Configuring EJB asynchronous methods using scripting

Use wsadmin scripting to configure Enterprise JavaBeans (EJB) asynchronous methods.

### Before you begin

You have working knowledge of Jacl or Jython and wsadmin scripting.

### About this task

The behavior for EJB asynchronous methods is configured using the EJBAsync configuration object in the `server.xml` file. If you are using EJB asynchronous methods, then you might must update the EJBAsync configuration object to obtain the best settings for your environment. The EJBAsync configuration object exists at the server level. This means that each server in a multiple-server environment has its own EJBAsync configuration object and must be configured individually.

### Procedure

1. Launch the wsadmin scripting tool using the Jython scripting language.
2. Determine the attributes on the EJBAsync configuration object that must be updated. You can update the following attributes on the EJBAsync configuration object:

*Table 82. Attributes on EJBAsync configuration object. This table describes the attributes on the EJBAsync configuration object.*

| Attribute | Description |
|---|---|
| maxThreads | Specifies the maximum number of threads that are used in the execution of asynchronous EJB methods.<br><br>The default value is `5`. |
| workReqQSize | Specifies the size of the work request queue. The work request queue is a buffer that holds requested asynchronous methods until a thread is available to run them on.<br><br>The sum of the maxThreads and the workReqQSize attributes is the total number of allowable in progress method requests.<br><br>For example, if the maxThreads is set to `5` threads, and the workReqQSize is set to `50`, then the total number of allowable in-progress method requests is `55`.<br><br>The default value is 0, indicating that the queue size is managed by the runtime environment. The run time currently uses the larger of 20 and maxThreads. |
| workReqQFullAction | Specifies the action taken when the thread pool is exhausted, and work request queue is full.<br><br>If set to 1, an exception occurs instead of waiting for a thread, or a place in the queue, to become available.<br><br>If set to 0, the thread that is requesting the asynchronous method execution waits until a thread, or place in the queue, becomes available.<br><br>The default value is 0. |

*Table 82. Attributes on EJBAsync configuration object (continued). This table describes the attributes on the EJBAsync configuration object.*

| Attribute | Description |
|---|---|
| customWorkManagerJNDIName | Specifies the Java Naming and Directory Interface (JNDI) name used to look up the custom defined work manager in the namespace.<br><br>The default value is null. |
| useCustomDefinedWM | Specifies whether a custom-defined work manager instance is used, or the default internal work manager instance.<br><br>When the useCustomDefinedWM attribute is set to true, this means that a custom work manager instance is used. In this case, the customWorkManagerJNDIName attribute must be set, and all other attributes are ignored.<br><br>When the useCustomDefinedWM attribute is set to `false`, the default, internal work manager instance is used. In this case, the customWorkManagerJNDIName attribute is ignored, and all other attributes are used to help configure the default work manager instance.<br><br>The default value is false. |
| futureTimeout | Specifies the amount of time, in seconds, that the server-side future object, which is created as a result of running a fire-and-return asynchronous method, is available. The server-side future object is not valid after you call the get() method, and a value is returned to the remote client. To avoid memory leaks, you must call the get() method on the future object, or specify a positive and non-zero future duration value.<br><br>A future duration value of zero indicates that the future object never times out.<br><br>The default value is `86400`, which means that the future object expires and gets cleaned up by the application server after 24 hours and is no longer available.<br><br>A org.omg.CORBA.OBJECT_NOT_EXIST exception is thrown when a call to the get() method is made after the future object expires.<br>**Note:** This value is only applicable for clients that call the enterprise bean using a remote business interface; the value is not used for local business interface or no-interface views. When the asynchronous work has completed, the server sets an alarm for the duration specified to the server-side future object. When the alarm is activated, the server releases all the resources associated with the future object, making it unavailable to the client. If the client calls the get() method on the future object before the duration amount of time, the alarm is canceled and all the resources associated with the future object are released.<br>**Note:** This attribute might affect the number of future objects on the server. Use the AsynchFutureObjectCount PMI statistic to determine the count of open FutureObjects on the server, which can help you determine whether applications are accumulating future objects without calling the get() method on those objects. See the topic, Enterprise bean counters, for more information. |

3. Obtain a reference to the correct EJBAsync configuration object and store it in a variable.

   Using Jacl:

   ```
   set async [$AdminConfig list EJBAsync]
   ```

   Using Jython:

   ```
   async = AdminConfig.list('EJBAsync')
   ```

   If you have a multiple-server environment, then multiple EJBAsync configuration objects are returned. Programmatically loop over the list and select the EJBAsync configuration object that corresponds to the server you must update.

   In a multiple-server environment, as an alternative to programmatically looping over the list of EJBAsync objects, you can manually select the correct EJBAsync object and copy and paste it into your variable.

   For example, the output of the `AdminConfig list` command is:

   ```
   (cells/myNode04Cell/nodes/myCellManager01/servers/dmgr|server.xml#EJBAsync_1)(cells/
   myNode04Cell/nodes/myNode04/servers/server1|server.xml#EJBAsync_1247498700906)
   ```

   You can copy and paste the reference for the needed EJBAsync object into your variable.

   Using Jacl:

   ```
   set async "(cells/myNode04Cell/nodes/myNode04/servers/server1|server.xml#EJBAsync_1247498700906)"
   ```

   Using Jython:

   ```
   async = "(cells/myNode04Cell/nodes/myNode04/servers/server1|server.xml#EJBAsync_1247498700906)"
   ```

4. Update attributes on the EJBAsync configuration object.

Update attributes on the EJBAsync configuration object using the AdminConfig modify command. As input to the command, specify the EJBAsync reference that you obtained in the previous step, and a list of attributeName and attributeValue combinations.

To set a max thread count of `10` threads, a queue size of `15`, and a futureTimeout of `3600` seconds:

Using Jacl:

```
set update "{maxThreads 10} {workReqQSize 15} {futureTimeout 3600}"
$AdminConfig modify $async $update
```

Using Jython:

```
AdminConfig.modify(async, '[ [maxThreads "10"] [workReqQSize "15"] [futureTimeout "3600"] ]')
```

5. Save the configuration changes.

   Using Jython:

   ```
   AdminConfig.save()
   ```

   Using Jacl:

   ```
   $AdminConfig save
   ```

### Results

As a result of your updates, the EJBAsync configuration object now reflects the attribute values that you specified. Restart your server so that the changes are updated on the server.

## EJB 3.1 asynchronous methods

The Enterprise JavaBeans™ (EJB) 3.1 specification includes functionality that application developers can use to configure EJB asynchronous methods, which are run on a separate thread from the caller thread.

This mechanism decouples the client invocation request from the actual method execution. The client thread can continue doing other work while the EJB method is run on a separate thread, as directed by the EJB container.

Later, the client might want to examine the result of the asynchronous method execution, which is sometimes referred to as *fire and return*. In this case, the EJB container returns to the client an object that implements the java.util.concurrent.Future<V> interface. The client can use this object to check status, results, or exceptions from the asynchronous method invocation. Alternatively, asynchronous methods might not return any results, which is sometimes referred to as *fire and forget.*

For more details, see information about how to use EJB asynchronous methods in your application.

Here are some example usage scenarios for EJB asynchronous methods:

- An application has multiple, independent, pieces of work that all must be executed to produce a final result. For example, suppose that a travel reservation consists of three parts:
  1. Making a plane reservation.
  2. Making a rental car reservation.
  3. Making a hotel reservation.

  In this example, a client can use EJB asynchronous methods to process the reservation requests in parallel. After all three reservation methods run, the client aggregates the results into a complete travel reservation.
- An application has multiple, independent, pieces of work that it must run, and the application is not concerned about the results of this work. For example, suppose that a retailer has four branch stores, and the home office wants to print a sales report from each store when the business day ends. The application developer can use EJB asynchronous methods as a batch processing mechanism. Multiple EJB method calls can be used to send a batch of get sales report requests, one to each branch store.

  In this example, presumably the application does not need to check for results from these method calls. Perhaps this is handled by the home office employee who picks up the sales reports from a printer the

next morning. Suppose that one of the branch stores failed to provide the requested report. The person collecting the reports can decide if that was expected, for example, the branch store was closed for renovations, or if the get sales report request must be reissued to that branch store.

# Developing client code that calls EJB asynchronous methods

You can use the sample code within this topic to develop client code that calls EJB asynchronous methods.

## Before you begin

This task assumes that the following interface and bean implementation classes exist:

```
public interface AcmeRemoteInterface {
   void fireAndForgetMethod ();
   Future<Integer> methodWithResults() throws AcmeException1, AcmeException2;
}
```

```
@Stateless
@Remote(AcmeRemoteInterface.class)
@Asynchronous
public class AcmeAsyncBean {
   public void fireAndForgetMethod () {
      // do non-critical work
   }

   public Integer methodWithResults() {
      Integer result;
      // do work, and then return results
      return result;
   }
}
```

## About this task

## Procedure

- Create client code that calls an asynchronous method where no results are returned, sometimes called a *fire and forget* method. This type of asynchronous method cannot result in application exceptions. However, system exceptions can occur that must be resolved.

  ```
  @EJB AcmeRemoteInterface myAsyncBean;

  try {
     myAsyncBean.fireAndForgetMethod();
  } catch (EJBException ejbex) {
     // Asynchronous method never dispatched, handle system error
  }
  ```

- Create client code that calls an asynchronous method where results are returned. The get call on the returned Future<V> object blocks the client thread until results are available. System exceptions can occur either if the asynchronous method cannot be dispatched, or during execution of the method. Additionally, application exceptions can occur during execution of the method.

  ```
  @EJB AcmeRemoteInterface myAsyncBean;

  Future<Integer>myFutureResult = null;
  Integer myResult = null;

  try {
     myFutureResult = myAsyncBean.methodWithResults();
  } catch (EJBException ejbex) {
     // Asynchronous method call was not dispatched; handle exception.
  }

  // The asynchronous method call will be dispatched on another thread.  Do other
  // work on this thread, and then wait for results.
  ```

```
// ...

try {
   myResult = myFutureResult.get();
} catch (InterruptedException iex) {
   // Asynchronous method execution interrupted, handle exception
} catch (ExecutionException eex) {
   // Exception during asynchronous method execution, handle exception
}
```

– Create client code that calls an asynchronous method where the client waits for up to 5 seconds (the client thread is blocked during this time window) to receive results. Exception handling requirements are the same as in the previous step. For example:

```
myResult = myFutureResult.get(5, TimeUnit.SECONDS);
```

– Create client code that calls an asynchronous method where results are not immediately obtained. After the method has executed, the client retrieves the results. This scheme prevents the client thread from blocking, and the client is free to execute other work while polling for results. Exception handling requirements are the same as in the previous steps. In this example, the client periodically polls the Future<V> object to determine when the asynchronous method has finished executing. For example:

```
while (!myFutureResult.isDone()) {
// Execute other work while waiting for the asynchronous method to complete.
}

// This call is guaranteed not to block because isDone returned true.
myResult = myFutureResult.get();
```

- Create client code to handle application exceptions. The client code calls an asynchronous method which returns an application exception in the Future<V> object. The following example demonstrates the exception handling code required to determine which application exception occurred.

```
@EJB AcmeRemoteInterface myAsyncBean;

Future<Integer>>myFutureResult = null;
Integer myResult = null;

try {
   myFutureResult = myAsyncBean.methodWithResults();
} catch (EJBException ejbx) {
   // Asynchronous method never dispatched, handle exception
}

// Method is eventually dispatched.  Wait for results.

try {
   myResult = myFutureResult.get();
} catch (ExecutionException ex) {
   // Determine which application exception that occurred during the
   // asynchronous method call.
   Throwable theCause = ex.getCause();
   if (theCause instanceof AcmeException1) {
      // Handle AcmeException1
   } else if (theCause instanceof AcmeException2) {
      // Handle AcmeException2
   } else {
      // Handle other causes.
   }
} catch ( ... ) {
   // Handle other exception.
}
```

- Create client code to identify system exceptions thrown by asynchronous method call during execution. The following example demonstrates the exception handling code required to determine if a system exception occurred.

```
@EJB AcmeRemoteInterface myAsyncBean;

Future<Integer>>myFutureResult = null;
Integer myResult = null;

try {
   myFutureResult = myAsyncBean.methodWithResults();
} catch (EJBException ejbx) {
   // Asynchronous method was not dispatched; handle exception.
}

// Method will eventually be dispatched so block now and wait for results

try {
   myResult = myFutureResult.get();
} catch (ExecutionException ex) {
   // Find the exception class that occurred during the asynchronous method
   Throwable theCause = ex.getCause();
   if (theCause instanceof EJBException) {
      // Handle the EJBException that might be wrapping a system exception
      // which occurred during the asynchronous method execution.
      Throwable theRootCause = theCause.getCause();
      if (theRootCause != null) {
         // Handle the system exception
      }
   } else ... // handle other causes
} catch (...) {
   // handle other exceptions
}
```

- Optionally create client code to cancel an asynchronous method call. If this attempt is successful, then the Future.isCancelled method returns true and the Future.get methods result in the CancellationException. The following example demonstrates the code required to cancel an asynchronous method call.

```
@EJB AcmeRemoteInterface myAsyncBean;

Future<Integer> myFutureResult = myFutureResult.methodWithResults();
Integer myResult;

if (myFutureResult.cancel(true)) {
   // Asynchronous method was not dispatched.
} else {
   // Asynchronous method already started executing.  The bean can still check
   // whether an attempt was made to cancel the call.
}

if (myFutureResult.isCancelled()) {
   // Asynchronous method call did not start executing because the cancel
   // method returned true in a previous line of the example.
}

try {
   myResult = myFutureResult.get();
} catch (CancellationException ex) {
   // Handle the exception that occurs because the cancel method returned true
   // in a previous line of the example.
}
```

- Optionally create bean code to check whether a client attempted to cancel the asynchronous method call. The following example demonstrates the bean code required to check whether the client attempted to cancel the asynchronous method call. If the client attempted to cancel the work, then the SessionContext.wasCancelCalled method returns true, and the bean code can avoid unnecessary work.

```
@Resource SessionContext myContext;

public Future<Integer> methodWithResults() {
   for (int i = 0; i < 3; i++) {
```

```
      // Do one piece of long-running work.

      // Before continuing, check whether the client attempted to cancel this work.
      if (myContext.wasCancelCalled()) {
         throw new AcmeCancelCalledException();
      }
   }

   // ...
}
```

- Pass back multiple output values from the asynchronous method invocation.

  In some cases, a method must pass back multiple pieces of data.

  One way to accomplish this task is by using pass-by-reference semantics. In this approach, an object is passed into the method as a parameter, updated by the method, and then the updated value is available to the client. This approach does work for asynchronous methods, but it is not the optimal pattern.

  To return multiple pieces of data, create a wrapper inside the Future object that is returned by the method. In this approach, a wrapper object is defined that contains instance variables which hold the different pieces of data that must be returned. The asynchronous method sets these pieces of data into the wrapper object and returns it, and the client code then retrieves this data from the Future object.

  Embedding multiple pieces of data inside the wrapper object is a local or remote, transparent pattern, that identifies exactly when the results are available. In contrast, the traditional pass-by-reference technique does not give the client an easy way to determine when the results are available. The passed in object is not updated until the asynchronous method runs, and the client cannot determine when that has occurred, other than by interrogating the Future object using the Future.isDone() or Future.get() methods.

```
// This is the result object that is returned from the asynchronous method.
// This object is wrappered in a Future object, and it contains the two pieces of data
// that must be returned from the method.
class ResultObject {
     public Boolean myResult;
     pubilc String myInfo;
}
// This is the asynchronous method code that gets the results and returns them.
@Asynchronous
public Future<ResultObject> asyncMethod1(Object someInputData) {
     boolean result = doSomeStuff();
     String info = doSomeMoreStuff();
     ResultObject theResult = new ResultObject();
     theResult.myResult = result;
     theResult.myInfo = info;
     return new javax.ejb.AsyncResult<ResultObject>(theResult);
}
// This is the client code that obtains the ResultObject, and then extracts the needed data from it.
Future<ResultObject> myFutureResult = myBeanRef.asyncMethod1(someInputData);
ResultObject theResult = myFutureResult.get();
boolean didItWork = theResult.myResult;
String explanation = theResult.myInfo;
```

## Client programming model for EJB asynchronous methods

As documented in the Enterprise JavaBeans (EJB) 3.1 specification, you can invoke EJB asynchronous methods through the following interface types: local business, remote business, or no-interface view. Invocations through an EJB 2.1 client view, or a web services view, are not allowed.

The interface specification for an EJB asynchronous method must have a return type of void, or of type java.util.concurrent.Future <V>. No other return types are supported on the interface. As documented in the EJB 3.1 specification, the bean implementation method must have the same return type.

When your application does not need to examine the result of an EJB asynchronous method call, use an interface signature with a return type of void. Conversely, when your application needs to examine the result of an EJB asynchronous method call, use an interface with a return type of Future<V>.

In addition to considering whether results are examined, clients must be prepared to handle exceptions. As documented in the EJB 3.1 specification, the client receives an exception if the container is unable to allocate the internal resources required to schedule the asynchronous method for execution. In this case, the client can assume that the asynchronous method does not run. Also, exceptions can occur while the asynchronous method is running on the non-client thread.

**Important:** When an asynchronous method has a return type of void, the client has no mechanism to retrieve exception information. The EJB container logs an informational message in this case. However, for asynchronous methods that have a return type of Future<V>, the EJB container saves exception information in the Future<V> object. In this case, the get methods associated with the Future<V> object produce the exception, ExecutionException. The client must invoke the getCause method on the ExecutionException to retrieve details about the exception.

Clients must know that the get methods on the Future<V> object block the client thread if the asynchronous method has not finished running when the get method is called. If clients do not want this behavior, they can poll the Future<V> object to determine when the asynchronous method is finished by periodically calling the isDone method.

Finally, clients can use the Future<V> object to cancel an asynchronous method call. If you attempt to cancel an asynchronous method call while it is waiting to run, then it does not run, and other interactions with the Future<V> object reflect the cancellation. Otherwise, if you attempt to cancel an asynchronous method after it has started running, then it continues to run, but the bean method can still determine that the client attempted to cancel the call and respond with an application-specific return value or exception.

Another alternative is for the client to use the get method, which includes a timeout parameter. This get method only waits for results during the specified timeout period. The get method returns to the client as soon as the method has finished running, or when the timeout expires, even if the method has not finished running.

Nested asynchronous calls are supported; an asynchronous method call can be made from within an asynchronous method.

**Note:** When nesting asynchronous method calls, take into consideration the work manager settings to allow enough resources (maximum number of threads and work request queue size). For more information, read about the EJB container work manager for asynchronous methods.

Read about Developing client code that calls EJB asynchronous methods.

## Bean implementation programming model for EJB asynchronous methods

You can configure asynchronous methods on session beans. However, as documented in the Enterprise JavaBeans (EJB) 3.1 specification, asynchronous methods must not be configured on entity beans, or message-driven beans.

Implementations of asynchronous methods must have a return type of void or of type, java.util.concurrent.Future <V>. No other return types are supported on the implementation. As documented in the EJB 3.1 specification, the bean implementation method must have the same return type as the interface specification. For more information, read about the client programming model for EJB asynchronous methods.

Nested asynchronous calls are supported; an asynchronous method call can be made from within an asynchronous method.

**Note:** When nesting asynchronous method calls, take into consideration the work manager settings to allow enough resources (maximum number of threads and work request queue size). For more information, read about the work manager for asynchronous methods.

Bean implementers must consider how long their asynchronous methods take to run because each request is invoked on a different thread. Another important consideration is the number of asynchronous method requests that an application is likely to start in parallel. These issues are important because the number of threads that are allocated to run asynchronous methods in the server process is a limited resource. Also, the buffer space that is allocated in the server process to queue asynchronous method requests, during times that all the allocated threads are busy, is a limited resource. For more information, read about the client programming model for EJB asynchronous methods.

Finally, bean implementers must follow the EJB 3.1 specification restrictions regarding the transaction attribute settings that are allowed on EJB asynchronous methods. For more information, read about the EJB container work manager for asynchronous methods.

## EJB container work manager for asynchronous methods

The default work manager used by the Enterprise JavaBeans (EJB) container to dispatch asynchronous methods is not configurable. The following configuration information is provided to help you understand the limits imposed by this work manager. Remember, one EJB container work manager exists for all asynchronous methods running in the application server process.

The EJB container work manager has the following thread pool settings:

- Minimum number of threads = 1
- Maximum number of threads = 5
- Work request queue size = 0 work objects
- Action taken when buffer overflows = Block
- Remote Future object duration = 86400 seconds

**Note:** Work request queue size is the maximum number of asynchronous method requests that can be queued while waiting for a thread to become available. If you specify a value of 0 (the default) or blank is specified, the queue size is managed by the run time.

Additionally, the EJB container work manager has configuration settings that specify which service contexts are propagated from the client thread to the work manager thread that runs the asynchronous method. The global transaction service context and the activity session service context are not propagated. The security context, and all of the WebSphere extension contexts, such as work area, internationalization, and so on, are propagated for use on the execution thread.

## EJB asynchronous methods settings

Use this page to modify settings on the work manager used in support of Enterprise JavaBeans asynchronous methods.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **EJB Container Settings** > **EJB asynchronous method invocation settings**

The Use internal work manager instance and Use custom work manager instance options are *mutually exclusive.*

### Use this work manager for asynchronous methods

Specifies a default work manager instance.

The product provides an internal work manager instance for support of EJB asynchronous methods. The internal work manager instance is pre-configured for basic EJB asynchronous method functionality, and provides limited configuration settings.

Clicking this button specifies that you want to use the internal work manager instance to manage your asynchronous method invocations. Selecting this choice precludes the Use custom work manager instance option.

The Use internal work manager instance option is the default. Alternatively, you can use a custom-defined work manager instance.

### Use custom work manager instance

Specifies a custom-defined work manager instance.

You can provide a more advanced configuration for EJB asynchronous methods by defining a custom work manager instance.

Selecting this choice allows you to use a work manager instance that you have already defined and configured in a way that is optimal for your environment.

Selecting this choice precludes the Use internal work manager instance option.

### Maximum number of threads

Specifies the maximum number of threads that are used in the execution of asynchronous EJB methods. The default is 5.

### Work request queue size

Specifies the size of the work request queue. The work request queue is a buffer that holds requested that asynchronous methods until a thread is available to run them on. The default is 0, indicating that the initial size is half way between the minimum and maximum number of threads.

The sum of the maximum number of threads and the work request queue size attributes is the total number of allowable in-progress method requests.

For example, if the maximum number of threads is set to five threads, and the work request queue size is set to 50, then the total number of allowable in-progress method requests is 55.

The default value is 0, indicating that the queue size is managed by the runtime environment. The runtime currently uses the larger of 20 and maxThreads.

### Work request queue full action

Specifies the action taken when the thread pool is exhausted, and the work request queue is full. The default is BLOCK.

If set to FAIL, an exception occurs instead of waiting for a thread, or a place in the queue, to become available.

You might want to use this option during development to help identify errors caused by long-running asynchronous methods. You might also use it to help determine the number of threads and queue size that should be configured.

If set to BLOCK, the thread that is requesting that the asynchronous method execution waits until a thread, or a place in the queue, becomes available.

### Work Manager JNDI name
Specifies the Java Naming and Directory Interface (JNDI) name used to look up the custom-defined work manager in the namespace.

### Remote future object duration
Specifies the amount of time that the server retains the future object of each fire-and-return-results asynchronous method call. If an application does not retrieve the results within the specified period of time, the server purges the results of that method call to prevent memory leakage and a potential OutOfMemory exception. You can specify 0 to never purge the objects; however, specifying a zero value means that the future object never times out and you disable protection from incorrectly written programs that might cause the referenced OutOfMemory exception. The default value is 86400 seconds (24 hours).

**Note:** If you call the get() or the get(time) method on the future object, then you might decrease performance because blocking can occur until either the work is done or until the specified time has passed. Therefore, to avoid blocking on the get(..) methods, call the isDone() method, which returns immediately. Then, call the get() method after the isDone() method returns true.

**Note:** This value is only applicable for clients that call the enterprise bean using a remote business interface, the value is not used for local business interface or no-interface views. When the asynchronous work has completed, the server sets an alarm for the duration specified to the server-side future object. When the alarm is activated, the server releases all the resources associated with the future object, making it unavailable to the client. If the client calls the get() method on the future object before the duration amount of time, the alarm is canceled and all the resources associated with the future object are released.

---

# Developing session beans

# Configuring EJB 3.1 session bean methods to be asynchronous
Use this task to configure Enterprise JavaBeans (EJB) 3.1 session bean methods to run asynchronously. You can make some or all of your bean methods asynchronous.

## Before you begin

**Attention:** In EJB 3.1 modules, you can set one or more session bean methods to be asynchronous, broadening parallel processing in your application.

- If you are not already familiar with EJB 3.1 asynchronous methods, read about EJB 3.1 asynchronous methods, client programming model for EJB asynchronous methods, bean implementation programming model for EJB asynchronous methods, and EJB container work manager for asynchronous methods. The topics provide an overview of EJB 3.1 asynchronous methods, describe the client and bean implementation programming models, and discuss the work manager that the EJB container uses to dispatch asynchronous methods.
- Develop a new EJB 3.1 session bean for your application, or change an existing session bean so that it conforms to the EJB 3.1 programming model requirements for asynchronous methods. For general information, see information about developing enterprise beans.

## About this task

After you have developed a session bean, complete the following steps to make one or more of the bean methods asynchronous.

## Procedure
1. Specify one or more methods of the bean implementation class as asynchronous. This can be accomplished by adding @Asynchronous annotations in your bean source code, by adding <async-method> stanzas in your module deployment descriptor, or by adding a combination of both

annotations and deployment descriptor stanzas. You can apply the @Asynchronous annotation or its superclasses only, to your bean implementation class. It cannot be applied to interface classes. Also, when the annotation is applied at the class level, all methods of that class are asynchronous. Likewise, all methods of a bean can be configured as asynchronous by applying "*" as the <method-name> in your deployment descriptor.

See the following examples of applying the @Asynchronous annotation:

- Apply the @Asynchronous annotation to one method of a bean with a no-interface view. In this example, the m1 method is synchronous and the m2 method is asynchronous.

```
@Stateless @LocalBean
public class MyLocalBean {

   public void m1() {

      // method code
   }

   @Asynchronous
   public Future<String> m2() {

      // method code

      return new javax.ejb.AsyncResult("Hello, Async World!");
   }
}
```

  **Important:** The javax.ejb.AsyncResult<V> object is a convenience implementation of the Future<V> interface. See the API documentation for more details.

- Apply the @Asynchronous annotation to the class level of a bean class. In this example, both the m1 method and the m2 method are asynchronous on this no-interface view bean.

```
@Stateless @LocalBean @Asynchronouspublic class MyLocalBean {

   public void m1() {

      // method code
   }

   public Future<String> m2() {

      // method code

      return new javax.ejb.AsyncResult("Hello, Async World!");
   }

}
```

- Apply the @Asynchronous annotation to one method of a bean implementation class. In this example, the m1 method is synchronous and the m2 method is asynchronous. This example also demonstrates how the return types might differ between the business interface and the implementation class.

```
public interface MyIntf {

   public void m1();

   public Future<Integer> m2();

}
@Stateless @Local(MyIntf.class)
public class MyBean {

   public void m1() {

      // method code
```

```
    }

    @Asynchronous
    public Integer m2() {

       // method code

       return new Integer(3);
    }
}
```

- Apply the @Asynchronous annotation to the class level of a bean implementation class. In this example, both the m1 method and the m2 method are asynchronous.

```
@Stateless @Local(MyIntf.class) @Asynchronous
public class MyBean {

   public void m1() {

      // method code
   }

   public Integer m2() {

      // method code

      return new Integer(8);
   }
}
```

See the following examples of modifying the EJB module deployment descriptor, `ejb-jar.xml`:

- In this example all business methods of the FullAyncBean bean implementation class and its superclasses are configured as asynchronous with the wildcard (*) method-name element.

```
<session>
   <display-name>FullAsyncEJB</display-name>
   <ejb-name>FullAsyncBean</ejb-name>
   <business-local>com.ibm.sample.async.ejb.FullAsyncIntf</business-local>
   <ejb-class>com.ibm.sample.async.ejb.FullAsyncBean</ejb-class>
   <session-type>Stateless</session-type>   <async-method>
      <method-name>*</method-name>
   </async-method>
</session>
```

- In this example only the specified methods and signatures -- all methods named m1 and the method m2 with a single String parameter -- are configured as asynchronous on the PartiallyAsyncBean bean implementation class.

```
<session>
   <display-name>PartiallyAsyncEJB</display-name>
   <ejb-name>PartiallyAsyncEJB</ejb-name>
   <business-local>com.ibm.sample.async.ejb.PartiallyAsyncIntf</business-local>
   <ejb-class>com.ibm.sample.async.ejb.PartiallyAsyncBean</ejb-class>
   <session-type>Stateless</session-type>   <async-method>
      <method-name>m1</method-name>
   </async-method>
   <async-method>
      <method-name>m2</method-name>
      <method-params>
         <method-param>java.lang.String</method-param>
      </method-params>
   </async-method>
</session>
```

See the following examples of applying a combination of the @Asynchronous annotation in the bean source code and modifying the EJB module deployment descriptor, `ejb-jar.xml`:

- In this example the @Asynchronous annotation configures method m2 to be asynchronous, and the deployment descriptor configures method m1 to also be an asynchronous method.

```
@Stateless @LocalBean
public class MyLocalBean {

   public void m1() {

      // method code
   }

   @Asynchronous
   public Future<String> m2() {

      // method code

      return new javax.ejb.AsyncResult("Hello, Async World!");
   }
}

<session>
   <display-name>MyLocalEJB</display-name>
   <ejb-name>MyLocalEJB</ejb-name>
   <local-bean/>
   <ejb-class>com.ibm.sample.async.ejb.MyLocalBean</ejb-class>
   <session-type>Stateless</session-type>   <async-method>
      <method-name>m1</method-name>
   </async-method>
</session>
```

- In this example the @Asynchronous annotation for method m2 is ignored because the deployment descriptor header contains the metadata-complete="true" flag. This flag causes configuration information to only be taken from the deployment descriptor elements. The result is that only method m1 of the MyLocalBean implementation is configured to be asynchronous.

```
@Stateless @LocalBean
public class MyLocalBean {

   public void m1() {

      // method code
   }

   @Asynchronous
   public Future<String> m2() {

      // method code

      return new javax.ejb.AsyncResult("Hello, Async World!");
   }
}

<ejb-jar id="ejb-jar_ID" ...
metadata-complete="true" version="3.1">
...
<session>
   <display-name>MyLocalEJB</display-name>
   <ejb-name>MyLocalEJB</ejb-name>
   <local-bean/>
   <ejb-class>com.ibm.sample.async.ejb.MyLocalBean</ejb-class>
   <session-type>Stateless</session-type>   <async-method>
      <method-name>m1</method-name>
   </async-method>
</session>
...
</ejb-jar>
```

2. Verify that the transaction attribute applied to any asynchronous method is either REQUIRED, REQUIRES_NEW, or NOT_SUPPORTED. These transaction attribute types are the only transaction

attribute types supported on asynchronous methods. You can complete this action by either applying @TransactionAttribute annotations in the bean source code, by adding <container-transaction> stanzas in the `ejb-jar.xml` file, or by adding a combination of both annotations and <container-transaction> stanzas in the deployment descriptor.

See the following example of setting the transaction attribute of an asynchronous method using annotations:

```
@Singleton @LocalBean
public class FullAsyncBean {
 @Asynchronous
 @TransactionAttribute(REQUIRED) // the default; specified for illustration
 public void m1() {
  // ...
 }

 @Asynchronous
 @TransactionAttribute(NOT_SUPPORTED)
 public void m2() {
  // ...
 }

 @Asynchronous
 @TransactionAttribute(REQUIRES_NEW)
 public void m3() {
  // ...
 }

 // ...
}
```

See the following example of setting the transaction attribute of an asynchronous method using the XML deployment descriptor:

```
  <assembly-descriptor>
    <container-transaction>
      <method>
        <ejb-name>FullAsyncBean</ejb-name>
        <method-name>m1</method-name>
      </method>
      <trans-attribute>Required</trans-attribute>
    </container-transaction>

    <container-transaction>
      <method>
        <ejb-name>FullAsyncBean</ejb-name>
        <method-name>m2</method-name>
      </method>
      <trans-attribute>NotSupported</trans-attribute>
    </container-transaction>

    <container-transaction>
      <method>
        <ejb-name>FullAsyncBean</ejb-name>
        <method-name>m3</method-name>
      </method>
      <trans-attribute>RequiresNew</trans-attribute>
    </container-transaction>
  </assembly-descriptor>
```

See the following example of using a combination of both annotations and the XML deployment descriptor to configure the transaction attributes of a bean. In this example the deployment descriptor stanzas for method m3 override the class level annotation. The result is that method m3 is configured as REQUIRES_NEW, while methods m1 and m2 are configured as REQUIRED:

```
@Singleton @LocalBean
@Asynchronous
@TransactionAttribute(REQUIRED) // the default; specified for illustration
public class FullAsyncBean {
```

```
 public void m1() {
  // ...
 }

 public void m2() {
  // ...
 }

 public void m3() {
  // ...
 }

 // ...
}

<assembly-descriptor>

   <container-transaction>
      <method>
         <ejb-name>FullAsyncBean</ejb-name>
         <method-name>m3</method-name>
      </method>
      <trans-attribute>RequiresNew</trans-attribute>
   </container-transaction>

</assembly-descriptor>
```

## What to do next

Continue to develop additional components for your application, or if you have finished all components required by your application, assemble and deploy your application. See information about assembling EJB modules and deploying EJB modules.

When you run your application, if it fails when it first attempts to use a session bean that has an asynchronous method, a configuration error might exist. Check the system log file for configuration error messages.

Analyze the trace data or forward it to the appropriate organization for analysis. EJB asynchronous method scheduling and invocation are traced in the EJB container trace. For instructions on enabling this trace see the information about enabling trace on a running server. To analyze trace data, see information about trace output.

## Configuring remote asynchronous EJB method results

Use this task to set the maximum number of unclaimed results for a remote asynchronous Enterprise JavaBeans (EJB) method call.

### About this task

When a remote asynchronous EJB method is called, the server must save the results of the remote method invocation until the client claims the results using the Future.get method. If the client never claims the result, unclaimed results can accumulate in the server and use memory. To avoid using too much memory, the server limits the number of unclaimed results to 1000 by default. If the number of unclaimed results approaches or exceeds the limit, the server issues the `CNTR0328W` warning.

### Procedure

1. Optional: Open the administrative console.
2. Select **Servers**.
3. Select **Server Types**.

4. Select **WebSphere application servers**.
5. Select the server that you want to configure.
6. From Server Infrastructure, select **Java and Process Management Process definition.**
7. From Additional Properties, select **Java Virtual Machine** .
8. In the Additional Properties area, select **Custom Properties** .
9. On the Application servers page, click **New** to specify an arbitrary name and value pair for your server.
10. In the **Name** entry field, type: `com.ibm.websphere.ejbcontainer.maxUnclaimedAsyncResults`
11. In the **Value** entry field, enter the wanted maximum number of unclaimed results. The special value `0` is interpreted as unlimited. The default value is `1000`.
12. Click **OK**.
13. Save the configuration.
14. Restart the server.

### Results

The maximum number of unclaimed asynchronous EJB method results for all EJBs is set.

## Configuring EJB asynchronous methods using scripting

Use wsadmin scripting to configure Enterprise JavaBeans (EJB) asynchronous methods.

### Before you begin

You have working knowledge of Jacl or Jython and wsadmin scripting.

### About this task

The behavior for EJB asynchronous methods is configured using the EJBAsync configuration object in the `server.xml` file. If you are using EJB asynchronous methods, then you might must update the EJBAsync configuration object to obtain the best settings for your environment. The EJBAsync configuration object exists at the server level. This means that each server in a multiple-server environment has its own EJBAsync configuration object and must be configured individually.

### Procedure

1. Launch the wsadmin scripting tool using the Jython scripting language.
2. Determine the attributes on the EJBAsync configuration object that must be updated. You can update the following attributes on the EJBAsync configuration object:

*Table 83. Attributes on EJBAsync configuration object. This table describes the attributes on the EJBAsync configuration object.*

| Attribute | Description |
|---|---|
| maxThreads | Specifies the maximum number of threads that are used in the execution of asynchronous EJB methods.<br><br>The default value is `5`. |
| workReqQSize | Specifies the size of the work request queue. The work request queue is a buffer that holds requested asynchronous methods until a thread is available to run them on.<br><br>The sum of the maxThreads and the workReqQSize attributes is the total number of allowable in progress method requests.<br><br>For example, if the maxThreads is set to `5` threads, and the workReqQSize is set to `50`, then the total number of allowable in-progress method requests is `55`.<br><br>The default value is 0, indicating that the queue size is managed by the runtime environment. The run time currently uses the larger of 20 and maxThreads. |

*Table 83. Attributes on EJBAsync configuration object (continued). This table describes the attributes on the EJBAsync configuration object.*

| Attribute | Description |
|---|---|
| workReqQFullAction | Specifies the action taken when the thread pool is exhausted, and work request queue is full.<br><br>If set to 1, an exception occurs instead of waiting for a thread, or a place in the queue, to become available.<br><br>If set to 0, the thread that is requesting the asynchronous method execution waits until a thread, or place in the queue, becomes available.<br><br>The default value is 0. |
| customWorkManagerJNDIName | Specifies the Java Naming and Directory Interface (JNDI) name used to look up the custom defined work manager in the namespace.<br><br>The default value is null. |
| useCustomDefinedWM | Specifies whether a custom-defined work manager instance is used, or the default internal work manager instance.<br><br>When the useCustomDefinedWM attribute is set to true, this means that a custom work manager instance is used. In this case, the customWorkManagerJNDIName attribute must be set, and all other attributes are ignored.<br><br>When the useCustomDefinedWM attribute is set to `false`, the default, internal work manager instance is used. In this case, the customWorkManagerJNDIName attribute is ignored, and all other attributes are used to help configure the default work manager instance.<br><br>The default value is false. |
| futureTimeout | Specifies the amount of time, in seconds, that the server-side future object, which is created as a result of running a fire-and-return asynchronous method, is available. The server-side future object is not valid after you call the get() method, and a value is returned to the remote client. To avoid memory leaks, you must call the get() method on the future object, or specify a positive and non-zero future duration value.<br><br>A future duration value of zero indicates that the future object never times out.<br><br>The default value is `86400`, which means that the future object expires and gets cleaned up by the application server after 24 hours and is no longer available.<br><br>A org.omg.CORBA.OBJECT_NOT_EXIST exception is thrown when a call to the get() method is made after the future object expires.<br>**Note:** This value is only applicable for clients that call the enterprise bean using a remote business interface; the value is not used for local business interface or no-interface views. When the asynchronous work has completed, the server sets an alarm for the duration specified to the server-side future object. When the alarm is activated, the server releases all the resources associated with the future object, making it unavailable to the client. If the client calls the get() method on the future object before the duration amount of time, the alarm is canceled and all the resources associated with the future object are released.<br>**Note:** This attribute might affect the number of future objects on the server. Use the AsynchFutureObjectCount PMI statistic to determine the count of open FutureObjects on the server, which can help you determine whether applications are accumulating future objects without calling the get() method on those objects. See the topic, Enterprise bean counters, for more information. |

3. Obtain a reference to the correct EJBAsync configuration object and store it in a variable.

   Using Jacl:

   ```
   set async [$AdminConfig list EJBAsync]
   ```

   Using Jython:

   ```
   async = AdminConfig.list('EJBAsync')
   ```

   If you have a multiple-server environment, then multiple EJBAsync configuration objects are returned. Programmatically loop over the list and select the EJBAsync configuration object that corresponds to the server you must update.

   In a multiple-server environment, as an alternative to programmatically looping over the list of EJBAsync objects, you can manually select the correct EJBAsync object and copy and paste it into your variable.

   For example, the output of the `AdminConfig list` command is:

   ```
   (cells/myNode04Cell/nodes/myCellManager01/servers/dmgr|server.xml#EJBAsync_1)(cells/
   myNode04Cell/nodes/myNode04/servers/server1|server.xml#EJBAsync_1247498700906)
   ```

   You can copy and paste the reference for the needed EJBAsync object into your variable.

   Using Jacl:

```
set async "(cells/myNode04Cell/nodes/myNode04/servers/server1|server.xml#EJBAsync_1247498700906)"
```

Using Jython:

```
async = "(cells/myNode04Cell/nodes/myNode04/servers/server1|server.xml#EJBAsync_1247498700906)"
```

4. Update attributes on the EJBAsync configuration object.

   Update attributes on the EJBAsync configuration object using the AdminConfig modify command. As input to the command, specify the EJBAsync reference that you obtained in the previous step, and a list of attributeName and attributeValue combinations.

   To set a max thread count of `10` threads, a queue size of `15`, and a futureTimeout of `3600` seconds:

   Using Jacl:

   ```
   set update "{maxThreads 10} {workReqQSize 15} {futureTimeout 3600}"
   $AdminConfig modify $async $update
   ```

   Using Jython:

   ```
   AdminConfig.modify(async, '[ [maxThreads "10"] [workReqQSize "15"] [futureTimeout "3600"] ]')
   ```

5. Save the configuration changes.

   Using Jython:

   ```
   AdminConfig.save()
   ```

   Using Jacl:

   ```
   $AdminConfig save
   ```

### Results

As a result of your updates, the EJBAsync configuration object now reflects the attribute values that you specified. Restart your server so that the changes are updated on the server.

## EJB 3.1 asynchronous methods

The Enterprise JavaBeans™ (EJB) 3.1 specification includes functionality that application developers can use to configure EJB asynchronous methods, which are run on a separate thread from the caller thread.

This mechanism decouples the client invocation request from the actual method execution. The client thread can continue doing other work while the EJB method is run on a separate thread, as directed by the EJB container.

Later, the client might want to examine the result of the asynchronous method execution, which is sometimes referred to as *fire and return*. In this case, the EJB container returns to the client an object that implements the java.util.concurrent.Future<V> interface. The client can use this object to check status, results, or exceptions from the asynchronous method invocation. Alternatively, asynchronous methods might not return any results, which is sometimes referred to as *fire and forget.*

For more details, see information about how to use EJB asynchronous methods in your application.

Here are some example usage scenarios for EJB asynchronous methods:

- An application has multiple, independent, pieces of work that all must be executed to produce a final result. For example, suppose that a travel reservation consists of three parts:
  1. Making a plane reservation.
  2. Making a rental car reservation.
  3. Making a hotel reservation.

  In this example, a client can use EJB asynchronous methods to process the reservation requests in parallel. After all three reservation methods run, the client aggregates the results into a complete travel reservation.
- An application has multiple, independent, pieces of work that it must run, and the application is not concerned about the results of this work. For example, suppose that a retailer has four branch stores, and the home office wants to print a sales report from each store when the business day ends. The

application developer can use EJB asynchronous methods as a batch processing mechanism. Multiple EJB method calls can be used to send a batch of get sales report requests, one to each branch store.

In this example, presumably the application does not need to check for results from these method calls. Perhaps this is handled by the home office employee who picks up the sales reports from a printer the next morning. Suppose that one of the branch stores failed to provide the requested report. The person collecting the reports can decide if that was expected, for example, the branch store was closed for renovations, or if the get sales report request must be reissued to that branch store.

## Developing client code that calls EJB asynchronous methods

You can use the sample code within this topic to develop client code that calls EJB asynchronous methods.

### Before you begin

This task assumes that the following interface and bean implementation classes exist:

```
public interface AcmeRemoteInterface {
   void fireAndForgetMethod ();
   Future<Integer> methodWithResults() throws AcmeException1, AcmeException2;
}
```

```
@Stateless
@Remote(AcmeRemoteInterface.class)
@Asynchronous
public class AcmeAsyncBean {
   public void fireAndForgetMethod () {
      // do non-critical work
   }

   public Integer methodWithResults() {
      Integer result;
      // do work, and then return results
      return result;
   }
}
```

### About this task

### Procedure

- Create client code that calls an asynchronous method where no results are returned, sometimes called a *fire and forget* method. This type of asynchronous method cannot result in application exceptions. However, system exceptions can occur that must be resolved.

  ```
  @EJB AcmeRemoteInterface myAsyncBean;

  try {
     myAsyncBean.fireAndForgetMethod();
  } catch (EJBException ejbex) {
     // Asynchronous method never dispatched, handle system error
  }
  ```

- Create client code that calls an asynchronous method where results are returned. The get call on the returned Future<V> object blocks the client thread until results are available. System exceptions can occur either if the asynchronous method cannot be dispatched, or during execution of the method. Additionally, application exceptions can occur during execution of the method.

  ```
  @EJB AcmeRemoteInterface myAsyncBean;

  Future<Integer>myFutureResult = null;
  Integer myResult = null;

  try {
     myFutureResult = myAsyncBean.methodWithResults();
  } catch (EJBException ejbex) {
     // Asynchronous method call was not dispatched; handle exception.
  ```

```
}

// The asynchronous method call will be dispatched on another thread.  Do other
// work on this thread, and then wait for results.
// ...

try {
   myResult = myFutureResult.get();
} catch (InterruptedException iex) {
   // Asynchronous method execution interrupted, handle exception
} catch (ExecutionException eex) {
   // Exception during asynchronous method execution, handle exception
}
```

– Create client code that calls an asynchronous method where the client waits for up to 5 seconds (the client thread is blocked during this time window) to receive results. Exception handling requirements are the same as in the previous step. For example:

```
myResult = myFutureResult.get(5, TimeUnit.SECONDS);
```

– Create client code that calls an asynchronous method where results are not immediately obtained. After the method has executed, the client retrieves the results. This scheme prevents the client thread from blocking, and the client is free to execute other work while polling for results. Exception handling requirements are the same as in the previous steps. In this example, the client periodically polls the Future<V> object to determine when the asynchronous method has finished executing. For example:

```
while (!myFutureResult.isDone()) {
// Execute other work while waiting for the asynchronous method to complete.
}

// This call is guaranteed not to block because isDone returned true.
myResult = myFutureResult.get();
```

- Create client code to handle application exceptions. The client code calls an asynchronous method which returns an application exception in the Future<V> object. The following example demonstrates the exception handling code required to determine which application exception occurred.

```
@EJB AcmeRemoteInterface myAsyncBean;

Future<Integer>>myFutureResult = null;
Integer myResult = null;

try {
   myFutureResult = myAsyncBean.methodWithResults();
} catch (EJBException ejbx) {
   // Asynchronous method never dispatched, handle exception
}

// Method is eventually dispatched.  Wait for results.

try {
   myResult = myFutureResult.get();
} catch (ExecutionException ex) {
   // Determine which application exception that occurred during the
   // asynchronous method call.
   Throwable theCause = ex.getCause();
   if (theCause instanceof AcmeException1) {
      // Handle AcmeException1
   } else if (theCause instanceof AcmeException2) {
      // Handle AcmeException2
   } else {
      // Handle other causes.
   }
} catch ( ... ) {
   // Handle other exception.
}
```

- Create client code to identify system exceptions thrown by asynchronous method call during execution. The following example demonstrates the exception handling code required to determine if a system exception occurred.

```
@EJB AcmeRemoteInterface myAsyncBean;

Future<Integer>>myFutureResult = null;
Integer myResult = null;

try {
   myFutureResult = myAsyncBean.methodWithResults();
} catch (EJBException ejbx) {
   // Asynchronous method was not dispatched; handle exception.
}

// Method will eventually be dispatched so block now and wait for results

try {
   myResult = myFutureResult.get();
} catch (ExecutionException ex) {
   // Find the exception class that occurred during the asynchronous method
   Throwable theCause = ex.getCause();
   if (theCause instanceof EJBException) {
      // Handle the EJBException that might be wrapping a system exception
      // which occurred during the asynchronous method execution.
      Throwable theRootCause = theCause.getCause();
      if (theRootCause != null) {
         // Handle the system exception
      }
   } else ... // handle other causes
} catch (...) {
   // handle other exceptions
}
```

- Optionally create client code to cancel an asynchronous method call. If this attempt is successful, then the Future.isCancelled method returns true and the Future.get methods result in the CancellationException. The following example demonstrates the code required to cancel an asynchronous method call.

```
@EJB AcmeRemoteInterface myAsyncBean;

Future<Integer> myFutureResult = myFutureResult.methodWithResults();
Integer myResult;

if (myFutureResult.cancel(true)) {
   // Asynchronous method was not dispatched.
} else {
   // Asynchronous method already started executing.  The bean can still check
   // whether an attempt was made to cancel the call.
}

if (myFutureResult.isCancelled()) {
   // Asynchronous method call did not start executing because the cancel
   // method returned true in a previous line of the example.
}

try {
   myResult = myFutureResult.get();
} catch (CancellationException ex) {
   // Handle the exception that occurs because the cancel method returned true
   // in a previous line of the example.
}
```

- Optionally create bean code to check whether a client attempted to cancel the asynchronous method call. The following example demonstrates the bean code required to check whether the client attempted to cancel the asynchronous method call. If the client attempted to cancel the work, then the SessionContext.wasCancelCalled method returns true, and the bean code can avoid unnecessary work.

```
@Resource SessionContext myContext;

public Future<Integer> methodWithResults() {
   for (int i = 0; i < 3; i++) {
      // Do one piece of long-running work.

      // Before continuing, check whether the client attempted to cancel this work.
      if (myContext.wasCancelCalled()) {
         throw new AcmeCancelCalledException();
      }
   }

   // ...
}
```

- Pass back multiple output values from the asynchronous method invocation.

  In some cases, a method must pass back multiple pieces of data.

  One way to accomplish this task is by using pass-by-reference semantics. In this approach, an object is passed into the method as a parameter, updated by the method, and then the updated value is available to the client. This approach does work for asynchronous methods, but it is not the optimal pattern.

  To return multiple pieces of data, create a wrapper inside the Future object that is returned by the method. In this approach, a wrapper object is defined that contains instance variables which hold the different pieces of data that must be returned. The asynchronous method sets these pieces of data into the wrapper object and returns it, and the client code then retrieves this data from the Future object.

  Embedding multiple pieces of data inside the wrapper object is a local or remote, transparent pattern, that identifies exactly when the results are available. In contrast, the traditional pass-by-reference technique does not give the client an easy way to determine when the results are available. The passed in object is not updated until the asynchronous method runs, and the client cannot determine when that has occurred, other than by interrogating the Future object using the Future.isDone() or Future.get() methods.

```
// This is the result object that is returned from the asynchronous method.
// This object is wrappered in a Future object, and it contains the two pieces of data
// that must be returned from the method.
class ResultObject {
     public Boolean myResult;
     pubilc String myInfo;
}
// This is the asynchronous method code that gets the results and returns them.
@Asynchronous
public Future<ResultObject> asyncMethod1(Object someInputData) {
     boolean result = doSomeStuff();
     String info = doSomeMoreStuff();
     ResultObject theResult = new ResultObject();
     theResult.myResult = result;
     theResult.myInfo = info;
     return new javax.ejb.AsyncResult<ResultObject>(theResult);
}
// This is the client code that obtains the ResultObject, and then extracts the needed data from it.
Future<ResultObject> myFutureResult = myBeanRef.asyncMethod1(someInputData);
ResultObject theResult = myFutureResult.get();
boolean didItWork = theResult.myResult;
String explanation = theResult.myInfo;
```

***Client programming model for EJB asynchronous methods:***

As documented in the Enterprise JavaBeans (EJB) 3.1 specification, you can invoke EJB asynchronous methods through the following interface types: local business, remote business, or no-interface view. Invocations through an EJB 2.1 client view, or a web services view, are not allowed.

The interface specification for an EJB asynchronous method must have a return type of void, or of type java.util.concurrent.Future <V>. No other return types are supported on the interface. As documented in the EJB 3.1 specification, the bean implementation method must have the same return type.

When your application does not need to examine the result of an EJB asynchronous method call, use an interface signature with a return type of void. Conversely, when your application needs to examine the result of an EJB asynchronous method call, use an interface with a return type of Future<V>.

In addition to considering whether results are examined, clients must be prepared to handle exceptions. As documented in the EJB 3.1 specification, the client receives an exception if the container is unable to allocate the internal resources required to schedule the asynchronous method for execution. In this case, the client can assume that the asynchronous method does not run. Also, exceptions can occur while the asynchronous method is running on the non-client thread.

**Important:** When an asynchronous method has a return type of void, the client has no mechanism to retrieve exception information. The EJB container logs an informational message in this case. However, for asynchronous methods that have a return type of Future<V>, the EJB container saves exception information in the Future<V> object. In this case, the get methods associated with the Future<V> object produce the exception, ExecutionException. The client must invoke the getCause method on the ExecutionException to retrieve details about the exception.

Clients must know that the get methods on the Future<V> object block the client thread if the asynchronous method has not finished running when the get method is called. If clients do not want this behavior, they can poll the Future<V> object to determine when the asynchronous method is finished by periodically calling the isDone method.

Finally, clients can use the Future<V> object to cancel an asynchronous method call. If you attempt to cancel an asynchronous method call while it is waiting to run, then it does not run, and other interactions with the Future<V> object reflect the cancellation. Otherwise, if you attempt to cancel an asynchronous method after it has started running, then it continues to run, but the bean method can still determine that the client attempted to cancel the call and respond with an application-specific return value or exception.

Another alternative is for the client to use the get method, which includes a timeout parameter. This get method only waits for results during the specified timeout period. The get method returns to the client as soon as the method has finished running, or when the timeout expires, even if the method has not finished running.

Nested asynchronous calls are supported; an asynchronous method call can be made from within an asynchronous method.

**Note:** When nesting asynchronous method calls, take into consideration the work manager settings to allow enough resources (maximum number of threads and work request queue size). For more information, read about the EJB container work manager for asynchronous methods.

Read about Developing client code that calls EJB asynchronous methods.

## Bean implementation programming model for EJB asynchronous methods

You can configure asynchronous methods on session beans. However, as documented in the Enterprise JavaBeans (EJB) 3.1 specification, asynchronous methods must not be configured on entity beans, or message-driven beans.

Implementations of asynchronous methods must have a return type of void or of type, java.util.concurrent.Future <V>. No other return types are supported on the implementation. As documented in the EJB 3.1 specification, the bean implementation method must have the same return type as the interface specification. For more information, read about the client programming model for EJB asynchronous methods.

Nested asynchronous calls are supported; an asynchronous method call can be made from within an asynchronous method.

**Note:** When nesting asynchronous method calls, take into consideration the work manager settings to allow enough resources (maximum number of threads and work request queue size). For more information, read about the work manager for asynchronous methods.

Bean implementers must consider how long their asynchronous methods take to run because each request is invoked on a different thread. Another important consideration is the number of asynchronous method requests that an application is likely to start in parallel. These issues are important because the number of threads that are allocated to run asynchronous methods in the server process is a limited resource. Also, the buffer space that is allocated in the server process to queue asynchronous method requests, during times that all the allocated threads are busy, is a limited resource. For more information, read about the client programming model for EJB asynchronous methods.

Finally, bean implementers must follow the EJB 3.1 specification restrictions regarding the transaction attribute settings that are allowed on EJB asynchronous methods. For more information, read about the EJB container work manager for asynchronous methods.

## EJB container work manager for asynchronous methods

The default work manager used by the Enterprise JavaBeans (EJB) container to dispatch asynchronous methods is not configurable. The following configuration information is provided to help you understand the limits imposed by this work manager. Remember, one EJB container work manager exists for all asynchronous methods running in the application server process.

The EJB container work manager has the following thread pool settings:

- Minimum number of threads = 1
- Maximum number of threads = 5
- Work request queue size = 0 work objects
- Action taken when buffer overflows = Block
- Remote Future object duration = 86400 seconds

**Note:** Work request queue size is the maximum number of asynchronous method requests that can be queued while waiting for a thread to become available. If you specify a value of 0 (the default) or blank is specified, the queue size is managed by the run time.

Additionally, the EJB container work manager has configuration settings that specify which service contexts are propagated from the client thread to the work manager thread that runs the asynchronous method. The global transaction service context and the activity session service context are not propagated. The security context, and all of the WebSphere extension contexts, such as work area, internationalization, and so on, are propagated for use on the execution thread.

## EJB asynchronous methods settings

Use this page to modify settings on the work manager used in support of Enterprise JavaBeans asynchronous methods.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **EJB Container Settings** > **EJB asynchronous method invocation settings**

The Use internal work manager instance and Use custom work manager instance options are *mutually exclusive.*

***Use this work manager for asynchronous methods:***

Specifies a default work manager instance.

The product provides an internal work manager instance for support of EJB asynchronous methods. The internal work manager instance is pre-configured for basic EJB asynchronous method functionality, and provides limited configuration settings.

Clicking this button specifies that you want to use the internal work manager instance to manage your asynchronous method invocations. Selecting this choice precludes the Use custom work manager instance option.

The Use internal work manager instance option is the default. Alternatively, you can use a custom-defined work manager instance.

***Use custom work manager instance:***

Specifies a custom-defined work manager instance.

You can provide a more advanced configuration for EJB asynchronous methods by defining a custom work manager instance.

Selecting this choice allows you to use a work manager instance that you have already defined and configured in a way that is optimal for your environment.

Selecting this choice precludes the Use internal work manager instance option.

***Maximum number of threads:***

Specifies the maximum number of threads that are used in the execution of asynchronous EJB methods. The default is 5.

***Work request queue size:***

Specifies the size of the work request queue. The work request queue is a buffer that holds requested that asynchronous methods until a thread is available to run them on. The default is 0, indicating that the initial size is half way between the minimum and maximum number of threads.

The sum of the maximum number of threads and the work request queue size attributes is the total number of allowable in-progress method requests.

For example, if the maximum number of threads is set to five threads, and the work request queue size is set to 50, then the total number of allowable in-progress method requests is 55.

The default value is 0, indicating that the queue size is managed by the runtime environment. The runtime currently uses the larger of 20 and maxThreads.

***Work request queue full action:***

Specifies the action taken when the thread pool is exhausted, and the work request queue is full. The default is BLOCK.

If set to FAIL, an exception occurs instead of waiting for a thread, or a place in the queue, to become available.

You might want to use this option during development to help identify errors caused by long-running asynchronous methods. You might also use it to help determine the number of threads and queue size that should be configured.

If set to BLOCK, the thread that is requesting that the asynchronous method execution waits until a thread, or a place in the queue, becomes available.

***Work Manager JNDI name:***

Specifies the Java Naming and Directory Interface (JNDI) name used to look up the custom-defined work manager in the namespace.

***Remote future object duration:***

Specifies the amount of time that the server retains the future object of each fire-and-return-results asynchronous method call. If an application does not retrieve the results within the specified period of time, the server purges the results of that method call to prevent memory leakage and a potential OutOfMemory exception. You can specify 0 to never purge the objects; however, specifying a zero value means that the future object never times out and you disable protection from incorrectly written programs that might cause the referenced OutOfMemory exception. The default value is 86400 seconds (24 hours).

**Note:** If you call the get() or the get(time) method on the future object, then you might decrease performance because blocking can occur until either the work is done or until the specified time has passed. Therefore, to avoid blocking on the get(..) methods, call the isDone() method, which returns immediately. Then, call the get() method after the isDone() method returns true.

**Note:** This value is only applicable for clients that call the enterprise bean using a remote business interface, the value is not used for local business interface or no-interface views. When the asynchronous work has completed, the server sets an alarm for the duration specified to the server-side future object. When the alarm is activated, the server releases all the resources associated with the future object, making it unavailable to the client. If the client calls the get() method on the future object before the duration amount of time, the alarm is canceled and all the resources associated with the future object are released.

# Developing a session bean to have a No-Interface Local View

## About this task

A session bean has a No-Interface Local view when:

- The bean does not expose any other client views (Local, Remote, 2.x Remote Home, 2.x Local Home, Web Service) and its implements clause is empty.
- The bean exposes at least one other client view. The bean designates that it exposes a no-interface view with the @LocalBean annotation on the bean class or in the deployment descriptor.

A couple of code snippets to demonstrate the points previously mentioned:

```
session bean with No-Interface view because no declared interfaces
@Stateless
public class CartBean
```

```
session bean with No-Interface view by using the @LocalBean annotation
@Stateless
@LocalBean
@Remote( Cart.class )
public class CartBean implements Cart
```

You can also declare metadata for a session bean with No-Interface Local view in the deployment descriptor rather than using annotations:

```
<?xml version="1.0"?>
<ejb-jar
  xmlns="http://java.sun.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
```

```
  xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_1.xsd"
  version="3.1">
  <enterprise-beans>
    <session>
      <ejb-name>CartBean</ejb-name>
      <local-bean/>
      <business-remote>com.ibm.example.Cart</business-remote>
      <ejb-class>com.ibm.example.CartBean</ejb-class>
      <session-type>Stateless</session-type>
    </session>
  </enterprise-beans>
</ejb-jar>
```

### No-Interface Local View

New in Enterprise JavaBeans (EJB) 3.1, session beans might now be exposed to clients through a No-Interface view. In prior versions of the specification, bean developers were required to provide an interface that would be used to expose the bean methods to a client.

The new No-Interface Local View enables the customer to use the Enterprise JavaBeans (EJB) class as the local interface. This is supported when:

- The bean does not expose any other client views (Local, Remote, 2.x Remote Home, 2.x Local Home, Web Service) and its implements clause is empty.
- The bean exposes at least one other client view. The bean designates that it exposes a no-interface view by means of the @LocalBean annotation on the bean class or in the deployment descriptor.

### A session bean might now subclass another session bean

New in Enterprise JavaBeans (EJB) 3.1, a session bean might now subclass another session bean. Prior versions of the EJB specification restricted a session bean from inheriting from another session bean.

**Important:** This new support only enables implementation inheritance but does not provide component inheritance. Therefore, any meta data or annotations on the superclass that defined it to be an enterprise bean, will not be inherited by the subclass.

## Developing singleton session beans

Create a bean implementation class for a singleton session bean, introduced by the Enterprise JavaBeans (EJB) 3.1 specification. The EJB container initializes only one instance of a singleton session bean, and that instance is shared by all clients. Because a single instance is shared by all clients, singleton session beans have special life cycle and concurrency semantics.

### Before you begin

Make sure that you understand the inheritance rules for each annotation you implement. For example, the @ConcurrencyManagement annotation is coded on the singleton session bean class only. You cannot use the @ConcurrencyManagement annotation in the class that it extends, or any class higher in the class inheritance tree.

### About this task

Singleton session beans can have business local, business remote, and web service client views; they cannot have EJB 2.1 local or remote client views. This singleton session bean support replaces the proprietary startup bean functionality, which has been deprecated.

The following example shows a basic singleton session bean:

```
public interface Configuration {
 Object get(String name);
 void set(String name, Object value);
}
```

```
@Singleton
public class ConfigurationBean implements Configuration {
 private Map<String, Object> settings = new HashMap<String, Object>();

 public Object get(String name) {
  return settings.get(name);
 }

 public void set(String name, Object value) {
  settings.put(name,value);
 }
}
```

As with other enterprise bean types, you can also declare metadata for singleton session beans in the deployment descriptor rather than using annotations; for example:

```
<?xml version="1.0"?>
<ejb-jar
  xmlns="http://java.sun.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_1.xsd"
  version="3.1"
>
  <enterprise-beans>
    <ejb-name>ConfigurationBean</ejb-name>
    <business-local>com.ibm.example.Configuration</business-local>
    <ejb-class>com.ibm.example.ConfigurationBean</ejb-class>
    <session-type>Singleton</session-type>
  </enterprise-beans>
</ejb-jar>
```

## Procedure

- Code the initialization and destruction methods, understanding how they relate to your options for setting the transaction context. During initialization, the instance is created, dependency injection occurs, and PostConstruct life cycle interceptor callbacks are started. The PreDestroy life cycle interceptor callbacks are started for a singleton session bean when its containing application is stopped.

  It can be useful to complete transactional activities during the PostConstruct and PreDestroy life cycle interceptor callbacks. For this reason, singleton session bean life cycle interceptor callbacks have a well-defined transaction context. The following transaction context values are similar to @Timeout methods: only REQUIRED (default), REQUIRES_NEW, and NOT_SUPPORTED can be used, and REQUIRED is translated to REQUIRES_NEW.

  Transaction attributes are only recognized when they are specified on life cycle interceptor methods on the bean class. The same transaction context is used for all life cycle interceptors. The following example illustrates a singleton session bean with transaction attributes specified for the PostConstruct and PreDestroy life cycle interceptor callbacks.

  ```
  @Singleton
  public class ConfigurationBean implements Configuration {
   @PostConstruct
   @TransactionAttribute(REQUIRED) // the default; specified for illustration
   public void initialize() {
    // ...
   }

   @PreDestroy
   @TransactionAttribute(NOT_SUPPORTED)
   public void destroy() {
    // ...
   }

   // ...
  }
  ```

Instead of using an annotation, you can specify the same metadata using the XML deployment descriptor. If you specify transaction attributes in the XML deployment descriptor, then any metadata obtained from the @TransactionAttribute annotation is ignored. The following example uses the XML deployment descriptor to specify the same metadata as the previous example.

```
<assembly-descriptor>
  <container-transaction>
    <method>
      <ejb-name>ConfigurationBean</ejb-name>
      <method-name>initialize</method-name>
    </method>
    <trans-attribute>Required</trans-attribute>
  </container-transaction>

  <container-transaction>
    <method>
      <ejb-name>ConfigurationBean</ejb-name>
      <method-name>destroy</method-name>
    </method>
    <trans-attribute>NotSupported</trans-attribute>
  </container-transaction>
</assembly-descriptor>
```

- Unless otherwise specified, the singleton session bean instance is typically initialized when the bean is first used through one of its client views, which is the same as any other session bean. Use the @Startup annotation or the corresponding XML deployment descriptor to mark a bean as a startup bean. Marking a singleton bean as a startup bean means that the EJB container must run the PostConstruct method before it supports any external client requests made to the application to run. A PostConstruct method in a singleton bean can create an EJB timer, add a message to a JMS queue or topic, call an asynchronous EJB method, or initiate other asynchronous mechanisms that call an EJB. However, to avoid a deadlock, the PostConstruct method must not wait for an EJB timer to run, a message-driven bean method to be called, or an asynchronous EJB method to finish.

  Application developers can place business logic in the PostConstruct methods of these startup singleton instances to complete tasks that must be performed before any client work being started by the container, such as preloading caches or initiating asynchronous work within the application.

  The following example illustrates a singleton session bean with startup initialization:

```
@Singleton
@Startup
public class ConfigurationBean implements Configuration {
 @PostConstruct
 public void initialize() {
  // 1. Create the database table if it does not exist.
  // 2. Initialize settings from the database table.
  // 3. Load a cache.
  // 4. Initiate asynchronous work (for example, work to a messaging queue or to
  //    calls to asynchronous session bean methods.
 }

 // ...
}
```

  Instead of using an annotation, you can specify the same metadata using the XML deployment descriptor. Specify `true` to mark this singleton bean as a startup singleton. Conversely, specify `false`, and the @Startup annotation is overridden, if it exists on the class file.

```
<session>
  <ejb-name>ConfigurationBean</ejb-name>
  <init-on-startup>true</init-on-startup>
</session>
```

- Determine whether the initialization method of the singleton session bean has an implicit dependency on another singleton session bean.

  If an implicit dependency exists, use dependency metadata to make the dependency explicit. The container ensures that dependency singleton beans are initialized before their dependent beans are

initialized and that they are destroyed after their dependent beans are destroyed. The following example illustrates a singleton session bean with dependency metadata:

```
@Singleton
public class DatabaseBean {
 @PostConstruct
 public void initialize() {
  // Create database tables.
 }
}

@Singleton
@DependsOn({"DatabaseBean"})
public class ConfigurationBean implements Configuration {
 @PostConstruct
 public void initialize() {
  // Initialize settings from a database table.
 }

 // ...
}
```

Additionally, you can make cross-module dependencies by using the ejb-link `module.jar#bean` syntax. Circular dependencies are not supported, and cause an application to fail.

Instead of using an annotation, you can specify the same metadata using the XML deployment descriptor. If you specify dependency metadata in the XML deployment descriptor, then any metadata from the @DependsOn annotation is ignored.

```
    <session>
      <ejb-name>ConfigurationBean</ejb-name>
      <depends-on>
        <ejb-name>DatabaseBean</ejb-name>
      </depends-on>
    </session>
```

- Decide whether to use container-managed concurrency or bean-managed concurrency. The @Lock and @AccessTimeout annotations are not applicable when bean-managed concurrency is used.

  You can implement the @ConcurrencyManagement annotation on the singleton session bean class only. It cannot be used on the class it extends or any class higher in the class inheritance tree. The following code example illustrates a singleton with bean-managed concurrency:

```
@Singleton
@ConcurrencyManagement(BEAN)
public class ConfigurationBean implements Configuration {
 private Map<String, Object> settings = new HashMap<String, Object>();

 synchronized public Object get(String name) {
  return settings.get(name);
 }

 synchronized public void set(String name, Object value) {
  settings.put(name, value);
 }
}
```

  Instead of using an annotation, you can specify the same metadata using the XML deployment descriptor. If the metadata is specified in both the XML deployment descriptor and using the @ConcurrencyManagement annotation, then the value must match or the application fails. The following example uses the XML deployment descriptor to specify the same metadata as the previous example.

```
    <session>
      <ejb-name>ConfigurationBean</ejb-name>
      <concurrency-management-type>Bean</concurrency-management-type>
    </session>
```

  The container does not do locking for each method called. Instead, the actual bean is responsible for the locking that is required. In the example, the bean provider has chosen to implement the methods using the synchronized keyword. This is supported for singleton session beans with bean-managed

concurrency, but it is not supported for other EJB component types. It is not required for the bean provider to use the synchronized keyword to provide concurrency. For example, the bean provider can use the java.util.concurrent.locks.ReentrantReadWriteLock class that is found in JDK 5 and later.

The locking semantics required by the EJB 3.1 specification for container-managed concurrency matches the behavior of the java.util.concurrent.locks.ReentrantReadWriteLock class.

- If you are using container-managed concurrency, use the @Lock notation to manage concurrency of methods.

  The following code example illustrates singleton with container-managed concurrency.

```
@Singleton
public class ConfigurationBean implements Configuration {
 private Map<String, Object> settings = new HashMap<String, Object>();

 @Lock(READ)
 public Object get(String name) {
  return settings.get(name);
 }

 public void set(String name, Object value) {
  settings.put(name, value);
 }
}
```

  Instead of using an annotation, you can specify the same metadata using the XML deployment descriptor. If the metadata is specified in both the XML deployment descriptor and the @Lock annotation, then the metadata obtained from the @Lock annotation is ignored. The following example uses the XML deployment descriptor to specify the same metadata as the previous example.

```
    <session>
      <ejb-name>ConfigurationBean</ejb-name>
      <concurrent-method>
        <method>
          <method-name>get</method-name>
        </method>
        <lock>Read</lock>
      </concurrent-method>
    </session>
```

  The example also illustrates annotating a method with @Lock(READ) to indicate that the container must get a read lock when that method is started. When a method is annotated with @Lock, it overrides the @Lock annotation that is specified at the class level. When there is no @Lock annotation at class level, the default is a write lock. In the example, the @Lock(READ) on the method is overriding the default write lock at the class level. When a method is not annotated at the method level and there is no annotation at the class level, the default of write lock is used by the container.

  Because most methods require a read lock, use @Lock(READ) at the class level to indicate that all business methods in this class require the container to obtain a read lock. For methods that require a write lock, annotate those methods with @Lock(WRITE) to show that it overrides the read lock that was specified at the class level.

  The following example illustrates this technique:

```
@Singleton
@Lock(READ)
public class ConfigurationBean implements Configuration {
 private Map<String, Object> settings = new HashMap<String, Object>();

 public Object get(String name) {
  return settings.get(name);
 }

 @Lock(WRITE)
 public void set(String name, Object value) {
  settings.put(name, value);
 }
}
```

The @Lock annotation applies only to methods that are declared in the same class as the @Lock annotation. For a given class, the metadata for @Lock is never inherited from a class higher in the class inheritance tree. Instead of using an annotation at the class level, the same metadata can be specified in the XML deployment descriptor by using the special method-name *, which matches all methods.

- If you are using container-managed concurrency, use the @AccessTimeout notation to limit how long a method waits for a lock to be granted. The following code example illustrates concurrent access timeouts.

```
@Singleton
public class ConfigurationBean implements Configuration {
 @Lock(READ)
 @AccessTimeout(1000)
 public Object get(String name) {
  // query the database
 }

 public void set(String name, Object value) {
  // update the database
 }
}
```

If no annotation is provided, the method defaults to wait until a lock is granted. There is no time limit for how long a client waits for the lock to be granted. Because nothing is coded at the class level, there is no wait time limit for a lock to be granted for all methods of the class. If the @AccessTimeout annotation is used and the container cannot grant the lock within the specified time limit, a javax.ejb.ConcurrentAccessTimeoutException is thrown to the client. The @AccessTimeout annotation applies only to methods that are declared in the same class as the @AccessTimeout annotation is in. For a given class, the metadata for the @AccessTimeout annotation is never inherited from a class higher in the class inheritance tree.

Like the @Lock annotation, you can also specify the @AccessTimeout annotation using the XML deployment descriptor, and if you use the XML deployment descriptor, the metadata from the @AccessTimeout annotation is ignored. The following example uses the XML deployment descriptor to specify the same metadata as the previous example.

```
<session>
  <ejb-name>ConfigurationBean</ejb-name>
  <concurrent-method>
    <method>
      <method-name>get</method-name>
    </method>
    <lock>Read</lock>
    <access-timeout>
      <timeout>1000</timeout>
      <unit>Milliseconds</unit>
    </access-timeout>
  </concurrent-method>
</session>
```

- It is important to know that the XML coding of the concurrent-methodType follows the three styles outlined in the EJB specification for composing the XML for container-transaction method elements.

  Remember that both the lock and access-timeout elements are optional. The three styles are described as follows:

  Style 1 uses the special method name * to apply the lock type, access-timeout value, or both to all business methods for the specified bean.

```
<!-- Example: Style 1 -->

    <concurrent-method>
      <method>
        <method-name>*</method-name>
      </method>
      <lock>Read</lock>
      <access-timeout>
```

```
          <timeout>2000</timeout>
          <unit>Milliseconds</unit>
        </access-timeout>
      </concurrent-method>
```

Style 2 is used to refer to a business method with a specific name and assign it the specified lock type, access-timeout value, or both. If the method name is overloaded, meaning multiple methods have the same name but different method signatures, all methods with this name have the specified lock type, access-timeout value, or both. Style 2 takes precedence over style 1.

```
<!-- Example: Style 2 -->

      <concurrent-method>
        <method>
          <method-name>businessMethod</method-name>
        </method>
        <lock>Read</lock>
        <access-timeout>
          <timeout>2000</timeout>
          <unit>Milliseconds</unit>
        </access-timeout>
      </concurrent-method>
```

Style 3 is used to refer to a distinct method that matches the given method name and has a method signature which matches the method parameters listed. Style 3 takes precedence over both style 1 and style 2.

```
<!-- Example: Style 3 -->

      <concurrent-method>
        <method>
          <method-name>businessMethod</method-name>
          <method-params>
            <method-param>long</method-param>
            <method-param>int</method-param>
          </method-params>
        </method>
        <lock>Read</lock>
        <access-timeout>
          <timeout>2000</timeout>
          <unit>Milliseconds</unit>
        </access-timeout>
      </concurrent-method>
```

If style 1 XML is used to define a lock type, then all @Lock annotations on the bean are ignored. The same is true for access timeout. If style 1 XML is used to define an access timeout value then all @AccessTimeout annotations on the bean are ignored.

- It is important to understand that the @Lock and @AccessTimeout annotations are treated independently of one another as is the corresponding XML deployment descriptor code for each.

  The implementation of this concept has multiple benefits. This separation of lock type and access timeout helps to prevent you from negatively affecting black box application code by not requiring you to know the lock type. You can safely leave the lock type value and adjust the access timeout value only to fit your environment needs, and avoid possible deadlock situations or other concurrency issues. Consider a scenario where you have a vendor supplied EJB application running and due to system slow down it keeps timing out. You do not want to change the locking logic for fear of causing a deadlock situation but you do want to modify the timeout limit. You can edit the deployment descriptor and specify the access timeout value you need for the methods you want to modify.

  The following example shows how you can specify just a method level @Lock(READ) annotation in the bean implementation and use style 2 for composing XML to specify the access-timeout element to be 2,000 milliseconds, not providing the optional lock element. The result is a method with a read lock that has an access timeout of 2,000 milliseconds.

```
@Singleton
public class ConfigurationBean implements Configuration {

 @Lock(READ)
```

```
 public Object businessMethod(long value) {
  // ...
 }

       // ...
}
```

```
    <session>
      <ejb-name>ConfigurationBean</ejb-name>
      <concurrent-method>
        <method>
          <method-name>businessMethod</method-name>
        </method>
        <access-timeout>
          <timeout>2000</timeout>
          <unit>Milliseconds</unit>
        </access-timeout>
      </concurrent-method>
    </session>
```

Similarly, you can use a class level lock annotation and then specify the wanted access timeout value in XML using either style 2, style 3, or both as shown in the following example.

```
@Singleton
@Lock(READ)
public class ConfigurationBean implements Configuration {

 public Object businessMethod(long value) {
  // ...
 }

 public Object businessMethod(long value, int i, Object value) {
  // ...
 }

 public Object businessMethod(long value, int i) {
  // ...
 }

}
```

```
    <session>
      <ejb-name>ConfigurationBean</ejb-name>
      <concurrent-method>
        <method>
          <method-name>businessMethod</method-name>
        </method>
        <access-timeout>
          <timeout>2000</timeout>
          <unit>Milliseconds</unit>
        </access-timeout>
      </concurrent-method>
      <concurrent-method>
        <method>
          <method-name>businessMethod</method-name>
          <method-params>
            <method-param>long</method-param>
            <method-param>int</method-param>
          </method-params>
        </method>
        <access-timeout>
          <timeout>8000</timeout>
          <unit>Milliseconds</unit>
        </access-timeout>
      </concurrent-method>
    </session>
```

The previous code example results in all methods named “businessMethod” having a lock type of read and an access timeout of 2,000 milliseconds. The exception is the one instance of the method

“businessMethod” that has a method signature with the first parameter being of type long and the second being of type int, This instance of method "businessMethod" has a lock type of read, but has an access timeout of 8,000 milliseconds. The same principle applies when style 1 XML is used to define only a lock type, but not an access timeout value. You can add an access timeout value to a specific method or methods using style 2, style 3, or both to get a specific lock type and access timeout value result. The following example illustrates this point:

```
    <session>
      <ejb-name>ConfigurationBean</ejb-name>
      <concurrent-method>
        <method>
          <method-name>*</method-name>
        </method>
        <lock>Read</lock>
      </concurrent-method>
      <concurrent-method>
        <method>
          <method-name>businessMethod</method-name>
        </method>
        <access-timeout>
          <timeout>2000</timeout>
          <unit>Milliseconds</unit>
        </access-timeout>
      </concurrent-method>
    </session>
```

The previous code example results in all business methods having a lock type of read and the method named, businessMethod, having a lock type of read and an access timeout of 2,000 milliseconds. You can also have a class level @Lock annotation to set the lock type for all methods and use style 1 for composing XML to set just the access timeout value for all methods. See the following example:

```
@Singleton
@Lock(READ)
public class ConfigurationBean implements Configuration {

 public Object businessMethod(long value) {
  // ...
 }

        // ...

}
```

```
    <session>
      <ejb-name>ConfigurationBean</ejb-name>
      <concurrent-method>
        <method>
          <method-name>*</method-name>
        </method>
        <access-timeout>
          <timeout>2000</timeout>
          <unit>Milliseconds</unit>
        </access-timeout>
      </concurrent-method>
    </session>
```

The previous example results in all business methods of bean, ConfigurationBean, having a lock type of read and an access timeout value of 2,000 milliseconds.

- Ensure that you understand the inheritance rules for the annotations that you have used.
- Avoid reentrant locking behavior that can occur if a read lock method calls a write lock method in the same singleton session bean.

  Suppose the business method of a singleton session bean either directly or indirectly causes another business method of the singleton session bean to be started. If the first method is a write lock method, then that method can call any other business method of the singleton session bean without any special consideration. However, you might carefully implement a read lock method if it were to call another

business method of that same singleton session bean class that is a write lock method. Then a `javax.ejb.IllegalLoopbackException` exception occurs.

### Changing singleton session bean locking policy

Use this task to override the default non-fair locking policy for all singleton session bean write locks within the server. This task is for WebSphere Application Server users who do not want lock requests for their Singleton session bean method invocations to follow a non-fair policy.

#### About this task

Locks for singleton session bean methods are obtained using a *non-fair* locking policy by default. When locks are constructed as *fair*, threads contend for entry using an approximate arrival-order policy. When lock is released, the longest waiting lock is granted regardless if it is reader or writer.

When locks are constructed as non-fair, the order in which locks are obtained is not guaranteed. If readers are active and a writer enters the queue, subsequent readers might get granted the read lock before the writer is granted the lock.

#### Procedure

1. Optional: Open the administrative console.
2. Select **Servers**.
3. Select **Server Types**.
4. Select **WebSphere application servers**.
5. Select the server that you want to configure.
6. From Server Infrastructure, select **Java and Process Management Process definition.**
7. From Additional Properties, select **Java Virtual Machine**.
8. In the Additional Properties area, select **Custom Properties**.
9. On the Application servers page, click **New** to specify an arbitrary name and value pair for your server.
10. In the **Name** entry field, type: `com.ibm.websphere.ejbcontainer.useFairSingletonLockingPolicy`
11. In the **Value** entry field, type `true`.

    **Attention:** Entering `true` causes all locks obtained for singleton session bean methods to use a fair policy. Entering `false` causes all locks obtained for singleton session bean methods to use a non-fair policy. The default policy is non-fair.
12. Click **OK**.
13. Save the configuration.
14. Restart the server.

#### Results

The locking policy has now been set for all locks obtained for singleton session beans within the server.

## Programming to use message-driven beans

Applications can use message-driven beans as asynchronous message consumers. You deploy a message-driven bean as a message listener for a destination. When a message arrives at the destination, the EJB container invokes the message-driven bean automatically without an application having to explicitly poll the destination.

## About this task

You can use a tool such as Rational Application Developer to develop applications that use message-driven beans. You can use the WebSphere Application Server runtime tools, such as the administrative console, to deploy and administer applications that use message-driven beans.

For more information about implementing enterprise applications that use message-drive beans, see the following topics:

## Procedure

- Develop message-driven beans.
- Design an enterprise application to use message-driven beans.
- Develop an enterprise application to use message-driven beans.
- Deploy an enterprise application to use message-driven beans with JCA 1.5-compliant resources.
- Deploy an enterprise application to use message-driven beans with listener ports.

# Developing message-driven beans

You can develop a bean implementation class for a message-driven bean as introduced by the Enterprise JavaBeans specification. A message-driven bean (MDB) is a message consumer that implements business logic and runs on the server.

## Before you begin

Determine the messaging model you want for your application regarding use of topics, queues, producers and consumers, publish or subscribe, and so on. You can refer to the message-driven bean component contract that is described in the Enterprise JavaBeans™ specification.

## About this task

A message-driven bean (MDB) is a consumer of messages from a Java Message Service (JMS) provider. An MDB is invoked on arrival of a message at the destination or endpoint that the MDB services. MDB instances are anonymous, and therefore, all instances are equivalent when not actively servicing a client message. The container controls the life cycle of bean instances, which hold no state that is visible to a client.

The following example is a basic message-driven bean:

```
@MessageDriven(activationConfig={
                @ActivationConfigProperty(propertyName="destination",     propertyValue="myDestination"),
                @ActivationConfigProperty(propertyName="destinationType", propertyValue="javax.jms.Queue")
})
public class MsgBean implements javax.jms.MessageListener {

  public void onMessage(javax.jms.Message msg) {

      String receivedMsg = ((TextMessage) msg).getText();
      System.out.println("Received message: " + receivedMsg);

   }

}
```

As with other enterprise bean types, you can also declare metadata for message-driven beans in the deployment descriptor rather than using annotations, for example:

```
<?xml version="1.0" encoding="UTF-8"?>

<ejb-jar id="EJBJar_1060639024453" version="3.0"
      xmlns="http://java.sun.com/xml/ns/javaee"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
```

```
      xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_0.xsd"
      metadata-complete="false">
  <enterprise-beans>

    <message-driven>

      <ejb-name>MsgBean</ejb-name>
      <ejb-class>com.acme.ejb.MsgBean</ejb-class>
      <activation-config>
         <activation-config-property>
            <activation-config-property-name>destination</activation-config-property-name>
            <activation-config-property-value>myDestination</activation-config-property-value>
         </activation-config-property>
         <activation-config-property>
           <activation-config-property-name>destinationType</activation-config-property-name>
           <activation-config-property-value>javax.jms.Queue</activation-config-property-value>
        </activation-config-property>
      </activation-config>

    </message-driven>

  </enterprise-beans>
</ejb-jar>
```

## Procedure

- Code the business logic of the message-driven bean, which must implement the appropriate message listener interface defined by the messaging type; for example, javax.jms.MessageListener. The business logic is invoked when the message listener method of the MDB is called to service a message; for example, `MessageListener.onMessage()`. If the MDB implements more than one interface, denote the message listener interface by coding the `messageListenerInterface` attribute of the `MessageDriven` annotation, or by coding the `<messaging-type>` element of the `message-driven` deployment descriptor element. You do not have to specify which is the message listener interface, as long as there is only one interface other than `java.io.Serializable`, `java.io.Externalizable`, or any of the `javax.ejb` package interfaces.
- You can optionally define message destination references on any type of enterprise bean. A message destination reference is a logical name by which an enterprise bean can refer to a message destination. The `Resource` annotation is used to inject a message destination reference, for example:

  ```
  @Resource (name="jms/Outlet", type=javax.jms.Queue) Queue salesOutlet;
  ```

  Alternatively, you can use the `<message-destination-ref>` element in the deployment descriptor to specify the message destination reference; for example:

  ```
  <message-destination-ref>
     <message-destination-ref-name>jms/Outlet</message-destination-ref-name>
     <message-destination-type>javax.jms.Queue</message-destination-type>
     <injection-target>
       <injection-target-class>com.acme.ejb.MsgBean</injection-target-class>
       <injection-target-name>salesOutlet</injection-target-name>
    </injection-target>
  </message-destination-ref>
  ```

  The `message-destination-ref` element is similar to the `resource-env-ref` element, but also has subelements, `message-destination-usage` with possible values `Produces`, `Consumes` or `ProducesConsumes`, and `message-destination-link`. You can use the `message-destination-link` element to tie two or more message-destination-ref references in the deployment descriptor together, which allows the deployer to bind the destination for several enterprise beans all at once, to the same destination. The message-destination-link value must match the `message-destination-name` value in the `message-destination` element; for example:

  ```
  <ejb-jar>

    <enterprise-beans>

      <session>
        <ejb-name>OutletBean</display-name>
        ...
  ```

```
      <message-destination-ref>
        <message-destination-ref-name>jms/target</message-destination-ref-name>
        <message-destination-type>javax.jms.Queue</message-destination-type>
        <message-destination-usage>Produces</message-destination-usage>
        <message-destination-link>destination</message-destination-link>
      </message-destination-ref>
      ...
    </session>

    <session>
      <ejb-name>InletBean</display-name>
      ...
      <message-destination-ref>
        <message-destination-ref-name>jms/source</message-destination-ref-name>
        <message-destination-type>javax.jms.Queue</message-destination-type>
        <message-destination-usage>Consumes</message-destination-usage>
        <message-destination-link>destination</message-destination-link>
      </message-destination-ref>
      ...
    </session>

    <message-driven>
      <ejb-name>InletBean</display-name>
      ...

      <ejb-name>MsgBean</ejb-name>
      <ejb-class>com.acme.MsgBean</ejb-class>
      <messaging-type>javax.jms.MessageListener</messaging-type>
      <message-destination-type>javax.jms.Queue</message-destination-type>
      <message-destination-link>destination</message-destination-link>

      ...
    </message-driven>

  </enterprise-beans>
      ...
  <assembly-descriptor>
    ...
    <message-destination>
      <message-destination-name>destination</message-destination-name>
    </message-destination>
    ...
  </assembly-descriptor>

</ejb-jar>
```

The `message-destination-link` element can refer to a destination that is defined in a different Java archive (JAR) file within the same application, as with an `ejb-link` element. For example, to link to the destination, `ProduceQueue`, defined in the `grocery.jar` file, enter the following line in the deployment descriptor:

```
<message-destination-link>grocery.jar#ProduceQueue</message-destination-link>
```

- As with any enterprise bean, you can package a message-driven bean in a JAR file, or in a web application archive (WAR) file.

### Results

You developed a simple message-driven bean, along with some deployment and packaging options.

### What to do next

Read related information about designing an enterprise application that uses message-driven beans.

## Designing an enterprise application to use message-driven beans

To help you design your enterprise application, consider a generic enterprise application that uses one message-driven bean to retrieve messages from a JMS queue destination, and passes the messages on to another enterprise bean that implements the business logic.

## About this task

To design an enterprise application to use message-driven beans, complete the following steps:

## Procedure

1. Identify the message listener interface for the message type that the message-driven bean is to handle. The message-driven bean class must implement this message listener interface. For example, an EJB message-driven bean class used for JMS messaging must implement the javax.jms.MessageListener interface.
2. Identify the resources that the application is to use. This helps to identify the properties of resources that must be used within the application and configured as application deployment descriptors or within WebSphere Application Server.

*Table 84. JMS resource types and examples of their properties. The left hand column of this table lists the JMS resource types, and the right hand column shows examples of the properties of each of the JMS resource types shown in the left hand column.*

| JMS resource type | Properties (for example) |
|---|---|
| JMS connection factory | **Name:** SamplePtoPQueueConnectionFactory<br>**JNDI Name:** Sample/JMS/QCF |
| JMS destination | **Name:** Q1<br>**JNDI Name:** Sample/JMS/Q1 |
| J2C activation specification properties | **Name:** MyMDBsActivationSpec<br>**JNDI Name:** eis/MyMDBsActivationSpec<br>**Destination JNDI Name:** MyQueue<br>**Destination type:** javax.jms.Queue |
| Message-driven bean (deployment properties) | **Name:** JMSppSampleMDBBean<br>**Transaction type:** Container<br>**Message selector:** JMSType='car'<br>**Acknowledge mode:** Dups OK Acknowledge<br>**Destination type:** javax.jms.Queue<br>**ActivationSpec JNDI name:** MyMDBsActivationSpec |
| Business logic bean | **Name:** MyLogicBean |

   Ensure that you use consistent values where needed; for example, the JNDI name for the J2C activation specification must be the same in both the activation specification and the Message-driven bean deployment attributes.
3. Separate out the business logic. You should develop a message-driven bean to delegate the business processing of incoming messages to another enterprise bean. This provides clear separation of message handling and business processing. This also enables the business processing to be invoked by either the arrival of incoming messages or, for example, from a WebSphere J2EE client.
4. Decide whether to configure security. Messages arriving at a destination being processed by a listener have no client credentials associated with them; the messages are anonymous. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component. For more information about EJB security, see EJB component security.
5. Understand how best effort nonpersistent messages are handled by the default messaging provider.

   If you have a non-transactional message-driven bean, the system either deletes the message when the message-driven bean starts, or when the message-driven bean completes. If the message-driven bean generates an exception, and therefore does not complete, the system takes one of the following actions:
   - If the system is configured to delete the message when the message-driven bean completes, then the message is despatched to a new instance of the message-driven bean, so the message has another opportunity to be processed.
   - If the system is configured to delete the message when the message-driven bean starts, then the message is lost.

The message is deleted when the message-driven bean starts if the quality of service is set to Best effort nonpersistent. For all other qualities of service, the message is deleted when the message-driven bean completes.

# Developing an enterprise application to use message-driven beans

Applications can use message-driven beans as asynchronous message consumers. You deploy a message-driven bean as a message listener for a destination. The message-driven bean is invoked by an activation specification or a JMS listener when a message arrives on the input destination that is being monitored.

## About this task

You develop an enterprise application to use a message-driven bean as with any other enterprise bean, except that a message-driven bean does not have a home interface or a remote interface.

You should develop your message-driven bean to delegate the business processing of incoming messages to another enterprise bean, which provides clear separation of message handling and business processing. This separation also means that the business processing can be invoked either by the arrival of incoming messages or, for example, by a WebSphere J2EE client. Responses can be handled by another enterprise bean acting as a sender bean, or they can be handled in the message-driven bean.

EJB 2.0 message-driven beans support only Java Message Service (JMS) messaging. EJB 2.1 and EJB 3 message-driven beans can support other messaging types in addition to JMS. All message-driven beans must implement the MessageDrivenBean interface. For JMS messaging, a message-driven bean must also implement the message listener interface javax.jms.MessageListener. Other Java EE Connector Architecture (JCA)-compliant resource adapters might provide their own message listener interfaces that must be implemented.

You can use the New Enterprise Bean wizard of Rational Application Developer to create an enterprise bean with a bean type of Message-driven bean. The wizard creates appropriate methods for the type of bean.

By convention, the message-driven bean class is named *name*Bean, where *name* is the name you assign to the message-driven bean; for example:

```
public class MyJMSppMDBBean implements MessageDrivenBean, javax.jms.MessageListener
```

A message-driven bean can be registered with the EJB timer service for time-based event notifications if it also implements the javax.ejb.TimedObject interface, and invokes the timer callback method by the following call: `void ejbTimeout(Timer)`. At the scheduled time, the container then calls the message-driven bean ejbTimeout method.

The message-driven bean class must define and implement the following methods:

- onMessage(message), which must meet the following requirements:
  - The method must have a single argument of type javax.jms.Message.
  - The `throws` clause must not define any application exceptions.
  - If the message-driven bean is configured to use bean-managed transactions, it must call the javax.transaction.UserTransaction interface to scope the transactions. Because these calls occur inside the onMessage() method, the transaction scope does not include the initial message receipt. For more information, see the topic about message-driven beans transaction support.

  To handle the message within the onMessage() method (for example, to pass the message on to another enterprise bean), you use standard JMS. This is known as bean-managed messaging.

  If you are using a JCA-compliant resource adapter with a different message listener interface, another method besides the onMessage() method might be needed. For information about the message listener interface needed, see the documentation that was provided with your JCA-compliant resource adapter.
- ejbCreate()

You must define and implement an ejbCreate method for each way in which you want a new instance of an enterprise bean to be created.

- ejbRemove()

  This method is invoked by the container when a client invokes the remove method inherited by the enterprise bean home interface from the javax.ejb.EJBHome interface. This method must contain any code that you want to execute before an enterprise bean instance is removed from the container (and the associated data is removed from the data source).
- ejbTimeout(Timer)

  This method is needed only to support notifications from the timer service, and contains the business logic that handles time events received.

## Procedure

1. Create the Enterprise Application project.
2. Create the message-driven bean class. You can use the New Enterprise Bean wizard of Rational(r) Application Developer to create the enterprise bean with a bean type of Message-driven bean.

   For an example of how to create the message-driven bean class, see the Example section of this topic. For more information, see *Creating message-driven beans* in the Rational Application Developer information center. The result of this step is a message-driven bean that can be assembled into an EAR file for deployment.
3. Optional: Use the EJB deployment descriptor editor to review and, if needed, change the deployment attributes. You can use the EJB deployment descriptor editor to review deployment attributes that you specified on the EJB creation wizard (such as **Transaction type** and **Message selector**) and other default deployment attributes.

   If needed, you can override the values of these attributes later, after the enterprise application has been exported into an EAR file for deployment, as described in “Configuring deployment attributes for a message-driven bean against JCA 1.5-compliant resources” on page 697 and “Configuring deployment attributes for a message-driven bean against a listener port” on page 700.

   a. In the property pane, select the **Bean** tab.

   b. On the main panel, configure the **Transaction type** attribute.

      **`Transaction type`**
      This attribute determines whether the message-driven bean manages its own transactions, or whether the container manages transactions on behalf of the bean.
      **Bean** The message-driven bean manages its own transactions.
      **Container**
      The container manages transactions on behalf of the bean.

   c. Under **Activation Configuration**, review the following attributes:

      **`acknowledgeMode`**
      This attribute determines how the session acknowledges any messages it receives.
      **Auto Acknowledge**
      The session automatically acknowledges delivery of each message.
      **Dups OK Acknowledge**
      The session lazily acknowledges the delivery of messages. This setting is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumer applications that are tolerant of duplicate messages.

      As defined in the EJB specification, clients cannot use the Message.acknowledge() method to acknowledge messages. If a value of CLIENT_ACKNOWLEDGE is passed on the create*xxx*Session call, then messages are automatically acknowledged by the application server and the Message.acknowledge() method is not used.

      **Note:**

      The acknowledgement is sent when the message is deleted.

If you have a non-transactional message-driven bean, the system either deletes the message when the message-driven bean starts, or when the message-driven bean completes. If the message-driven bean generates an exception, and therefore does not complete, the system takes one of the following actions:

- If the system is configured to delete the message when the message-driven bean completes, then the message is despatched to a new instance of the message-driven bean, so the message has another opportunity to be processed.
- If the system is configured to delete the message when the message-driven bean starts, then the message is lost.

The message is deleted when the message-driven bean starts if the quality of service is set to Best effort nonpersistent. For all other qualities of service, the message is deleted when the message-driven bean completes.

**destinationType**

This attribute determines whether the message-driven bean uses a queue or topic destination.

**Queue**
The message-driven bean uses a queue destination.

**Topic** The message-driven bean uses a topic destination.

**subscriptionDurability**

This attribute determines whether a JMS topic subscription is durable or nondurable.

**Durable**
A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the subscription in the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription messages until they are received by the subscription or until they expire.

**Nondurable**
Nondurable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.

A nondurable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created.

**messageSelector**

This attribute determines the JMS message selector that is used to select which messages the message-driven bean receives. For example:

```
JMSType='car' AND color='blue' AND weight>2500
```

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

d. Specify bindings deployment attributes.

Under **WebSphere Bindings**, select the **JCA Adapter** option then specify the bindings deployment attributes:

**ActivationSpec JNDI name**
This attribute specifies the JNDI name of the activation specification that is used to deploy this message-driven bean. This name must match the name of an activation specification that you define to WebSphere Application Server.

**ActivationSpec Authorization Alias**
This attribute specifies the name of an authentication alias used for authentication of connections to the JCA resource adapter. An authentication alias specifies the user ID and password that is used to authenticate the creation of a new connection to the JCA resource adapter.

**Destination JNDI name**
This attribute specifies the JNDI name that the message-driven bean uses to look up the JMS destination in the JNDI namespace.

e. Optional: Specify **Destination Link** to enable message linking.

Message linking allows the routing of messages to a specific message-driven bean in a deployment. Message linking allows message flow to be orchestrated between components in the same application.

For a message to be consumed and processed by a message-driven bean, the<message-destination-link> element must be defined in the deployment descriptor associated with the message-driven bean. The destination identified by the <message-destination-link> element corresponds to the logical destination.

When the <message-destination-ref> includes a <message-destination-link> element, messages are consumed at that destination.

In order to get the message-driven bean to consume messages sent to a destination, you can declare a <message-destination-link> element in the deployment descriptor, or alternatively set it in the activation specification.

4. Assemble and package the application for deployment.

## Results

The result of this task is an EAR file, containing the message-driven bean, for the enterprise application that can be deployed in WebSphere Application Server.

## Example

The following example shows how to create the message-driven bean class. The example code shows how to access the text and the JMS **MessageID**, from a JMS message of type TextMessage. In this example, first the onMessage() method of a message-driven bean is used to unpack the incoming text message and to extract the text and message identifier; then a private putMessage method (defined within the same message bean class) is used to put the message onto another queue:

```
public void onMessage(javax.jms.Message msg)
{
        String text      = null;
        String messageID = null;

        try
        {
                text = ((TextMessage)msg).getText();

                System.out.println("senderBean.onMessage(), msg text2: "+text);

                //
                // store the message id to use as the Correlator value
                //
                messageID = msg.getJMSMessageID();

                // Call a private method to put the message onto another queue
                putMessage(messageID, text);
        }
        catch  (Exception err)
        {
                err.printStackTrace();
        }
        return;
}
```

### What to do next

After you have developed an enterprise application to use message-driven beans, configure and deploy the application. For example, define activation specifications for the message-driven beans and, optionally, change the deployment descriptor attributes for the application. For more information, see “Deploying an enterprise application to use message-driven beans with JCA 1.5-compliant resources” and “Deploying an enterprise application to use message-driven beans with listener ports” on page 699.

## Deploying an enterprise application to use message-driven beans with JCA 1.5-compliant resources

Message-driven beans can be configured as listeners on a Java EE Connector Architecture (JCA) 1.5 resource adapter, such as the default messaging provider or the WebSphere MQ messaging provider in WebSphere Application Server.

### Before you begin

This task assumes that you have an EAR file that contains an enterprise application, developed as a message-driven bean, that can be deployed in WebSphere Application Server.

**Note:** You can continue to deploy message-driven beans against a listener port. You might want to do this for compatability with existing message-driven bean applications. However, listener ports are stabilized, and you should plan to migrate all your message-driven beans to use JCA 1.5-compliant resources.

### About this task

You deploy message-driven beans against JCA 1.5-compliant resources, and configure the resources as deployment descriptor attributes and (for EJB 3) as annotations.

### Procedure

1. For each message-driven bean in the application, create a J2C activation specification.
2. For each message-driven bean in the application, configure the J2C deployment attributes, as described in “Configuring deployment attributes for a message-driven bean against JCA 1.5-compliant resources.”
3. Use the WebSphere Application Server administrative console to install the application.

### Configuring deployment attributes for a message-driven bean against JCA 1.5-compliant resources

You can configure the message-driven bean deployment attributes for a Java EE Connector Architecture (JCA) 1.5-compliant enterprise application, to override the deployment attributes defined within the application EAR file.

#### Before you begin

This task assumes that you have an EAR file that contains an enterprise application, developed as a message-driven bean, that can be deployed in WebSphere Application Server.

**Note:** You can continue to configure message-driven beans against a listener port. You might want to do this for compatability with existing message-driven bean applications. However, listener ports are stabilized, and you should plan to migrate all your message-driven beans to use JCA 1.5-compliant resources.

## About this task

You configure the deployment attributes of a message-driven bean application by using an assembly tool. Detailed steps given in this task are for Rational Application Developer, but other tools have very similar steps.

## Procedure

1. Start your assembly tool.
2. Edit the application EAR file. For example, use the Rational Application Developer import wizard to import the EAR file into the assembly tool. To start the import wizard:
   a. Click **File** > **Import** > **EAR file**.
   b. Click **Next**, then select the EAR file.
   c. Click **Finish**.
3. Open the deployment attributes for editing. In the Java EE Hierarchy view, right-click the EJB module for the message-driven bean then click **Open With** > **Deployment Descriptor Editor**. A property dialog notebook for the message-driven bean is displayed in the property pane.
4. Review and, if needed, change the deployment attributes.
   a. In the property pane, select the **Bean** tab.
   b. Under **Activation Configuration**, review the attributes.

      **Note:** For EJB 3 message-driven beans, you can instead use an EJB 3 annotation to configure the activation configuration properties. Do not use an EJB 3 annotation to change or replace what is specified in the bean deployment descriptor. If an activation configuration property is specified in both places, the value used is the one that is given in the deployment descriptor.

      **`acknowledgeMode`**
      This attribute determines how the session acknowledges any messages it receives.
      **Auto Acknowledge**
      The session automatically acknowledges delivery of each message.
      **Dups OK Acknowledge**
      The session lazily acknowledges the delivery of messages. This setting is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumer applications that are tolerant of duplicate messages.

      **`destinationType`**
      This attribute determines whether the message-driven bean uses a queue or topic destination.
      **Queue**
      The message-driven bean uses a queue destination.
      **Topic** The message-driven bean uses a topic destination.

      **`subscriptionDurability`**
      This attribute determines whether a JMS topic subscription is durable or nondurable.
      **Durable**
      A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the subscription in the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription messages until they are received by the subscription or until they expire.
      **Nondurable**
      Nondurable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.

A nondurable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created.

**messageSelector**
This attribute determines the JMS message selector that is used to select which messages the message-driven bean receives. For example:

```
JMSType='car' AND color='blue' AND weight>2500
```

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

c. Specify bindings deployment attributes.

Under **WebSphere Bindings**, select the **JCA Adapter** option then specify the bindings deployment attributes:

**ActivationSpec JNDI name**
This attribute specifies the JNDI name of the activation specification that is used to deploy this message-driven bean. This name must match the name of an activation specification that you define to WebSphere Application Server.

**ActivationSpec Authorization Alias**
This attribute specifies the name of an authentication alias used for authentication of connections to the JCA resource adapter. An authentication alias specifies the user ID and password that is used to authenticate the creation of a new connection to the JCA resource adapter.

**Destination JNDI name**
This attribute specifies the JNDI name that the message-driven bean uses to look up the JMS destination in the JNDI namespace.

5. Save your changes to the deployment descriptor:
   a. Close the deployment descriptor editor.
   b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.
6. Verify the archive files.
7. From the pop-up menu for the project, click **Deploy** to generate EJB deployment code.
8. Optional: Test your completed module on a WebSphere Application Server installation.

   Right-click a module, click **Run on Server**, then follow the instructions in the displayed wizard.

   **Restriction:** **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only. You cannot deploy remotely to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

   **Important:** Use **Run on Server** for unit testing only. When an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use on production servers.

### What to do next

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that will run the application; for example, use the administrative console as described in Deploying and managing applications.

## Deploying an enterprise application to use message-driven beans with listener ports

Define the listener ports for your application. For each message-driven bean in the application, configure the deployment attributes to match the listener port definitions. Install the application, specifying the name of the listener port to use for late responses.

## Before you begin

Listener ports are stabilized. For more information, read the article on stabilized features. You should only deploy your application against a listener port for compatability with existing message-driven bean applications. Otherwise, you should deploy your application against JCA 1.5-compliant resources.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

This task assumes that you have an EAR file, which contains an enterprise application developed as a message-driven bean, that can be deployed in WebSphere Application Server.

## Procedure

1. Define the listener ports for your application, by using the WebSphere Application Server administrative console as described in Creating a new listener port.
2. For each message-driven bean in the application, configure the deployment attributes to match the listener port definitions, as described in “Configuring deployment attributes for a message-driven bean against a listener port.”
3. Install the application, as described in Installing enterprise application files with the console.

   When you install the application, you are prompted to specify the name of the listener port that the application is to use for late responses. Select the listener port, then click **OK**.

## Configuring deployment attributes for a message-driven bean against a listener port

You can configure the message-driven beans deployment attributes for an enterprise bean, to override the deployment attributes defined within the application EAR file.

### Before you begin

Listener ports are stabilized. For more information, read the article on stabilized features. You should only configure your application against a listener port for compatability with existing message-driven bean applications. Otherwise, you should configure your application against JCA 1.5-compliant resources.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

This task assumes that you have an EAR file that contains an enterprise application, developed as a message-driven bean, that can be deployed in WebSphere Application Server.

### About this task

You configure the deployment attributes of a message-driven bean application by using an assembly tool. Detailed steps given in this task are for Rational Application Developer, but other tools have very similar steps.

### Procedure

1. Start your assembly tool.
2. Edit the application EAR file. For example, use the Rational Application Developer import wizard to import the EAR file into the assembly tool. To start the import wizard:
   a. Click **File** > **Import** > **EAR file**.
   b. Click **Next**, then select the EAR file.
   c. Click **Finish**.

3. Open the deployment attributes for editing. In the Java EE Hierarchy view, right-click the EJB module for the message-driven bean then click **Open With** > **Deployment Descriptor Editor**. A property dialog notebook for the message-driven bean is displayed in the property pane.
4. Specify general deployment attributes.
   a. In the property pane, select the **Bean** tab.
   b. On the main panel, configure the **Transaction type** attribute.

      This attribute determines whether the message-driven bean manages its own transactions, or whether the container manages transactions on behalf of the bean.

      **Bean** The message-driven bean manages its own transactions.

      **Container**
      The container manages transactions on behalf of the bean.
5. Under **Activation Configuration**, review the following attributes:

   **Note:** For EJB 3 message-driven beans, you can instead use an EJB 3 annotation to configure the activation configuration properties. Do not use an EJB 3 annotation to change or replace what is specified in the bean deployment descriptor. If an activation configuration property is specified in both places, the value used is the one that is given in the deployment descriptor.

   **`acknowledgeMode`**
   This attribute determines how the session acknowledges any messages it receives.

   **Auto Acknowledge**
   The session automatically acknowledges delivery of each message.

   **Dups OK Acknowledge**
   The session lazily acknowledges the delivery of messages. This setting is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumer applications that are tolerant of duplicate messages.

   **`destinationType`**
   This attribute determines whether the message-driven bean uses a queue or topic destination.

   **Queue**
   The message-driven bean uses a queue destination.

   **Topic** The message-driven bean uses a topic destination.

   **`subscriptionDurability`**
   This attribute determines whether a JMS topic subscription is durable or nondurable.

   **Durable**
   A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the subscription in the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription messages until they are received by the subscription or until they expire.

   **Nondurable**
   Nondurable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.

   A nondurable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created.

   **`messageSelector`**
   This attribute determines the JMS message selector that is used to select which messages the message-driven bean receives. For example:

   ```
   JMSType='car' AND color='blue' AND weight>2500
   ```

   The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

6. Specify the bindings deployment attribute.
   a. Under **WebSphere Bindings**, specify the following attribute:
      **Listener port name**
      Type the name of the listener port for this message-driven bean.
7. Save your changes to the deployment descriptor:
   a. Close the deployment descriptor editor.
   b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.
8. Verify the archive files.
9. From the pop-up menu for the project, click **Deploy** to generate EJB deployment code.
10. Optional: Test your completed module on a WebSphere Application Server installation.
    Right-click a module, click **Run on Server**, then follow the instructions in the displayed wizard.

    **Restriction:** **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only. You cannot deploy remotely to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

    **Important:** Use **Run on Server** for unit testing only. When an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use on production servers.

### What to do next

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that will run the application; for example, use the administrative console as described in Deploying and managing applications.

---

# Assembling EJB 2.1 enterprise beans

# Assembling EJB 2.x modules

An enterprise bean is a Java component that can be combined with other resources to create Java EE applications. This topic describes assembling Enterprise JavaBeans (EJB) modules based on the EJB 2.x and earlier specifications.

## Before you begin

Create and unit tested an enterprise bean that you want to assemble in an enterprise application and deploy onto an application server.

## About this task

Assemble an EJB module to contain enterprise beans and related code artifacts. Group web components, client code, and resource adapter code in separate modules. After the EJB module is assembled, install it as a stand-alone application or combine it with other modules into an enterprise application.

Use an assembly tool to assemble an EJB module in any of the following ways:
- Import an existing EJB module (EJB JAR file)
- Create a EJB module
- Copy code artifacts, such as entity beans, from one EJB module into a new EJB module

For information about assembling EJB modules, refer to assembly tool information center for your assembly tool.

### Results

The EJB module is migrated or created, reflecting the Java EE structure that specifies the location of enterprise bean content files, class files, class paths, the deployment descriptor, and supporting metadata. For more information about the location of the content see the assembly tool information center.

### What to do next

After you finish assembling your EJB module, you are ready to deploy your module.

## Sequence grouping for container-managed persistence in assembled EJB modules

After assembling an Enterprise JavaBeans (EJB) module that contains container-managed persistence (CMP) beans, you can prevent certain types of database-related exceptions from occurring during application run time. Using *sequence grouping*, you can specify the order in which entity beans update relational database tables.

**Note:** Entity beans are not supported in EJB 3.x modules.

### Eliminate exceptions resulting from referential integrity (RI) violations

Sequence grouping is particularly useful for preventing violations of database *referential integrity* (RI). A database RI policy prescribes rules for how data is written to and deleted from the database tables to maintain relational consistency. Run-time requirements for managing bean persistence, however, can cause an EJB application to violate RI rules, which can cause database exceptions. These runtime requirements mandate that:

- Entity bean creates and remove operations correlate to the database immediately upon method invocation.
- Entity bean changes are cached by the EJB container until either a finder method is called, or the transaction ends.

Consequently, the order in which entity beans update the database is unpredictable. That randomness translates into high risk of the application violating database RI. Although caching the operations for batch processing overrides these runtime requirements, it does not guarantee a bean persistence sequence that follows any given RI policy.

The only way to guarantee a persistence sequence that honors database RI is to designate the sequence, which you do in the EJB deployment descriptor editor of the assembly tool. Through the sequence grouping feature, you assign beans to CMP groups. Within each group, you specify the order in which the persistence manager inserts bean data into the database to accomplish updates without violating RI.

See the “Setting the run time for CMP sequence groups” on page 704 topic for detailed instructions on designating sequence groups. Consult your database administrator about the RI policy with which you need to synchronize.

### Minimize exception risk for optimistic concurrency control schemes

Sequence grouping can also reduce the risk of transaction rollback exceptions for entity beans that are configured for optimistic concurrency control. In these concurrency control schemes, database locks are held for minimal amounts of time so that a maximum number of transactions consistently have access to the data. The relatively unrestricted state of the database can lead to transaction rollback exceptions for two common reasons:

- When concurrent transactions attempt to lock the same table row, database deadlock occurs.
- Transactions can occur in an order that violates application logic.

Use the sequence grouping feature to order bean persistence so that these scenarios are less likely to occur.

## Setting the run time for CMP sequence groups

By designating container managed persistence (CMP) sequence groups for entity beans, you can prevent certain types of database-related exceptions during the run time of your Enterprise JavaBeans (EJB) application. Specify in each group the order in which the beans update your relational database tables.

### Before you begin

When you define a sequence group, you designate it as one of two types:

- RI_INSERT, for setting a bean persistence sequence to prevent database referential integrity (RI) violations. See the topic Sequence grouping for container-managed persistence in assembled EJB modules for more information.
- UPDATE_LOCK, for setting a bean persistence sequence to minimize exceptions resulting from optimistic concurrency control

### About this task

Both types of sequence groups must be created after you have assembled the beans into an EJB module, before installing your application on the product. If you need to edit sequence groups, uninstall the application, make your changes with an assembly tool, and reinstall your application.

**Attention:** If you already selected or plan to use top-down mapping for mapping your enterprise beans to back-end data, you do not need to create a sequence group with an RI_INSERT type. The product does not generate an RI policy for the database schema that it creates when you select top-down mapping.

To learn how to complete this task see the assembly tool information center.

### What to do next

You are now ready to deploy your EJB module or combine it with other modules into a Java EE application. For more information about these two tasks, see the topics Installing enterprise application files and Assembling Java EE client applications.

# Assembling EJB 3.x enterprise beans

## EJB 3.0 and EJB 3.1 application bindings overview

Before you can start an application that is installed on an application server, all Enterprise JavaBeans (EJB) references and resource references defined in the application must be bound to the actual artifacts (enterprise beans or resources) defined in the application server.

**Note:** Bindings support in the EJB container has been expanded. The EJB container assigns default JNDI bindings for EJB 3.x business interfaces based on application name, module name, and component name. You do not have to explicitly define JNDI binding names for each of the interfaces or EJB homes within an EJB 3.x module or no-interface views within an EJB 3.1 module.

When defining bindings, you specify Java Naming and Directory Interface (JNDI) names for the referenceable and referenced artifacts in an application. The jndiName values specified for artifacts must be qualified lookup names.

You do not need to manually assign JNDI bindings names for each of the interfaces, EJB homes, or no-interface views on your enterprise beans in EJB 3.x modules. If you do not explicitly assign bindings, the EJB container assigns default bindings.

### Namespaces for default EJB JNDI bindings

Default EJB bindings may be placed by the application server into both the classic and java:[scope] sets of namespaces.

The set of classic namespaces consists of the ejblocal: and Global JNDI namespaces. The classic namespaces include a WebSphere extension, and they existed in the application server before version 8.0

The set of java:[scope] namespaces consists of the java:global, java:app, and java:module namespaces. The java:[scope] namespaces are defined by the Java EE 6 specification, and are introduced into theWebSphere Application Server in Version 8. They are not a replacement for the classic namespaces. Rather, they are added in addition to the classic namespaces.

### Classic namespace details

For the EJB 3.x level, the product provides two distinct classic namespaces for EJB interfaces, depending on whether the interface is local or remote. The same provision applies to EJB homes and no-interface views, which can be considered special types of interfaces. The following classic namespaces exist:

- Java virtual machine (JVM)-scoped, ejblocal: namespace
- Global JNDI namespace

Local EJB interfaces, homes, and no-interface views must be bound into a JVM-scoped classic ejblocal: namespace; they are accessible only from within the same application server process.

In contrast, remote EJB interfaces and homes must always be bound into the classic globally scoped WebSphere JNDI namespace; they can be accessed from anywhere, including other server processes and other remote clients. Local interfaces and no-interface views cannot be bound into the classic globally scoped JNDI namespace, nor can remote interfaces be bound into the JVM-scoped classic ejblocal: namespace.

The classic ejblocal: and classic globally scoped JNDI namespaces are separate and distinct. For example, an EJB local interface or no-interface view bound at "ejblocal:AccountHome" is a not the same as a remote interface bound at "AccountHome" in the classic globally scoped namespace. This behavior helps maintain the distinction between your local and remote interface references. Having a JVM-scoped local namespace also makes it possible for your applications to directly look up or reference local EJB interfaces and no-interface views from anywhere in the JVM server process, including across Java Platform, Enterprise Edition (Java EE) application boundaries.

### Default classic JNDI bindings for EJB business interfaces in the EJB 3.x container with the Application, Module, and Component names

The EJB container assigns default classic JNDI bindings for EJB 3.x business interfaces based on application name, module name, and component name, so it is important to understand how these names are defined. Each of these names is a character string.

Java EE applications are packaged in a standardized format called an Enterprise Application Archive (EAR) file. The EAR is a packed file format like a .zip or .tar file format, and can thus be visualized as a collection of logical directories and files packed together into a single physical file. Within each EAR file are one or more Java EE module files, which can include:

- Java Application Archive (JAR) files for EJB modules, Java EE application client modules and utility class modules
- Web Application Archive (WAR) files for web modules
- Other technology-specific modules such as Resource Application Archive (RAR) files and other types of modules

Within each module file are typically one or more Java EE components. Examples of Java EE components are enterprise beans, servlets, and application client main classes.

Since Java EE modules are packaged within Java EE application archives, and Java EE components are in turn packaged within Java EE modules, the "nesting path" of each component can be used to uniquely identify every component within a Java EE application archive, according to its application name, module name, and component name.

**Application name used in classic bindings**

The name of an application is defined by the following (in order of priority):

- The value of the application name specified to the product administrative console, or the **appname** parameter supplied to the wsadmin command-line scripting tool, during installation of the application into the product.
- The value of the **<display-name>** parameter within the `META-INF/application.xml` deployment descriptor for the application.
- The EAR file name, excluding the `.ear` file suffix. For example, an application EAR file named `CustomerServiceApp.ear` would have an application name of "CustomerServiceApp" in this case.

The Java EE 6 specification provides for EJB JNDI lookup names of the general form, java:global[/*appName*]/*moduleName*/*beanName*. The *appName* component of the lookup name is shown as optional because it does not apply to beans deployed in stand-alone modules. Only beans packaged in .ear files contain the *appName* component in the java:global lookup name. The rules that determine the value for *appName* are different from the rules described previously for application names. The *appName* value in the java:global lookup name template shown previously is defined by the following, in order of priority:

- The value of the **<application-name>** parameter within the `application.xml` deployment descriptor for the application.
- The EAR file name, excluding the `.ear` file suffix. For example, an application EAR file named `CustomerServiceApp.ear` has an application name of "CustomerServiceApp". If the application is a stand-alone module, the java:global lookup name does not contain an application component.

The value for *appName* is also the string value bound under the name, java:app/AppName, in accordance with the Java EE 6 specification.

**Module name used in classic bindings**

The name of a module is defined as the Uniform Resource Identifier (URI) of the module file, relative to the root of the EAR file in which it resides. Stated another way, the module name is the file name of the module relative to the root of the EAR file, including any subdirectories in which the module file is nested. This naming convention is still true even when a logical module name is explicitly specified using the module-name element in the deployment descriptor.

In the following example, the CustomerServiceApp application contains three modules whose names are `AccountProcessing.jar`, `Utility/FinanceUtils.jar`, and `AppPresentation.war`:

```
CustomerServiceApp.ear:AccountProcessing.jar
com/mycompany/AccountProcessingServiceBean.class AccountProcessingService.class
Utility/FinanceUtils.jar META-INF/ejb-jar.xml
com/mycompany/InterestCalculatorServiceBean.class InterestCalculatorService.class
AppPresentation.war META-INF/web.xml
```

The Java EE 6 specification provides for EJB JNDI lookup names of the general form, java:global[/*appName*]/*moduleName*/*beanName*. The *appName* component of the lookup name is shown as optional because it does not apply to beans deployed in stand-alone modules. Only beans packaged in `.ear` files contain the *appName* component in the java:global lookup name. Another JNDI lookup name

variant that includes the module name is java:app/*moduleName*/*beanName*. The value for *moduleName* is not the module URI. The *moduleName* value in the java:global and java:app lookup name templates is defined by the following, in order of priority:

- The value of the **<module-name>** parameter within the `ejb-jar.xml` or `web.xml` deployment descriptor for the module.
- The module URI, excluding its `.jar` or `.war` suffix. For example, a module with a URI of [1] or `CustomerService.war` has a module name of "CustomerService".

The value for *moduleName* is also the string value bound under the name, java:module/*moduleName*, in accordance with the Java EE 6 specification. This also applies to client modules. For client modules, the **<module-name>** parameter is located in the `application-client.xml` deployment descriptor file.

#### EJB component name used in classic bindings

The name of an EJB component is defined by the following value, in order of priority:

- The value of the ejb-name tag associated with the bean in the `ejb-jar.xml` deployment descriptor, if present.
- The value of the "name" parameter, if present, in the @Stateless or @Stateful annotation associated with the bean.
- The name of the bean implementation class, without any package-level qualifier.

## Bindings

Review the following bindings that are supported by EJB 3.x modules:

- Default classic bindings for business interfaces, homes, and no-interface views
- Default classic binding pattern
- java:[scope] bindings
- User-defined bindings for EJB business interfaces, homes, and no-interface views
- User-defined bindings for resolving references and injection targets
- Default resolution of EJB references and EJB injections: The AutoLink feature
- Resolution of EJB and resource references and injections: The lookup feature
- “Overriding environment entries defined in applications ” on page 722
- “Overriding data source definitions ” on page 722
- Naming considerations in clustered environments
- User-defined EJB extension settings
- Legacy (XMI) bindings
- User-specified XML bindings

## Default classic bindings for EJB business interfaces, homes, and no-interface views

You do not have to explicitly define JNDI binding names for each of the interfaces or EJB homes within an EJB 3.x module or no-interface views within an EJB 3.1 module. If you do not explicitly assign bindings, the EJB container of the product assigns default classic bindings using the rules outlined here. This is different from the EJB support in the product before the support of the EJB 3.0 specification.

The EJB container performs two default classic bindings for each interface (business, remote home, or local home) or no-interface view on each enterprise bean. These two classic bindings are referred to here as the views of the interface or no-interface *short* binding and *long* binding. The short binding uses just the package-qualified Java class name of the interface or no-interface view, while the long binding uses the component ID of the enterprise bean as an extra qualifier before the package-qualified interface or no-interface view class name, with a hash or number sign (# symbol) between the component ID and the

1. CustomerService.jar

interface or no-interface view class name. You can think of the difference between the two forms as being analogous to a *short* TCP/IP host name (just the machine name) versus a *long* host name (machine name with domain name prepended to it).

For example, the short and long default classic bindings for an interface or no-interface view might be com.mycompany.AccountService and AccountApp/module1.jar/ServiceBean#com.mycompany.AccountService, respectively.

By default, the component ID for EJB default classic bindings is formed using the application name, module name, and component name of the enterprise bean, but you can assign any string you want instead. By defining your own string as the component ID, you can set up a naming convention where the long-form bindings of the enterprise bean share a common user-defined portion, yet also have a system-defined portion based on the name of each interface or no-interface view class. It also allows you to make the default EJB binding names independent of how you have packaged the enterprise beans within the application module hierarchy. Overriding a default component ID of an enterprise bean is described in the "User-defined bindings for EJB business interfaces, homes, and no-interface views" section of this topic.

As mentioned earlier in the section on the classic JVM-scoped local namespace and the classic globally scoped JNDI namespace, all local interfaces, homes, and no-interface views must be bound into the classic ejblocal: namespace, which is accessible only within the same server process (JVM), while remote interfaces and homes must be bound into the classic globally scoped namespace, which is accessible from anywhere in the WebSphere product cell. As you would expect, the EJB container follows these rules for the default bindings.

In addition, the *long* default bindings for remote interfaces follow recommended Java EE best practices in that they are grouped under an ejb context name. By default, EJB remote home and business interfaces are bound into the root of the application server naming context. However, the application server root context is used for binding more than just EJB interfaces, so to keep this context from getting too cluttered, it is a good practice to group EJB-related bindings into a common "ejb" subcontext rather than placing them directly in the server root context. It is like why you would use subdirectories on a disk volume rather than putting all the files in the root directory.

The *short* default bindings for remote interfaces are not bound in the ejb context. The short default bindings are located in the root of the server root context. Even though it is a best practice to group all the EJB-related bindings under an ejb context, there are other considerations including the following situations:

- The short default bindings provide a simple, direct way to access an EJB interface. Placing them directly in the server root context and referring to them by just the interface name or the interface name prepended with ejblocal: was in keeping with that goal of simplicity.
- At the same time, placing the long default bindings in the ejb context, or the ejblocal: context in the case of a local interface, kept those bindings out of the root context of the server and reduced the clutter there enough to allow having the short bindings in the root context.
- It provides a degree of cross-compatibility with other Java EE application servers that use similar naming conventions.

To summarize, all local default bindings, both short and long, are placed in the classic ejblocal: server/JVM-scoped namespace, while remote default bindings are placed in the root context of the server of the classic globally scoped namespace if they are short, or in the <server_root>/ejb context (just below the root context of the server) if they are long. Thus, the only default bindings in the globally scoped root context of the server are the short bindings for remote interfaces, which is the best balance between providing a simple, portable usage model and keeping the globally scoped root context of the server from becoming too cluttered.

## Default classic binding pattern

The patterns for each type of classic binding are displayed in the table. In these patterns, strings written in *<bracketed italics>* represent a value. For example, *<package.qualified.interface>* might be com.mycompany.AccountService, and *<component-id>* might be AccountApp/module1.jar/ServiceBean.

*Table 85. Default binding patterns. Default binding patterns*

| Binding patterns | Description |
|---|---|
| ejblocal:*<package.qualified.interface>* | Short form local interfaces, homes, and no-interface views |
| *<package.qualified.interface>* | Short form remote interfaces and homes |
| ejblocal:*<component-id>*#*<package.qualified.interface>* | Long form local interfaces, homes, and no-interface views |
| ejb/*<component-id>*#*<package.qualified.interface>* | Long form remote interfaces and homes |

The *component-id* default pattern is *<application-name>*/*<module-jar-name>*/*<ejb-name>* unless it is overridden in the EJB module binding file using the component-id attribute as described in the next section, "Conflicts in short default binding names when multiple enterprise beans implement the same interface." The *<module-jar-name>* variable, when not overridden by the EJB module binding file, is the name of the physical module file within the EAR including the extension, for example, `.jar`, `.ear`, `.war`, as described in the previous "Module name" section, even if a logical module name is specified in the deployment descriptor.

### Conflicts in short default classic binding names when multiple enterprise beans implement the same interface

When more than one enterprise bean that is running in the application server implements a given interface or no-interface view, the short default classic binding name becomes ambiguous because the short name might refer to any of the Enterprise JavaBeans that implement this interface or no-interface view. To avoid this situation, you must either explicitly define a binding for each Enterprise JavaBeans that implements the given interface or no-interface view as described in the next section, or disable short default classic bindings for applications containing these Enterprise JavaBeans by defining a WebSphere product JVM custom property, com.ibm.websphere.ejbcontainer.disableShortDefaultBindings. For more information about defining the JVM custom property, read about Java Virtual machine custom properties.

To use this JVM custom property, set the property name to com.ibm.websphere.ejbcontainer.disableShortFormBinding and the property value to either * (asterisk) as a wildcard value to disable short form default classic bindings for all applications in the server, or to a colon-delimited sequence of the Java EE application names for which you want to disable short default classic bindings, for example, PayablesApp:InventoryApp:AccountServicesApp.

### Effect of explicit assignment on default classic bindings

If you explicitly assign a binding definition for an interface, home, or no-interface view, no short or long default classic bindings are performed for that interface or no-interface view.

**Note:** This only applies to the specific interfaces or no-interface views for which you assign an explicit binding. Other interfaces on that enterprise bean, without explicitly assigned bindings, are bound by using default classic binding names.

## java:[scope] namespaces

The java:global, java:app, and java:module namespaces are introduced by the Java EE 6 specification. They provide a mechanism for binding and looking up resources that are portable across application servers.

The server always creates a default long-form binding for each EJB interface, including the no-interface view, and places them into the java:global, java:app, and java:module namespaces. A short-form binding is also created and placed into the java:global, java:app, and java:module namespaces, if the bean exposes only one interface, including the no-interface view. The default bindings are only created for session beans. They are not created for entity beans or message driven beans.

The long-form and short-form bindings both contain the application name, the module name, and the bean component name. The application name is defaulted to the base name of the .ear file, without the extension. The application name can be overridden using the application-name element in the application.xml file. The module name is defaulted to the path name of the module, with the extension removed and any directory names included. The module name can be overridden using the module-name element in the ejb-jar.xml or web.xml files. The bean component name defaults to the unqualified name of the bean class. The bean component name can be overridden using the name attribute on the EJB component defining annotation, or the ejb-name element in the ejb-jar.xml file.

The long-form binding pattern is java:global/*<applicationName>*/*<moduleName>*/*<bean component name>*!*<fully qualified interface name>*.

The short-form binding pattern is java:global/*<applicationName>*/*<moduleName>*/*<bean component name>*.

For example, the bean component MyBeanComponent exposes just the one com.foo.MyBeanComponentLocalInterface interface, and is packaged in the `myModule.jar` module in the `myApp.ear` file. As a result, the following bindings are created in the java:[scope] namespaces:

- java:global/myApp/myModule/MyBeanComponent!com.foo.MyBeanComponentLocalInterface
- java:global/myApp/myModule/MyBeanComponent
- java:app/myModule/MyBeanComponent!com.foo.MyBeanComponentLocalInterface
- java:app/myModule/MyBeanComponent
- java:module/MyBeanComponent!com.foo.MyBeanComponentLocalInterface
- java:module/MyBeanComponent

The MyBeanComponent bean can be obtained from the java:[scope] namespaces using one of the following techniques:

- Use the lookup attribute on the @EJB annotation; for example:
  ```
  @EJB(lookup="java:global/myApp/myModule/MyBeanComponent")
  ```
- Use the lookup-name element in ejb-jar.xml; for example:
  ```
  <lookup-name>java:global/myApp/myModule/MyBeanComponent!com.ibm.MyBeanComponentLocalInterfaces</lookup-name>
  ```
- Complete a lookup on the InitialContext object; for example:
  ```
  initialContext.lookup("java:global/myApp/myModule/MyBeanComponent!com.foo.MyBeanComponentLocalInterfaces")
  ```

In addition to the default bindings created by the application server, you can define references in the java:global, java:app, and java:module namespaces. References defined in the java:global, java:app, and java:module namespaces do not go into the component namespace. References defined in the java:global, java:app, or java:module namespaces must be looked up or injected from those namespaces. They cannot be looked up or injected from the component namespace.

A bean component can use the java:module namespace to declare a reference that is usable by a component packaged in the same module. It can use the java:app namespace to declare a reference that is usable by a component packaged in a different module within the same application. It can use the java:global namespace to declare a reference that is usable by a component packaged in a different application.
