| **myBean.class**<br>`// Code to get a connection`<br><br>`// Code to get the data`<br>`Select * from myTable;`<br><br>`// Code to close the connection`<br><br>**JSP file**<br>`<tsx:repeat index=abc>`<br>`<tsx:getProperty name="myBean"`<br>`property="col1(abc)" />`<br>`</tsx:repeat>`<br><br>**Notes:**<br>• The bean (myBean.class) is a static bean.<br>• The method to access the bean properties is myBean.get(*property*(*index*)).<br>• You can omit the property index, in which case the index of the enclosing <tsx:repeat> tag is used. You can also omit the index on the <tsx:repeat> tag.<br>• The <tsx:repeat> tag iterates over the bean properties row by row, beginning with the start row. | **JSP file**<br>`<tsx:dbconnect id="conn"`<br>`userid="alice"passwd="test"`<br>`url="jdbc:db2:sample"`<br>`driver="COM.ibm.db2.jdbc.app.DB2Driver">`<br>`</tsx:dbconnect >`<br><br>`<tsx:dbquery id="dynamic"`<br>`connection="conn" >`<br>`Select * from myTable;`<br>`</tsx:dbquery>`<br><br>`<tsx:repeat index=abc>`<br>`<tsx:getProperty name="dynamic"`<br>`property="col1(abc)" />`<br>`</tsx:repeat>`<br><br>**Notes:**<br>• The bean (dynamic) is generated by the <tsx:dbquery> tag and does not exist until the syntax executes.<br>• The method to access the bean properties is dynamic.getValue("*property*", *index*).<br>• You can omit the property index, in which case the index of the enclosing <tsx:repeat> tag is used. You can also omit the index on the <tsx:repeat> tag.<br>• The <tsx:repeat> tag syntax iterates over the bean properties row by row, beginning with the start row. |

### Implicit and explicit indexing

Examples 1, 2, and 3 show how to use the <tsx:repeat> tag. The examples produce the same output if all indexed properties have 300 or fewer elements. If there are more than 300 elements, Examples 1 and 2 display all elements, while Example 3 shows only the first 300 elements.

Example 1 shows *implicit indexing* with the default start and default end index. The bean with the smallest number of indexed properties restricts the number of times the loop repeats.

```
<table>
<tsx:repeat>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="city" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="address" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="telephone" />
  </tr></td>
</tsx:repeat>
</table>
```

Example 2 shows indexing, starting index, and ending index:

```
<table>
<tsx:repeat index=myIndex start=0 end=2147483647>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=city(myIndex) />
  </tr></td>
```

```
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=address(myIndex) />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=telephone(myIndex) />
</tr></td>
</tsx:repeat>
</table>
```

Example 3 shows *explicit indexing* and ending index with implicit starting index. Although the index attribute is specified, you can still implicitly index the indexed property city because the (`myIndex`) tag is not required.

```
<table>
<tsx:repeat index=myIndex end=299>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="city" /t>
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="address(myIndex)" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="telephone(myIndex)" />
  </tr></td>
</tsx:repeat>
</table>
```

**Nesting <tsx:repeat> blocks**

You can nest <tsx:repeat> blocks. Each block is separately indexed. This capability is useful for interleaving properties on two beans, or properties that have subproperties. In the example, two <tsx:repeat> blocks are nested to display the list of songs on each compact disc in the user's shopping cart.

```
<tsx:repeat index=cdindex>
  <h1><tsx:getProperty name="shoppingCart" property=cds.title /></h1>
  <table>
  <tsx:repeat>
    <tr><td><tsx:getProperty name="shoppingCart" property=cds(cdindex).playlist />
    </td></tr>
  </tsx:repeat>
  </table>
 </tsx:repeat>
```

# Developing JSF files

Learn about JSF files.

## JavaServer Faces

JavaServer Faces (JSF) is a user interface framework or application programming interface (API) that eases the development of Java-based web applications.

**Note:** WebSphere Application Server supports JavaServer Faces 2.0 at a runtime level.

The JSF runtime also:

- Makes it easy to construct a user interface from a set of reusable user interface components
- Simplifies migration of application data to and from the user interface
- Helps manage user interface state across server requests
- Provides a simple model for wiring client-generated events to server-side application code
- Supports custom user interface components to be easily build and reused

Both the Sun Reference Implementation and Apache MyFaces implementation are shipped with the product.

The Apache MyFaces JSF Implementation provides the foundation of the code used for the JSF support in WebSphere Application Server. The version of the JSF runtime provided by the Application Server resides

in the normal runtime library location and is available to all web applications that use JSF APIs. Loading the JSF servlet works in the same manner as if the run time was packaged with the web application. The bundled version includes enhancements for better integration with the built-in annotation scanning and other runtime components of WebSphere Application Server.

The specification-related classes (javax.faces.*) for JSF and the IBM modified version of the Apache MyFaces JSF Implementation and the JSF Sun reference implementation are packaged in the Application Server run time.

Typically, web applications that use this API/Framework embed the JSF API and implementation Java archive (JAR) files within their web application archive (WAR) file. This practice is not required when these web applications are deployed and run within WebSphere Application Server. Only the removal of these JAR files along with any JSTL JAR files from the WAR file is required. However, because JavaServer Faces 2.0 is a part of the Java Platform, Enterprise Edition (Java EE) platform, a web application does not need to bundle a JavaServer Faces implementation when it runs on a web container that is Java EE technology compliant. If a JavaServer Faces implementation is bundled with a web application, it is ignored as the JavaServer Faces implementation provided by the platform always takes precedence.

The JSF run time for WebSphere Application Server does not support the use of a single class loader for the entire application. This support is not available when the application contains multiple web modules and one of those modules is a JSF module. A single class loader for the entire application is not supported because the FacesConfig initialization requires a single class loader for each JSF module to perform the initialization. Therefore, you must use multiple class loaders when the application contains multiple web modules and at least one JSF module.

For using different implementations of JSF, the WebSphere Application Server JSF engine determines if the SUN RI or Apache MyFaces is used from the application server run time. After the JSF engine determines the implementation that is used, the correct listener class is registered with the web container. You do not need to add the com.sun.faces.ConfigureListener or the org.apache.myfaces.StartupConfigureListener to the `web.xml` file.

If you want to use a third party JSF implementation that is not shipped with the product, leave the configuration set to MyFaces, add the third party listener to the `web.xml` file that is required and add the third party implementation JAR files to the web module as an isolated shared library. Using an isolated shared library, the web application version of the JSF or JSTL classes load before the Application Server.

## JavaServer Faces widget library (JWL)

JavaServer Faces widget library (JWL) is an IBM JSF-based web widget library that integrates widgets from a number of sources. The IBM JSF-based web widget library is deprecated, however, you can obtain the latest version from Rational Application Developer version 6 to work with JSF 1.2.

JWL includes the JSF components from Rational Application Developer except for the base JSF components, which are included in the Application Server run time. This includes the IBM extended JSF components and the extended FacesClient Component. JWL also extends JSF with client-side features for rich browser-based experiences in the form of the FacesClient Component.

**Important:** JWL is not supported in pages using the JSF 2.0 Facelets format.

### JWL Java archive files

JWL is packaged into two Java archive (JAR) files, `odc-jsf.jar` and `jsf-ibm.jar`, which are located in the `${WAS_HOME}\optionalLibraries\IBM\jwl\2.0` directory.

To include JWL in your application, you can use the JWL shared library named JWLLib, which is created at installation time. To assign the library to an application, see the topic, Using installed optional packages.

## Configuring JavaServer Faces implementation

Use this task to specify which JavaServer Faces implementation to use. You can use Apache MyFaces 2.0 or the SUN Reference Implementation 1.2 of JSF, or your own implementation.

### Before you begin

Ensure that your application is configured for JavaServer Faces (JSF) using the specific `web.xml` context parameters for the implementation that you have chosen.

**Attention:** The JSF implementation is a server-wide configuration setting. Thus, if you have multiple applications which require different JSF implementations, you must separate the applications into different application servers or clusters, and specify the implementation by following the steps in this topic for each application server or cluster. Alternatively, you can use an isolated shared library, as described for third-party JSF implementations, as follows.

### About this task

**Note:** The Application Server JSF engine determines if the SUN Reference Implementation (RI) 1.2 or Apache MyFaces 2.0 is used from the Application Server run time. If either is used, the correct listener class is registered with the web container. You do not need to add the com.sun.faces.ConfigureListener or the org.apache.myfaces.StartupConfigureListener to your `web.xml` file.

**Be Aware:** If you want to use a third-party JSF implementation that is not shipped with the product, then:

- Keep the configuration set to MyFaces.
- Add the third-party listener to the `web.xml` file that is required.
- Add the third-party implementation Java archive (JAR) files to the application as an isolated shared library and associate it with your application.

You can also configure the JSF implementation on the Provide JSP reloading options for web modules panel for application installation and update wizards.

### Procedure

Configure the server or cluster to use the JSF implementation that you want. You can do this task using the administrative console or the wsadmin tool.

- In the administrative console panel, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **JSP and JSF options**

  Select one of the following implementations:

  – Sun Reference Implementation 1.2 - Select this option to use the Sun Reference Implementation 1.2 JSF implementation.

  – MyFaces 2.0 - Select this option to use the MyFaces 2.0 JSF implementation. This option is the default JSF implementation.

- Using the wsadmin tool:

  – An example of setting a single server to use the Sun RI 1.2 JSF implementation:

```
wsadmin>set server [$AdminConfig list ApplicationServer *server1*]
server1(cells/myNode01Cell/nodes/myNode01/servers/server1|server.xml#ApplicationServer_1183122130078)
wsadmin>$AdminConfig modify $server {{jsfProvider SunRi1.2}}

wsadmin>$AdminConfig save
```

  – An example of setting a cluster to use the MyFaces 2.0 JSF implementation:

```
wsadmin>set cluster [$AdminConfig list ServerCluster]
cluster1(cells/myNode01Cell/nodes/myNode01/clusters/cluster1|cluster.xml#ServerCluster_1173916133721)
wsadmin>$AdminConfig modify $cluster {{jsfProvider MyFaces}}

wsadmin>$AdminConfig save
```

## Results

**Note:** Your application server or cluster has now been configured with the JSF implementation you specified. Any application that uses JSF technology uses that implementation, unless it is associated with an isolated shared library that contains a different implementation.

## What to do next

Configure JSF engine parameters as necessary.

***Configuring JSF engine parameters:***
**About this task**

WebSphere Application Server does not support the modification of deployment descriptor extension parameters through the administrative console or through administrative scripting.

To add, change or delete JSF engine configuration parameters, complete the following steps:

**Procedure**

1. Open the WEB-INF/web.xml file.

   JSP engine configuration parameters are stored in a web module's configuration directory or in a web modules's binaries directory in the WEB-INF/web.xml file. Open the WEB-INF/web.xml file from:

   - The configuration directory, as in the following example: {WAS_ROOT}/profiles/*profilename*/config/cells/*cellname*/applications/*enterpriseappname*/ deployments/*deployedname*/*webmodulename*
   - The binaries directory if an application was deployed into WebSphere Application Server with the flag "Use Binary Configuration" set to true. An example of a binaries directory is: {WAS_ROOT}/profiles/*profilename*/installedApps/*nodename*/*EnterpriseAppName*/*WebModuleName*/
2. Edit the WEB-INF/web.xml file.
   - To add configuration parameters, use the following format:

     ```
     <context-param>
       <description>descriptive text</description>
       <param-name>parameter name</param-name>
       <param-value>parameter value</param-value>
     </context-param>
     ```
   - To delete configuration parameters, either delete the line from the file, or enclose the statement with <!-- --> tags.
3. Save the file.
4. Restart the Enterprise Application. It is not necessary to restart the server for parameter changes to take effect. However, some JSP engine configuration parameters affect the Java source code that is generated for a JSP. If such a parameter is changed, then you must retranslate the JSP files in the web module to regenerate Java source. You can use the batch compiler to retranslate all JSP files in a web module. The batch compiler uses the JSP engine configuration parameters that you have set in the web.xml file, unless you specifically override them. The JSP engine configuration topic identifies the parameters that affect the generated Java source.

**Example**

The following is a sample of the WEB-INF/web.xml file.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns="http://java.sun.com/xml/ns/javaee" xmlns:web="http://java.sun.com/xml/ns/javaee/web-app_2_5.xsd"
 xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/web-app_2_5.xsd"
 id="WebApp_ID" version="2.5">
 <display-name>Servlet 2.5 example</display-name>
 <welcome-file-list>
```

```
  <welcome-file>index.html</welcome-file>
  <welcome-file>index.htm</welcome-file>
  <welcome-file>index.jsp</welcome-file>
  <welcome-file>default.html</welcome-file>
  <welcome-file>default.htm</welcome-file>
  <welcome-file>default.jsp</welcome-file>
 </welcome-file-list>
 <context-param>
       <param-name>javax.faces.CONFIG_FILES</param-name>
       <param-value>/WEB-INF/faces-config.xml</param-value>
    </context-param>
    <context-param>
        <param-name>javax.faces.STATE_SAVING_METHOD</param-name>
        <param-value>server</param-value>
    </context-param>
    <context-param>
        <param-name>com.ibm.ws.jsf.LOAD_FACES_CONFIG_AT_STARTUP</param-name>
        <param-value>true</param-value>
    </context-param>
    <servlet>
        <servlet-name>Faces Servlet</servlet-name>
        <servlet-class>javax.faces.webapp.FacesServlet</servlet-class>
    </servlet>
    <servlet-mapping>
        <servlet-name>Faces Servlet</servlet-name>
        <url-pattern>/faces/*</url-pattern>
    </servlet-mapping>
    <servlet-mapping>
        <servlet-name>Faces Servlet</servlet-name>
        <url-pattern>*.faces</url-pattern>
    </servlet-mapping>
</web-app>
```

*JSF engine configuration parameters:*

In WebSphere Application Server, you can configure the JavaServer Faces (JSF) engine configuration parameters for optimal performance in a production server environment and for the needs of developers in a development environment.

The JSF engine parameters are case-sensitive. If the value specified for a parameter is composed of two or more words separated by spaces, you must add quotation marks around the value.

### JSF options using SUN RI

*Table 172. JSF options using SUN RI. The table shows SUN RI parameter names, descriptions and default values.*

| SUN RI parameter name | Description | Default value |
|---|---|---|
| com.sun.faces.numberOfViewsInSession | Specifies the number of views that are stored in the session when Server-Side State Saving is used. If set to true while client-side state saving is being used, reduces the number of bytes sent to the client by compressing the state before it is encoded and written as a hidden field. | 15 |
| com.sun.faces.numberOfLogicalViews | Specifies the number of logical views that are stored in the session when Server-Side State Saving is used. | 15 |
| com.sun.faces.enableHighAvailability | If set to true while server-side state saving is used, a serialized representation of the view is stored on the server. This provides failover and server clustering support. | false |
| com.sun.faces.injectionProvider | Defines an injection provider that is used for JSF annotations. | |
| com.sun.faces.serializationProvider | Defines a serialization provider that is used for serializing JSF objects into session. | |
| com.sun.faces.responseBufferSize | Define the size of the response buffer for a JSF response. | 1048 |
| com.sun.faces.clientStateWriteBufferSize | | 8192 |
| com.sun.faces.expressionFactory | Specifies the default EL Expression Factory to use. | org.apache.el.ExpressionFactoryImpl |
| com.sun.faces.clientStateTimeout | The timeout value used for client side state saving. When the value set has been reached then the state is lost. | infinite |
| com.sun.faces.displayConfiguration | | false |

*Table 172. JSF options using SUN RI (continued). The table shows SUN RI parameter names, descriptions and default values.*

| SUN RI parameter name | Description | Default value |
|---|---|---|
| com.sun.faces.validateXml | When set to true, tag library XML files and faces configuration XML files using schema are validated during application start. | false |
| com.sun.faces.verifyObjects | | false |
| com.sun.faces.forceLoadConfiguration | | false |
| com.sun.faces.disableVersionTracking | | false |
| com.sun.faces.enableHtmTagLibValidator | | false |
| com.sun.faces.prerefXHTML | | false |
| com.sun.faces.compressViewState | | true |
| com.sun.faces.compressJavaScript | | true |
| com.sun.faces.sendPoweredByHeader | | true |
| com.sun.faces.enableJSStyleHiding | | false |
| com.sun.faces.writeStateAtFormEnd | | true |
| com.sun.faces.enableLazyBeanValidation | | true |
| com.sun.faces.enableLoadBundle11Compatibility | | false |
| com.sun.faces.enableRestoreView11Compatibilty | | false |
| com.sun.face.serializeServerState | | false |
| com.ibm.ws.jsf.JSP_UPDATE_CHECK | This parameter monitors Faces JavaServer Pages (JSP) files for modifications and synchronizes a running server with the changes without restarting the server. If this parameter is set to false or removed from the deployment descriptor, any changes made to Faces JSP files might not be seen by the server until it is restarted. Set this parameter to true while developing and debugging the Faces JSP files to improve the performance of the development environment. | |
| com.ibm.ws.jsf.JSF_IMPL_CHECK | Set the com.ibm.ws.jsf.JSF_IMPL_CHECK parameter to true to check at application restart if the SUN RI and MyFaces implementations were switched. If the implementation has switched, then the runtime removes any generated JSP files from the temp directory and the JSP file is retranslated the next time it is requested. | |
| com.ibm.ws.jsf.associateLabelWithId | The com.ibm.ws.jsf.associateLabelWithId custom property changes the rendering behavior for both the <h:selectOneRadio> and <h:selectManyCheckbox> components. The label no longer wraps the input element. Instead, each input element has a unique ID and the label is associated with that ID used for that attribute. Define and set the com.ibm.ws.jsf.associateLabelWithId context parameter to `true` in the web.xml file.<br><br>Use the following code as an example.<br>`<context-param>`<br>`<description>`<br>`Set to true to explicitly associate labels`<br>`with their input elements for select one`<br>`radio buttons and select many check box lists.`<br>`</description>`<br>`<param-name>com.ibm.ws.jsf.associateLabelWithId`<br>`</param-name>`<br>`<param-value>true</param-value>`<br>`</context-param>` | |

*Table 172. JSF options using SUN RI (continued). The table shows SUN RI parameter names, descriptions and default values.*

| SUN RI parameter name | Description | Default value |
|---|---|---|
| com.ibm.ws.jsf.disableEnqueuedMessagesWarning | The com.ibm.ws.jsf.disableEnqueuedMessagesWarning custom property disables the `FacesMessage(s) have been enqueued, but may not have been displayed` warning message. When this property is set to `true` in the web.xml file, this warning message is not included in the `SystemOut.log` file .<br>**gotcha:** This context parameter only applies to JSF applications that use the Sun Reference Implementation (RI) for JSF implementation.<br>**Note:** This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.<br><br>Use the following code as an example of how to define and set the com.ibm.ws.jsf.disableEnqueuedMessagesWarning context parameter to `true` in the web.xml file.<br>`<context-param>`<br>`<description>`<br>`Set to true to disable the following warning`<br>`message:`<br>`FacesMessage(s) have been enqueued, but might`<br>`not have been displayed`<br>`</description>`<br>`<param-name>`<br>`com.ibm.ws.jsf.disableEnqueuedMessagesWarning`<br>`</param-name>`<br>`<param-value>true</param-value>`<br>`</context-param>` | |
| com.ibm.ws.jsf.disableStylePassthroughForCheckboxList | This custom property prevents passing the style information into the items in the check box list. This property defaults to false to maintain the current behavior. Define and set the com.ibm.ws.jsf.disableStylePassthroughForCheckboxList context parameter to `true` in the web.xml file prevent passing style information into items in the check box list. Use the following code as an example.<br>`<context-param>`<br>`<description>`<br>`Set to true if style information should not`<br>`be passed into items of check box list`<br>`</description>`<br>`<param-name>`<br>`com.ibm.ws.jsf.disableStylePassthroughForCheckboxList`<br>`</param-name>`<br>`<param-value>true</param-value>`<br>`</context-param>` | |
| com.ibm.ws.jsf.DISABLE_UIDATA_NESTED_CHECK | The com.ibm.ws.jsf.DISABLE_UIDATA_NESTED_CHECK custom property determines whether unique IDs are generated for UIData components that are nested inside iterator components that are not UIData components. When this property is set to `true` in the web.xml file, unique IDs are generated for UIData components even if they are nested inside iterator components that are not UIData components.<br><br>When this property is set to `false`, if a JSF dataTable component is nested within a component that does not extend UIData, such as the Java Widget Library (JWL) dataIterator component, the IDs that are generated for the rows do not increment properly. This situation can result in duplicate IDs being assigned to multiple JSF components.<br><br>Use the following code as an example of how to define and set the com.ibm.ws.jsf.DISABLE_UIDATA_NESTED_CHECK context parameter to `true` in the web.xml file.<br>`<context-param>`<br>`<description>`<br>`Set to true to enable unique IDs to be`<br>`generated for UIData components evenif they`<br>`are nested inside iterator components that are`<br>`not UIData components.`<br>`</description>`<br>`<param-name>`<br>`com.ibm.ws.jsf.DISABLE_UIDATA_NESTED_CHECK`<br>`</param-name>`<br>`<param-value>true</param-value>`<br>`</context-param>` | |

*Table 172. JSF options using SUN RI (continued). The table shows SUN RI parameter names, descriptions and default values.*

| SUN RI parameter name | Description | Default value |
|---|---|---|
| com.ibm.ws.jsf.loadExternalDtd | When parsing the faces-config.xml file from included libraries, the Faces configuration parser attempts to load the DTD even when validation is disabled. The Faces configuration parser uses a SAXParser to read the faces-config.xml. The default behavior of the SAXParser parser is to always load the DTD even if validation is disabled. This behavior can lead to errors initializing the Faces Servlet on systems isolated from the internet.<br><br>In your `web.xml` file, set the com.ibm.ws.jsf.loadExternalDtd context paramater to `false` to have the Faces configuration parser set the "http://apache.org/xml/features/nonvalidating/load-external-dtd" feature to false.<br>`<context-param>`<br>`<description>`<br>`When set to false, this property sets a`<br>`feature on the SAX parser to prevent loading`<br>`the external DTD.`<br>`</description>`<br>`<param-name>com.ibm.ws.jsf.loadExternalDtd</param-name>`<br>`<param-value>false</param-value>`<br>`</context-param>` | |
| enableRestoreView11Compatibility | A JSF 1.2 application might create the ViewExpiredException exception under load when using the Sun Reference Implementation. If your view is not found in session, you can use a compatibility mode in JSF to create a new view. This can have adverse behaviors because it is a new view and items that are usually in the view, such as state, will no longer be available. Use the following code as an example to set the com.sun.faces.enableRestoreView11Compatibility context parameter to `true` in the web.xml file. This is only applicable when the Sun Reference Implementation is in use.<br>`<context-param>`<br>`<param-name>`<br>`com.sun.faces.enableRestoreView11Compatibility`<br>`</param-name>`<br>`<param-value>true</param-value>`<br>`</context-param>` | |
| enableViewStateIdRendering | The com.sun.faces.enableViewStateIdRendering custom property controls the rendering of the id attribute of the javax.faces.ViewState hidden field. Use the following code as an example to set the com.sun.faces.enableViewStateIdRendering context parameter to `true` in the web.xml file.<br>`<context-param>`<br>`<param-name>com.sun.faces.enableViewStateIdRendering`<br>`</param-name>`<br>`<param-value>true</param-value>`<br>`</context-param>` | |

## JSF options for MyFaces

*Table 173. JSF options for MyFaces. The table shows JSF parameter names, descriptions and default values.*

| JSF parameter name | Description | Default value |
|---|---|---|
| org.apache.myfaces.RESOURCE_VIRTUAL_PATH | | /faces/myFacesExtensionResource |
| org.apache.myfaces.PRETTY_HTML | If this value is true, rendered HTML code is formatted so that it is human-readable. Additional line separators and white space are written that do not influence the HTML code. | true |
| org.apache.myfaces.ALLOW_JAVASCRIPT | This parameter tells MyFaces if javascript code is allowed in the rendered HTML output. If javascript is allowed, command_link anchors have javascript code that submits the corresponding form. If javascript is not allowed, the state saving information and nested parameters are added as URL parameters. | true |
| org.apache.myfaces.DETECT_JAVASCRIPT | | false |
| org.apache.myfaces.AUTO_SCROLL | If true, a javascript function is rendered that can restore the former vertical scroll on every request. This feature is convenient if you have pages with long lists and you do not want the browser page to jump to the top of the page if you trigger a link or button action that stays on the same page. | false |
| org.apache.myfaces.ADD_RESOURCE_CLASS | | org.apache.myfaces.renderkit.html.util.DefaultAddResource |
| org.apache.myfaces.CHECK_EXTENSIONS_FILTER | This parameter checks for a properly-configured Extensions-Filter if it is needed by the web application. | true |
| org.apache.myfaces.READONLY_AS_DISABLED_FOR_SELECTS | | true |

*Table 173. JSF options for MyFaces (continued). The table shows JSF parameter names, descriptions and default values.*

| JSF parameter name | Description | Default value |
|---|---|---|
| org.apache.myfaces.SERIALIZE_STATE_IN_SESSION | Set this option to `true` to serialize the state to a byte stream before it is written to the session. If this option is set to `false`, the state is not serialized to a byte stream. This option is only applicable if the state saving method is set to server. | true |
| org.apache.myfaces.COMPRESS_STATE_IN_SESSION | Set this option to `true` to compress the serialized state before it is written to the session. If this option is set to `false`, the state is not compressed. This option is only applicable if the state saving method is set to server and if org.apache.myfaces.SERIALIZE_STATE_IN _SESSION is set to `true`. | true |
| org.apache.myfaces.NUMBER_OF_VIEWS_IN_SESSION | Defines the number of the latest views that are stored in session. This option is only applicable if the state saving method is set to server. | 20 |
| com.ibm.ws.jsf.disablealternatefacesconfigsearch | Disables MyFaces searching for META-INF/*.faces-config.xml for only the web application that this context parameter is set on. If the context parameter and the web container custom property are set, the context parameter takes precedence. | false |

## JSF options using SUN RI or MyFaces

The following options are valid for both the SUN RI and the MyFaces implementations.

*Table 174. JSF options using SUN RI or MyFaces. The table shows JSF parameter names, descriptions and default values.*

| JSF parameter name | Description | Default value |
|---|---|---|
| javax.faces.STATE_SAVING_METHOD | Specifies the location where state information is saved. Valid values are 'server', which is saved in HttpSession, and 'client', which is saved as a hidden field in the form. | server |
| javax.faces.CONFIG_FILES | Use this parameter to specify a comma-delimited list of context-relative resource paths under which the JSF implementation looks for application configuration resources before loading a configuration resource named `/WEB-INF/facesconfig.xml`, if a resource exists. | n/a |
| javax.faces.DEFAULT_SUFFIX | Specifies the default suffix for extension-mapped resources that contain JSF components. | .jsp |
| javax.faces.LIFECYCLE_ID | Use this parameter to configure an alternate life cycle ID. | n/a |
| com.ibm.ws.jsf.JSF_IMPL_CHECK | Specifies that the JSP files in a web module must be recompiled when the application is restarted because the implementation of JSF that is used has changed. After the application is restarted, the next time a JSP file is accessed for this module the JSP file is recompiled against the selected implementation of JSF specified in the administration console. Subsequent calls to the JSP file do not recompile. The default setting for this option is false. Use this option for development and not in a production environment. | n/a |

## Sun RI context parameters that have an equivalent behavior in MyFaces

*Table 175. Sun RI context parameters and equivalent MyFaces behavior. The table shows SUN RI parameters names and MyFaces equivalent.*

| SUN RI parameter name | Description | RI default | MyFaces equivalent | MyFaces default |
|---|---|---|---|---|
| com.sun.faces.numberOfViewsInSession | Defines the maximum number of serialized views stored in the session. Works with server state saving. | 15 | org.apache.myfaces.NUMBER_OF_VIEWS_IN_SESSION | 20 |

*Table 175. Sun RI context parameters and equivalent MyFaces behavior (continued). The table shows SUN RI parameters names and MyFaces equivalent.*

| SUN RI parameter name | Description | RI default | MyFaces equivalent | MyFaces default |
|---|---|---|---|---|
| com.sun.faces.compressViewState | When true the view is compressed after it is serialized and before base64 encoded. Works with client state saving. As of 1.2_09, this option also affects server-side state saving when com.sun.faces.serializeServerState is set to true (this has a large impact of the size of the state in the session when using this option, at the expense of more CPU.) | true | org.apache.myfaces.COMPRESS_STATE_IN_CLIENT for client-side state saving or org.apache.myfaces.COMPRESS_STATE_IN_SESSION for server-side state saving | false for client-side state saving, true for server-side state saving |
| com.sun.faces.validateXml | When true JSF validates the configuration files. | false | org.apache.myfaces.VALIDATE | false |
| com.sun.faces.injectionProvider | This parameter specifies a class that implements the InjectionProvider. | n/a | injection provider is provided by the WebSphere Application Server run time | n/a |
| com.sun.faces.serializationProvider | This parameter specifies a class that implements the SerializationProvider SPI. This implementation represents a hook the JSF implementation uses to enable using alternate Serialization implementations. | n/a | org.apache.myfaces.SERIAL_FACTORY - class must implement org.apache.myfaces.shared_impl.util.serial.SerialFactory SPI instead of com.sun.faces.spi.SerializationProvider | n/a |
| com.sun.faces.enabledJSStyleHiding | If true, inline JavaScript rendered by the HTML ResponseWriter implementation is rendered so that the script is hidden from older browser implementations. | false | org.apache.myfaces.WRAP_SCRIPT_CONTENT_WITH_XML _COMMENT_TAG | true |
| com.sun.faces.serializeServerState | If enabled the component state (not the tree) is serialized before being stored in the session. This might be desirable for applications that have issues with view state being sensitive to model changes. | false | org.apache.myfaces.SERIALIZE_STATE_IN_SESSION | true |

# Defining an extension for the registry filter

The registry filter specifies if an extensions is applicable to all registry instances or to specified instances.

## Before you begin

You must have an extensible application to define an extension for the registry filter.

## About this task

Complete the following steps to filter out extensions for an application.

## Procedure

1. Define an extension for the registry filter extension point for a named registry instance in the `plugin.xml` file.

```
<extension point="org.eclipse.extensionregistry.RegistryFilter">
 <filter name="AdminConsole*"
   class="com.ibm.ws.admin.AdminConsoleExtensionFilter"/>
 </extension>
```

2. Add the filter implementation to the application by creating a class to implement the com.ibm.workplace.extension.IExtensionRegistryFilter interface.

```
package com.ibm.ws.admin;
import com.ibm.workplace.extension.IExtensionRegistryFilter;
public class AdminConsoleExtensionFilter implements IExtensionRegistryFilter {
        :
}
```

3. The extensible application declares the registry name by defining an extension for the RegistryInstance extension point. This way, the registry can prepare an IExtensionRegistry instance and put it in JNDI in advance.

```
<extension point="org.eclipse.extensionregistry.RegistryInstance">
  <registry name="AdminConsole"/>

</extension>
```

4. The extensible application obtains a named instance of the registry to activate any associated filters:

```
InitialContext ic = new InitialContext();
String lookupName = "services/extensionregistry/AdminConsole";
IExtensionRegistry reg = (IExtensionRegistry)ic.lookup( lookupName );
```

## Application extension registry

WebSphere Application Server has enabled the Eclipse extension framework for applications to use. Applications are extensible when they contain a defined extension point and provide the extension processing code for the extensible area of the application.

An application can be plugged in to another extensible application by defining an extension that adheres to what the target extension point requires. The extension point can find the newly added extension dynamically and the new function is seamlessly integrated in the existing application. It works on a cross Java Platform, Enterprise Edition (Java EE) module basis. The application extension registry uses the Eclipse plug-in descriptor format and application programming interfaces (APIs) as the standard extensibility mechanism for WebSphere applications. Developers that build WebSphere application modules can use WebSphere Application Server extensions to implement their functionality to an extensible application, which defines an extension point. This is done through the application extension registry mechanism.

The architecture of extensible Java EE applications follow a modular design to add new functional modules or to replace an existing module, particularly by those outside of its core development team. Each module is a pluggable unit, or plug-in that is either deployed into the portal or removed from the Java EE application using a deployment tool that is based upon standard Java EE and portal web module deployment tooling. A plug-in module describes where it is extensible and what capability it provides to other plug-ins in the `plugin.xml` file. The `plugin.xml` manifest file can be created with a simple text editor or in Eclipse's Plug-in Development Environment (PDE), which provides a simplified view of the same underlying XML data.

### WebSphere Application Server implementations to the Eclipse model

Some minor differences exist in the WebSphere Application Server implementation of this architecture because of platforms, specifically, Eclipse Workbench or Java 2 Platform, Enterprise Edition (Java EE). The highlights of the WebSphere Application Server implementation include:

- Implementing all of the extension registry-related interfaces from Eclipse 3.1.
- The identical `plugin.xml` syntax, however, some attributes are not used, for example, <runtime>.
- The discovery and addition of plug-ins to the registry, when the containing Java EE module starts, and plug-ins are dismissed and removed from the registry when the containing Java EE module stops.
- Access to an IExtensionRegistry object is through the Java Naming and Directory Interface (JNDI), instead of by using the Platform.getExtensionRegistry method in the Eclipse Workbench.
- Filtering capability is available by providing a filter implementation and using a named registry instance that finds and invokes the filter as necessary. See the developer API documentation for the IExtensionRegistryFilter interface for more details.

### Available Eclipse 3.1 interfaces

The following Eclipse 3.1 interfaces are available on WebSphere Application Server:

- Extension registry API

- Extension point API
- Extension API
- Configuration element API
- Registry change listener API
- Registry change event API
- Extension delta API
- Status API

The following interfaces are recognized and processed the same as in Eclipse:

- Executable extension API
- Executable extension factory API

## Application extension registry filtering

The extension registry exposes the registry filter extension point. The registry filter removes elements within the extension registry for client applications. Extensions that are attached to the registry filter extension point and that also implement this interface are called as necessary when a client operates on a named registry instance that matches the target specification.

You can create a filter extension for all registry instances or for named instances that are specified by the extension. In the first case, the filter is applied to all instances of the extension registry, and all client applications use the filter without requesting the filter. In the latter case, a client application must predefine the registry name by defining an extension, called *RegistryInstance*, which is another extension point that is exposed by the extension registry. After the registry name is defined, the client can obtain the named registry instance and use that registry instance. The filter extension is invoked by the named registry instance as necessary.

### Registry filter API

Supported arguments include:

**org.eclipse.core.runtime.IExtension[]**
doFilter(org.eclipse.core.runtime.IExtension[] extensions)

This code returns an array of IExtension objects that are included in the valid extension list.

### Registry instance extension point

The extension registry exposes the *RegistryInstance* . The instance name is declared in the application's `plugin.xml` file, and the application requests an registry instance for that name at runtime.

## plugin.xml file

A plug-in is described in an XML manifest file, called `plugin.xml`, which is part of the plug-in deployment files. The manifest file tells the portal application's runtime what it needs to know to register and activate the plug-in. The manifest file essentially serves as the contract between the pluggable component and the portal application's runtime. Although the WebSphere Application Server `plugin.xml` closely follows the one provided for the Eclipse workbench, it does diverge from the Eclipse workbench in several places as outlined below.

### Location

The `plugin.xml` file must reside in the `WEB-INF` directory under the context of the hierarchy of directories that exist for a web application or when included in the Web application archive file.. The `plugin.xml` file must reside in the root directory when the`plugin.xml` file is placed in an Enterprise JavaBeans Java archive (JAR) file or shared library JAR file. The extension registry service includes the `plugin.xml` file as the participating components are loaded and started on the application server.

### Usage notes

- Is this file read-only?

  No
- Is this file updated by a product component?

  ???
- If so, what triggers its update?

  Rational Application Developer updates the `web.xml` file when you assemble web components into a web module, or when you modify the properties of the web components or the web module.
- How and when are the contents of this file used?

  WebSphere Application Server functions use information in this file during the configuration and deployment phases of web application development.
- The manifest markup definitions below make use of various naming tokens and identifiers. To eliminate ambiguity, the following are productions rules for these naming conventions. In general, all identifiers are case-sensitive.

```
SimpleToken := sequence of characters from ('a-z','A-Z','0-9')
ComposedToken := SimpleToken | (SimpleToken '.' ComposedToken)
PlugInId := ComposedToken
PlugInPrereq := PlugInId
ExtensionId := SimpleToken
ExtensionPointId := SimpleToken
ExtensionPointReference := ExtensionPointId | (PlugInId '.' ExtensionPointId)
```

### Sample file entry

The entire plug-in manifest DTD is as follows. XML Schema is not used to define the manifest since the current Eclipse tooling for plug-in's requires a DTD. The XML DTD construction rule element* means zero or more occurrences of the element; element? means zero or one occurrence of the element; and element+ means one or more occurrences of the element.

```
<?xml encoding="US-ASCII"?>

<!ELEMENT plugin (requires?, extension-point*, extension*)>
<!ATTLIST plugin
  name CDATA #IMPLIED
  id CDATA #REQUIRED
  version CDATA #REQUIRED
  provider-name CDATA #IMPLIED
>
<!ELEMENT requires (import+)>
<!ELEMENT import EMPTY>
<!ATTLIST import
  plugin CDATA #REQUIRED
  version CDATA #IMPLIED
  match (exact | compatible | greaterOrEqual) #IMPLIED
>
<!ELEMENT extension-point EMPTY>
<!ATTLIST extension-point
  name CDATA #IMPLIED
  id CDATA #REQUIRED
  schema CDATA #IMPLIED
>
<!ELEMENT extension ANY>
<!ATTLIST extension
  point CDATA #REQUIRED
  id CDATA #IMPLIED
  name CDATA #IMPLIED
>
```

## WebSphere Application Server differences

The `plugin.xml` file closely follows the `plugin.xml` file provided for the Eclipse workbench. However it diverges within the following elements.

**The `plugin` element**

The plugin element provided in this manifest does not contain class attributes. The class attribute is unnecessary since the plug-in mechanism does not require the plug-in developer to extend or use any specific classes as is required by the Eclipse workbench. Also, the plugin element does not contain a runtime element since standards such as J2EE that already define the location of runtime libraries for the applications.

**The `import` element**

The requires element does not contain export attribute since J2EE modules are encouraged to be self-contained to improve manageability. In addition to eliminating the export attribute, the match attribute has an option for a greater than or equal to match for versions (greaterOrEqual).

**The `extension-point` element**

The extension-point element has the name attribute as optional since it has no real use in this J2EE implementation.

you can find details regarding the plug-in manifest in the Eclipse documentation, under Platform Plug-In Developer Guide>Other reference information>Plug-in manifest.

The following is an example of how adding a link to an existing page can be accomplished by an extension point. The plug-in manifest of this plug-in declares an extension point (linkExtensionPoint) and an extension to this extension point (linkExtension). The plug-in declaring the extension point does not need to be the plug-in that implements the extension point. Another plug-in can also define an extension to the link extension point in its plug-in manifest by including the contents of the <extension> and </extension> tags in its manifest.

```
<?xml version="1.0"?>
<!--the plugin id is derived from the vendor domain name -->
<plugin
   id="com.ibm.ws.console.core"
   version="1.0.0"
   provider-name="IBM WebSphere">

  <!--declaration of prerequisite plugins-->
 <requires>
    <import plugin="com.ibm.data" version="2.0.1" match="compatible"/>
    <import plugin="com.ibm.resources" version="3.0" match="exact"/>
 </requires>

 <!--declaration of link extension point -->
 <extension-point
    id="linkExtensionPoint"
    schema="/schemas/linkSchema.xsd"/>

 <!--declaration of an extension to the link extension point -->
 <extension
    point="com.ibm.ws.console.core.linkExtensionPoint"
    id="linkExtension">

   <link
     label="Example.displayName"
     actionView="com.ibm.ws.console.servermanagement.forwardCmd.do?
        forwardName=example.config.view&
        lastPage=ApplicationServer.config.view">
   </link>
 </extension>
</plugin>
```

# Contexts and Dependency Injection (CDI)

Learn about Contexts and Dependency Injection (CDI).

## Developing applications that use Contexts and Dependency Injection (CDI)

Use this task to provide a summary of the WebSphere Application Server extensions that you can use to develop servlets.

### About this task

Several WebSphere Application Server extensions are provided for enhancing your servlets. This task provides a summary of the extensions that you can use.

### Procedure

1. Review the supported specifications.

   Create Java™ components, referring to the CDI specifications from Sun Microsystems. Place a beans.xml file in the WEB-INF directory of the WAR module, or META-INF directory of a JAR file, so the container identifies it as a bean deployment archive.
2. Use your favorite integrated development environment (IDE), or a text editor, to develop or migrate code artifacts that meet the specifications.
3. Test the code artifacts.

### What to do next

Assemble your code artifacts into a web module using assembly tools as a prerequisite to deploying the code to the application server.

## Contexts and Dependency Injection (CDI)

Contexts and Dependency Injection for the Java EE platform (CDI) is a JSR 299 implementation that is based on Apache OpenWebBeans.

CDI is activated in an application by the presence of a beans.xml file inside that module, as defined by the JSR 299 specification. You can find the beans.xml file in the WEB-INF directory of a web archive (WAR) or META-INF directory of other types of archives. When activated, the container provides services such as:

- Context management
- Type-safe dependency injection: A CDI-managed bean is instantiated and injected as needed.
- Decorators, which implement one or more bean interfaces and can contain business logic. Decorators are disabled by default. You can have multiple decorators per bean and order is defined by the beans.xml file.
- Interceptor bindings. Interceptors, which are enabled manually in the beans.xml file, are bound using an interceptor binding type.
- Event model
- Integration into JavaServer Faces (JSF) and JavaServer Pages (JSP) files using the Expression Language (EL)

The specification-related API classes for JSR 299 and JSR 330 and IBM modified implementation classes that are based on Apache OpenWebBeans are packaged with the application server runtime environment.

Although the WebSphere Application Server CDI implementation is based on Apache OpenWebBeans, there are some changes and additions on top of OpenWebBeans to support integration with the server run time:

- Integration with other Java Platform, Enterprise Edition (Java EE) containers in WebSphere Application Server that support injectable components.
- ScannerService implementation that uses the WebSphere Application Server byte code scanner.

- Direct use of WebSphere Application Server Enterprise JavaBeans (EJB) metadata for determining EJB types.
- Automatic registration of Servlet Listeners, Filters, Interceptors for CDI applications so these no longer must be added by each application.
- WebSphere Application Server-specific implementations of many OpenWebBeans Service Programming Interfaces (SPI), such as ResourceInjectionService, TransactionService, failover service, and so on.

**Important:** Container-managed transactions and security are not provided by CDI.

***Contexts and Dependency Injection custom properties:***

WebSphere Application Server Contexts and Dependency Injection (CDI) implementation is based on OpenWebBeans, which is configurable through the openwebbeans.properties file.

To specify CDI custom properties, place the openwebbeans.properties file inside the META-INF/openwebbeans directory of your application. Properties that are not listed below, such as those that control the lifecycle and services, should remain at the default value for the application server. See the following list of some of the available CDI custom properties:

*org.apache.webbeans.conversation.Conversation.periodicDelay:*

Specifies a delay in milliseconds. Use the conversation periodic delay custom property to search for and delete unused conversations.

| Value | Default |
|---|---|
| integer | 15000 |

*org.apache.webbeans.application.jsp:*

Specifies that an application is a full JavaServer Pages (JSP) application. Specify true if you want to add the JSP ELResolver class to the application.

| Value | Default |
|---|---|
| true | true |

*org.apache.webbeans.useOwbSpecificXmlConfig:*

Specify true if you want to use OpenWebBeans-specific beans.xml files for the application. The default value is false, which is the portable specification beans.xml format.

| Value | Default |
|---|---|
| true | false |

*org.apache.webbeans.fieldInjection.useOwbSpecificInjection:*

Specify true if you want to use OpenWebBeans-specific injection for the application. The default value is false, which is the portable specification behavior.

| Value | Default |
|---|---|
| true | false |

*org.apache.webbeans.application.useJSF2Extensions:*

Specify true to enable JavaServerFaces (JSF) 2.0-based CDI extensions.

| Value | Default |
|---|---|
| true | false |

*org.apache.webbeans.application.supportsConversation:*

Specify true to support conversation scopes in the application.

| Value | Default |
|---|---|
| true | true |

***CDI integration with JavaServer Faces:***

Contexts and Dependency Injection (CDI) primarily integrates with JavaServer Faces (JSF) through the Expression Language (EL). It enables CDI beans to be exposed through the unified EL-to-JSF components. It also provides a built-in context for conversation scope that is active during standard JSF life cycle phases.

As part of the WebSphere Application Server integration with CDI containers, several JSF components are automatically registered for CDI applications, including:

- EL Resolver
- Phase Listener
- View Handler
- Application Factory

Only the default JSF implementation (based on MyFaces) is supported for use with CDI.

***Contexts and Dependency Injection (CDI) integration with EJB container:***

The CDI specification enhances the EJB component model with contextual life cycle management.

**Relationship of the CDI to the EJB specification**

**Note:** The EJB specification defines a programming model for application components that access transactional resources in a multi-user environment. Concerns, such as role-based security, transaction demarcation, concurrency, and scalability are specified declaratively using annotations and XML deployment descriptors that are enforced by the EJB container at run time. EJB components might be stateful, but are not by nature, contextual.

The following session bean instances are obtained using dependency injection:

- Contextual
- Bound to a life cycle context
- Available to other instances that launch in that context
- Container creates an instance when needed
- Container destroys an instance when context ends

The WebSphere Application Server CDI container performs dependency injection on all session and message-driven bean instances, even instances that are not contextual instances. WebSphere Application Server CDI supports injection of CDI beans inside enterprise beans and vice versa.

**Usage**

**Note:** Use the following best practices when injecting enterprise beans:

- Use the @Inject method for contextual injection of local session beans.
- Use the @EJB method for remote session beans

See the following examples of using the @EJB method in CDI:

Define producers making the EJB available for non-contextual injection:

```
@Produces @EJB PaymentService paymentService;
```

Consume the injected types in other CDI beans:

```
@Inject PaymentService myPaymentService
```

**Practical considerations**

You can define CDI-style interceptors with interceptor bindings and decorators enterprise beans. Interceptors are declared using @Interceptors methods or in ejb-jar.xml files, which are called before interceptors and are declared using interceptor bindings. Interceptors are called before decorators.

WebSphere Application Server supports failover (activation and passivation) of CDI beans and enterprise beans, along with their interceptors and decorators. EJB failover support with CDI only works for stateful session beans and requires the same configuration as stateful session bean failover. See the stateful session bean failover for the EJB container topic for more information. Configure EJB failover with web HTTP session failover. See the "Configuring for database session persistence" and the "Configuring memory-to-memory replication for the peer-to-peer mode (default memory-to-memory replication)" topics for more information. Except for abstract decorators, failover services are based on currentWebSphere Application Server failover providers. Web session failover and EJB stateful session bean failover and configured separately.

When a contextual (@Injected) instance of an EJB container is destroyed as a result of going out of scope, and if the underlying EJB container was not already removed by direct invocation of a remove method by the application, the WebSphere Application Server CDI container removes the stateful session bean.

The WebSphere Application Server CDI container removes the stateful session bean when:

- You use the @Inject method to create a contextual injection instance and that instance in an EJB container is destroyed as a result of going out of scope.
- The underlying EJB container was not already removed by direct invocation of a remove method by the application.

You must also consider the scope and state propagation of CDI beans. The request and application scope CDI beans maintain state in their respective contexts across the web and EJB containers. For instance, a request-scoped CDI bean injected in a servlet holds its state when a business method on stateful session enterprise bean accesses the same request-scoped bean.

# Developing servlet applications using asyncrhonous request dispatcher

## Developing servlet applications using asynchronous request dispatcher

Web modules can dispatch requests concurrently on separate threads. Requests can be dispatched by the server or client.

### Before you begin

For additional information about the AsyncRequestDispatcherConfig and the AsyncRequestDispatcher interfaces, review the com.ibm.websphere.webcontainer.async package in the application programming interfaces (API) documentation. The generated API documentation is available in the information center table of contents from the path Reference > APIs - Application Programming Interfaces.

Review the asynchronous request dispatcher application (ARD) design considerations topic before completing the following steps.

### About this task

Concurrent dispatching can improve servlet response time. If operations are dependant on each other, do not enable asynchronous request dispatching, therefore, select Disabled. Concurrent dispatching might result in errors when operations are dependant. Select Server side to enable the server to aggregate requests dispatched concurrently. Select Client side to enable the client to aggregate requests dispatched concurrently.

### Procedure

1. Logically separate resource intensive operations.
2. Develop servlets that use an asynchronous request dispatcher to include these operations.
3. Enable asynchronous request dispatching on an application server.
4. Deploy the application in an application server that has asynchronous request dispatching enabled.
5. Select an aggregation type for the application that needs ARD.
6. Optional: Configure the AsyncRequestDispatcherWorkManager work manager that is used for the request dispatch threads.
7. Restart the application server.

### What to do next

Restart the modified applications if already installed or start newly installed applications to enable ARD on each application.

---

# Assembling web applications

# Assembling web applications

Assemble a web module to contain servlets, JavaServer Pages (JSP) files, and related code artifacts. (Group enterprise beans, client code, and resource adapter code in separate modules). After assembling a web module, you can install it as a stand-alone application or combine it with other modules into an enterprise application.

## Before you begin

This topic assumes that you have created and unit tested Servlets and JavaServer Pages (JSP) files and other web components that you want to assemble in an enterprise application and deploy onto an application server.

## About this task

Use an assembly tool to assemble a web module in any of the following ways:
- Import an existing web module (WAR file).
- Create a new web module.
- Copy code artifacts (such as servlets) from one web module into a new web module.

Although you can input various properties for web archives, available properties are specific to the Servlet, JSP, and Java Platform, Enterprise Edition (Java EE) specification level.

## Procedure

1. Start an assembly tool.
2. If you have not done so already, configure the assembly tool for work on Java EE modules. Ensure that **J2EE** and **Web** capabilities are enabled.
3. Migrate WAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an assembly tool. To migrate files, import your WAR files to the assembly tool.
4. Create a new web module.
5. Copy code artifacts (such as servlets) from one web module into a new web module.

## Results

A web project is migrated or created. Files for the Web project are shown in the Project Explorer view under **Enterprise Applications** and **Web Projects**.

## What to do next

You can now deploy your web project to an application server.

## web.xml file

The `web.xml` file provides configuration and deployment information for the web components that comprise a web application.

The Java Servlet specification defines the `web.xml` deployment descriptor file in terms of an XML schema document. For backwards compatibility, any `web.xml` file that is written to Servlet 2.2 or above that worked in previous versions of WebSphere Application Server are supported by the web container.

If you use Rational Application Developer Version 6 to create your portlets, you must remove the following reference to the `std-portlet.tld` from the `web.xml` file:

```
<taglib id="PortletTLD">
  <taglib-uri>http://java.sun.com/portlet</taglib-uri>
  <taglib-location>/WEB-INF/tld/std-portlet.tld</taglib-location>
</taglib>
```

### Location

The `web.xml` file must reside in the `WEB-INF` directory under the context of the hierarchy of directories that exist for a web application.

For example, if the application is `client.war`, then the `web.xml` file is placed in the *install_root*/*client war*/`WEB-INF` directory.

### Usage notes

- Is this file read-only?

  No
- Is this file updated by a product component?

  This file is updated by the assembly tool.
- If so, what triggers its update?

  The assembly tool updates the `web.xml` file when you assemble web components into a web module, or when you modify the properties of the web components or the web module.
- How and when are the contents of this file used?

WebSphere Application Server functions use information in this file during the configuration and deployment phases of web application development.

## Sample file entry

**Note:** The web.xml file does not represent the entire configuration that is available for the web application. There are other servlets filters, and listeners that can be defined using programmatic configurations, annotations, and web fragments.

**Note:** Marking the web application metadata complete will prevent annotations and web fragments from being able to configure components.

```
<?xml version="1.0" encoding="UTF-8"?>

 <servlet-mapping>
  <servlet-name>welcome</servlet-name>
  <url-pattern>/hello.welcome</url-pattern>
 </servlet-mapping>
 <servlet-mapping>
  <servlet-name>ServletErrorPage</servlet-name>
```

```
  <url-pattern>/ServletErrorPage</url-pattern>
 </servlet-mapping>
 <servlet-mapping>
  <servlet-name>IncludedServlet</servlet-name>
  <url-pattern>/IncludedServlet</url-pattern>
 </servlet-mapping>
 <servlet-mapping>
  <servlet-name>ForwardedServlet</servlet-name>
  <url-pattern>/ForwardedServlet</url-pattern>
 </servlet-mapping>
 <welcome-file-list>
  <welcome-file>hello.welcome</welcome-file>
 </welcome-file-list>
 <error-page>
  <exception-type>java.lang.ArrayIndexOutOfBoundsException</exception-type>
  <location>/ServletErrorPage</location>
 </error-page>
  <error-page>
   <error-code>404</error-code>
   <location>/error404.html</location>
  <error-page>
</web-app>
```

**Note:** For each `<error-page>` declaration, select either `<exception-type>` or `<error-code>`, but not both. The `<location>` tag is required.

## File serving

In file serving, web applications can serve static file types, such as HTML. File-serving attributes are used by the servlet that implements file-serving behavior.

The file-serving behavior is implemented by setting the fileservingenabled property to true when configuring the web module.

### Example attributes:

**bufferSize**

Sets buffer size that is used for serving static files.

**extendedDocumentRoot**

Enables you to configure an application with one or more directory paths from which you can serve static files and Java ServerPages (JSP) files. You can use this attribute when an application requires access to files that exist outside of the application web application archive (WAR) directory. For example, if several applications require access to a set of common files, you can place the common files in a directory to which you can link each application as an extended document root directory.

Use this attribute in addition to the contextRoot attribute.

You can also use this attribute to define a WebSphere variable on multiple nodes to the appropriate directory.

**Example:**

```
<fileServingAttributes xmi:id="FileServingAttribute_1" name="extendedDocumentRoot"
   value="${MY_CUSTOM_VARIABLE}"/>
```

where *MY_CUSTOM_VARIABLE* is the WebSphere variable that you want to define on multiple nodes.

For more information, see JSP engine configuration parameters.

**file.serving.patterns.allow**

Specifies that only files matching the specified pattern are served.

**file.serving.patterns.deny**

Specifies that files that match the specified file pattern are denied

# Configuring JavaServer Faces implementation

## Configuring JavaServer Faces implementation

Use this task to specify which JavaServer Faces implementation to use. You can use Apache MyFaces 2.0 or the SUN Reference Implementation 1.2 of JSF, or your own implementation.

### Before you begin

Ensure that your application is configured for JavaServer Faces (JSF) using the specific `web.xml` context parameters for the implementation that you have chosen.

**Attention:** The JSF implementation is a server-wide configuration setting. Thus, if you have multiple applications which require different JSF implementations, you must separate the applications into different application servers or clusters, and specify the implementation by following the steps in this topic for each application server or cluster. Alternatively, you can use an isolated shared library, as described for third-party JSF implementations, as follows.

### About this task

**Note:** The Application Server JSF engine determines if the SUN Reference Implementation (RI) 1.2 or Apache MyFaces 2.0 is used from the Application Server run time. If either is used, the correct listener class is registered with the web container. You do not need to add the com.sun.faces.ConfigureListener or the org.apache.myfaces.StartupConfigureListener to your `web.xml` file.

**Be Aware:** If you want to use a third-party JSF implementation that is not shipped with the product, then:

- Keep the configuration set to MyFaces.
- Add the third-party listener to the `web.xml` file that is required.
- Add the third-party implementation Java archive (JAR) files to the application as an isolated shared library and associate it with your application.

You can also configure the JSF implementation on the Provide JSP reloading options for web modules panel for application installation and update wizards.

### Procedure

Configure the server or cluster to use the JSF implementation that you want. You can do this task using the administrative console or the wsadmin tool.

- In the administrative console panel, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **JSP and JSF options**

  Select one of the following implementations:

  – Sun Reference Implementation 1.2 - Select this option to use the Sun Reference Implementation 1.2 JSF implementation.

  – MyFaces 2.0 - Select this option to use the MyFaces 2.0 JSF implementation. This option is the default JSF implementation.

- Using the wsadmin tool:

  – An example of setting a single server to use the Sun RI 1.2 JSF implementation:

```
wsadmin>set server [$AdminConfig list ApplicationServer *server1*]
server1(cells/myNode01Cell/nodes/myNode01/servers/server1|server.xml#ApplicationServer_1183122130078)
wsadmin>$AdminConfig modify $server {{jsfProvider SunRi1.2}}

wsadmin>$AdminConfig save
```

  – An example of setting a cluster to use the MyFaces 2.0 JSF implementation:

```
wsadmin>set cluster [$AdminConfig list ServerCluster]
cluster1(cells/myNode01Cell/nodes/myNode01/clusters/cluster1|cluster.xml#ServerCluster_1173916133721)
wsadmin>$AdminConfig modify $cluster {{jsfProvider MyFaces}}

wsadmin>$AdminConfig save
```

### Results

**Note:** Your application server or cluster has now been configured with the JSF implementation you specified. Any application that uses JSF technology uses that implementation, unless it is associated with an isolated shared library that contains a different implementation.

### What to do next

Configure JSF engine parameters as necessary.

# Deploying JavaServer Pages and JavaServer Faces files

## JSP class loading settings

You can configure a JavaServer Pages (JSP) class to be loaded by either the JSP engine's class loader or by the web module's class loader.

By default, a JSP class is loaded by a unique instance of the JSP engine's class loader. The JSP engine's class loader enables reloading at runtime of a JSP class when the JSP source or one of its dependents is modified. This allows you to reload a single JSP class when necessary, without affecting any other loaded JSP classes.

JSP classes are loaded by the web module's class loader under either of the following scenarios.

1. The JSP engine configuration parameter useFullPackageNames is set to true, and the JSP file is configured as a servlet in the `web.xml` file using the <servlet-class> scenario in the table below.
2. The JSP engine configuration parameters useFullPackageNames and disableJspRuntimeCompilation are both set to true. In this case, you do not need to configure a JSP file does as a servlet in the `web.xml` file.

### Configuring JSP files as Servlets

You can configure a JSP file as a servlet in the `web.xml` file. There are two ways to do this. They are described in the table below.

Before you configure a JSP file as a servlet, consider the following.

1. Reloading capability - If runtime reloading of JavaServer Pages files is desired, requests for JavaServer Pages files must be handled by the JSP engine. The <servlet-class> scenario in the table below disables runtime JSP file reloading, while the <jsp-file> scenario is compatible with reloading.
2. Reducing the number of class loaders - If you do not require runtime reloading of modified JSP pages and you want to reduce the number of class loader instances, then you can use the <servlet-class> scenario in the table below. Similarly, scenario 2 in section 1 above can be used without having to configure a JSP file as a servlet.

*Table 176. Example: Configure a JSP file as a servlet in the `web.xml` file.. Configure a JSP file as a servlet*

| Scenario | Example | compatible with runtime reloading | multiple class loaders used? | useFullPackageNames |
|---|---|---|---|---|

*Table 176. Example: Configure a JSP file as a servlet in the web.xml file. (continued). Configure a JSP file as a servlet*

| | | | | |
|---|---|---|---|---|
| <jsp-file> | <servlet><br><servlet-name>jspOne</servlet-name><br><jsp-file>jspOne.jsp</jsp-file><br></servlet> | Yes | Yes | Can be true or false |
| <servlet-class> | <servlet><br><servlet-name>jspTwo</servlet-name><br><servlet-class>_ibmjsp.jspTwo</servlet-class><br></servlet> | No | No | Must be true |

The JSP batch compiler tool helps you configure JavaServer Pages files as servlets. When useFullPackageNames is true, the JSP batch compiler generates <servlet> and <servlet-mapping> elements for each JSP file that it successfully translates and compiles. The elements are written to a web.xml fragment file named generated_web.xml which is located in the binaries WEB-INF directory of a web module processed by the JSP file batch compiler (this directory is located within the deployed application's ear file). You can copy and paste all or some of these elements into the web.xml file to configure JavaServer Pages files as servlets.

Take note of the location of the web.xml that is used by the application server. The application specific configuration is obtained from either the application binaries (the application's ear file) or from the configuration repository. If an application is deployed into WebSphere Application Server with the flag Use Binary Configuration set to true, then the WEB-INF/web.xml file is looked for in a web module's binaries directory, not in the configuration repository. Below are examples of these two locations.

- An example of a configuration repository directory is {WAS_ROOT}/profiles/profilename/config/cells/*cellname*/applications/*enterpriseappname*/deployments/*deployedname*/*webmodulename*
- An example of an application binaries directory is: {WAS_ROOT}/profiles/*profilename*/installedApps/*nodename*/EnterpriseAppName/*WebModuleName*/

If the JSP batch compiler is executed on a pre-deployed application then the web.xml file is in the web module's WEB-INF directory.

## JavaServer Pages (JSP) runtime reloading settings

JavaServer Pages files can be translated and compiled at run time when the JSP file or its dependencies are modified. This is known as JSP reloading.

**Note:** Use an assembly tool, such as Rational Application Developer, to modify IBM extension and binding files. You can convert extension and binding files within modules from XMI to XML using the IBM Bindings and Extensions Conversion Tool for Multi-Platforms.

JSP reloading is enabled through the **reloadEnabled** JSP engine parameter in the WEB-INF/ibm-web-ext.xmi or WEB-INF/ibm-web-ext.xml file.

**ibm-web-ext.xmi example:**

```
<jspAttributes xmi:id="JSPAttribute_1" name="reloadEnabled" value="true"/>
```

**ibm-web-ext.xml example:**

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
   xmlns="http://websphere.ibm.com/xml/ns/javaee"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
      version="1.0">
```

```
   <jsp-attribute name="trackDependencies" value="true" />
   <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
   <jsp-attribute name="reloadEnabled" value="true"/>

   <reload-interval value="5"/>
   <auto-encode-requests value="false"/>
   <auto-encode-responses value="false"/>
   <enable-directory-browsing value="false"/>
   <enable-file-serving value="false"/>
   <pre-compile-jsps value="false"/>
   <enable-reloading value="true"/>
   <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

**Note:** For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named ibm-*-ext.xmi or ibm-*-bnd.xmi where * is the type of extension or binding file such as app, application, ejb-jar, or web. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be .xmi.
- For an application or module that uses Java EE 5 or later, the file extension must be .xml. If .xmi files are included with the application or module, the product ignores the .xmi files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the .xmi file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the .xmi file extensions.

The following table contains suggested reload settings for production and development environments.

*Table 177. Suggested reload settings for production and development environments.. Reload settings*

| | Settings | |
|---|---|---|
| **Configuration Attribute** | **Production Environment** | **Development Environment** |
| reloadEnabled | false | true |
| reloadInterval | n/a (ignored if reloadEnabled is false) | approximately 5 seconds |
| trackDependencies | n/a (ignored if reloadEnabled is false) | true Alternatively, set this to false to improve response time if dependencies are not changing |
| disableJspRuntimeCompilation | true - Alternatively, set this to false if JSP files are not pre-compiled and therefore need to be compiled on the first request. | false |

The default for the **reloadEnabled** parameter is true. If the **reloadEnabled** parameter is set to true, a JSP file is reloaded at run time if the JSP file and its class file do not have the same timestamp. In addition, if **trackDependencies** is set to true then the JSP file is reloaded if the timestamp of any of its dependencies has changed since the JSP class file was last generated. If the **reloadEnabled** parameter is set to false, a JSP file is still compiled if necessary on the first request to it unless the parameter **disableJspRuntimeCompilation** is true. For example, when **disableJspRuntimeCompilation** is false and **reloadEnabled** is false, a JSP file is compiled on the first request if the class file is outdated. It would not compile on subsequent requests, even if the JSP source file is modified or the class file is deleted,, unless **reloadEnabled** is true.

## Reload interval

The reload interval is set through the **reloadInterval** JSP engine parameter.

**`ibm-web-ext.xmi` example:**

```
<jspAttributes xmi:id="JSPAttribute_1" name="reloadInterval" value="5"/>
```

**ibm-web-ext.xml example:**

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
   xmlns="http://websphere.ibm.com/xml/ns/javaee"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
      version="1.0">

   <jsp-attribute name="trackDependencies" value="true" />
   <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
   <jsp-attribute name="reloadInterval" value="5"/>

   <reload-interval value="5"/>
   <auto-encode-requests value="false"/>
   <auto-encode-responses value="false"/>
   <enable-directory-browsing value="false"/>
   <enable-file-serving value="false"/>
   <pre-compile-jsps value="false"/>
   <enable-reloading value="true"/>
   <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

If reloading is enabled, the **reloadInterval** parameter value determines the delay between checks to see if a JSP file is outdated. For example, if **reloadInterval** is 5, the JSP engine checks to see if a JSP file is outdated only when the last such check was done more than five seconds prior to the current request for the JSP file. Once the **reloadInterval** is exceeded, reload checking is performed and the reload interval timer is reset to 0 for that JSP file. The larger the **reloadInterval**, the less frequently the JSP engine checks for the need to reload a JSP file.

## Dependency tracking

Dependency tracking is set through the **trackDependencies** JSP engine parameter.

**ibm-web-ext.xmi example:**

```
<jspAttributes xmi:id="JSPAttribute_1" name="trackDependencies" value="true"/>
```

**ibm-web-ext.xmi example:**

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
   xmlns="http://websphere.ibm.com/xml/ns/javaee"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
      version="1.0">

   <jsp-attribute name="trackDependencies" value="true" />
   <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
   <jsp-attribute name="reloadInterval" value="5"/>

   <reload-interval value="5"/>
   <auto-encode-requests value="false"/>
   <auto-encode-responses value="false"/>
   <enable-directory-browsing value="false"/>
   <enable-file-serving value="false"/>
   <pre-compile-jsps value="false"/>
   <enable-reloading value="true"/>
   <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

If reloading is enabled, the **trackDependencies** parameter value determines whether the JSP engine tracks modifications to the requested JSP file dependencies as well as to the JSP file itself. The three types of dependencies tracked by the JSP engine are:

- files statically included in the JSP file
- tag files that are referenced in the JSP file (excluding tag files that are in JAR files)
- TLDs that are referenced in the JSP file (excluding TLDs that are in JAR files)

Dependency tracking information is always included in the generated class file even if **trackDependencies** is false. The information is not used by the JSP engine or batch compiler unless the **trackDependencies** parameter is true. This means that you can enable dependency tracking without having to recompile JSP files.

For example, the toplevel.jsp file statically includes the footer.jspf file. When the toplevel.jsp file is compiled, the path to the footer.jspf file and its timestamp are stored in the toplevel.jsp's class file. As a result, the footer.jspf file is modified and the toplevel.jsp file is requested. Now that the reload interval for the toplevel.jsp file has been exceeded, the JSP engine compares the timestamp stored in the class file with the footer.jspf file timestamp on disk. Because the timestamps are different, the toplevel.jsp file is compiled, picking up the modification to the footer.jspf file. In order for dependency tracking to work, the **trackDependencies** value must be set to true at the time a JSP file is requested at run time or is processed by the batch compiler.

## Disabling compilation

Disablement of run time compilation of JavaServer Pages is set via the disableJspRuntimeCompilation JSP engine parameter.

**ibm-web-ext.xmi example:**

```
<jspAttributes xmi:id="JSPAttribute_1" name="disableJspRuntimeCompilation" value="true"/>
```

**ibm-web-ext.xml example:**

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
   xmlns="http://websphere.ibm.com/xml/ns/javaee"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
      version="1.0">

   <jsp-attribute name="trackDependencies" value="true" />
   <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
   <jsp-attribute name="reloadInterval" value="5"/>

   <reload-interval value="5"/>
   <auto-encode-requests value="false"/>
   <auto-encode-responses value="false"/>
   <enable-directory-browsing value="false"/>
   <enable-file-serving value="false"/>
   <pre-compile-jsps value="false"/>
   <enable-reloading value="true"/>
   <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

If the **disableJspRuntimeCompilation** parameter is set to true, the JSP engine at run time does not translate and compile JSP files; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order for the class files to be loaded. With this option set to true, an application can be installed without JSP source, but must have precompiled class files. There is a web container custom property of the same name that can be used to determine the behavior of all web modules installed in a server. If both the web container custom property and the JSP engine option are set, the JSP engine option takes precedence. Setting the **disableJspRuntimeCompilation** parameter to true automatically sets **reloadEnabled** to false.

## Reload processing sequence

The processing sequence pertaining to JSP file reloading when **trackDependencies** is false is shown in Figure 1.

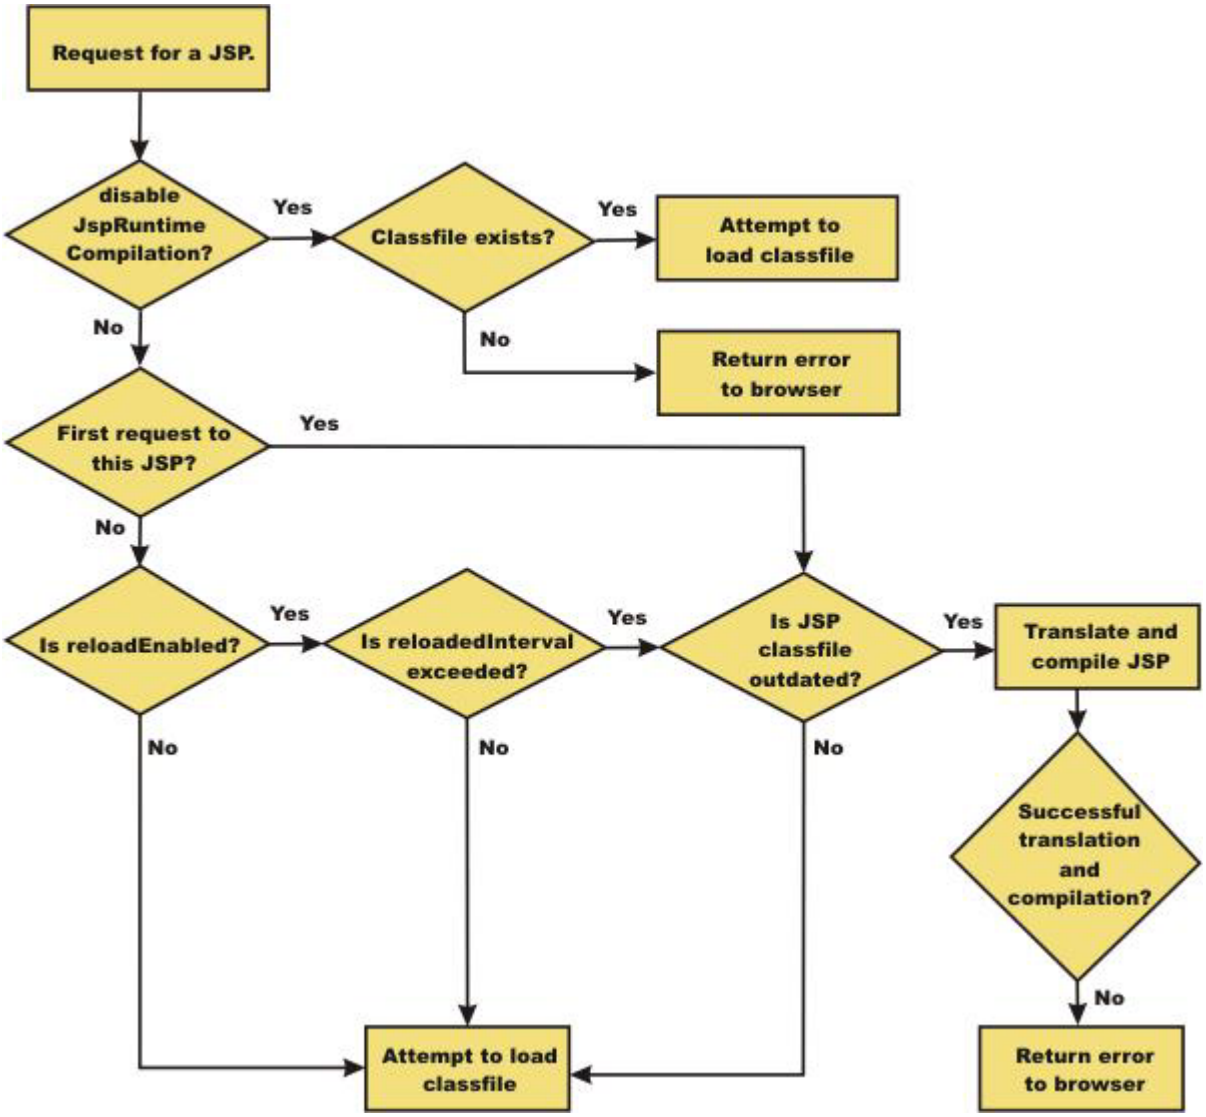

*Figure 3. Reload processing sequence when* **trackDependencies** *is false.*

When **trackDependencies** is true, the JSP engine does additional file system processing to determine if any of a JSP file's dependencies have changed since the JSP file was last translated and compiled. Figure 2 shows the additional processes that are performed on the 'No' path of flow chart labeled "is JSP class file outdated?". You can see that the path taken when disableJspRuntimeCompilation is true is the most efficient path.

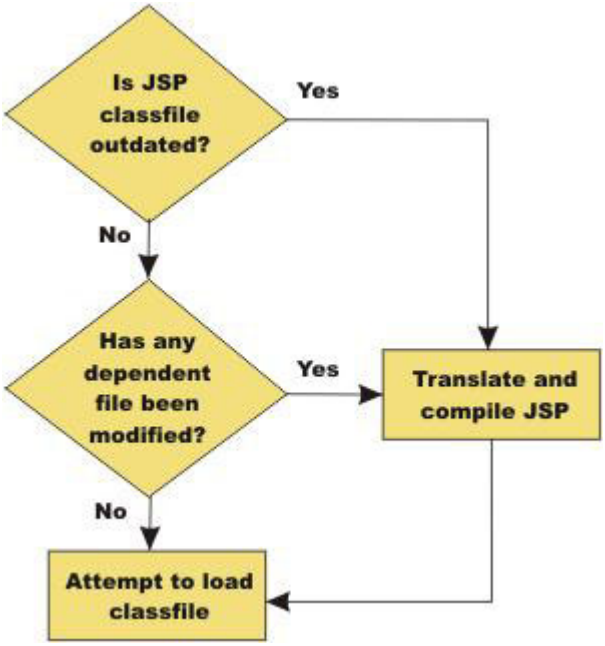

*Figure 4. Additional reload processing performed when* **trackDependencies** *is true.*

## JSP and JSF option settings

Use this panel to configure the class reloading of web modules such as JavaServer Pages (JSP) files and to select a JSF implementation to use with this application.

To view this administrative console panel, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **JSP and JSF options**. This panel is the same as the **Provide JSP reloading options for web modules** panel on the application installation and update wizards.

The following note applies to the files with a .xmi extension in this topic:

**Note:** For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named ibm-*-ext.xmi or ibm-*-bnd.xmi where * is the type of extension or binding file such as app, application, ejb-jar, or web. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be .xmi.
- For an application or module that uses Java EE 5 or later, the file extension must be .xml. If .xmi files are included with the application or module, the product ignores the .xmi files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the .xmi file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the .xmi file extensions.

### Web module

Specifies the name of a web module in the installed or deployed application.

### URI
Specifies the location of the module that is relative to the root of the application (EAR file).

### JSP enable class reloading
Specifies whether to enable class reloading when JSP files are updated.

A web container reloads JSP files only when the IBM extension reloadEnabled in the jspAttributes of the `ibm-web-ext.xmi` file is set to `true`.

Java Platform, Enterprise Edition 5 (Java EE 5) applications IBM extension files are in `.xml` file format. For applications versions earlier than Java EE 5, they are in the `.xmi` file format.

### JSP reload interval in seconds
Specifies the number of seconds to scan the application file system for updated JSP files. The default is the value of the reloading interval attribute in the IBM extension (`META-INF/ibm-web-ext.xmi`) file of the web module.

To enable reloading, specify a value greater than zero (for example, 1 to 2147483647). The default reload interval is 5. To disable reloading, specify zero (0). The range is from 0 to 2147483647.

The reloading interval attribute takes effect only if class reloading is enabled.

Java EE 5 applications IBM extension files are in `.xml` file format. For applications versions earlier than Java EE 5, they are in the `.xmi` file format.

### Sun Reference Implementation 1.2
Select this option to use the Sun Reference Implementation 1.2 JSF implementation.

If you change the JSF implementation that you are using for your application, you must delete any previously compiled JSP files. If you precompiled your application, you must recompile. If you did not precompile, but have already requested JSP files from this application, you must delete the JSP files from the temp directory of your profile.

You can set the JSF engine configuration parameter, com.ibm.ws.jsf.JSF_IMPL_CHECK, to true to automatically mark the JSP files to recompile at application startup.

### MyFaces 2.0
Select this option to use the MyFaces JSF implementation. This is the default JSF implementation.

If you change the JSF implementation that you are using for your application, you must delete any previously compiled JSP files. If you precompiled your application, you must recompile. If you did not precompile, but have already requested JSP files from this application, you must delete the JSP files from the temp directory of your profile.

You can set the JSF engine configuration parameter, com.ibm.ws.jsf.JSF_IMPL_CHECK, to true to automatically mark the JSP files to recompile at application startup.

In a mixed-version cell, a V7 node uses MyFaces 1.2 if the MyFaces selection is toggled, while a V8 node uses MyFaces 2.0. For WebSphere Application Server versions before V7 (for example, V6.1 and earlier), this toggle is ineffective because JSF implementation switching was not supported before V7.

## JSP run time compilation settings
By default, the JavaServer Pages (JSP) engine translates a requested JSP file, compiles the `.java` file, and loads the compiled servlet into the run time environment. You can change the JSP engine default behavior by indicating that a JSP file must not be translated or compiled at run time, even when a `.class` file does not exist.

If run time compilation is disabled, you must precompile the JSP files, which provides the following advantages:
- Reduces compilation related disk operations.
- Minimizes disk storage requirements necessary for handling temporary `.java` files generated during a run time compilation.
- Allows you to not include the JSP source files in the application.
- Allows verification that a JSP file compiled successfully before deploying and installing the application in the product

You can disable run time JSP file compilation on a global or an individual web application basis:
- To disable the translation and compilation of JSP files for all Web applications, in the administrative console, click **Servers > Server Types > WebSphere application servers >** *server_name*. Then, in the Container Settings section, click **Web container settings > Web container > Custom properties**.

  If the disableJspRuntimeCompilation property appears in the list of defined custom properties, but is set to `false`, click the property name, and then set the property to `true`.

  If this property is not included in the list of defined custom properties, click **New**, and then specify `disableJspRuntimeCompilation` in the **Name** field and `true` in the **Value** field.

  Valid settings for this property are `true` or `false`. When this property is set to `true`, translation and compilation of the JSP files is disabled at run time for all web applications.
- To disable the translation and compilation of JSP files for a specific web application, set the JSP engine initialization parameter disableJspRuntimeCompilation to `true`. This setting, if enabled, determines the run time behavior of the JSP engine and overrides the web container custom property setting.

  Set this parameter through the **JavaServer Pages attribute assembly settings** page when assembling applications.

  Valid values for this setting are `true` or `false`. If this parameter is set to `true`, then, for that specific web application, translation and compilation of the JSP files is disabled at run time, and the JSP engine only loads precompiled files.
- If neither the web container custom property nor the JSP parameter is set, the first request for a JSP file results in the translation and compilation of the JSP file when the `.class` file does not exist or is outdated. Subsequent requests for the file also result in translations and compilations, but only if the following conditions are met:
  - Translations are required because the `.class` file is outdated.
  - Reloading is enabled for the web module.
  - Reload interval is exceeded.

If you disable run time compilation and a request arrives for a JSP file that does not have a matching .class file, the JSP engine returns the following 404 error to the browser:

```
Error 404: SRVE0200E: Servlet [org.apache.jsp._jsp1]: Could not find required servlet class - _jsp1.class
```

In this case, an exception is written to the System Out (SYSOUT) and First Failure Data Capture (FFDC) logs. .

If a JSP file has a matching .class file but that file is out of date, the JSP engine still loads the .class file into memory.

## Provide options to compile JavaServer Pages settings

Use this page to specify options to be used by the JavaServer Pages (JSP) compiler.

This administrative console page is a step in the application installation and update wizards. To view this page, you must select **Precompile JavaServer Pages files** on the **Select installations options** page. Thus, to view this page, click **Applications** > **New Application** > **New Enterprise Application** > ***application_path*** > **Next** > **Detailed - Show me all installation options and parameters** > **Next** > **Next** or **Continue** > **Precompile JavaServer Pages files** > **Next** > **Step: Provide options to compile JSPs**.

You can specify the JSP compiler options on this page only when installing or updating an application that contains web modules. After the application is installed, you must edit the JSP engine configuration parameters of a web module `WEB-INF/ibm-web-ext.xmi` file to change its JSP compiler options.

**Note:** For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named ibm-*-ext.xmi or ibm-*-bnd.xmi where * is the type of extension or binding file such as app, application, ejb-jar, or web. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be .xmi.
- For an application or module that uses Java EE 5 or later, the file extension must be .xml. If .xmi files are included with the application or module, the product ignores the .xmi files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the .xmi file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the .xmi file extensions.

## Web module
Specifies the name of a module within the application.

## URI
Specifies the location of the module relative to the root of the application (EAR file).

## JSP class path
Specifies a temporary class path for the JSP compiler to use when compiling JSP files during application installation. This class path is not saved when the application installation is complete and is not used when the application is running. This class path is used only to identify resources outside of the application which are necessary for JSP compilation and which will be identified by other means (such as shared libraries) after the application is installed. In network deployment configurations, this class path is specific to the deployment manager machine.

To specify that multiple web modules use the same class path:
1. In the list of web modules, select the **Select** check box beside each web module that you want to use a particular class path.
2. Expand **Apply Multiple Mappings**.
3. Specify the desired class path.
4. Click **Apply**.

## Use full package names
Specifies whether the JSP engine generates and loads JSP classes using full package names.

When full package names are used, precompiled JSP class files can be configured as servlets in the `web.xml` file, without having to use the `jsp-file` attribute. When full package names are not used, all JSP classes are generated in the same package, which has the benefit of smaller file-system paths.

When the options useFullPackageNames and disableJspRuntimeCompilation are both `true`, a single class loader is used to load all JSP classes, even if the JSP files are not configured as servlets in the `web.xml` file.

This option is the same as the useFullPackageNames JSP engine parameter.

### JDK source level

Specifies the source level at which the Java compiler compiles JSP Java sources. Valid values are `13`, `14`, and `15`. The default value is `13` for pre-Java EE 5 web modules, which specifies source level 1.3 and `15` for Java EE 5 and later web modules.

### Disable JSP runtime compilation

Specifies whether a JSP file should never be translated or compiled at run time, even when a `.class` file does not exist.

When this option is set to `true`, the JSP engine does not translate and compile JSP files at run time; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order to load class files. You can install an application without JSP source, but the application must have precompiled class files.

For a single web application class loader to load all JSP classes, this compiler option and the **Use full package names** option both must be set to `true`.

This option is the same as the disableJspRuntimeCompilation JSP engine parameter.

## Developing session management in servlets

### About this task

This information, combined with the coding example SessionSample.java, provides a programming model for implementing sessions in your own servlets.

### Procedure

1. Get the HttpSession object.

   To obtain a session, use the getSession method of the javax.servlet.http.HttpServletRequest object in the Java Servlet 3.0 API.

   When you first obtain the HttpSession object, the Session Management facility uses one of three ways to establish tracking of the session: cookies, URL rewriting, or Secure Sockets Layer (SSL) information.

   **Note:** Session tracking using the SSL ID is deprecated in WebSphere Application Server version 7.0. You can configure session tracking to use cookies or modify the application to use URL rewriting

   Assume the Session Management facility uses cookies. In such a case, the Session Management facility creates a unique session ID and typically sends it back to the browser as a *cookie*. Each subsequent request from this user (at the same browser) passes the cookie containing the session ID, and the Session Management facility uses this ID to find the user's existing HttpSession object.

   In Step 1 of the code sample, the Boolean(create) is set to `true` so that the HttpSession object is created if it does not already exist. (With the Servlet 2.3 API and later, the javax.servlet.http.HttpServletRequest.getSession() method with no boolean defaults to `true` and creates a session if one does not already exist for this user.)

2. Store and retrieve user-defined data in the session.

   After a session is established, you can add and retrieve user-defined data to the session. The HttpSession object has methods similar to those in java.util.Dictionary for adding, retrieving, and removing arbitrary Java objects.

   In Step 2 of the code sample, the servlet reads an integer object from the HttpSession, increments it, and writes it back. You can use any name to identify values in the HttpSession object. The code sample uses the name sessiontest.counter.

   Because the HttpSession object is shared among servlets that the user might access, consider adopting a site-wide naming convention to avoid conflicts.

3. (Optional) Output an HTML response page containing data from the HttpSession object.
4. Provide feedback to the user that an action has taken place during the session. You may want to pass HTML code to the client browser indicating that an action has occurred. For example, in step 3 of the code sample, the servlet generates a web page that is returned to the user and displays the value of the sessiontest.counter each time the user visits that web page during the session.
5. (Optional) Notify Listeners. Objects stored in a session that implement the javax.servlet.http.HttpSessionBindingListener interface are notified when the session is preparing to end and become invalidated. This notice enables you to perform post-session processing, including permanently saving the data changes made during the session to a database.
6. End the session. You can end a session:
   - Automatically with the Session Management facility if a session is inactive for a specified time. The administrators provide a way to specify the amount of time after which to invalidate a session.
   - By coding the servlet to call the invalidate() method on the session object.

### Example

```
import java.io.*;
import java.util.*;
import javax.servlet.*;
import javax.servlet.http.*;

public class SessionSample  extends HttpServlet {
  public void doGet (HttpServletRequest request, HttpServletResponse response)
       throws ServletException, IOException {

   // Step 1: Get the Session object

      boolean create = true;
      HttpSession session = request.getSession(create);

   // Step 2: Get the session data value

      Integer ival = (Integer)
      session.getAttribute ("sessiontest.counter");
      if (ival == null) ival = new Integer (1);
      else ival = new Integer (ival.intValue () + 1);
      session.setAttribute ("sessiontest.counter", ival);

   // Step 3: Output the page

      response.setContentType("text/html");
      PrintWriter out = response.getWriter();
      out.println("<html>");
      out.println("<head><title>Session Tracking Test</title></head>");
      out.println("<body>");
      out.println("<h1>Session Tracking Test</h1>");
      out.println ("You have hit this page " + ival + " times" + "<br>");
      out.println ("Your " + request.getHeader("Cookie"));
      out.println("</body></html>");
   }
}
```

## Assembling so that session data can be shared

By default, the Session Management facility supports session scoping by web module in accordance with the Servlet 2.3 and later API specification. Only servlets in the same web module can access the data associated with a particular session. However, you can use the IBMApplicationSession object or the IBM extension, shared session context, to share data outside of the web module scope.

## About this task

**Attention:** The IBMApplicationSession object is the recommended method for sharing session attributes. The IBM extension, shared session context, is deprecated.

The IBMApplicationSession object is a parent session object that can be retrieved by a web module's session and can share session attributes across all of the web modules in a business-level application. The default scope of the business-level application is the enterprise application. The shared session context option extends the scope of the session attributes as well. Using the shared session context extension, there is only one session object for the entire business-level application or for the default enterprise application.

If you are using a shared session for a business-level application, then the class files for all objects placed in the session must exist in an isolated shared library and be common among all applications.

The benefit to using the IBMApplicationSession method is that each web module can maintain its own session as well as have a reference to the shared session.

If you're migrating an application from a previous version of the product, the IBMApplicationSession method requires a change to the application logic of the application.

**Restriction:**To use a shared session, you must install all applications within a business-level application on a given server. You cannot split up the enterprise application by servers. For example, you cannot use this option when one enterprise application in "BLA1" is installed on one server and a second enterprise application also in "BLA1" is installed on a different server. In such split installations, applications might share session attributes across web modules using distributed sessions, but session data integrity is lost when concurrent access to a session is made in different web modules. It also severely restricts use of some Session Management features, like TIME_BASED_WRITES.

For enterprise applications on which this shared session context extension is enabled, the Session Management configuration on the web module inside the enterprise application is ignored. Then Session Management configuration defined on enterprise application is used if Session Management is overwritten at the enterprise application level. Otherwise, the Session Management configuration on the web container is used. If using multiple enterprise applications within a business-level application, the session management configuration must be common among all applications and web modules within this business-level application.

#### Servlet API Behavior

**Note:** HttpSession listeners defined in all the web modules inside the business-level application or enterprise application are invoked for session events. The order of listener invocation is not guaranteed.

Complete the following to share session data across the business-level application.

## Procedure

1. Complete the following to share session data using the IBMApplicationSession object within the application code.
   a. Retrieve the session object
      ```
      HttpSession session = request.getSession();
      ```
   b. Cast this object to an IBMSession object and call the getIBMApplicationSession method.
      ```
      IBMApplicationSession appSession = ((IBMSession)session).getIBMApplicationSession();
      ```
   c. Use the appSession like a normal session object.
2. Do the following to share session data using the Shared session context extension.

a. Start an assembly tool.
b. In the assembly tool, right-click the application (EAR file) that you want to share and click **Open With > Deployment Descriptor Editor**.
c. In the application deployment descriptor editor of the assembly tool, select **Shared session context** under **WebSphere Extensions**. Make sure the class definition of attributes put into session are available to all web modules in the enterprise application. The shared session context does not fully meet the requirements of the specifications.
d. Save the application (EAR) file. In the assembly tool, after you close the application deployment descriptor editor, confirm that you want to save changes made to the application.

# Chapter 33. Developing web services

This page provides a starting point for finding information about web services.

Web services are self-contained, modular applications that can be described, published, located, and invoked over a network. They implement a services oriented architecture (SOA), which supports the connecting or sharing of resources and data in a very flexible and standardized manner. Services are described and organized to support their dynamic, automated discovery and reuse.

## Using JAXB for XML data binding

Java Architecture for XML Binding (JAXB) is a Java technology that provides an easy and convenient way to map Java classes and XML schema for simplified web services development. JAXB provides the xjc schema compiler, the schemagen schema generator and a runtime framework to support marshalling and unmarshalling of XML documents to and from Java objects.

### About this task

JAXB is an XML-to-Java binding technology that enables transformation between schema and Java objects and between XML instance documents and Java object instances. JAXB technology consists of a runtime API and accompanying tools that simplify access to XML documents. You can use JAXB APIs and tools to establish mappings between Java classes and XML schema. An XML schema defines the data elements and structure of an XML document. JAXB technology provides tooling to enable you to convert your XML documents to and from Java objects. Data stored in an XML document is accessible without the need to understand the XML data structure.

JAXB is the default data binding technology used by the Java API for XML Web Services (JAX-WS) tooling and implementation within this product. You can develop JAXB objects to use within your JAX-WS applications. You can also use JAXB independently of the JAX-WS programming model as a convenient way to leverage the XML data binding technology to manipulate XML within your Java applications.

JAXB is also the default data binding technology used by Service Component Architecture (SCA) applications. JAXB enables the SCA service implementation side and the SCA client reference side to interact with Java objects without worrying about how the data is transformed into and from XML.

**Note:** This version of the application server supports the JAXB 2.2 specification. JAX-WS 2.2 requires JAXB 2.2 for data binding. JAXB 2.2 provides minor enhancements to its annotations for improved schema generation and better integration with JAX-WS.

**Note:** The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

JAXB provides the xjc schema compiler tool, the schemagen schema generator tool, and a runtime framework. The xjc schema compiler tool enables you to start with an XML schema definition (XSD) to create a set of JavaBeans that map to the elements and types defined in the XSD schema. You can also start with a set of JavaBeans and use the schemagen schema generator tool to create the XML schema. After using either the schema compiler or the schema generator command-line tools, you can convert your XML documents both to and from Java objects and use the resulting Java classes to assemble a web services application.

In addition to using the tools from the command-line, you can invoke these JAXB tools from within the Ant build environments. Use the `com.sun.tools.xjc.XJCTask` Ant task from within the Ant build environment to invoke the xjc schema compiler tool. Use the `com.sun.tools.jxc.SchemaGenTask` Ant task from within the

© Copyright IBM Corp. 2011

Ant build environment to invoke the schemagen schema generator tool. These Ant tasks require that the com.ibm.jaxb.tools.jar and the com.ibm.jaxws.tools.jar files be in the classpath.

JAXB annotated classes and artifacts contain all the information that the JAXB runtime API needs to process XML instance documents. The JAXB runtime API enables marshaling of JAXB objects to XML files and unmarshaling the XML document back to JAXB class instances. The JAXB binding package, `javax.xml.bind`, defines the abstract classes and interfaces that are used directly with content classes. In addition the package defines the marshal and unmarshal APIs.

You can optionally use JAXB binding customizations to override the default generated type mappings. You can customize JAXB bindings using inline annotations in the source schema, or by using an external bindings customization file to pass your customizations to the JAXB binding compiler, xjc, to control the Java type mappings. Alternatively, you can add Java annotations to existing Java classes to pass to the schema generator, schemagen, to control the schema or XML type mappings. See the JAXB specification for information regarding binding customization options and Java annotations.

Using JAXB, you can manipulate data objects in the following ways:

### Procedure

- Generate an XML schema from a Java class. Use the schema generator schemagen command to generate an XML schema from Java classes.
- Generate Java classes from an XML schema. Use the schema compiler xjc command to create a set of JAXB-annotated Java classes from an XML schema.
- Marshal and unmarshal XML documents. After the mapping between XML schema and Java classes exists, use the JAXB binding runtime to convert XML instance documents to and from Java objects.

### Results

You now have JAXB objects that your Java application can use to manipulate XML data.

## Using JAXB schemagen tooling to generate an XML schema file from a Java class

Use Java Architecture for XML Binding (JAXB) schemagen tooling to generate an XML schema file from Java classes.

### Before you begin

Identify the Java classes or a set of Java objects to map to an XML schema file.

### About this task

Use JAXB APIs and tools to establish mappings between Java classes and XML schema. XML schema documents describe the data elements and relationships in an XML document. After a data mapping or binding exists, you can convert XML documents to and from Java objects. You can now access data stored in an XML document without the need to understand the data structure.

To develop web services using a bottom-up development approach starting from existing JavaBeans or enterprise beans, use the wsgen tool to generate the artifacts for Java API for XML-Based Web Services (JAX-WS) applications. After the Java artifacts for your application are generated, you can create an XML schema document from an existing Java application that represents the data elements of a Java application by using the JAXB schema generator, schemagen command-line tool. The JAXB schema generator processes either Java source files or class files. Java class annotations provide the capability to customize the default mappings from existing Java classes to the generated schema components. The

XML schema file along with the annotated Java class files contain all the necessary information that the JAXB runtime requires to parse the XML documents for marshaling and unmarshaling.

You can create an XML schema document from an existing Java application that represents the data elements of a Java application by using the JAXB schema generator, schemagen command-line tool. The JAXB schema generator processes either Java source files or class files. Java class annotations provide the capability to customize the default mappings from existing Java classes to the generated schema components. The XML schema file along with the annotated Java class files contain all the necessary information that the JAXB runtime requires to parse the XML documents for marshaling and unmarshaling.

**Note:** The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

**Note:** WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The wsimport, wsgen, schemagen and xjc command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

**Note:** This product supports the JAXB 2.2 specification. JAX-WS 2.2 requires JAXB 2.2 for data binding.

JAXB provides compilation support to enable you to configure the schemagen schema generator so that it does not automatically generate a new schema. This is helpful if you are using a common schema such as the World Wide Web Consortium (W3C), XML Schema, Web Services Description Language (WSDL), or WS-Addressing and you do not want a new schema generated for a particular package that is referenced. The location attribute on the @XmlSchema annotation causes the schemagen generator to refer to the URI of the existing schema instead of generating a new one.

In addition to using the schemagen tool from the command-line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.jxc.SchemaGenTask` Ant task from within the Ant build environment to invoke the schemagen schema generator tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

**Note:** When running the schemagen tool, the schema generator does not correctly read the @XmlSchema annotations from the package-info class file to derive targetNamespaces. Instead of using the @XMLSchema annotation, use one of the following methods:

- Provide a package-info.java file with the @XmlSchema; for example:

```
schemagen sample.Address sample\package-info.java
```

- Use the @XmlType annotation namespace attribute to specify a namespace; for example:

```
@XmlType(namespace="http://myNameSpace")
```

## Procedure

1. Locate the Java source files or Java class files to use in generating an XML schema file. Ensure that all classes referenced by your Java class files are contained in the classpath or are provided to the tool using the`-classpath/-cp` options.
2. Use the JAXB schema generator, schemagen command to generate an XML schema. The schema generator is located in the *app_server_root*\bin\ directory.

Windows

```
app_server_root\bin\schemagen.bat myObj1.java myObj2.java
```

AIX HP-UX Linux Solaris

```
app_server_root/bin/schemagen.sh myObj1.java myObj2.java
```

The parameters, `myObj1.java` and `myObj2.java`, are the names of the Java files containing the data objects. If `myObj1.java` or `myObj2.java` refer to Java classes that are not passed into the schemagen command, you must use the `-cp` option to provide the classpath location for these Java classes.Read about the schemagen command to learn more about this command and additional options that you can specify.

3. (Optional) Use JAXB program annotations defined in the `javax.xml.bind.annotations` package to customize the JAXB XML schema mappings.
4. (Optional) Configure the `location` property on the @XmlSchema annotation to indicate to the schema compiler to use an existing schema rather than generating a new one. For example,

```
@XmlSchema(namespace="foo")
package foo;
@XmlType
class Foo {
@XmlElement Bar zot;
}
@XmlSchema(namespace="bar",
location="http://example.org/test.xsd")
package bar;
@XmlType
class Bar {
...
}
<xs:schema targetNamespace="foo">
<xs:import namespace="bar"
schemaLocation="http://example.org/test.xsd"/>
<xs:complexType name="foo">
<xs:sequence>
<xs:element name="zot" type="bar:Bar" xmlns:bar="bar"/>
</xs:sequence>
</xs:complex
```

the `location="http://example.org/test.xsd"` indicates the location on the existing schema to the schemagen tool and a new schema is not generated.

## Results

Now that you have generated an XML schema file from Java classes, you are ready to marshal and unmarshal the Java objects as XML instance documents.

**Note:** The schemagen command does not differentiate the XML namespace between multiple @XMLType annotations that have the same @XMLType name defined within different Java packages. When this scenario occurs, the following error is produced:

```
Error: Two classes have the same XML type name ....
Use @XmlType.name and @XmlType.namespace to assign different names to them...
```

This error indicates you have class names or @XMLType.name values that have the same name, but exist within different Java packages. To prevent this error, add the @XML.Type.namespace class to the existing @XMLType annotation to differentiate between the XML types.

## Example

The following example illustrates how JAXB tooling can generate an XML schema file from an existing Java class, Bookdata.java.

1. Copy the following `Bookdata.java` file to a temporary directory.

```
package generated;

import javax.xml.bind.annotation.XmlAccessType;
import javax.xml.bind.annotation.XmlAccessorType;
import javax.xml.bind.annotation.XmlAttribute;
import javax.xml.bind.annotation.XmlElement;
```

```
import javax.xml.bind.annotation.XmlType;
import javax.xml.datatype.XMLGregorianCalendar;

@XmlAccessorType(XmlAccessType.FIELD)
@XmlType(name = "bookdata", propOrder = {
    "author",
    "title",
    "genre",
    "price",
    "publishDate",
    "description"
})
public class Bookdata {

    @XmlElement(required = true)
    protected String author;
    @XmlElement(required = true)
    protected String title;
    @XmlElement(required = true)
    protected String genre;
    protected float price;
    @XmlElement(name = "publish_date", required = true)
    protected XMLGregorianCalendar publishDate;
    @XmlElement(required = true)
    protected String description;
    @XmlAttribute
    protected String id;

     public String getAuthor() {
        return author;
    }
    public void setAuthor(String value) {
        this.author = value;
    }
    public String getTitle() {
        return title;
    }

     public void setTitle(String value) {
        this.title = value;
    }

    public String getGenre() {
        return genre;
    }

    public void setGenre(String value) {
        this.genre = value;
    }

    public float getPrice() {
        return price;
    }

    public void setPrice(float value) {
        this.price = value;
    }

    public XMLGregorianCalendar getPublishDate() {
        return publishDate;
    }

    public void setPublishDate(XMLGregorianCalendar value) {
        this.publishDate = value;
    }

    public String getDescription() {
        return description;
    }

    public void setDescription(String value) {
        this.description = value;
    }

    public String getId() {
        return id;
    }

    public void setId(String value) {
```

```
        this.id = value;
    }

}
```

2. Open a command prompt.
3. Run the schemagen schema generator tool from the directory where you copied the `Bookdata.java` file.

Windows

```
app_server_root\bin\schemagen.bat Bookdata.java
```

Linux AIX HP-UX Solaris

```
app_server_root/bin/schemagen.sh Bookdata.java
```

4. The XML schema file, `schema1.xsd` is generated:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<xs:schema version="1.0" xmlns:xs="http://www.w3.org/2001/XMLSchema">

  <xs:complexType name="bookdata">
    <xs:sequence>
      <xs:element name="author" type="xs:string"/>
      <xs:element name="title" type="xs:string"/>
      <xs:element name="genre" type="xs:string"/>
      <xs:element name="price" type="xs:float"/>
      <xs:element name="publish_date" type="xs:anySimpleType"/>
      <xs:element name="description" type="xs:string"/>
    </xs:sequence>
    <xs:attribute name="id" type="xs:string"/>
  </xs:complexType>
</xs:schema>
```

Refer to the JAXB Reference implementation documentation for additional information about the **schemagen** command.

# Using JAXB xjc tooling to generate JAXB classes from an XML schema file

Use Java Architecture for XML Binding (JAXB) xjc tooling to compile an XML schema file into fully annotated Java classes.

## Before you begin

Develop or obtain an XML schema file.

## About this task

Use JAXB APIs and tools to establish mappings between an XML schema and Java classes. XML schemas describe the data elements and relationships in an XML document. After a data mapping or binding exists, you can convert XML documents to and from Java objects. You can now access data stored in an XML document without the need to understand the data structure.

To develop web services using a top-down development approach starting with an existing Web Services Description Language (WSDL) file, use the wsimport tool to generate the artifacts for your Java API for XML-Based Web Services (JAX-WS) applications when starting with a WSDL file. After the Java artifacts for your application are generated, you can generate fully annotated Java classes from an XML schema file by using the JAXB schema compiler, xjc command-line tool. The resulting annotated Java classes contain all the necessary information that the JAXB runtime requires to parse the XML for marshaling and unmarshaling. You can use the resulting JAXB classes within Java API for XML Web Services (JAX-WS) applications or other Java applications for processing XML data.

**Note:** WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The wsimport, wsgen, schemagen and xjc command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the

tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

**Note:** This product supports the JAXB 2.2 specification. JAX-WS 2.2 requires JAXB 2.2 for data binding.

In addition to using the xjc tool from the command-line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.xjc.XJCTask` Ant task from within the Ant build environment to invoke the xjc schema compiler tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

**Note:** If you are using the xjc Ant task, you must use the `destdir` parameter to specify the destination directory instead of the `target` option. Specifying the `target` option when using the xjc Ant task causes an error.

## Procedure

1. Use the JAXB schema compiler, xjc command to generate JAXB-annotated Java classes. The schema compiler is located in the *app_server_root*\bin\ directory. The schema compiler produces a set of packages containing Java source files and JAXB property files depending on the binding options used for compilation.
2. (Optional) Use custom binding declarations to change the default JAXB mappings. Define binding declarations either in the XML schema file or in a separate bindings file. You can pass custom binding files by using the **-b** option with the xjc command.
3. Compile the generated JAXB objects. To compile generated artifacts, add the Thin Client for JAX-WS with WebSphere Application Server to the classpath.

## Results

Now that you have generated JAXB objects, you can write Java applications using the generated JAXB objects and manipulate the XML content through the generated JAXB classes.

## Example

The following example illustrates how JAXB tooling can generate Java classes when starting with an existing XML schema file.

1. Copy the following `bookSchema.xsd` schema file to a temporary directory.

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema">
   <xsd:element name="CatalogData">
     <xsd:complexType >
       <xsd:sequence>
         <xsd:element name="books" type="bookdata" minOccurs="0"
    maxOccurs="unbounded"/>
       </xsd:sequence>
     </xsd:complexType>
   </xsd:element>
   <xsd:complexType name="bookdata">
     <xsd:sequence>
       <xsd:element name="author" type="xsd:string"/>
       <xsd:element name="title" type="xsd:string"/>
       <xsd:element name="genre" type="xsd:string"/>
       <xsd:element name="price" type="xsd:float"/>
       <xsd:element name="publish_date" type="xsd:dateTime"/>
       <xsd:element name="description" type="xsd:string"/>
     </xsd:sequence>
     <xsd:attribute name="id" type="xsd:string"/>
   </xsd:complexType>
 </xsd:schema>
```

2. Open a command prompt.

3. Run the JAXB schema compiler, xjc command from the directory where the schema file is located. The xjc schema compiler tool is located in the *app_server_root*\bin\ directory.

Windows

```
app_server_root\bin\xjc.bat bookSchema.xsd
```

Linux AIX HP-UX Solaris

```
app_server_root/bin/xjc.sh bookSchema.xsd
```

Running the xjc command generates the following JAXB Java files:

```
generated\Bookdata.java
generated\CatalogdData.java
generated\ObjectFactory.java
```

4. Use the generated JAXB objects within a Java application to manipulate XML content through the generated JAXB classes.

Refer to the JAXB Reference implementation documentation for additional information about the xjc command.

# Using the JAXB runtime to marshal and unmarshal XML documents

Use the Java Architecture for XML Binding (JAXB) run time to manipulate XML instance documents.

## Before you begin

Use JAXB to generate Java classes from an XML schema with the schema compiler, xjc command or to generate an XML schema from a Java class with the schema generator, schemagen command.

## About this task

Use JAXB APIs and tools to establish mappings between an XML schema and Java classes. After data bindings exist, use the JAXB binding runtime API to convert XML instance documents to and from Java objects. Data stored in an XML document is accessible without the need to understand the data structure. JAXB annotated classes and artifacts contains all the information that the JAXB runtime API needs to process XML instance documents. The JAXB runtime API enables marshaling of JAXB objects to XML and unmarshaling the XML document back to JAXB class instances.

## Procedure

- Marshal JAXB objects to XML instance documents.

  Use the JAXB runtime API to marshal or convert JAXB object instances into an XML instance document.

  1. Instantiate your JAXB classes.
  2. Invoke the JAXB marshaller.

  This example demonstrates how to instantiate the generated JAXB objects within an application and use the JAXBContext class and the JAXB runtime marshaller APIs to marshal the JAXB objects into XML instances.

```
JAXBContext jc = JAXBContext.newInstance("myPackageName");
//Create marshaller
Marshaller m = jc.createMarshaller();
//Marshal object into file.
m.marshal(myJAXBObject, myOutputStream);
```

  The JAXB Reference Implementation introduces additional vendor specific marshaller properties such as namespace prefix mapping, indentation, and character escaping control that are not defined by the JAXB specification. Use these properties to specify additional controls of the marshaling process. These properties operate with the JAXB Reference Implementation only and might not with other JAXB providers. Additional information regarding the vendor specific properties is located in the Java Architecture for XML Binding JAXB RI Vendor Extensions Runtime Properties specification.

- Unmarshal XML files to JAXB objects.

Use the JAXB runtime API to unmarshal or convert an XML instance document to JAXB object instances.

1. Obtain an existing XML instance document.
2. Invoke the JAXB unmarshaller.

This example demonstrates a program that reads an XML document and unmarshals or converts the XML document into JAXB object instances. Use the JAXBContext class and JAXB runtime Unmarshaller APIs to unmarshal the XML document.

```
JAXBContext jc = JAXBContext.newInstance("myPackageName");
//Create unmarshaller
Unmarshaller um = jc.createUnmarshaller();
//Unmarshal XML contents of the file myDoc.xml into your Java
  object instance.
MyJAXBObject myJAXBObject = (MyJAXBObject)
um.unmarshal(new java.io.FileInputStream( "myDoc.xml" ));
```

### Results

You can now marshal JAXB Java classes, and unmarshal XML data using the JAXB binding framework. Refer to the JAXB Reference implementation documentation for additional information about the marshal and unmarshal runtime APIs

**Note:** If Java 2 Security is enabled, wrap your JAXBContext.newInstance(), Unmarshaller.unmarshal() and, Marshaller.marshal() method calls within a AccessController.doPrivileged method to avoid a security exception.

.

## xjc command for JAXB applications

Use the Java Architecture for XML Binding (JAXB) tools to generate Java classes from an XML schema with the xjc schema compiler tool.

JAXB is an XML-to-Java binding technology that enables transformation between schema and Java objects and between XML instance documents and Java object instances. JAXB technology consists of a runtime API and accompanying tools that simplify access to XML documents. You can use JAXB APIs and tools to establish mappings between Java classes and XML schema. An XML schema defines the data elements and structure of an XML document. JAXB technology provides a runtime environment to enable you to convert your XML documents to and from Java objects. Data stored in an XML document is accessible without the need to understand the XML data structure.

You can generate fully annotated Java classes from an XML schema file by using the JAXB schema compiler, xjc command-line tool. Use the xjc schema compiler tool to start with an XML schema definition (XSD) to create a set of JavaBeans that map to the elements and types defined in the XSD schema. Once the mapping between XML schema and Java classes exists, XML instance documents can be converted to and from Java objects through the use of the JAXB binding runtime API. The resulting annotated Java classes contains all the necessary information that the JAXB runtime requires to parse the XML for marshaling and unmarshaling. You can use the resulting JAXB classes within Java API for XML Web Services (JAX-WS) applications or in your non-JAX-WS Java applications for processing XML data.

**Note:** The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

**Note:** WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The wsimport, wsgen, schemagen and xjc command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the

tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

In addition to using the xjc tool from the command line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.xjc.XJCTask` Ant task from within the Ant build environment to invoke the xjc schema compiler tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

**Note:** If you are using the xjc Ant task, you must use the `destdir` parameter to specify the destination directory instead of the `target` option. Specifying the `target` option when using the xjc Ant task causes an error.

## Syntax

The command-line syntax is:

Windows

```
app_server_root\bin\xjc.bat [options] <schema_file/URL/directory_or_jar> ...[-b<binding_information>] ...
```

AIX HP-UX Linux Solaris

```
app_server_root/bin/xjc.sh [options] <schema_file/URL/directory_or_jar> ...[-b<binding_information>] ...
```

If a directory is specified, all schema files in the directory are compiled.

## Parameters

The schema file/URL JAR file name or location of the directory is the only parameter that is required. The following parameters are optional for the xjc command:

**-b <file_name or directory>**
Specifies the external JAX-WS or JAXB binding files. You can specify multiple JAX-WS and JAXB binding files by using the `-b` option; however, each file must be specified with its own `-b` option. If a directory is specified, `**/*.xjb` is searched.

**-catalog <file_name>**
Specifies the catalog file to resolve external entity references. It supports the TR9401, XCatalog, and the OASIS XML Catalog formats.

**-classpath <path>**
Specifies the location of the class files.

**-d <directory>**
Specifies where to place the generated output files.

**-dtd**
Specifies to treat the input as XML Document Type Definition (DTD). This option is unsupported and experimental.

**-extension**
Specifies whether to enable custom extensions for functionality not specified by the JAXB specification. Use of the extensions can result in applications that are not portable or do not interoperate with other implementations.

**-help**
Displays the help menu.

**-httpproxy <[user[:password]@]<proxyhost>:<proxyport>>**
Specifies an HTTP or HTTPs proxy.

**-httpproxyfile <file_name>**
This parameter is similar to the -httpproxy parameter, but takes the argument in a file to protect the password.

**-no-header**
Specifies to suppress the generation of a file header with a timestamp.

**-npa**
Specifies to suppress the generation of the `**/package-info.java` package level annotation.

**-nv**
Specifies to not perform a strict validation of the input schemas.

**-p <package_name>**
Specifies a target package.

**-quiet**
Specifies to suppress the output from the xjc tool.

**-relaxng**
Specifies to treat the input as REgular LAnguage for XML Next Generation (RELAX NG). This option is unsupported and experimental.

**-readOnly**
Specifies that the generated files are in read-only mode.

**-relaxng-compact**
Specifies to treat the input as REgular LAnguage for XML Next Generation (RELAX NG) compact syntax. This option is unsupported and experimental.

**-target <version>**
Specifies to generate output to conform to the specified level of the JAX-WS specification. Specify 2.0 or 2.1 for the tool to generate compliant code for the JAXB 2.0 or JAX-WS 2.1 specification respectively. Specify 2.1 for the tool to generate compliant code for the JAXB 2.1 specification. The default target version is 2.2 and generates compliant code for the JAXB 2.2 specification.

**-verbose**
Specifies to output messages about what the compiler is doing.

**-version**
Prints the version information. If you specify this option, only the version information is output and typical command processing does not occur.

**-wsdl**
Specifies to treat the input as a Web Services Description Language (WSDL) file and compile schemas inside the WSDL. This option is unsupported and experimental.

**-xmlschema**
Specifies to treat the input as a World Wide Web Consortium (W3C) XML schema. This value is the default.

## schemagen command for JAXB applications

Use the schema generator tool, schemagen, to generate an XML schema using Java Architecture for XML Binding (JAXB).

Use JAXB APIs and tools to establish mappings between an XML schema and Java classes. XML schemas describe the data elements and relationships in an XML document. After a data mapping or

binding exists, you can convert XML documents to and from Java objects. You can now access data stored in an XML document without the need to understand the data structure.

You can generate a schema file from Java classes using the schemagen schema generator tool to create the XML schema. After the mapping between XML schema and Java classes exists, XML instance documents can be converted to and from Java objects through the use of the JAXB binding runtime API. The resulting Java classes contain all the necessary information that the JAXB run time requires to parse the XML for marshaling and unmarshaling. You can use the JAXB classes within Java API for XML Web Services (JAX-WS) applications or in your non-JAX-WS Java applications for processing XML data.

**Note:** The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

**Note:** WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The wsimport, wsgen, schemagen and xjc command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

**Note:** When running the schemagen tool to process JavaBeans, the schema generator will not automatically process the @XmlSchema annotations from existing package-info.class files to derive targetNamespaces. To assure that the schemagen tool processes namespace values correctly, use one of the following methods:

- Explicitly specify the package-info.java source file in the schemagen invocation; for example:

```
schemagen sample.Address sample\package-info.java
```

- Use the @XmlType annotation namespace attribute within your JavaBeans to specify a namespace; for example:

```
@XmlType(namespace="http://myNameSpace")
public class Address {...}
```

In addition to using the schemagen tool from the command line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.jxc.SchemaGenTask` Ant task from within the Ant build environment to invoke the schemagen schema generator tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

## Syntax

The command-line syntax is:

Windows

*app_server_root*\bin\schemagen.bat [*options*] <*java_files*>

AIX HP-UX Linux Solaris

*app_server_root*/bin/schemagen.sh [*options*] <*java_files*>

## Parameters

The following parameters are optional for the schemagen command:

**-classpath <path>**
Specifies the location of the Java source or class files.

**-cp <path>**
Specifies the location of the Java source or class files.

**-d <path>**
Specifies where to place the processor and the generated Java class files.

**-episode<file_name>**
Specifies to generate an episode file for separate compilation.

**-encoding <encoding>**
Specifies to use encoding when invoking the -apt or -javac tool. This property is applicable for JAXB 2.2 and later.

**-help**
Displays the help menu.

**-version**
Prints the version information. If you specify this option, only the version information is output and typical command processing does not occur.

# Developing JAX-WS web services (bottom up)

## Setting up a development environment for web services

The application server provides command-line tools to develop web services clients and implementations that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. You must set up your development environment before you start developing web services.

### Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information on installing the application server, read about installing your application server environment.

### About this task

Set up a web services development environment by completing the following actions.

### Procedure

1. Set up the environment.

   Windows Run the `setupCmdLine.bat` command from the *`/profile_root/<application_server>/bin`* directory.

   Linux AIX HP-UX Solaris Operating systems such as AIX or Linux ***source*** the script to the parent shell to inherit the exported variables by running this command:

```
. ./setupCmdLine.sh  (Notice the space between the periods.)
```

   from the *`. /profile_root/<application_server>/bin`* directory.

   You can set `WAS_USER_SCRIPT` to *`profile_root`*`\<application_server>\bin\setupCmdLine.bat`, which has the same effect as running the setupCmdLine command.

2. Configure the path. You can add the WebSphere and Java `bin` directories to your path by typing:

   Windows

```
set PATH=%WAS_PATH%;%PATH%
```

   AIX HP-UX Solaris Linux

```
export PATH=$WAS_PATH:$PATH
```

### Results

You have set up an environment so that you can develop Web services.

### What to do next

Implement web services applications. See the task overview for implementing web services applications information to learn about how to develop and implement a Java EE web service.

## Developing JAX-WS web services with annotations

Java API for XML-Based Web Services (JAX-WS) supports two different service endpoint implementations types, the standard web service endpoint interface and a new Provider interface to enable services to work at the XML message level. By using annotations on the service endpoint implementation or client, you can define the service endpoint as a web service.

### Before you begin

Set up a development environment for web services.

### About this task

This task is a required step to develop JAX-WS web services.

JAX-WS technology supports the implementation of web services based on both the standard service endpoint interface and a new Provider interface. JAX-WS endpoints are like the endpoint implementations in the Java API for XML-based RPC (JAX-RPC) specification. Unlike JAX-RPC, the requirement for a service endpoint interface (SEI) is optional for JAX-WS web services. JAX-WS services that do not have an associated SEI are regarded as having an implicit SEI; whereas services that have an associated SEI are regarded as having an explicit SEI. The service endpoint interfaces required by JAX-WS are also more generic than the service endpoint interfaces required by JAX-RPC. With JAX-WS, the SEI is not required to extend the `java.rmi.Remote` interface as required by the JAX-RPC specification.

The JAX-WS programming model also uses support for annotating Java classes with metadata to define a service endpoint implementation as a web service and define how a client can access the web service. JAX-WS supports annotations based on the Metadata Facility for the Java Programming Language (JSR 175) specification, the Web Services Metadata for the Java Platform (JSR 181) specification and annotations defined by the JAX-WS 2.0 (JSR 224) specification, which includes Java Architecture for XML Binding (JAXB) annotations. Using annotations, the service endpoint implementation can independently describe the web service without requiring a WSDL file. Annotations can provide all the WSDL information necessary to configure your service endpoint implementation or web services client. You can specify annotations on the service endpoint interface used by the client and the server, or on the server-side service implementation class.

For details regarding the supported standards and specifications, see the web services specifications and API documentation.

When developing a JAX-WS web service starting from existing Java classes, known as the bottom-up approach, you must annotate the class with either the `@WebService` (`javax.jws.WebService`) annotation or `@WebServiceProvider` (`javax.xml.ws.Provider`) annotation to initially define the class as a web service. The `@WebService` annotation defines the service as an SEI-based endpoint, while the `@WebServiceProvider` annotation defines the service as a Provider-based endpoint.

**Develop SEI-based JAX-WS web services**

For an SEI-based endpoint, the service endpoint interface (SEI), whether it is a Java class or a Java interface, declares the business methods provided by a particular web service. The only methods that a web services client can invoke on a JAX-WS endpoint are the business methods that are defined in the explicit or implicit SEI.

All SEI-based endpoints are required to have the `@WebService` annotation included on the implementation class. If the service implementation uses an explicit SEI, then that interface must be referenced by the `endpointInterface` attribute on the `@WebService` annotation. If the service implementation does not use an explicit SEI, then the service is described implicitly by the implementation class and is an implicit SEI.

**Develop JAX-WS web services using the Provider interface**

The JAX-WS programming model introduces the Provider interface for Provider endpoints, `javax.xml.ws.Provider`, as the dynamic alternative to SEI-based endpoints. The Provider interface supports a more messaging-oriented approach to web services. With the Provider interface, you can create a Java class that implements a simple interface to produce a generic service implementation class. The Provider interface defines one method, the `invoke` method, which uses generics to control both the input and output types when working with various messages or message payloads. All Provider endpoints must be annotated with the `@WebServiceProvider` (`javax.xml.ws.WebServiceProvider`) annotation. A service implementation cannot specify the `@WebService` annotation if it implements the `javax.xml.ws.Provider` interface.

**Note:** Starting with WebSphere Application Server Version 7.0 and later, Java EE 5 application modules (web application modules version 2.5 or above, or EJB modules version 3.0 or above) are scanned for annotations to identify JAX-WS services and clients. However, pre-Java EE 5 application modules (web application modules version 2.4 or before, or EJB modules version 2.1 or before) are not scanned for JAX-WS annotations, by default, for performance considerations. In the Version 6.1 Feature Pack for Web Services, the default behavior is to scan pre-Java EE 5 web application modules to identify JAX-WS services and to scan pre-Java EE 5 web application modules and EJB modules for service clients during application installation. Because the default behavior for WebSphere Application Server Version 7.0 and later is to not scan pre-Java EE 5 modules for annotations during application installation or server startup, to preserve backward compatability with the feature pack from previous releases, you must configure either the UseWSFEP61ScanPolicy property in the META-INF/MANIFEST.MF of a web application archive (WAR) file or EJB module or define the Java virtual machine custom property, com.ibm.websphere.webservices.UseWSFEP61ScanPolicy, on servers to request scanning during application installation and server startup. To learn more about annotations scanning, see the JAX-WS annotations information.

## Procedure

1. Determine if you want to define your web services using SEI endpoints or the Provider interface. If you prefer a high-level Java-centric abstraction that hide the details of converting between Java objects and their XML representation, consider using SEI-based endpoints to develop your web services. However, if you prefer that your web service operate more at the XML message level, consider using Provider-based endpoints.
2. Annotate the service endpoints.
   a. Annotate the SEI-based endpoint with the `javax.jws.WebService` annotation.
      - For an SEI-based endpoint, annotate the implementation class with the `javax.jws.WebService` annotation. You can choose to explicitly reference a service endpoint interface by defining the `@WebService.endpointInterface` attribute, which specifies this endpoint is an explicit SEI. In this case, the Java interface that is referenced must also contain the `javax.jws.WebService` annotation. If the `endpointInterface` attribute is not defined or is empty, the implementation bean is considered an implicit SEI. You can add the `@WebMethod` annotation to methods of a service endpoint interface to customize the Java-to-WSDL mappings. All public methods are

considered exposed methods regardless of whether the `@WebMethod` annotation is specified. It is incorrect to have an `@WebMethod` annotation on a service endpoint interface that contains the `exclude` attribute.

- If you use an implicit SEI, you can apply more granular control on how the methods are exposed through selective use of the `@WebMethod` annotation. For a more detailed explanation, see the exposing methods in SEI-based JAX-WS web services information.

b. Annotate the Provider-based endpoint with the `javax.xml.ws.WebServiceProvider` annotation.

- For a Provider-based endpoint, annotate the implementation class with the `javax.xml.ws.WebServiceProvider` annotation. This annotation must be specified only on a class that implements a strongly typed `javax.xml.ws.Provider.interface` class such as `Provider<Source>` or `Provider<SOAPMessage>`, in contrast to a class that is unbounded, such as `Provider<T>`. A strongly typed class is one that is associated with a specific input and output Java type, such as `Source` or `SOAPMessage`, for example.

```
@WebServiceProvider(
        serviceName="StringProviderService",
        wsdlLocation="META-INF/echostring.wsdl",
        targetNamespace="http://stringprovider.sample.test.org")
```

- (optional) According the JAX-WS 2.2 specification, if you are defining a Provider-based endpoint so that the Provider implementation returns a null value, no response is needed. If the `javax.xml.ws.WebServiceProvider` annotation does not specify a WSDL, and the Provider `invoke()` method returns a null value, the default behavior of the JAX-WS runtime environment is to return a response that consists of a `SOAPEnvelope` that contains an empty `SOAPBody`. You can set the JVM property, `jaxws.provider.interpretNullAsOneway`, to `true` if you want the JAX-WS runtime environment to interpret this scenario as a request-only operation and not return a response.

3. Understand and apply best practices for exposing methods as operations in SEI-based JAX-WS web services.

   Because of ambiguity across multiple web services specifications regarding which methods are exposed as web services operations for SEI-based endpoints, you can ensure consistent behavior by following best practices, regardless of the JAX-WS implementation that you use.

## Results

You have defined the service endpoint implementation that represents the web services application. See the JAX-WS annotations documentation to learn more about the supported JAX-WS annotations.

## Example

### Sample JavaBeans service endpoint implementation and interface

The following example illustrates a simple explicit JavaBeans service endpoint implementation and the associated service endpoint interface:

```
/** This is an excerpt from the service implementation file, EchoServicePortTypeImpl.java.
package com.ibm.was.wssample.echo;
import java.io.ByteArrayInputStream;
import java.io.ByteArrayOutputStream;

import javax.xml.bind.JAXBContext;
import javax.xml.bind.Marshaller;
import javax.xml.bind.Unmarshaller;
import javax.xml.transform.stream.StreamSource;

@javax.jws.WebService(serviceName = "EchoService", endpointInterface =
"com.ibm.was.wssample.echo.EchoServicePortType", targetNamespace="http://com/ibm/was/wssample/echo/",
portName="EchoServicePort")
public class EchoServicePortTypeImpl implements EchoServicePortType {

                public EchoServicePortTypeImpl() {
                }
```

```
                public String echo(String obj) {
                        String str;
                        ....
                        str = obj;
                        ....

                        return str;

                }

}
/**  This is a sample EchoServicePortType.java service interface. */

import javax.jws.WebMethod;
import javax.jws.WebService;
import javax.xml.ws.*;

@WebService(name = "EchoServicePortType", targetNamespace = "http://com/ibm/was/wssample/echo/",
wsdlLocation="WEB-INF/wsdl/Echo.wsdl")
public interface EchoServicePortType {

    /** ...the method process ...*/
        @WebMethod

}
```

### Sample Provider endpoint implementation

The following example illustrates a simple Provider service endpoint interface for a Java class:

```
package jaxws.provider.source;

import javax.xml.ws.Provider;
import javax.xml.ws.WebServiceProvider;
import javax.xml.transform.Source;

@WebServiceProvider()
public class SourceProvider implements Provider<Source> {

    public Source echo(Source data) {
        return data;
    }
}
```

In the Provider implementation example, the `javax.xml.transform.Source` type is specified in the generic `<Source>` method. The generic `<Source>` method specifies that both the input and output types are `Source` objects.

## What to do next

Develop Java artifacts for JAX-WS applications from JavaBeans. To learn more, see the generating Java artifacts for JAX-WS applications information.

## Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

### Default product locations (distributed)

The following file paths are default locations. You can install the product and other components or create profiles in any directory where you have write access. Multiple installations of WebSphere Application Server - Express products or components require multiple locations. Default values for installation actions by root and nonroot users are given. If no nonroot values are specified, then the default directory values are applicable to both root and nonroot users.

*app_client_root*

*Table 178. Default installation root directories for the Application Client for IBM WebSphere Application Server.*

*This table shows the default installation root directories for the Application Client for IBM WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppClient` (Java EE Application client only)<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\Program Files\IBM\WebSphere\AppClient` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\IBM\WebSphere\AppClient` |

*app_server_root*

*Table 179. Default installation directories for WebSphere Application Server.*

*This table shows the default installation directories for WebSphere Application Server - Express.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppServer`<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppServer`<br>Windows `C:\Program Files\IBM\WebSphere\AppServer` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppServer`<br>Windows *user_home*`\IBM\WebSphere\AppServer` |

*component_root*

The component installation root directory is any installation root directory described in this topic. Some programs are for use across multiple components—in particular, the Web Server Plug-ins, the Application Client, and the IBM HTTP Server. All of these components are part of the product package.

*gskit_root*

IBM Global Security Kit (GSKit) can now be installed by any user. GSKit is installed locally inside the installing product's directory structure and is no longer installed in a global location on the target system. The following list shows the default installation root directory for Version 8 of the GSKit, where *product_root* is the root directory of the product that is installing GSKit, for example IBM HTTP Server or the web server plug-in.

AIX HP-UX Linux Solaris

*product_root*`/gsk8`

Windows

*product_root*`\gsk8`

*profile_root*

*Table 180. Default profile directories.*

*This table shows the default directories for a profile named profile_name on each distributed operating system.*

## Exposing methods in SEI-based JAX-WS web services

You can use the @WebService and @WebMethod annotations on a service endpoint implementation to specify Java methods that you want to expose as Java API for XML-Based Web Services (JAX-WS) web services.

### Before you begin

JAX-WS technology enables the implementation of web services based on both the standard service endpoint interface and a Provider interface. When developing a JAX-WS web service starting from existing Java classes, known as the bottom-up approach, you must annotate the class with either the @WebService or @WebServiceProvider annotation to initially define the class as a web service.

Using the Provider interface is the dynamic approach to defining your JAX-WS services. To use the Provider interface, your class must implement the javax.xml.ws.Provider interface, and contain the @WebServiceProvider annotation. The Provider interface has one method, the invoke method, which uses generics in the Java programming language to control both the input and output types when working with various messages or message payloads.

In contrast, this topic describes how you can use Java annotations to describe your web services using the service endpoint interface (SEI) approach.

### About this task

To initially define a web service, annotate the Java class with the @WebService annotation. You can also selectively annotate individual methods with the @WebMethod annotation to control their exposure as web services operations.

Because of ambiguities across multiple web services specifications regarding how methods are exposed as operations, use the following guidelines to help ensure consistent behavior regardless of the JAX-WS implementation that you use.

- To define a basic web service, annotate the implementation class with the @WebService annotation.
- To define your web services using an explicit SEI, explicitly reference a Java interface class using the endpointInterface attribute of the @WebService annotation.
- Provide a reference to a WSDL file in the wsdlLocation attribute of the @WebService annotation. By specifying a pre-defined WSDL file, performance is improved. Also, discrepancies between the WSDL file and the annotations are reported to you by the runtime environment.
- When you use an explicit SEI, all public methods in the SEI and inherited classes are always exposed. You only need to add @WebMethod annotations if you want to further customize the methods that are already exposed.
- Providing a reference in the @WebService annotation to an explicit SEI or to an existing WSDL file helps to remove possible ambiguities when exposing methods.
- If you do not use an explicit SEI, follow these rules to ensure that your methods are exposed consistently:

– Add an @WebService annotation to your implementation class and all its superclasses that contain methods that you want to expose. Adding an @WebService annotation to a class exposes all public methods in that class that are not static or final.
– If you want more granular control to expose only certain methods, use the @WebMethod annotation on selected methods. To ensure that a method is exposed, annotate it with the @WebMethod annotation. If you want to make sure that a method is not exposed, annotate it with the @WebMethod(exclude=true) annotation.

**Note:**

**Behavior change for exposing methods that are not annotated:**

The behavior of JAX-WS has changed regarding exposing methods as web services operations. This complies with recent clarifications to JAX-WS specifications.

Applications without an explicit SEI or WSDL that are migrated from prior versions might have additional operations exposed as shown below. You can set a property so the JAX-WS runtime environment uses the legacy behavior. You might need this when migrating applications without a WSDL or an SEI so that additional methods are not exposed.

```
@WebService
public class Foo {
 @WebMethod
 public void a() {} // exposed now, exposed before
 public void b() {} // exposed now, not exposed before
}
```

Using the new interpretation, public methods in an implementation class and its superclasses are only exposed under the following conditions:

- The containing class has an @WebService annotation.
- The method does not have an @WebMethod(exclude=true) annotation.

Using the legacy interpretation, a method in an implementation class and its superclasses are only exposed under the following conditions:

- The containing class has an @WebService annotation.
- The method has no @WebMethod annotations AND no other methods have @WebMethod annotations.
- The method has an @WebMethod or @WebMethod(exclude=false) annotation.

To specify that the JAX-WS runtime environment use the legacy @WebMethod behavior, configure the `jaxws.runtime.legacyWebMethod=true` property. You can configure this property as a Java Virtual Machine (JVM) system property or as a property in the `META-INF/MANIFEST.MF` file of a web application archive (WAR) file. By default, this property is set to `false` and the application server uses the new behavior.

You might encounter a WSWS7054E error message if all of the following conditions are true:

- Your web service application consists of unannotated methods.
- The methods are not meant to be mapped to a web service operation.
- Your application does not reference an SEI nor package a WSDL file.

The error message contains information that is similar to the following text:

```
javax.xml.ws.WebServiceException: WSWS7054E:
 The Web Services Description Language (WSDL) file could not be generated for the XXXX Web service implementation
 class because of the following error: javax.xml.ws.WebServiceException: Unable to create JAXBContext
```

The JAX-WS tooling complies with the JAX-WS specification with respect to @WebMethod mapping principles. This change might affect applications that have been dependent on previously non-compliant default behavior. If your applications package and reference WSDL or an SEI and have ALL methods correctly annotated with the @WebMethod exclude flag in the SEI implementation, then this change does not affect you. However, if you are affected, add explicit annotations to your methods to ensure that they are excluded in WSDL generation. For example:

@WebMethod(exclude=true) Also, you can package a WSDL with your application to eliminate the need for the run time to generate a WSDL on your behalf.

**Behavior change for exposing static and final methods:**

Static or final methods in a service without an explicit SEI are no longer exposed as web services operations. To expose them, package the WSDL with the application and set `jaxws.runtime.legacyWebMethod=true`.

## Procedure

1. Identify the methods that you want to expose as web services operations.
2. Review the rules for exposing methods as operations on classes annotated with the @WebService annotation.
3. Use the best practices for applying the @WebMethod and @WebService annotations in applications without SEIs to appropriately expose methods as operations within your web services.

## Results

You have used the @WebMethod annotation to specify which methods to expose as web services operations.

**Note:**

If you have upgraded your application server environment and you are experiencing problems, review the following troubleshooting information.

**Client errors indicate a mismatch between the WSDL file and portType when using a JAX-WS tooling version 2.1.6 or higher environment**

You might receive a client-side error message like the following message:

```
javax.xml.ws.WebServiceException: The Endpoint validation failed to validate due to the following errors:
:: Invalid Endpoint Interface ::
:: The number of operations in the WSDL portType does not match the number of methods in the SEI or web service
 implementation class.  wsdl operations = [...] dispatch operations = [....]
```

To correct this problem, you must regenerate client artifacts to match the WSDL file.

**Note:** Be sure to regenerate your client side artifacts any time you receive an updated WSDL file.

**Clients that perform a ?WSDL operation on web services have non-dispatchable operations**

After performing a ?WSDL operation, you might receive a WSDL file that contains more operations than the JAX-WS runtime environment can dispatch. If the client tries to invoke any of the non-dispatchable operations, the client receives an error like the following message:

```
The endpoint reference (EPR) for the Operation not found is http://localhost:9086/example/BeanImpl2Service and the WSA
Action = <WSA_action_from_server>. If this EPR was previously reachable, contact the server administrator.
```

Clients must only access the operations that the web service intends to expose. You can correct this problem in one of the following ways:

- Modify the @WebMethod annotations in the web services application so that the resulting WSDL file exposes the correct set of operations.
- Set the `jaxws.runtime.legacyWebMethod` property to `false` to ensure that all operations in the WSDL are dispatched.

## What to do next

Develop Java artifacts for JAX-WS applications from JavaBeans.

## JAX-WS annotations

Java API for XML-Based Web Services (JAX-WS) relies on the use of annotations to specify metadata associated with web services implementations and to simplify the development of web services. Annotations describe how a server-side service implementation is accessed as a web service or how a client-side Java class accesses web services.

The JAX-WS programming standard introduces support for annotating Java classes with metadata that is used to define a service endpoint application as a web service and how a client can access the web service. JAX-WS supports the use of annotations based on the Metadata Facility for the Java Programming Language (Java Specification Request (JSR) 175) specification, the Web Services Metadata for the Java Platform (JSR 181) specification and annotations defined by the JAX-WS 2.0 and later (JSR 224) specification which includes JAXB annotations. Using annotations from the JSR 181 standard, you can simply annotate the service implementation class or the service interface and now the application is enabled as a web service. Using annotations within the Java source simplifies development and deployment of web services by defining some of the additional information that is typically obtained from deployment descriptor files, WSDL files, or mapping metadata from XML and WSDL into the source artifacts.

Use annotations to configure bindings, handler chains, set names of portType, service and other WSDL parameters. Annotations are used in mapping Java to WSDL and schema, and at runtime to control how the JAX-WS runtime processes and responds to web service invocations.

For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

**Note:**

Starting with WebSphere Application Server Version 7.0 and later, Java EE 5 application modules (Web application modules version 2.5 or above, or EJB modules version 3.0 or above) are scanned for annotations to identify JAX-WS services and clients. However, pre-Java EE 5 application modules (web application modules version 2.4 or before, or EJB modules version 2.1 or before) are not scanned for JAX-WS annotations, by default, for performance considerations.

In the Version 6.1 Feature Pack for Web Services, the default behavior is to scan pre- Java Platform, Enterprise Edition (Java EE) 5 web application modules to identify JAX-WS services and to scan pre-Java EE 5 web application modules and EJB modules for service clients during application installation. Because the default behavior for WebSphere Application Server Version 7.0 and later is to not scan pre-Java EE 5 modules for annotations during application installation or server startup, to preserve backward compatability with the feature pack from previous releases, you must configure one of the following properties:

- You can set the `UseWSFEP61ScanPolicy` property in the META-INF/MANIFEST.MF of a WAR file or EJB module to `true`. For example:

```
Manifest-Version: 1.0
UseWSFEP61ScanPolicy: true
```

  When this property is set to `true` in the META-INF/MANIFEST.MF file of the module, the module is scanned for JAX-WS annotations regardless of the Java EE version of the module. The default value is `false` and when the default value is in effect, JAX-WS annotations are only supported in modules whose version is Java EE 5 or later.
- You can set the `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` custom Java virtual machine (JVM) property using the administrative console. See the JVM custom properties documentation for the correct navigation path to use. To request annotation scanning in all modules regardless of their Java EE version, set the custom property

`com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` to `true`. You must change the setting on each server that requires a change in the default behavior.

If the property is set within the META-INF/MANIFEST.MF file of the module, this setting takes precedence over the server's custom JVM property. When using either property, you must establish the desired annotation scanning behavior before the application is installed. You cannot dynamically change the scanning behavior once an application is installed. If changes to the behavior are required after your application is installed, you must first uninstall the application, specify the desired scanning behavior using the appropriate property and then install the application again. When federating nodes that have the `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` set to `true` in the configuration of the servers contained within the node, this property does not affect the deployment manager. You must set the property to `true` on the deployment manager before the node is federated to preserve the behavior as it was on the node before federation.

Annotations supported by JAX-WS are listed in the table below. The target for annotations is applicable for these Java objects:

- types such as a Java class, enum or interface
- methods
- fields representing local instance variables within a Java class
- parameters within a Java method

*Table 184. Web services Metadata Annotations (JSR 181). Describes the supported web services metadata annotations and their associated properties.*

| Annotation class | Annotation | Properties |
|---|---|---|
| `javax.jws. WebService` | The **@WebService** annotation marks a Java class as implementing a Web service or marks a service endpoint interface (SEI) as implementing a web service interface.<br><br>**Important:**<br><br>• A Java class that implements a web service must specify either the @WebService or @WebServiceProvider annotation. Both annotations cannot be present.<br><br>This annotation is applicable on a client or server SEI or a server endpoint implementation class.<br><br>• If the annotation references an SEI through the `endpointInterface` attribute, the SEI must also be annotated with the @WebService annotation.<br><br>• See the exposing methods in SEI-based JAX-WS web services information to learn about best practices for using the @WebService and @WebMethod annotations on a service endpoint implementation to specify Java methods that you want to expose as JAX-WS web services. | • Annotation target: Type<br>• Properties:<br><br>- **`name`**<br>The name of the `wsdl:portType`. The default value is the unqualified name of the Java class or interface. (String)<br><br>- **`targetNamespace`**<br>Specifies the XML namespace of the WSDL and XML elements generated from the web service. The default value is the namespace mapped from the package name containing the web service. (String)<br><br>- **`serviceName`**<br>Specifies the service name of the web service: `wsdl:service`. The default value is the simple name of the Java class + *Service*. (String)<br><br>- **`endpointInterface`**<br>Specifies the qualified name of the service endpoint interface that defines the services' abstract web service contract. If specified, the service endpoint interface is used to determine the abstract WSDL contract. (String)<br><br>- **`portName`**<br>The `wsdl:portName`. The default value is WebService.name +*Port* . (String)<br><br>- **`wsdlLocation`**<br>Specifies the web address of the WSDL document defining the web service. The web address is either relative or absolute. (String) |
| `javax.jws. WebMethod` | The **@WebMethod** annotation denotes a method that is a web service operation.<br><br>Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.<br><br>Solaris HP-UX<br>**Note:** Beginning with Sun and HP JDK Version 1.6 containing JAX-WS tooling Version 2.1.6, the behavior of the JAX-WS runtime environments and tooling has changed in how it determines which methods are exposed as web services operations in an effort to better adhere to the JAX-WS specifications. Applications that might be affected by this change include web services applications that do not specify a WSDL file or an explicit service endpoint interface (SEI). To learn more, see the exposing methods in SEI-based JAX-WS web services information. | • Annotation target: Method<br>• Properties:<br><br>- **`operationName`**<br>Specifies the name of the `wsdl:operation` matching this method. The default value is the name of Java method. (String)<br><br>- **`action`**<br>Defines the action for this operation. For SOAP bindings, this value determines the value of the SOAPAction header. The default value is the name of Java method. (String)<br><br>- **`exclude`**<br>Specifies whether to exclude a method from the web service. The default value is `false`. (Boolean) |

*Table 184. Web services Metadata Annotations (JSR 181) (continued). Describes the supported web services metadata annotations and their associated properties.*

| Annotation class | Annotation | Properties |
|---|---|---|
| `javax.jws. Oneway` | The **@Oneway** annotation denotes a method as a web service one-way operation that only has an input message and no output message.<br><br>Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class. | • Annotation target: Method<br>• There are no properties on the Oneway annotation. |
| `javax.jws. WebParam` | The **@WebParam** annotation customizes the mapping of an individual parameter to a web service message part and XML element.<br><br>Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class. | • Annotation target: Parameter<br>• Properties:<br>**- name**<br>The name of the parameter. If the operation is remote procedure call (RPC) style and the `partName` attribute is not specified, then this is the name of the `wsdl:part` attribute representing the parameter. If the operation is document style or the parameter maps to a header, then `-name` is the local name of the XML element representing the parameter. This attribute is required if the operation is document style, the parameter style is `BARE`, and the mode is `OUT` or `INOUT`. (String)<br>**- partName**<br>Defines the name of `wsdl:part` attribute representing this parameter. This is only used if the operation is RPC style, or the operation is document style and the parameter style is `BARE`. (String)<br>**- targetNamespace**<br>Specifies the XML namespace of the XML element for the parameter. Applies only for document bindings when the attribute maps to an XML element. The default value is the `targetNamespace` for the web service. (String)<br>**- mode**<br>The value represents the direction the parameter flows for this method. Valid values are `IN`, `INOUT`, and `OUT`. (String)<br>**- header**<br>Specifies whether the parameter is in a message header rather than a message body. The default value is `false`. (Boolean) |

*Table 184. Web services Metadata Annotations (JSR 181) (continued). Describes the supported web services metadata annotations and their associated properties.*

| Annotation class | Annotation | Properties |
|---|---|---|
| `javax.jws. WebResult` | The **@WebResult** annotation customizes the mapping of a return value to a WSDL part or XML element.<br><br>Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class. | • Annotation target: Method<br>• Properties:<br>**- name**<br>Specifies the name of the return value as it is listed in the WSDL file and found in messages on the wire. For RPC bindings, this is the name of the `wsdl:part` attribute representing the return value. For document bindings, the `-name` parameter is the local name of the XML element representing the return value. The default value is `return` for RPC and DOCUMENT/WRAPPED bindings. The default value is the method name + `Response` for DOCUMENT/BARE bindings. (String)<br>**- targetNamespace**<br>Specifies the XML namespace for the return value. This parameter is only used if the operation is RPC style or if the operation is DOCUMENT style and the parameter style is BARE. (String)<br>**- header**<br>Specifies whether the result is carried in a header. The default value is `false`. (Boolean)<br>**- partName**<br>Specifies the part name for the result with RPC or DOCUMENT/BARE operations. The default value is `@WebResult.name`. (String) |
| `javax.jws. HandlerChain` | The **@HandlerChain** annotation associates the web service with an externally defined handler chain.<br><br>You can only configure the server side handler by using the @HandlerChain annotation on the Service Endpoint Interface (SEI) or the server endpoint implementation class.<br><br>Use one of several ways to configure a client side handler. You can configure a client side handler by using the @HandlerChain annotation on the generated service class or SEI. Additionally, you can programmatically register your own implementation of the HandlerResolver interface on the Service, or programmatically set the handler chain on the Binding object. | • Annotation target: Type<br>• Properties:<br>**- file**<br>Specifies the location of the handler chain file. The file location is either an absolute java.net.URL in external form or a relative path from the class file. (String)<br>**- name**<br>Specifies the name of the handler chain in the configuration file. (String) |

*Table 184. Web services Metadata Annotations (JSR 181) (continued). Describes the supported web services metadata annotations and their associated properties.*

| Annotation class | Annotation | Properties |
|---|---|---|
| `javax.jws. SOAPBinding` | The **@SOAPBinding** annotation specifies the mapping of the web service onto the SOAP message protocol.<br><br>Apply this annotation to a type or methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.<br><br>The method level annotation is limited in what it can specify and is only used if the `style` property is `DOCUMENT`. If the method level annotation is not specified, the **@SOAPBinding** behavior from the type is used. | • Annotation target: Type or Method<br>• Properties:<br>**- `style`**<br>Defines encoding style for messages sent to and from the web service. The valid values are `DOCUMENT` and `RPC`. The default value is `DOCUMENT`. (String)<br>**- `use`**<br>Defines the formatting used for messages sent to and from the web service. The default value is `LITERAL`. `ENCODED` is not supported. (String)<br>**- `parameterStyle`**<br>Determines whether the method's parameters represent the entire message body or whether parameters are elements wrapped inside a top-level element named after the operation. Valid values are `WRAPPED` or `BARE`. You can only use the `BARE` value with `DOCUMENT` style bindings. The default value is `WRAPPED`. (String) |

*Table 185. JAX-WS Annotations (JSR 224). Describes the supported JAX-WS annotations and their associated properties.*

| Annotation class | Annotation | Properties |
|---|---|---|
| `javax.xml.ws. Action` | The **@Action** annotation specifies the WS-Addressing action that is associated with a web service operation.<br><br>When you use this annotation with a particular method, and generate the corresponding WSDL document, the WS-Addressing Action extension attribute is added to the input and output elements of the WSDL operation that corresponds to that method.<br><br>To add this attribute to the WSDL operation, you must also specify the @Addressing annotation on the server endpoint implementation class. If you do not want to use the @Addressing annotation you can supply your own WSDL document with the Action attribute already defined. | • Annotation target: Method<br>• Properties:<br>**- fault**<br>Specifies the array of FaultAction for the wsdl:fault of the operation. (String)<br>**- input**<br>Specifies the action for thewsdl:input of the operation. (String)<br>**- output**<br>Specifies the action for thewsdl:output of the operation. (String) |
| `javax.xml.ws. BindingType` | The **@BindingType** annotation specifies the binding to use when publishing an endpoint of this type.<br><br>Apply this annotation to a server endpoint implementation class.<br><br>**Important:**<br><br>• You can use the @BindingType annotation on the JavaBeans endpoint implementation class to enable MTOM by specifying either `javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_MTOM_BINDING` or `javax.xml.ws.soap.SOAPBinding.SOAP12HTTP_MTOM_BINDING` as the value for the annotation. | • Annotation target: Type<br>• Properties:<br>**- value**<br>Indicates the binding identifier web address. Valid values are `javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_BINDING`, `javax.xml.ws.soap.SOAPBinding.SOAP12HTTP_BINDING`, and `javax.xml.ws.http.HTTPBinding.HTTP2HTTP_BINDING`. The default value is `javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_BINDING`. (String) |
| `javax.xml.ws. FaultAction` | The **@FaultAction** annotation specifies the WS-Addressing action that is added to a fault response.<br><br>This annotation must be contained within an @Action annotation.<br><br>When you use this annotation with a particular method, the WS-Addressing FaultAction extension attribute is added to the fault element of the WSDL operation that corresponds to that method.<br><br>To add this attribute to the WSDL operation, you must also specify the @Addressing annotation on the server endpoint implementation class. If you do not want to use the @Addressing annotation you can supply your own WSDL document with the Action attribute already defined. | • Annotation target: Method<br>• Properties:<br>**- value**<br>Specifies the action of the wsdl:fault of the operation. (String)<br>**- output**<br>Specifies the name of the exception class. (String)<br>**- className**<br>Specifies the name of the class representing the request wrapper. (String) |

*Table 185. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.*

| Annotation class | Annotation | Properties |
|---|---|---|
| `javax.xml.ws. RequestWrapper` | The **@RequestWrapper** annotation supplies the JAXB generated request wrapper bean, the element name, and the namespace for serialization and deserialization with the request wrapper bean that is used at runtime.<br><br>When starting with a Java object, this element is used to resolve overloading conflicts in document literal mode. Only the `className` attribute is required in this case.<br><br>Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class. | • Annotation target: Method<br>• Properties:<br>- **`localName`**<br>Specifies the local name of the XML schema element representing the request wrapper. The default value is the `operationName` as defined in javax.jws.WebMethod annotation. (String)<br>- **`targetNamespace`**<br>Specifies the XML namespace of the request wrapper method. The default value is the target namespace of the SEI. (String)<br>- **`className`**<br>Specifies the name of the class representing the request wrapper. (String)<br>- **`partName`**<br>Specifies the name of the wsdl:part attribute that represents the XML schema element for the RequestWrapper class. This property is applicable for JAX-WS 2.2 and later. (String) |
| `javax.xml.ws. ResponseWrapper` | The **@ResponseWrapper** annotation supplies the JAXB generated response wrapper bean, the element name, and the namespace for serialization and deserialization with the response wrapper bean that is used at runtime.<br><br>When starting with a Java object, this element is used to resolve overloading conflicts in document literal mode. Only the `className` attribute is required in this case.<br><br>Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class. | • Annotation target: Method<br>• Properties:<br>- **`localName`**<br>Specifies the local name of the XML schema element representing the request wrapper. The default value is the `operationName` + *Response*. `operationName` is defined in javax.jws.WebMethod annotation. (String)<br>- **`targetNamespace`**<br>Specifies the XML namespace of the request wrapper method. The default value is the target namespace of the SEI. (String)<br>- **`className`**<br>Specifies the name of the class representing the response wrapper. (String)<br>- **`partName`**<br>Specifies the name of the wsdl:part attribute that represents the XML schema element for the ResponseWrapper class. This property is applicable for JAX-WS 2.2 and later. (String) |

*Table 185. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.*

| Annotation class | Annotation | Properties |
|---|---|---|
| `javax.xml.ws. RespectBinding` | The **@RespectBinding** annotation specifies whether the JAX-WS implementation must use the contents of the wsdl:binding for an endpoint.<br><br>When this annotation is specified, a check is performed to ensure all required WSDL extensibility elements with the enabled attribute set to true are supported.<br><br>Apply this annotation to methods on a server endpoint implementation class. | • Annotation target: Method<br>• Properties:<br>**- enabled**<br>Specifies whether the wsdl:binding must be used or not. The default value is `true`. (Boolean) |
| `javax.xml.ws. ServiceMode` | The **@ServiceMode** annotation specifies whether a service provider needs to have access to an entire protocol message or just the message payload.<br><br>**Important:**<br><br>• The @ServiceMode annotation is only supported on classes that are annotated with the @WebServiceProvider annotation. | • Annotation target: Type<br>• Properties:<br>**- value**<br>Indicates whether the provider class accepts the payload of the message, `PAYLOAD` or the entire message `MESSAGE`. The default value is `PAYLOAD`. (String) |
| `javax.xml.ws. soap.Addressing` | The **@Addressing** annotation specifies that this service wants to enable WS-Addressing support.<br><br>Apply this annotation to methods on a server endpoint implementation class. | • Annotation target: Type<br>• Properties:<br>**- enabled**<br>Specifies if WS-Addressing is enabled or not. The default value is `true`. (Boolean)<br>**- required**<br>Specifies that WS-Addressing headers must be present on incoming messages. The default value is `false`. (Boolean)<br>**- responses**<br>Specifies the message exchange pattern to use. The default value is `Responses.ALL`. This property is applicable for JAX-WS 2.2 and later. (String) |

*Table 185. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.*

| Annotation class | Annotation | Properties |
|---|---|---|
| `javax.xml.ws. soap.MTOM` | The **@MTOM** annotation specifies whether binary content in the body of a SOAP message is sent using MTOM.<br><br>Apply this annotation to a service endpoint implementation class. | • Annotation target: Class<br>• Properties:<br>- **`enabled`**<br>Specifies if MTOM is enabled for the JAX-WS endpoint. The default value is `true`. (Boolean)<br>- **`threshold`**<br>Specifies the minimum size for messages that are sent using MTOM. When the message size is less than this specified integer, the message is inlined in the XML document as base64 or hexBinary data. (integer) |
| `javax.xml.ws. WebFault` | The **@WebFault** annotation maps WSDL faults to Java exceptions. It is used to capture the name of the fault during the serialization of the JAXB type that is generated from a global element referenced by a WSDL fault message. It can also be used to customize the mapping of service specific exceptions to WSDL faults.<br><br>This annotation can only be applied to a fault implementation class on the client or server. | • Annotation target: Type<br>• Properties:<br>- **`name`**<br>Specifies the local name of the XML element that represents the corresponding fault in the WSDL file. The actual value must be specified. (String)<br>- **`targetNamespace`**<br>Specifies the namespace of the XML element that represents the corresponding fault in the WSDL file. (String)<br>- **`faultBean`**<br>Specifies the name of the fault bean class. (String)<br>- **`messageName`**<br>Specifies the name of the wsdl:message attribute that represents the corresponding fault in the WSDL file. This property is applicable for JAX-WS 2.2 and later. (String) |

*Table 185. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.*

| Annotation class | Annotation | Properties |
|---|---|---|
| `javax.xml.ws. WebServiceProvider` | The **@WebServiceProvider** annotation denotes that a class satisfies requirements for a JAX-WS Provider implementation class.<br><br>**Important:**<br><br>• A Java class that implements a web service must specify either the @WebService or @WebServiceProvider annotation. Both annotations cannot be present.<br><br>• The @WebServiceProvider annotation is only supported on the service implementation class.<br><br>Any class with the @WebServiceProvider annotation must implement the javax.xml.ws.Provider interface. | • Annotation target: Type<br>• Properties:<br>- **`targetNamespace`**<br>Specifies the XML namespace of the WSDL and XML elements generated from the web service. The default value is the namespace mapped from the package name containing the web service. (String)<br>- **`serviceName`**<br>Specifies the service name of the web service: `wsdl:service`. The default value is the simple name of the Java class + *Service*. (String)<br>- **`portName`**<br>The `wsdl:portName`. The default value is the name of the class + *Port*. (String)<br>- **`wsdlLocation`**<br>The web address of the WSDL document defining the web service. This attribute is required. (String) |

*Table 185. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.*

| Annotation class | Annotation | Properties |
|---|---|---|
| `javax.xml.ws. WebServiceRef` | The **@WebServiceRef** annotation defines a reference to a web service invoked by the client.<br><br>**Important:**<br><br>• The @WebServiceRef annotation can be used to inject instances of JAX-WS services and ports.<br><br>• The @WebServiceRef annotation is only supported in certain class types. Examples are JAX-WS endpoint implementation classes, JAX-WS handler classes, Enterprise JavaBeans classes, and servlet classes. This annotation is supported in the same class types as the @Resource annotation. See the Java Platform, Enterprise Edition (Java EE) 5 specification for a complete list of supported class types. | • Annotation target: Type, Field or Method<br>• Properties:<br>- **`name`**<br>Specifies the JNDI name of the resource. The field name is the default for field annotations. The JavaBeans property name that corresponds to the method is the default for method annotations. You must specify a value for class annotations as there is no default. (String)<br>- **`type`**<br>Indicates the Java type of the resource. The field type is the default for field annotations. The type of the JavaBeans property is the default for method annotations. You must specify a value for class annotations as there is no default. (Class)<br>- **`mappedName`**<br>Specifies the name to map this resource to. (String)<br>- **`value`**<br>Indicates the value of the service class and it is a type that extends `javax.xml.ws.Service`. This attribute is required when the type of the reference is a service endpoint interface. (Class)<br>- **`wsdlLocation`**<br>The web address of the WSDL document defining the web service. This attribute is required. (String)<br>- **`lookup`**<br>Specifies the JNDI lookup name for the target web service. This property is applicable for JAX-WS 2.2 and later. (String) |
| `javax.xml.ws. WebServiceRefs` | The **@WebServiceRefs** annotation associates multiple @WebServiceRef annotations with a specific class.<br><br>**Important:**<br><br>• The @WebServiceRef annotation is only supported in certain class types. Examples are JAX-WS endpoint implementation classes, JAX-WS handler classes, Enterprise JavaBeans classes, and servlet classes. This annotation is supported in the same class types as the @Resource annotation. See the Java Platform, Enterprise Edition (Java EE) 5 specification for a complete list of supported class types. | • Annotation target: Type<br>• Properties:<br>- **`value`**<br>Specifies an array for multiple web service reference declarations. This attribute is required. |

*Table 186. JAX-WS Common Annotations (JSR 250). Describes the supported JAX-WS common annotations and their associated properties.*

| Annotation class | Annotation | Properties |
|---|---|---|
| `javax.annotation. Resource` | The **@Resource** annotation marks a WebServiceContext resource needed by the application.<br><br>**Important:**<br><br>Applying this annotation to a WebServiceContext type field on the server endpoint implementation class for a JavaBeans endpoint or a Provider endpoint results in the container injecting an instance of the WebServiceContext into the specified field.<br><br>When this annotation is used in place of the @WebServiceRef annotation, the rules described for the @WebServiceRef annotation apply. | • Annotation target: Field or Method<br>• Properties:<br>**- type**<br>Indicates the Java type of the resource. You are required to use the default, `java.lang.Object` or `javax.xml.ws.Web ServiceContext` value. If the type is the default, the resource must be injected into a field or a method. In this case, the type of the field or the type of the JavaBeans property defined by the method must be `javax.xml.ws.WebServiceContext`. (Class)<br><br>If you are using this annotation to inject a web service, see the description of the @WebServiceRef type attribute. |
| `javax.annotation. Resources` | The **@Resources** annotation associates multiple @Resource annotations with a specific class and serves as a container for multiple resource declarations. | • Annotation target: Field or Method<br>• Properties:<br>**- value**<br>Specifies an array for multiple @Resource annotations. This attribute is required. |
| `javax.annotation. PostConstruct` | The **@PostConstruct** annotation marks a method that needs to run after dependency injection is performed on the class.<br><br>Apply this annotation to a JAX-WS application handler, a server endpoint implementation class. | • Annotation target: Method |
| `javax.annotation. PreDestroy` | The **@PreDestroy** annotation marks a method that must be run when the instance is in the process of being removed by the container.<br><br>Apply this annotation to a JAX-WS application handler or a server endpoint implementation class. | • Annotation target: Method |

*Table 187. IBM proprietary annotations. Describes the supported IBM proprietary annotations and their associated properties.*

| Annotation class | Annotation | Properties |
|---|---|---|
| `com.ibm.websphere. wsaddressing. jaxws21. SubmissionAddressing` | The **@SubmissionAddressing** annotation specifies that this service wants to enable WS-Addressing support for the 2004/08 WS-Addressing specification.<br><br>This annotation is part of the IBM implementation of the JAX-WS 2.1 specification.<br><br>Apply this annotation to methods on a server endpoint implementation class. | • Annotation target: Type<br>• Properties:<br>- **`enabled`**<br>Specifies if WS-Addressing is enabled or not. The default value is `true`. (Boolean)<br>- **`required`**<br>Specifies that WS-Addressing headers must be present on incoming messages. The default value is `false`. (Boolean) |

# Generating Java artifacts for JAX-WS applications

Use Java API for XML-Based Web Services (JAX-WS) tools to generate the necessary JAX-WS and Java Architecture for XML Binding (JAXB) Java artifacts that are needed for JAX-WS web services applications when starting from JavaBeans or enterprise beans components.

## Before you begin

To develop a Java API for XML-Based Web Services (JAX-WS) web service application, you must first develop a service endpoint interface (SEI) implementation that explicitly or implicitly describes the SEI.

## About this task

When using a bottom-up approach to develop JAX-WS web services, use the wsgen command-line tool on the existing service endpoint implementation. The wsgen tool processes a compiled service endpoint implementation class as input and generates the following portable artifacts:

- Java Architecture for XML Binding (JAXB) classes that are required to marshal and unmarshal the message contents.
- a Web Services Description Language (WSDL) file if the optional *-wsdl* argument is specified.

**Note:** The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

**Note:** WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The wsimport, wsgen, schemagen and xjc command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

You are not required to develop a WSDL file when developing JAX-WS Web services using the bottom-up approach of starting with JavaBeans. The use of annotations provides all of the WSDL information necessary to configure the service endpoint or the client. The application server supports WSDL 1.1 documents that comply with Web Services-Interoperability (WS-I) Basic Profile 1.1 specifications and are either Document/Literal style documents or RPC/Literal style documents. Additionally, WSDL documents with bindings that declare a `USE` attribute of value `LITERAL` are supported while the value, `ENCODED`, is not supported. For WSDL documents that implement a Document/Literal wrapped pattern, a root element is declared in the XML schema and is used as an operation wrapper for a message flow. Separate wrapper element definitions exist for both the request and the response.

To ensure the wsgen command does not miss inherited methods on a service endpoint implementation bean, you must either add the @WebService annotation to the desired superclass or you can override the inherited method in the implementation class with a call to the superclass method.

Although a WSDL file is typically optional when developing a JAX-WS service implementation bean, it is required if your JAX-WS endpoints are exposed using the SOAP over JMS transport and you are publishing your WSDL file. If you are developing an enterprise JavaBeans service implementation bean that is invoked using the SOAP over JMS transport, and you want to publish the WSDL so that the

published WSDL file contains the fully resolved JMS endpoint URL, then have wsgen tool generate the WSDL file by specifying the *-wsdl* argument. In this scenario, you must package the WSDL file with your web service application.

In addition to using the tools from the command-line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsGen` Ant task from within the Ant build environment to invoke the wsgen tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

## Procedure

1. Locate your service endpoint implementation class file.
2. Run the wsgen command to generate the portable artifacts. The wsgen tool is located in the *app_server_root*/bin/ directory.

   Windows

```
app_server_root\bin\wsgen.bat [options] service_implementation_class
```

   AIX HP-UX Linux Solaris

```
app_server_root/bin/ wsgen.sh [options] service_implementation_class
```

   (Optional) Use the following options with the wsgen command:
   - Use the **-verbose** option to see a list of generated files along with additional informational messages.
   - Use the **-keep** option to keep generated Java files.
   - Use the **-wsdl** option to generate a WSDL file. If you are developing a service implementation bean that will be invoked using the HTTP transport, then the WSDL file generated by the wsgen command-line tool during this step is optional. However, if you are developing a service implementation bean that will be invoked using the SOAP over JMS transport, then the WSDL file generated by the wsgen tool during this step is required in subsequent developing JAX-WS applications steps, so it is not optional.

   Read about wsgen to learn more about this command and additional options that you can specify.

## Results

You have the required Java artifacts to create a JAX-WS web service.

**Note:** The wsgen command does not differentiate the XML namespace between multiple XMLType annotations that have the same @XMLType name defined within different Java packages. When this scenario occurs, the following error is produced:

```
Error: Two classes have the same XML type name ....
Use @XmlType.name and @XmlType.namespace to assign different names to them...
```

This error indicates that you have classes or @XMLType.name values that have the same name, but exist within different Java packages. To prevent this error, add the @XML.Type.namespace class to the existing @XMLType annotation to differentiate between the XML types.

Solaris HP-UX

**Note:** Beginning with Sun and HP JDK Version 1.6 containing JAX-WS tooling Version 2.1.6, the behavior of the JAX-WS runtime environments and tooling has changed in how it determines which methods are exposed as web services operations in an effort to better adhere to the JAX-WS specifications. Applications that might be affected by this change include web services applications that do not specify a WSDL file or an explicit service endpoint interface (SEI). To learn more, see the exposing methods in SEI-based JAX-WS web services information.

With JAX-WS applications, the wsgen command-line tool might not locate shared class files. You can specify the location of these class files using the com.ibm.websphere.webservices.wsdl_generation_extra_classpath custom property. For more information, see the documentation about the Java virtual machine custom properties.

## Example

The following example demonstrates how to use the wsgen command to process the service endpoint implementation class to generate JAX-WS artifacts. This example EchoService service implementation class uses an explicit JavaBeans service endpoint.

1. Copy the sample `EchoServicePortTypeImpl` service implementation class file and the associated `EchoServicePortType` service interface class file into a directory. The directory must contain a directory tree structure that corresponds to the `com.ibm.was.wssample.echo` package name for the class file.

```
/* This is a sample EchoServicePortTypeImpl.java file.    */
package com.ibm.was.wssample.echo;

@javax.jws.WebService(serviceName = "EchoService", endpointInterface =
"com.ibm.was.wssample.echo.EchoServicePortType",
targetNamespace="http://com/ibm/was/wssample/echo/",
portName="EchoServicePort")

public class EchoServicePortTypeImpl implements EchoServicePortType {

 public EchoServicePortTypeImpl() {
 }

 public String invoke(String obj) {
  System.out.println(">> JAXB Provider Service:
Request received.\n");
  String str = "Failed";
  if (obj != null) {
   try {
    str = obj;
   } catch (Exception e) {
    e.printStackTrace();
   }
  }
  return str;

 }

}
```

```
/* This is a sample EchoServicePortType.java file.    */
package com.ibm.was.wssample.echo;

import javax.jws.WebMethod;
import javax.jws.WebParam;
import javax.jws.WebResult;
import javax.jws.WebService;
import javax.xml.ws.RequestWrapper;
import javax.xml.ws.ResponseWrapper;

@WebService(name = "EchoServicePortType", targetNamespace =
"http://com/ibm/was/wssample/echo/",
 wsdlLocation="WEB-INF/wsdl/Echo.wsdl")

public interface EchoServicePortType {

    /**
     *
     * @param arg0
     * @return
     *     returns java.lang.String
     */
    @WebMethod
    @WebResult(name = "response", targetNamespace =
    "http://com/ibm/was/wssample/echo/")
    @RequestWrapper(localName = "invoke", targetNamespace =
    "http://com/ibm/was/wssample/echo/",
     className = "com.ibm.was.wssample.echo.Invoke")
    @ResponseWrapper(localName = "echoStringResponse",
     targetNamespace = "http://com/ibm/was/wssample/echo/",
     className = "com.ibm.was.wssample.echo.EchoStringResponse")
    public String invoke(
        @WebParam(name = "arg0", targetNamespace =
```

```
        "http://com/ibm/was/wssample/echo/")
        String arg0);

}
```

2. Run the wsgen command from the *app_server_root*\bin\ directory. The `-cp` option specifies the location of the service implementation class file. The `-s` option specifies the directory for the generated source files. The `-d` option specifies the directory for the generated output files. When using the `-s` or `-d` options, you must first create the directory for the generated output files.

   Windows

```
app_server_root\bin\wsgen.bat -wsdl -s c:\generated_source\ -cp c:\my_application\classes\
com.ibm.was.wssample.echo.EchoServicePortTypeImpl -verbose -d c:\generated_artifacts\
```

   Linux AIX HP-UX Solaris Run the wsgen command; for example:

```
app_server_root/bin/wsgen.sh -wsdl -s c:/generated_source/ -cp c:/my_application/classes/
com.ibm.was.wssample.echo.EchoServicePortTypeImpl -verbose -d c:/generated_artifacts/
```

After generating the Java artifacts using the wsgen command, the following files are generated:

```
/generated_source/com/ibm/was/wssample/echo/EchoStringResponse.java
/generated_source/com/ibm/was/wssample/echo/Invoke.java
/generated_artifacts/EchoService.wsdl
/generated_artifacts/EchoService_schema1.xsd
/generated_artifacts/com/ibm/was/wssample/echo/EchoStringResponse.class
/generated_artifacts/com/ibm/was/wssample/echo/Invoke.class
```

The EchoStringResponse.java and Invoke.java files are the generated Java class files. The compiled versions of the generated Java files are EchoStringResponse.class and Invoke.class files. The EchoService.wsdl and EchoService_schema1.xsd files are generated because the -wsdl option was specified.

## What to do next

Complete the implementation of your JAX-WS web service application.

## Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

### Default product locations (distributed)

The following file paths are default locations. You can install the product and other components or create profiles in any directory where you have write access. Multiple installations of WebSphere Application Server - Express products or components require multiple locations. Default values for installation actions by root and nonroot users are given. If no nonroot values are specified, then the default directory values are applicable to both root and nonroot users.

*app_client_root*

*Table 188. Default installation root directories for the Application Client for IBM WebSphere Application Server.*

*This table shows the default installation root directories for the Application Client for IBM WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppClient` (Java EE Application client only)<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\Program Files\IBM\WebSphere\AppClient` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\IBM\WebSphere\AppClient` |

*app_server_root*

*Table 189. Default installation directories for WebSphere Application Server.*

*This table shows the default installation directories for WebSphere Application Server - Express.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppServer`<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppServer`<br>Windows `C:\Program Files\IBM\WebSphere\AppServer` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppServer`<br>Windows *user_home*`\IBM\WebSphere\AppServer` |

*component_root*

The component installation root directory is any installation root directory described in this topic. Some programs are for use across multiple components—in particular, the Web Server Plug-ins, the Application Client, and the IBM HTTP Server. All of these components are part of the product package.

*gskit_root*

IBM Global Security Kit (GSKit) can now be installed by any user. GSKit is installed locally inside the installing product's directory structure and is no longer installed in a global location on the target system. The following list shows the default installation root directory for Version 8 of the GSKit, where *product_root* is the root directory of the product that is installing GSKit, for example IBM HTTP Server or the web server plug-in.

AIX HP-UX Linux Solaris

*product_root*`/gsk8`

Windows

*product_root*`\gsk8`

*profile_root*

*Table 190. Default profile directories.*

*This table shows the default directories for a profile named profile_name on each distributed operating system.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppServer/profiles/`*profile_name*<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppServer/profiles/`*profile_name*<br>Windows `C:\Program Files\IBM\WebSphere\AppServer\profiles\`*profile_name* |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppServer/profiles`<br>Windows *user_home*`\IBM\WebSphere\AppServer\profiles` |

*plugins_root*

*Table 191. Default installation root directories for the Web Server Plug-ins.*

*This table shows the default installation root directories for the Web Server Plug-ins for WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/Plugins`<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/Plugins`<br>Windows `C:\Program Files\IBM\WebSphere\Plugins` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/Plugins`<br>Windows `C:\IBM\WebSphere\Plugins` |

*wct_root*

| Root | AIX `/usr/IBM/HTTPServer`<br>HP-UX Linux Solaris `/opt/IBM/HTTPServer`<br>Windows `C:\Program Files\IBM\HTTPServer` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/HTTPServer`<br>Windows `C:\IBM\HTTPServer` |

## wsgen command for JAX-WS applications

The wsgen command-line tool generates the necessary artifacts required for Java API for XML Web Services (JAX-WS) applications when starting from Java code. The generated artifacts are Java 5 compliant, making them portable across different Java versions and platforms.

When using a bottoms-up approach to develop JAX-WS web services and you are starting from a service endpoint implementation, use the wsgen tool to generate the required JAX-WS artifacts.

**Note:** The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

**Note:** WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The wsimport, wsgen, schemagen and xjc command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

The wsgen tool accepts a properly annotated service endpoint implementation using the @WebService annotation as input and generates the following artifacts:

- any additional Java Architecture for XML Binding (JAXB) classes that are required to marshal and unmarshal the message contents.
- a WSDL file if the optional -wsdl argument is specified. The wsgen tool does not automatically generate the WSDL file.

When using JAX-WS V2.2 tools, java.lang.RuntimeException and java.rmi.RemoteException references and their subclasses are no longer mapped in the WSDL file. This behavior change complies with the JAX-WS V2.1 specification conformance rule that is described in section 3.7 of the specification. This conformance rule specifies that the java.lang.RuntimeException and java.rmi.RemoteException classes and their subclasses cannot be treated as service-specific exceptions and mapped in the WSDL file.

In addition to using the tools from the command line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsGen` Ant task from within the Ant build environment to invoke the wsgen tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

**Note:** The wsgen command does not differentiate the XML namespace between multiple XMLType annotations that have the same @XMLType name defined within different Java packages. When this scenario occurs, the following error is produced:

```
Error: Two classes have the same XML type name ....
Use @XmlType.name and @XmlType.namespace to assign different names to them...
```

This error indicates you have class names or @XMLType.name values that have the same name, but exist within different Java packages. To prevent this error, add the @XML.Type.namespace class to the existing @XMLType annotation to differentiate between the XML types.

Solaris HP-UX

**Note:** Beginning with Sun and HP JDK Version 1.6 containing JAX-WS tooling Version 2.1.6, the behavior of the JAX-WS runtime environments and tooling has changed in how it determines which methods are exposed as web services operations in an effort to better adhere to the JAX-WS specifications. Applications that might be affected by this change include web services applications that do not specify a WSDL file or an explicit service endpoint interface (SEI). To learn more, see the exposing methods in SEI-based JAX-WS web services information.

With JAX-WS applications, the wsgen command-line tool might not locate shared class files. You can specify the location of these class files using the

com.ibm.websphere.webservices.wsdl_generation_extra_classpath custom property. For more information, see the documentation about the Java virtual machine custom properties.

## Syntax

The command-line syntax is:

Windows

*app_server_root*\bin\wsgen.bat [*options*] *service_implementation_class*

AIX HP-UX Linux Solaris

*app_server_root*/bin/wsgen.sh [*options*] *service_implementation_class*

## Parameters

The *service_implementation_class* name is the only parameter that is required. The following parameters are optional for the wsgen command:

**-classpath <path>**
Specifies the location of the service implementation class.

**-cp <path>**
Specifies the location of the service implementation class. This parameter is the same as *-classpath <path>*.

**-d <directory>**
Specifies where to place the generated output files.

**-extension**
Specifies whether to enable custom extensions for functionality not specified by the JAX-WS specification. Use of the extensions can result in applications that are not portable or do not interoperate with other implementations.

**-help**
Displays the help menu.

**-keep**
Specifies whether to keep the generated source files.

**-r <directory>**
This parameter is only used with the -wsdl parameter. Specifies where to place the generated WSDL file.

**-s <directory>**
Specifies the directory to place the generated source files.

**-verbose**
Specifies to output messages about what the compiler is doing.

**-version**
Prints the version information. If you specify this option, only the version information is output and normal command processing does not occur.

**-wsdl [:protocol]**
By default, the wsgen tool does not generate a WSDL file. This optional parameter causes wsgen to generate a WSDL file and is typically only used to enable a developer to review a WSDL file before the endpoint is deployed. The `protocol` is optional and specifies the protocol used in the `wsdl:binding`. Valid values for `protocol` are `soap 1.1` and `Xsoap 1.2`. The default value is `soap 1.1`. The `Xsoap 1.2` value is not standard and is only used with the *-extension* option.

**-servicename <name>**
This parameter is only used with the -wsdl option. Specifies a `wsdl:service` name to be generated in the WSDL file. For example,

```
-service name "{http://mynamespace/}MyService"
```

**-portname**
This parameter is only used with the -wsdl option. Specifies a `wsdl:port` name to be generated in the WSDL file. For example,

```
-portname "{http://mynamespace/}MyPort"
```

### Mapping between Java language, WSDL and XML for JAX-WS applications

Data for Java API for XML Web Services (JAX-WS) applications flows as extensible Markup Language (XML). JAX-WS applications use mappings to describe the data conversion between the Java language and extensible Markup Language (XML) technologies, including XML Schema, Web Services Description Language (WSDL) and SOAP that are supported by the application server.

For web services based on the JAX-WS programming model, mappings between the Java language and XML are specified by the JAX-WS specification and the Java Architecture for XML Binding (JAXB) specification for data bindings. JAX-WS leverages the JAXB API and tools as the binding technology for mappings between Java objects and XML documents. JAX-WS tooling relies on JAXB tooling for default data binding for two-way mappings between Java objects and XML documents.

The JAX-WS specification describes the mapping between Web Services Description Language (WSDL) files and the Java language. The supported mappings include WSDL-to-Java mappings and Java-to-WSDL mappings. WSDL 1.1 is required by the JAX-WS 2.0 specification. You can use annotations to customize the mapping from Java artifacts to their associated WSDL components. Refer to the JAX-WS specification for details describing the WSDL-to-Java mappings and Java-to-WSDL mappings.

Data binding mappings used by the JAX-WS programming model are described by the JAXB specification. Refer to the JAXB specification for details that describe the JAXB mappings for the Java representation of XML content, including the default and custom bindings between XML schema to Java representations.

## Enabling MTOM for JAX-WS web services

With Java API for XML-Based Web Services (JAX-WS), you can send binary attachments such as images or files along with web services requests. JAX-WS adds support for optimized transmission of binary data as specified by the SOAP Message Transmission Optimization Mechanism (MTOM) specification.

### About this task

JAX-WS supports the use of SOAP Message Transmission Optimized Mechanism (MTOM) for sending binary attachment data. By enabling MTOM, you can send and receive binary data optimally without incurring the cost of data encoding needed to embed the binary data in an XML document.

The application server supports sending attachments using MTOM only for JAX-WS applications. This product also provides the ability to provide attachments with Web Services Security SOAP messages by using the new MTOM and XOP standards.

JAX-WS applications can send binary data as base64 or hexBinary encoded data contained within the XML document. However, to take advantage of the optimizations provided by MTOM, enable MTOM to send binary base64 data as attachments contained outside the XML document. MTOM optimization is not enabled by default. JAX-WS applications require separate configuration of both the client and the server artifacts to enable MTOM support.

## Procedure

1. Develop Java artifacts for your JAX-WS application that includes an XML schema or Web Services Description Language (WSDL) file that represents your web services application data that includes a binary attachment.
   a. If you are starting with a WSDL file, develop Java artifacts from a WSDL file by using the wsimport command to generate the required JAX-WS portable artifacts.
   b. If you are starting with JavaBeans components, develop Java artifacts for JAX-WS applications and optionally generate a WSDL file using the wsgen command. The XML schema or WSDL file includes a `xsd:base64Binary` or `xsd:hexBinary` element definition for the binary data.
   c. You can also include the `xmime:expectedContentTypes` attribute on the element to affect the mapping by JAXB.
2. Enable MTOM on your endpoint implementation class using one of the following methods:
   - Use the @MTOM annotation on the endpoint.

     To enable MTOM on an endpoint, use the @MTOM (javax.xml.ws.soap.MTOM) annotation on the endpoint. The @MTOM annotation has two parameters, enabled and threshold. The enabled parameter has a boolean value and indicates if MTOM is enabled for the JAX-WS endpoint. The threshold parameter has an integer value, that must be greater than or equal to zero. When MTOM is enabled, any binary data whose size, in bytes, exceeds the threshold value is XML-binary Optimized Packaging (XOP) encoded or sent as an attachment. When the message size is less than the threshold value, the message is inlined in the XML document as either base64 or hexBinary data.

     The following example snippet illustrates adding the @MTOM annotation so that MTOM is enabled for the JAX-WS `MyServiceImpl` endpoint and specifies a threshold value of 2048 bytes:

```
@MTOM(enabled=true, threshold=2048)
@WebService
public class MyServiceImpl {
...
}
```

     Additionally, you can use the @BindingType (javax.xml.ws.BindingType) annotation on an endpoint implementation class to specify that the endpoint supports one of the MTOM binding types so that the response messages are MTOM-enabled. The javax.xml.ws.SOAPBinding class defines two different constants, `SOAP11HTTP_MTOM_BINDING` and `SOAP12HTTP_MTOM_BINDING` that you can use for the value of the @BindingType annotation; for example:

```
// This example is for SOAP version 1.1.
@BindingType(value = SOAPBinding.SOAP11HTTP_MTOM_BINDING)
@WebService
public class MyServiceImpl {
...
}

// This example is for SOAP version 1.2.
@BindingType(value = SOAPBinding.SOAP12HTTP_MTOM_BINDING)
@WebService
public class MyServiceImpl {
...
}
```

     The presence and value of an @MTOM annotation overrides the value of the @BindingType annotation. For example, if the @BindingType indicates MTOM is enabled, but an @MTOM annotation is present with an enabled value of `false`, then MTOM is not enabled.

   - Use the `<enable-mtom>` and `<mtom-threshold>` deployment descriptor elements.

     You can use the `<enable-mtom>` and `<mtom-threshold>` elements within the `<port-component>` element in the webservices.xml deployment descriptor as an alternative to using the @MTOM annotation on the service endpoint implementation class; for example:

```
<port-component>
   <port-component-name>MyPort1</port-component-name>
   <enable-mtom>true</enable-mtom>
   <mtom-threshold>2048</mtom-threshold>
   <service-impl-bean>
    <servlet-link>MyPort1ImplBean</servlet-link>
   </service-impl-bean>
</port-component>
```

**Note:** The deployment descriptor elements take precedence over the corresponding attributes in the MTOM annotation. For example, if the `enabled` attribute is set to `true` in the annotation, but the `<enable-mtom>` element is set to `false` in the `webservices.xml` file, MTOM is not enabled for the corresponding endpoint.

3. Enable MTOM on your client to optimize the binary messages that are sent from the client to the server. Use one of the following methods to enable MTOM on your client:
   - Enable MTOM on a Dispatch client.

     The following examples use SOAP version 1.1.

     The first method uses SOAPBinding.setMTOMEnabled(); for example:

```
SOAPBinding binding = (SOAPBinding)dispatch.getBinding();
    binding.setMTOMEnabled(true);
```

     The second method uses Service.addPort; for example:

```
    Service svc = Service.create(serviceName);
    svc.addPort(portName,SOAPBinding.SOAP11HTTP_MTOM_BINDING,endpointUrl);
```

     The third method uses MTOMFeature; for example:

```
   MTOMFeature mtom = new MTOMFeature(true, 2048);
    Service svc = Service.create(serviceName);
    svc.addPort(portName, SOAPBinding.SOAP11_HTTP_BINDING, endpointUrl);
    Dispatch<Source> dsp = svc.createDispatch(portName, Source.class, Service.Mode.PAYLOAD, mtom);
```

   - Enable MTOM on a Dynamic Proxy client.

```
// Create a BindingProvider bp from a proxy port.
  Service svc = Service.create(serviceName);
  MtomSample proxy = svc.getPort(portName, MtomSample.class);
  BindingProvider bp = (BindingProvider) proxy;

  //Enable MTOM using the SOAPBinding.
  MtomSample proxy = svc.getPort(portName, MtomSample.class);
  BindingProvider bp = (BindingProvider) proxy;
  SOAPBinding binding = (SOAPBinding) bp.getBinding();
  binding.setMTOMEnabled(true);

  //Or, you can enable MTOM with the MTOMFeature.
  MTOMFeature mtom = new MTOMFeature();
  MtomSample proxy = svc.getPort(portName, MtomSample.class, mtom);
```

   - Enable MTOM on your client using the @MTOM annotation; for example:

```
public class MyClientApplication {

    // Enable MTOM for a port-comonent-ref resource injection.
     @MTOM(enabled=true, threshold=1024)
     @WebServiceRef(MyService.class)
     private MyPortType myPort;
    ...
}
```

   - Enable MTOM on your client using deployment descriptor elements within a port-component-ref element; for example:

```
<service-ref>
    <service-ref-name>service/MyPortComponentRef</service-ref-name>
    <service-interface>com.example.MyService</service-ref-interface>
    <port-component-ref>
        <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
        <enable-mtom>true</enable-mtom>
        <mtom-threshold>1024</mtom-threshold>
    </port-component-ref>
</service-ref>
```

     **Note:** The deployment descriptor elements take precedence over the corresponding attributes in the MTOM annotation. For example, if the `enabled` attribute is set to `true` in the annotation, but the `<enable-mtom>` element is set to `false` in the deployment descriptor entry for the service-ref of the client, MTOM is not enabled for that service reference.

## Results

You have developed a JAX-WS web services server and client application that optimally sends and receives binary data using MTOM.

## Example

The following example illustrates enabling MTOM support on both the web services client and server endpoint when starting with an WSDL file.

1. Locate the WSDL file containing an `xsd:base64Binary` element. The following example is a portion of a WSDL file that contains an `xsd:base64Binary` element.

```
<types>
  ........
  <xs:complexType name="ImageDepot">
      <xs:sequence>
          <xs:element name="imageData"
                      type="xs:base64Binary"
                      xmime:expectedContentTypes="image/jpeg"/>

      </xs:sequence>
  </xs:complexType>
  ........
</types>
```

2. Run the **wsimport** command from the *app_server_root*\bin\ directory against the WSDL file to generate a set of JAX-WS portable artifacts.

   Windows

   *app_server_root*\bin\wsimport.bat *<wsdl_url>*

   AIX HP-UX Linux Solaris

   *app_server_root*/bin/wsimport.sh *<wsdl_url>*

   Depending on the `expectedContentTypes` value contained in the WSDL file, the JAXB artifacts generated are in the Java type as described in the following table:

*Table 194. Mapping of MIME type and Java type. Describes the mapping between MIME types and Java types.*

| MIME Type | Java Type |
|---|---|
| image/gif | java.awt.Image |
| image/jpeg | java.awt.Image |
| text/plain | java.lang.String |
| text/xml | javax.xml.transform.Source |
| application/xml | javax.xml.transform.Source |
| */* | javax.activation.DataHandler |

3. Use the JAXB artifacts in the same manner as in any other JAX-WS application. Use these beans to send binary data from both the Dispatch and the Dynamic Proxy client APIs.
4. Enable MTOM on a Dispatch client.

```
//Create the Dispatch instance.
        JAXBContext jbc = JAXBContext.newInstance("org.apache.axis2.jaxws.sample.mtom");
        Dispatch<Object> dispatch = svc.createDispatch(portName, jbc, Service.Mode.PAYLOAD);

//Enable MTOM.
        SOAPBinding binding = (SOAPBinding) dispatch.getBinding();
        binding.setMTOMEnabled(true);
```

5. Enable MTOM on a Dynamic Proxy client.

```
//Create the Dynamic Proxy instance.
        Service svc = Service.create(serviceName);
        MtomSample proxy = svc.getPort(portName, MtomSample.class);

//Enable MTOM.
        BindingProvider bp = (BindingProvider) proxy;
        SOAPBinding binding = (SOAPBinding) bp.getBinding();
        binding.setMTOMEnabled(true);
```

   Now that you have enabled the JAX-WS client for MTOM, messages sent to the server have MTOM enabled. However, for the server to respond back to the client using MTOM, you must enable MTOM on the endpoint.
6. Enable MTOM on the endpoint implementation class.

```
@MTOM(enabled, threshold=4096)
@WebService (endpointInterface="org.apache.axis2.jaxws.sample.mtom.MtomSample")

public class MtomSampleService implements MtomSample {
   ....
}
```

The `jaxax.xml.ws.SOAPBinding` class has a static member for each of the supported binding types. Include either the `SOAP11HTTP_MTOM_BINDING` or the `SOAP12HTTP_MTOM_BINDING` as the value for the `@BindingType` annotation. This value enables all server responses to have MTOM enabled.

When you enable MTOM on the server and the client, the binary data that represents the attachment is included as a Multipurpose Internet Mail Extensions (MIME) attachment to the SOAP message. Without MTOM, the same data is encoded in the format that describes the XML schema, either base64 or hexadecimal encoding, and included inline in the XML document.

This example illustrates an MTOM enabled SOAP version 1.1 message with an attachment. The `type` and `content-type` attributes both have the value, `application/xop+xml`, which indicates that the message was successfully optimized using XML-binary Optimized packaging (XOP) when MTOM was enabled. This example demonstrates how the optimized message looks on the wire with MTOM enabled.

```
... other transport headers ...
Content-Type: multipart/related; boundary=MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812;
type="application/xop+xml"; start="
<0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>"; start-info="text/xml"; charset=UTF-8

--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: application/xop+xml; charset=UTF-8; type="text/xml";
content-transfer-encoding: binary
content-id:
   <0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>

<?xml version="1.0" encoding="UTF-8"?>
         <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
            <soapenv:Header/>
            <soapenv:Body>
               <sendImage xmlns="http://org/apache/axis2/jaxws/sample/mtom">
                  <input>
                     <imageData>
                        <xop:Include xmlns:xop="http://www.w3.org/2004/08/xop/include"
href="cid:1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org"/>
                     </imageData>
                  </input>
               </sendImage>
            </soapenv:Body>
         </soapenv:Envelope>
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: text/plain
content-transfer-encoding: binary
content-id:
         <1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org>

... binary data goes here ...
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812--
```

In contrast, this example demonstrates a SOAP version 1.1 message on the wire without MTOM enabled. The binary data is included in the body of the SOAP message, and the SOAP message is not optimized.

```
... other transport headers ...
Content-Type: text/xml; charset=UTF-8

<?xml version="1.0" encoding="UTF-8"?>
   <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
      <soapenv:Header/>
      <soapenv:Body>
         <sendImage xmlns="http://org/apache/axis2/jaxws/sample/mtom">
            <input>
               <imageData>R0lGAD1 ... more base64 encoded data ... KTJk8giAAA7</imageData>
            </input>
         </sendImage>
      </soapenv:Body>
   </soapenv:Envelope>
```

For additional information, refer to the Samples section of the Information Center which includes a sample that demonstrates the use of MTOM with JAX-WS web services.

## Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

### Default product locations (distributed)

The following file paths are default locations. You can install the product and other components or create profiles in any directory where you have write access. Multiple installations of WebSphere Application Server - Express products or components require multiple locations. Default values for installation actions by root and nonroot users are given. If no nonroot values are specified, then the default directory values are applicable to both root and nonroot users.

*app_client_root*

*Table 195. Default installation root directories for the Application Client for IBM WebSphere Application Server.*

*This table shows the default installation root directories for the Application Client for IBM WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppClient` (Java EE Application client only)<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\Program Files\IBM\WebSphere\AppClient` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\IBM\WebSphere\AppClient` |

*app_server_root*

*Table 196. Default installation directories for WebSphere Application Server.*

*This table shows the default installation directories for WebSphere Application Server - Express.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppServer`<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppServer`<br>Windows `C:\Program Files\IBM\WebSphere\AppServer` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppServer`<br>Windows *user_home*`\IBM\WebSphere\AppServer` |

*component_root*

The component installation root directory is any installation root directory described in this topic. Some programs are for use across multiple components—in particular, the Web Server Plug-ins, the Application Client, and the IBM HTTP Server. All of these components are part of the product package.

*gskit_root*

IBM Global Security Kit (GSKit) can now be installed by any user. GSKit is installed locally inside the installing product's directory structure and is no longer installed in a global location on the target system. The following list shows the default installation root directory for Version 8 of the GSKit, where *product_root* is the root directory of the product that is installing GSKit, for example IBM HTTP Server or the web server plug-in.

AIX HP-UX Linux Solaris

*product_root*/gsk8

Windows

*product_root*\gsk8

### *profile_root*

*Table 197. Default profile directories.*

*This table shows the default directories for a profile named profile_name on each distributed operating system.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/AppServer/profiles/*profile_name*<br>HP-UX Linux Solaris /opt/IBM/WebSphere/AppServer/profiles/*profile_name*<br>Windows C:\Program Files\IBM\WebSphere\AppServer\profiles*profile_name* |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/AppServer/profiles<br>Windows *user_home*\IBM\WebSphere\AppServer\profiles |

### *plugins_root*

*Table 198. Default installation root directories for the Web Server Plug-ins.*

*This table shows the default installation root directories for the Web Server Plug-ins for WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/Plugins<br>HP-UX Linux Solaris /opt/IBM/WebSphere/Plugins<br>Windows C:\Program Files\IBM\WebSphere\Plugins |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/Plugins<br>Windows C:\IBM\WebSphere\Plugins |

### *wct_root*

*Table 199. Default installation root directories for the WebSphere Customization Toolbox.*

*This table shows the default installation root directories for the WebSphere Customization Toolbox.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/Toolbox<br>HP-UX Linux Solaris /opt/IBM/WebSphere/Toolbox<br>Windows C:\Program Files\IBM\WebSphere\Toolbox |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/Toolbox<br>Windows C:\IBM\WebSphere\Toolbox |

### *web_server_root*

*Table 200. Default installation root directories for the IBM HTTP Server.*

*This table shows the default installation root directories for the IBM HTTP Server.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/HTTPServer`<br>HP-UX Linux Solaris `/opt/IBM/HTTPServer`<br>Windows `C:\Program Files\IBM\HTTPServer` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/HTTPServer`<br>Windows `C:\IBM\HTTPServer` |

# Enforcing adherence to WSDL bindings in JAX-WS web services

Java API for XML-Based Web Services (JAX-WS) Version 2.1 introduced the concept of *features* as a way to programmatically control specific functions and behaviors. The RespectBindingFeature is one of the supported standard features. You can use the RespectBindingFeature to control whether a JAX-WS implementation is required to respect the contents of a Web Services Description Language (WSDL) binding that is associated with an endpoint.

## About this task

While WSDL documents are often used during the development process, the actual enforcement of the use of the WSDL document specifications, when they are provided, at run time has not been well defined in versions of the JAX-WS specification previous to Version 2.1. The JAX-WS Version 2.1 specification added the feature, RespectBindingFeature, to clarify the impact of the wsdl:binding in a JAX-WS runtime environment.

Enabling the feature, RespectBindingFeature, causes the JAX-WS runtime environment to inspect the wsdl:binding for an endpoint at run time to ensure that the binding of service endpoint interface (SEI) parameters and return values is respected. Additionally, this feature ensures that all required wsdl:binding extensions are either understood and used by the runtime environment, or the extensions have been explicitly disabled by the application. Your JAX-WS application can disable a specific wsdl:binding extension that has a defined WebServiceFeature interface by using the appropriate annotation that is associated with that feature, using an API that accepts the javax.xml.ws.WebServiceFeature interface, or configuring the deployment descriptors.

When the RespectBindingFeature feature is not enabled, which is the default, the runtime environment can choose whether any part of the wsdl:binding is enforced.

## Procedure

1. Develop Java artifacts for your JAX-WS application that includes a Web Services Description Language (WSDL) file that represents your web services application.
   a. If you are starting with a WSDL file, develop Java artifacts from a WSDL file by using the wsimport command to generate the required JAX-WS portable artifacts.
   b. If you are starting with JavaBeans components, develop Java artifacts for JAX-WS applications and generate a WSDL file using the wsgen command.
2. If you want to enable RespectBindingFeature on your endpoint implementation class, use one of the following methods:
   - Use the @RespectBinding annotation on the endpoint.

     To enable RespectBinding on an endpoint, use the @RespectBinding (javax.xml.ws.RespectBinding) annotation on the endpoint. The @RespectBinding annotation has only one parameter, `enabled`.

This parameter is optional. The enabled parameter has a Boolean value and indicates if RespectBindingFeature is enabled for the JAX-WS endpoint.

The following example snippet illustrates adding the @RespectBinding annotation for the JAX-WS `MyServiceImpl` endpoint:

```
@RespectBinding(enabled=true))
@WebService
public class MyServiceImpl {
...
}
```

- Use the `<respect-binding>` deployment descriptor element.

  You can use the `<respect-binding>` element within the `<port-component>` element in the webservices.xml deployment descriptor as an alternative to using the @RespectBinding annotation on the service endpoint implementation class; for example:

```
<port-component>
     <port-component-name>MyPort1</port-component-name>
     <respect-binding>
         <enabled>true</enabled>
     </respect-binding>
     <service-impl-bean>
         <servlet-link>MyPort1ImplBean</servlet-link>
     </service-impl-bean>
</port-component>
```

3. If you want to enable RespectBindingFeature on your client, use one of the following methods:
   - Enable RespectBindingFeature on a dispatch client; for example:

```
RespectBindingFeature respectBinding = new RespectBindingFeature();
Service svc = Service.create(serviceName);
svc.addPort(portName, SOAPBinding.SOAP11_HTTP_BINDING, endpointUrl);
Dispatch<Source> dsp = svc.createDispatch(portName, Source.class, Service.Mode.PAYLOAD, respectBinding);
```

   - Enable RespectBindingFeature on a dynamic proxy client; for example:

```
// Create a dynamic proxy with RespectBinding enabled.
  Service svc = Service.create(serviceName);
  RespectBindingFeature respectBinding = new RespectBindingFeature();
  RespectBindingSample proxy = svc.getPort(portName, RespectBindingSample.class, respectBinding);
```

   - Enable RespectBindingFeature on your client using the @RespectBinding annotation; for example:

```
public class MyClientApplication {

               // Enable RespectBinding for a port-component-ref resource injection.
                   @RespectBinding(enabled=true)
                   @WebServiceRef(MyService.class)
                   private MyPortType myPort;
               ...
}
```

   - Enable RespectBindingFeature on your client using deployment descriptor elements within a port-component-ref element; for example:

```
<service-ref>
    <service-ref-name>service/MyPortComponentRef</service-ref-name>
    <service-interface>com.example.MyService</service-ref-interface>
    <port-component-ref>
        <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
        <respect-binding>
            <enabled>true</enabled>
        </respect-binding>
    </port-component-ref>
</service-ref>
```

### Results

By implementing the feature, RespectBindingFeature, you have specified to enforce adherence of the contents of a WSDL binding that is associated with an endpoint for your JAX-WS application.

## Developing a webservices.xml deployment descriptor for JAX-WS applications

*Deployment descriptors* are standard text files, formatted using XML and packaged in a web services application. You can optionally use the webservices.xml deployment descriptor to augment or override application metadata specified in annotations within Java API for XML-Based Web Services (JAX-WS) web services.

## About this task

Similar to Java API for XML-based RPC (JAX-RPC) Web services, you can use deployment descriptors to describe JAX-WS web services. For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

A JAX-WS web service requires that you annotate your Java class with the `javax.jws.WebService` annotation or the `javax.jws.WebServiceProvider` annotation for Provider endpoints. You can use server-side deployment descriptors to override corresponding attributes of the annotation or to enhance information in annotations. There is a defined relationship between the deployment descriptor elements and the @WebService and @WebServiceProvider annotations. Refer to section 5.3 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification, Version 1.2 for detailed information regarding the deployment descriptor elements and the mapping to the @WebService and @WebServiceProvider annotation attributes. There are also elements in the `webservice.xml` deployment descriptor that map to other annotations. For example, the deployment descriptor element <protocol-binding> maps to the @BindingType annotation, and the deployment descriptor element <enable-mtom> maps to the @MTOM annotation. For more information regarding the web services deployment descriptor elements, see section 7.1 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification.

## Procedure

Use assembly tools to generate the `webservice.xml` deployment descriptor.

## Results

You have deployment descriptor templates that you can use to override JAX-WS annotation attributes or specify attributes that are not defined by the annotation.

## Example

In the following example, the service implementation class for a JAX-WS web service includes the @WebService annotation:

```
@WebService(wsdlLocation="http://myhost.com/location/of/the/wsdl/ExampleService.wsdl")
```

The associated `webservices.xml` deployment descriptor specifies a different filename for the WSDL document as follows:

```
<webservices>
<webservice-description>
<webservice-description-name>ExampleService</webservice-description-name>
<wsdl-file>META-INF/wsdl/ExampleService.wsdl</wsdl-file>
...
</webservice-description>
</webservices>
```

The value that is specified in the deployment descriptor, `META-INF/wsdl/ExampleService.wsdl`, overrides the annotation value.

## What to do next

Configure the `webservice.xml` deployment descriptor. After you configure the deployment descriptors, you must assemble the Web services application for deployment.

## Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

## Default product locations (distributed)

The following file paths are default locations. You can install the product and other components or create profiles in any directory where you have write access. Multiple installations of WebSphere Application Server - Express products or components require multiple locations. Default values for installation actions by root and nonroot users are given. If no nonroot values are specified, then the default directory values are applicable to both root and nonroot users.

*app_client_root*

*Table 201. Default installation root directories for the Application Client for IBM WebSphere Application Server.*

*This table shows the default installation root directories for the Application Client for IBM WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppClient` (Java EE Application client only)<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\Program Files\IBM\WebSphere\AppClient` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\IBM\WebSphere\AppClient` |

*app_server_root*

*Table 202. Default installation directories for WebSphere Application Server.*

*This table shows the default installation directories for WebSphere Application Server - Express.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppServer`<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppServer`<br>Windows `C:\Program Files\IBM\WebSphere\AppServer` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppServer`<br>Windows *user_home*`\IBM\WebSphere\AppServer` |

*component_root*

The component installation root directory is any installation root directory described in this topic. Some programs are for use across multiple components—in particular, the Web Server Plug-ins, the Application Client, and the IBM HTTP Server. All of these components are part of the product package.

*gskit_root*

IBM Global Security Kit (GSKit) can now be installed by any user. GSKit is installed locally inside the installing product's directory structure and is no longer installed in a global location on the target system. The following list shows the default installation root directory for Version 8 of the GSKit, where *product_root* is the root directory of the product that is installing GSKit, for example IBM HTTP Server or the web server plug-in.

AIX HP-UX Linux Solaris

*product_root*`/gsk8`

Windows

*product_root*`\gsk8`

*profile_root*

*Table 203. Default profile directories.*

*This table shows the default directories for a profile named profile_name on each distributed operating system.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/AppServer/profiles/*profile_name*<br>HP-UX Linux Solaris /opt/IBM/WebSphere/AppServer/profiles/*profile_name*<br>Windows C:\Program Files\IBM\WebSphere\AppServer\profiles*profile_name* |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/AppServer/profiles<br>Windows *user_home*\IBM\WebSphere\AppServer\profiles |

*plugins_root*

*Table 204. Default installation root directories for the Web Server Plug-ins.*

*This table shows the default installation root directories for the Web Server Plug-ins for WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/Plugins<br>HP-UX Linux Solaris /opt/IBM/WebSphere/Plugins<br>Windows C:\Program Files\IBM\WebSphere\Plugins |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/Plugins<br>Windows C:\IBM\WebSphere\Plugins |

*wct_root*

*Table 205. Default installation root directories for the WebSphere Customization Toolbox.*

*This table shows the default installation root directories for the WebSphere Customization Toolbox.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/Toolbox<br>HP-UX Linux Solaris /opt/IBM/WebSphere/Toolbox<br>Windows C:\Program Files\IBM\WebSphere\Toolbox |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/Toolbox<br>Windows C:\IBM\WebSphere\Toolbox |

*web_server_root*

*Table 206. Default installation root directories for the IBM HTTP Server.*

*This table shows the default installation root directories for the IBM HTTP Server.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/HTTPServer<br>HP-UX Linux Solaris /opt/IBM/HTTPServer<br>Windows C:\Program Files\IBM\HTTPServer |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/HTTPServer<br>Windows C:\IBM\HTTPServer |

# Completing the JavaBeans implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) web service, you must complete the JavaBeans implementation to assemble a web application archive (WAR) file. The resulting WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

## Before you begin

Generate Java artifacts for JAX-WS applications and optionally generate a WSDL file using the wsgen command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS web services.

## About this task

For JAX-WS applications, complete the JavaBeans implementation by writing your business application.

## Procedure

1. Write the JavaBeans implementation. The JavaBeans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

## Results

You have now written your JavaBeans implementation to complete your web service application.

## What to do next

After completing the JavaBeans implementation, assemble your web services application.

# Completing the EJB implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file. The resulting JAR file contains the Enterprise JavaBeans implementation and the supported classes created from the tooling.

## Before you begin

Generate Java artifacts for JAX-WS applications and optionally generate a WSDL file using the **wsgen** command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS web services.

### About this task

For JAX-WS applications, complete the enterprise beans implementation by writing your business application.

### Procedure

1. Write the enterprise beans implementation. The enterprise beans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

### Results

You have now written your enterprise beans implementation to complete your web service application.

### What to do next

After completing the enterprise beans implementation, assemble your web services application.

---

# Developing JAX-WS web services with WSDL files (top down)

## Setting up a development environment for web services

The application server provides command-line tools to develop web services clients and implementations that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. You must set up your development environment before you start developing web services.

### Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information on installing the application server, read about installing your application server environment.

### About this task

Set up a web services development environment by completing the following actions.

### Procedure

1. Set up the environment.

   Windows Run the `setupCmdLine.bat` command from the *`/profile_root/<application_server>/bin`* directory.

   Linux AIX HP-UX Solaris Operating systems such as AIX or Linux ***source*** the script to the parent shell to inherit the exported variables by running this command:

```
. ./setupCmdLine.sh  (Notice the space between the periods.)
```

   from the *`. /profile_root/<application_server>/bin`* directory.

   You can set `WAS_USER_SCRIPT` to *`profile_root`*`\<application_server>\bin\setupCmdLine.bat`, which has the same effect as running the setupCmdLine command.

2. Configure the path. You can add the WebSphere and Java `bin` directories to your path by typing:

   Windows

```
set PATH=%WAS_PATH%;%PATH%
```

   AIX HP-UX Solaris Linux

```
export PATH=$WAS_PATH:$PATH
```

### Results

You have set up an environment so that you can develop Web services.

### What to do next

Implement web services applications. See the task overview for implementing web services applications information to learn about how to develop and implement a Java EE web service.

## Generating Java artifacts for JAX-WS applications from a WSDL file

Use JAX-WS tools to generate the Java artifacts that are needed to develop JAX-WS web services when starting with a Web Services Description Language (WSDL) file.

### Before you begin

When using a top-down development approach to developing Java API for XML-Based Web Services (JAX-WS) web services by starting with a Web Services Description Language (WSDL) file, you must obtain the Uniform Resource Locator (URL) of the WSDL file.

Windows If the WSDL file is a local file, the URL looks like this example: file:*drive:**path**file_name*.wsdl.

Linux AIX HP-UX Solaris If the WSDL file is a local file, the URL looks like this example: file:/*path*/*file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

### About this task

You can use the JAX-WS tool, wsimport, to process a WSDL file and generate portable Java artifacts that are used to create a web service. The portable Java artifacts created using the wsimport tool are:

- Service endpoint interface (SEI)
- Service class
- Exception class that is mapped from the `wsdl:fault` class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types

**Note:** The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

**Note:** WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The wsimport, wsgen, schemagen and xjc command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

In addition to using the tools from the command-line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsImport` Ant task from within the Ant build environment to invoke the wsimport tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

## Procedure

Run the wsimport command to generate the portable client artifacts. The wsimport tool is located in the *app_server_root*\bin\ directory.

Windows

*app_server_root*\bin**wsimport.bat** ***wsdl_URL***

AIX HP-UX Linux Solaris

*app_server_root*/bin/**wsimport.sh** ***wsdl_URL***

(Optional) Use the following options with the wsimport command:

- Use the **-verbose** option to see a list of generated files when you run the command.
- Use the **-keep** option to keep generated Java files.
- Use the **-wsdlLocation** option to specify the location of the WSDL file.

  **Note:** A best practice for ensuring that you produce a JAX-WS web services client enterprise archive (EAR) file that is portable to other systems is to package the WSDL document within the application module such as a web services client Java archive (JAR) file or a web application archive (WAR) file. You can specify a relative URI for the location of your WSDL file by using the `-wsdllocation` annotation attribute. For example, if your `MyService.wsdl` file is located in the `META-INF/wsdl/` directory, then run the wsimport tool and use the `-wsdllocation` option to specify the value to be used for the location of the WSDL file. This ensures that the generated artifacts contain the correct `-wsdllocation` information needed when the application is loaded into the administrative console; for example:

```
wsimport -keep -wsdllocation=META-INF/wsdl/MyService.wsdl
```

- Use the **-b** option if you are using WSDL or schema customizations to specify external binding files that contain your customizations.

  You can customize the bindings in your WSDL file to enable asynchronous mappings or attachments. To generate asynchronous interfaces, add the client-side only customization `enableAsyncMapping` binding declaration to the `wsdl:definitions` element or in an external binding file that is defined in the WSDL file. Use the `enableMIMEContent` binding declaration in your custom client or server binding file to enable or disable the default mime:content mapping rules. For additional information on custom binding declarations, see chapter 8 the JAX-WS specification.

Read about the wsimport command to learn more about this command and additional options that you can specify.

## Results

You have the required Java artifacts to create a JAX-WS web service. To learn more about the usage, syntax, and parameters for the wsimport command, see the wsimport command for JAX-WS applications documentation.

## Example

The following example illustrates how the wsimport command is used to process the sample Ping WSDL file to generate portable artifacts.

1. Copy the following `ping.wsdl` WSDL file to a temporary directory.

```
<?xml version="1.0" encoding="UTF-8"?>
<!--
 * This program can be used, run, copied, modified and distributed
 * without royalty for the purpose of developing, using, marketing, or distributing.
 -->
<wsdl:definitions xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
 xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
 xmlns:tns="http://com/ibm/was/wssample/sei/ping/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema" name="PingService"
 targetNamespace="http://com/ibm/was/wssample/sei/ping/">
 <wsdl:types>
  <xsd:schema
   targetNamespace="http://com/ibm/was/wssample/sei/ping/"
   xmlns:xsd="http://www.w3.org/2001/XMLSchema">

   <xsd:element name="pingStringInput">
    <xsd:complexType>
     <xsd:sequence>
      <xsd:element name="pingInput" type="xsd:string" />
     </xsd:sequence>
    </xsd:complexType>
   </xsd:element>
  </xsd:schema>
 </wsdl:types>
 <wsdl:message name="pingOperationRequest">
  <wsdl:part element="tns:pingStringInput" name="parameter" />
 </wsdl:message>
 <wsdl:portType name="PingServicePortType">
  <wsdl:operation name="pingOperation">
   <wsdl:input message="tns:pingOperationRequest" />

  </wsdl:operation>
 </wsdl:portType>
 <wsdl:binding name="PingSOAP" type="tns:PingServicePortType">
  <soap:binding style="document"
   transport="http://schemas.xmlsoap.org/soap/http" />
  <wsdl:operation name="pingOperation">
   <soap:operation soapAction="pingOperation" style="document" />
   <wsdl:input>
    <soap:body use="literal" />
   </wsdl:input>
  </wsdl:operation>
 </wsdl:binding>
 <wsdl:service name="PingService">
  <wsdl:port binding="tns:PingSOAP" name="PingServicePort">
   <soap:address
    location="http://localhost:9080/WSSampleSei/PingService" />
  </wsdl:port>
 </wsdl:service>
</wsdl:definitions>
```

2. Run the wsimport command from the *app_server_root*\bin\ directory.

   Windows

```
app_server_root\bin\wsimport.bat -keep -verbose ping.wsdl
```

   Linux AIX HP-UX Solaris Operating systems such as AIX or Linux *source* the script to the parent shell to inherit the exported variables by running the following command:

```
. ./setupCmdLine.sh  (Notice the space between the periods.)
```

   from the . */app_server_root*>/bin directory. Run the wsimport command,

```
app_server_root/bin/wsimport.sh -keep -verbose ping.wsdl
```

After generating the template files using the wsimport command, the following files are generated:

```
com\ibm\was\wssample\sei\ping\ObjectFactory.java
com\ibm\was\wssample\sei\ping\package-info.java
com\ibm\was\wssample\sei\ping\PingServicePortType.java
com\ibm\was\wssample\sei\ping\PingStringInput.java
com\ibm\was\wssample\sei\ping\PingService.java
```

The `ObjectFactory.java` file contains factory methods for each Java content interface and Java element interface generated in the associated ping package. The `package-info.java` file takes the targetNamespace value and creates the directory structure. The `PingServicePortType.java` file is the

generated service endpoint interface (SEI) class that contains the `ping` method definition. The `PinStringInput.java` file contains the JAXB generated type values which are Java classes mapped from XML schema types. The `PingService.java` file is the generated service provider class file that is used by the JAX-WS client.

## What to do next

Complete the implementation of your web service application by completing the JavaBeans or enterprise beans implementation.

## wsimport command for JAX-WS applications

The wsimport command-line tool processes an existing Web Services Description Language (WSDL) file and generates the required artifacts for developing Java API for XML-Based Web Services (JAX-WS) web service applications. The generated artifacts are Java 5 compliant, making them portable across different Java versions and platforms.

The wsimport command-line tool supports the top-down approach to developing JAX-WS web services. When you start with an existing WSDL file, use the wsimport command-line tool to generate the required JAX-WS artifacts.

**Note:** The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

**Note:** WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The wsimport, wsgen, schemagen and xjc command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

The wsimport tool reads an existing WSDL file and generates the following artifacts:

- Service Endpoint Interface (SEI) - The SEI is the annotated Java representation of the WSDL file for the web service. This interface is used for implementing JavaBeans endpoints or creating dynamic proxy client instances.
- `javax.xml.ws.Service` extension class - This is a generated class that extends the `javax.xml.ws.Service` class. This class is used to configure and create both dynamic proxy and dispatch instances.
- required data beans, including any Java Architecture for XML Binding (JAXB) beans that are required to model the web service data.

You can package the generated artifacts in a web application archive (WAR) file with the WSDL file and schema documents along with the endpoint implementation to be deployed.

**Note:** To correctly use the wsimport tool, you must adhere to the following requirements:

- You must define all your services within the main WSDL file. Services that are defined within an imported WSDL file are not processed by the wsimport tool.

- If you run the wsimport tool on a WSDL file that implements a Document or Literal style pattern, the complexTypes elements that define the input and output types must be composed of unique names to prevent naming conflicts in the parameter list for the operation..
- If you run the wsimport tool and pass a `?wsdl` Uniform Resource Identifier (URI) as a parameter for a WSDL file, ensure that you are using the actual resolved WSDL URI. The wsimport tool correctly resolves the `?wsdl` URI, but other relative URIs that are referenced might not resolve correctly.

In addition to using the tools from the command line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsImport` Ant task from within the Ant build environment to invoke the wsimport tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

## Syntax

The command-line syntax is:

Windows

*app_server_root*\bin\wsimport.bat [*options*] *WSDL_URI*

AIX HP-UX Linux Solaris

*app_server_root*/bin/wsimport.sh [*options*] *WSDL_URI*

## Parameters

The *WSDL_URI* is the only parameter that is required. The following parameters are optional for the wsimport command:

**-b <path>**
Specifies the external JAX-WS or JAXB binding files. You can specify multiple JAX-WS and JAXB binding files by using the `-b` option; however, each file must be specified with its own `-b` option.

**-B <jaxbOption>**
Specifies to pass this option to the JAXB schema compiler.

**-catalog**
Specifies the catalog file to resolve external entity references. It supports the TR9401, XCatalog, and the OASIS XML Catalog formats

**-d <directory>**
Specifies where to place the generated output files.

**-extension**
Specifies whether to accept custom extensions for functionality that are not specified by the JAX-WS specification. The use of custom extensions can result in applications that are not portable or do not interoperate with other implementations.

**-help**
Displays the help menu.

**-httpproxy:<host>:<port>**
Specifies an HTTP proxy. The default port value is 8080.

**-keep**
Specifies whether to keep the generated source files.

**-p <package_name>**
Specifies a target package with this command-line option and overrides any WSDL file and schema binding customization for the package name and the default package name algorithm defined in the JAX-WS specification.

**-quiet**
Specifies to suppress the wsimport output.

**-s <directory>**
Specifies the directory to place the generated source files.

**-target <version>>**
Specifies to generate code that is compliant with a specific JAX-WS specification level. Specify version 2.0 or 2.1 to generate code that is compliant with the JAX-WS 2.0 or JAX-WS 2.1 specification respectively. Specifying version 2.1 indicates to generate code that is compliant with the JAX-WS 2.1 specification. The default value is version 2.2 and generates compliant code for the JAXB 2.2 specification.

**-verbose**
Specifies to output messages about what the compiler is doing.

**-version**
Prints the version information. If you specify this option, only the version information is included in the output and normal command processing does not occur.

**-wsdlLocation**
Specifies the `@WebServiceClient.wsdlLocation` value.

**Note:** The wsimport tool does not set the `@WebService.wsdlLocation` value either by default or when the -wsdlLocation attribute is specified. The wsimport command-line tool updates the @WebServiceClient.wsdlLocation annotation only. You can manually update the @WebService.wsdlLocation annotation with a relative URL that specifies the location of the Web Services Description Language (WSDL) file. If the @WebService.wsdlLocation annotation is present on an endpoint implementation class, then the value must be a relative URL and the WSDL document that it references must be packaged with the application.

**Note:** If you specify an HTTPS URL for the -wsdlLocation parameter, the wsimport tool generates a service class with a no-argument constructor that is not valid. Avoid using the no-argument service constructor to instantiate your service. Instead, pass the HTTPS URL to one of the service class constructors that takes a WSDL URL for an argument; for example:

```
MyService("https://example.ibm.com/My?wsdl");
```

# Enabling MTOM for JAX-WS web services

With Java API for XML-Based Web Services (JAX-WS), you can send binary attachments such as images or files along with web services requests. JAX-WS adds support for optimized transmission of binary data as specified by the SOAP Message Transmission Optimization Mechanism (MTOM) specification.

## About this task

JAX-WS supports the use of SOAP Message Transmission Optimized Mechanism (MTOM) for sending binary attachment data. By enabling MTOM, you can send and receive binary data optimally without incurring the cost of data encoding needed to embed the binary data in an XML document.

The application server supports sending attachments using MTOM only for JAX-WS applications. This product also provides the ability to provide attachments with Web Services Security SOAP messages by using the new MTOM and XOP standards.

JAX-WS applications can send binary data as base64 or hexBinary encoded data contained within the XML document. However, to take advantage of the optimizations provided by MTOM, enable MTOM to send binary base64 data as attachments contained outside the XML document. MTOM optimization is not enabled by default. JAX-WS applications require separate configuration of both the client and the server artifacts to enable MTOM support.

## Procedure

1. Develop Java artifacts for your JAX-WS application that includes an XML schema or Web Services Description Language (WSDL) file that represents your web services application data that includes a binary attachment.
   a. If you are starting with a WSDL file, develop Java artifacts from a WSDL file by using the wsimport command to generate the required JAX-WS portable artifacts.
   b. If you are starting with JavaBeans components, develop Java artifacts for JAX-WS applications and optionally generate a WSDL file using the wsgen command. The XML schema or WSDL file includes a `xsd:base64Binary` or `xsd:hexBinary` element definition for the binary data.
   c. You can also include the `xmime:expectedContentTypes` attribute on the element to affect the mapping by JAXB.
2. Enable MTOM on your endpoint implementation class using one of the following methods:
   - Use the @MTOM annotation on the endpoint.

     To enable MTOM on an endpoint, use the @MTOM (javax.xml.ws.soap.MTOM) annotation on the endpoint. The @MTOM annotation has two parameters, enabled and threshold. The enabled parameter has a boolean value and indicates if MTOM is enabled for the JAX-WS endpoint. The threshold parameter has an integer value, that must be greater than or equal to zero. When MTOM is enabled, any binary data whose size, in bytes, exceeds the threshold value is XML-binary Optimized Packaging (XOP) encoded or sent as an attachment. When the message size is less than the threshold value, the message is inlined in the XML document as either base64 or hexBinary data.

     The following example snippet illustrates adding the @MTOM annotation so that MTOM is enabled for the JAX-WS `MyServiceImpl` endpoint and specifies a threshold value of 2048 bytes:

```
@MTOM(enabled=true, threshold=2048)
@WebService
public class MyServiceImpl {
...
}
```

     Additionally, you can use the @BindingType (javax.xml.ws.BindingType) annotation on an endpoint implementation class to specify that the endpoint supports one of the MTOM binding types so that the response messages are MTOM-enabled. The javax.xml.ws.SOAPBinding class defines two different constants, `SOAP11HTTP_MTOM_BINDING` and `SOAP12HTTP_MTOM_BINDING` that you can use for the value of the @BindingType annotation; for example:

```
// This example is for SOAP version 1.1.
@BindingType(value = SOAPBinding.SOAP11HTTP_MTOM_BINDING)
@WebService
public class MyServiceImpl {
...
}

// This example is for SOAP version 1.2.
@BindingType(value = SOAPBinding.SOAP12HTTP_MTOM_BINDING)
@WebService
public class MyServiceImpl {
...
}
```

     The presence and value of an @MTOM annotation overrides the value of the @BindingType annotation. For example, if the @BindingType indicates MTOM is enabled, but an @MTOM annotation is present with an enabled value of `false`, then MTOM is not enabled.
   - Use the `<enable-mtom>` and `<mtom-threshold>` deployment descriptor elements.

     You can use the `<enable-mtom>` and `<mtom-threshold>` elements within the `<port-component>` element in the webservices.xml deployment descriptor as an alternative to using the @MTOM annotation on the service endpoint implementation class; for example:

```
<port-component>
   <port-component-name>MyPort1</port-component-name>
   <enable-mtom>true</enable-mtom>
   <mtom-threshold>2048</mtom-threshold>
   <service-impl-bean>
    <servlet-link>MyPort1ImplBean</servlet-link>
   </service-impl-bean>
</port-component>
```

**Note:** The deployment descriptor elements take precedence over the corresponding attributes in the MTOM annotation. For example, if the `enabled` attribute is set to `true` in the annotation, but the `<enable-mtom>` element is set to `false` in the `webservices.xml` file, MTOM is not enabled for the corresponding endpoint.

3. Enable MTOM on your client to optimize the binary messages that are sent from the client to the server. Use one of the following methods to enable MTOM on your client:
   - Enable MTOM on a Dispatch client.

     The following examples use SOAP version 1.1.

     The first method uses SOAPBinding.setMTOMEnabled(); for example:

```
SOAPBinding binding = (SOAPBinding)dispatch.getBinding();
    binding.setMTOMEnabled(true);
```

     The second method uses Service.addPort; for example:

```
    Service svc = Service.create(serviceName);
    svc.addPort(portName,SOAPBinding.SOAP11HTTP_MTOM_BINDING,endpointUrl);
```

     The third method uses MTOMFeature; for example:

```
   MTOMFeature mtom = new MTOMFeature(true, 2048);
    Service svc = Service.create(serviceName);
    svc.addPort(portName, SOAPBinding.SOAP11_HTTP_BINDING, endpointUrl);
    Dispatch<Source> dsp = svc.createDispatch(portName, Source.class, Service.Mode.PAYLOAD, mtom);
```

   - Enable MTOM on a Dynamic Proxy client.

```
// Create a BindingProvider bp from a proxy port.
  Service svc = Service.create(serviceName);
  MtomSample proxy = svc.getPort(portName, MtomSample.class);
  BindingProvider bp = (BindingProvider) proxy;

  //Enable MTOM using the SOAPBinding.
  MtomSample proxy = svc.getPort(portName, MtomSample.class);
  BindingProvider bp = (BindingProvider) proxy;
  SOAPBinding binding = (SOAPBinding) bp.getBinding();
  binding.setMTOMEnabled(true);

  //Or, you can enable MTOM with the MTOMFeature.
  MTOMFeature mtom = new MTOMFeature();
  MtomSample proxy = svc.getPort(portName, MtomSample.class, mtom);
```

   - Enable MTOM on your client using the @MTOM annotation; for example:

```
public class MyClientApplication {

    // Enable MTOM for a port-comonent-ref resource injection.
     @MTOM(enabled=true, threshold=1024)
     @WebServiceRef(MyService.class)
     private MyPortType myPort;
    ...
}
```

   - Enable MTOM on your client using deployment descriptor elements within a port-component-ref element; for example:

```
<service-ref>
    <service-ref-name>service/MyPortComponentRef</service-ref-name>
    <service-interface>com.example.MyService</service-ref-interface>
    <port-component-ref>
        <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
        <enable-mtom>true</enable-mtom>
        <mtom-threshold>1024</mtom-threshold>
    </port-component-ref>
</service-ref>
```

**Note:** The deployment descriptor elements take precedence over the corresponding attributes in the MTOM annotation. For example, if the `enabled` attribute is set to `true` in the annotation, but the `<enable-mtom>` element is set to `false` in the deployment descriptor entry for the service-ref of the client, MTOM is not enabled for that service reference.

## Results

You have developed a JAX-WS web services server and client application that optimally sends and receives binary data using MTOM.

## Example

The following example illustrates enabling MTOM support on both the web services client and server endpoint when starting with an WSDL file.

1. Locate the WSDL file containing an `xsd:base64Binary` element. The following example is a portion of a WSDL file that contains an `xsd:base64Binary` element.

```
  <types>
    ........
    <xs:complexType name="ImageDepot">
        <xs:sequence>
            <xs:element name="imageData"
                        type="xs:base64Binary"
                        xmime:expectedContentTypes="image/jpeg"/>

        </xs:sequence>
    </xs:complexType>
    ........
</types>
```

2. Run the **wsimport** command from the *app_server_root*\bin\ directory against the WSDL file to generate a set of JAX-WS portable artifacts.

   Windows

   *app_server_root*\bin\wsimport.bat <*wsdl_url*>

   AIX HP-UX Linux Solaris

   *app_server_root*/bin/wsimport.sh <*wsdl_url*>

   Depending on the `expectedContentTypes` value contained in the WSDL file, the JAXB artifacts generated are in the Java type as described in the following table:

*Table 207. Mapping of MIME type and Java type. Describes the mapping between MIME types and Java types.*

| MIME Type | Java Type |
|---|---|
| image/gif | java.awt.Image |
| image/jpeg | java.awt.Image |
| text/plain | java.lang.String |
| text/xml | javax.xml.transform.Source |
| application/xml | javax.xml.transform.Source |
| */* | javax.activation.DataHandler |

3. Use the JAXB artifacts in the same manner as in any other JAX-WS application. Use these beans to send binary data from both the Dispatch and the Dynamic Proxy client APIs.
4. Enable MTOM on a Dispatch client.

```
//Create the Dispatch instance.
        JAXBContext jbc = JAXBContext.newInstance("org.apache.axis2.jaxws.sample.mtom");
        Dispatch<Object> dispatch = svc.createDispatch(portName, jbc, Service.Mode.PAYLOAD);

//Enable MTOM.
        SOAPBinding binding = (SOAPBinding) dispatch.getBinding();
        binding.setMTOMEnabled(true);
```

5. Enable MTOM on a Dynamic Proxy client.

```
//Create the Dynamic Proxy instance.
        Service svc = Service.create(serviceName);
        MtomSample proxy = svc.getPort(portName, MtomSample.class);

//Enable MTOM.
        BindingProvider bp = (BindingProvider) proxy;
        SOAPBinding binding = (SOAPBinding) bp.getBinding();
        binding.setMTOMEnabled(true);
```

   Now that you have enabled the JAX-WS client for MTOM, messages sent to the server have MTOM enabled. However, for the server to respond back to the client using MTOM, you must enable MTOM on the endpoint.

6. Enable MTOM on the endpoint implementation class.

```
@MTOM(enabled, threshold=4096)
@WebService (endpointInterface="org.apache.axis2.jaxws.sample.mtom.MtomSample")

public class MtomSampleService implements MtomSample {
   ....
}
```

The `jaxax.xml.ws.SOAPBinding` class has a static member for each of the supported binding types. Include either the `SOAP11HTTP_MTOM_BINDING` or the `SOAP12HTTP_MTOM_BINDING` as the value for the `@BindingType` annotation. This value enables all server responses to have MTOM enabled.

When you enable MTOM on the server and the client, the binary data that represents the attachment is included as a Multipurpose Internet Mail Extensions (MIME) attachment to the SOAP message. Without MTOM, the same data is encoded in the format that describes the XML schema, either base64 or hexadecimal encoding, and included inline in the XML document.

This example illustrates an MTOM enabled SOAP version 1.1 message with an attachment. The `type` and `content-type` attributes both have the value, `application/xop+xml`, which indicates that the message was successfully optimized using XML-binary Optimized packaging (XOP) when MTOM was enabled. This example demonstrates how the optimized message looks on the wire with MTOM enabled.

```
... other transport headers ...
Content-Type: multipart/related; boundary=MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812;
type="application/xop+xml"; start="
<0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>"; start-info="text/xml"; charset=UTF-8

--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: application/xop+xml; charset=UTF-8; type="text/xml";
content-transfer-encoding: binary
content-id:
   <0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>

<?xml version="1.0" encoding="UTF-8"?>
         <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
            <soapenv:Header/>
            <soapenv:Body>
               <sendImage xmlns="http://org/apache/axis2/jaxws/sample/mtom">
                  <input>
                     <imageData>
                        <xop:Include xmlns:xop="http://www.w3.org/2004/08/xop/include"
href="cid:1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org"/>
                     </imageData>
                  </input>
               </sendImage>
            </soapenv:Body>
         </soapenv:Envelope>
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: text/plain
content-transfer-encoding: binary
content-id:
         <1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org>

... binary data goes here ...
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812--
```

In contrast, this example demonstrates a SOAP version 1.1 message on the wire without MTOM enabled. The binary data is included in the body of the SOAP message, and the SOAP message is not optimized.

```
... other transport headers ...
Content-Type: text/xml; charset=UTF-8

<?xml version="1.0" encoding="UTF-8"?>
   <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
      <soapenv:Header/>
      <soapenv:Body>
         <sendImage xmlns="http://org/apache/axis2/jaxws/sample/mtom">
            <input>
               <imageData>R0lGAD1 ... more base64 encoded data ... KTJk8giAAA7</imageData>
            </input>
         </sendImage>
      </soapenv:Body>
   </soapenv:Envelope>
```

For additional information, refer to the Samples section of the Information Center which includes a sample that demonstrates the use of MTOM with JAX-WS web services.

## Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

### Default product locations (distributed)

The following file paths are default locations. You can install the product and other components or create profiles in any directory where you have write access. Multiple installations of WebSphere Application Server - Express products or components require multiple locations. Default values for installation actions by root and nonroot users are given. If no nonroot values are specified, then the default directory values are applicable to both root and nonroot users.

*app_client_root*

*Table 208. Default installation root directories for the Application Client for IBM WebSphere Application Server.*

*This table shows the default installation root directories for the Application Client for IBM WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppClient` (Java EE Application client only)<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\Program Files\IBM\WebSphere\AppClient` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\IBM\WebSphere\AppClient` |

*app_server_root*

*Table 209. Default installation directories for WebSphere Application Server.*

*This table shows the default installation directories for WebSphere Application Server - Express.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppServer`<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppServer`<br>Windows `C:\Program Files\IBM\WebSphere\AppServer` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppServer`<br>Windows *user_home*`\IBM\WebSphere\AppServer` |

*component_root*

The component installation root directory is any installation root directory described in this topic. Some programs are for use across multiple components—in particular, the Web Server Plug-ins, the Application Client, and the IBM HTTP Server. All of these components are part of the product package.

*gskit_root*

IBM Global Security Kit (GSKit) can now be installed by any user. GSKit is installed locally inside the installing product's directory structure and is no longer installed in a global location on the target system. The following list shows the default installation root directory for Version 8 of the GSKit, where *product_root* is the root directory of the product that is installing GSKit, for example IBM HTTP Server or the web server plug-in.

AIX HP-UX Linux Solaris

*product_root*/gsk8

Windows

*product_root*\gsk8

### *profile_root*

*Table 210. Default profile directories.*

*This table shows the default directories for a profile named profile_name on each distributed operating system.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/AppServer/profiles/*profile_name*<br>HP-UX Linux Solaris /opt/IBM/WebSphere/AppServer/profiles/*profile_name*<br>Windows C:\Program Files\IBM\WebSphere\AppServer\profiles*profile_name* |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/AppServer/profiles<br>Windows *user_home*\IBM\WebSphere\AppServer\profiles |

### *plugins_root*

*Table 211. Default installation root directories for the Web Server Plug-ins.*

*This table shows the default installation root directories for the Web Server Plug-ins for WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/Plugins<br>HP-UX Linux Solaris /opt/IBM/WebSphere/Plugins<br>Windows C:\Program Files\IBM\WebSphere\Plugins |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/Plugins<br>Windows C:\IBM\WebSphere\Plugins |

### *wct_root*

*Table 212. Default installation root directories for the WebSphere Customization Toolbox.*

*This table shows the default installation root directories for the WebSphere Customization Toolbox.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/Toolbox<br>HP-UX Linux Solaris /opt/IBM/WebSphere/Toolbox<br>Windows C:\Program Files\IBM\WebSphere\Toolbox |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/Toolbox<br>Windows C:\IBM\WebSphere\Toolbox |

### *web_server_root*

*Table 213. Default installation root directories for the IBM HTTP Server.*

*This table shows the default installation root directories for the IBM HTTP Server.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/HTTPServer`<br>HP-UX Linux Solaris `/opt/IBM/HTTPServer`<br>Windows `C:\Program Files\IBM\HTTPServer` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/HTTPServer`<br>Windows `C:\IBM\HTTPServer` |

# Enforcing adherence to WSDL bindings in JAX-WS web services

Java API for XML-Based Web Services (JAX-WS) Version 2.1 introduced the concept of *features* as a way to programmatically control specific functions and behaviors. The RespectBindingFeature is one of the supported standard features. You can use the RespectBindingFeature to control whether a JAX-WS implementation is required to respect the contents of a Web Services Description Language (WSDL) binding that is associated with an endpoint.

## About this task

While WSDL documents are often used during the development process, the actual enforcement of the use of the WSDL document specifications, when they are provided, at run time has not been well defined in versions of the JAX-WS specification previous to Version 2.1. The JAX-WS Version 2.1 specification added the feature, RespectBindingFeature, to clarify the impact of the wsdl:binding in a JAX-WS runtime environment.

Enabling the feature, RespectBindingFeature, causes the JAX-WS runtime environment to inspect the wsdl:binding for an endpoint at run time to ensure that the binding of service endpoint interface (SEI) parameters and return values is respected. Additionally, this feature ensures that all required wsdl:binding extensions are either understood and used by the runtime environment, or the extensions have been explicitly disabled by the application. Your JAX-WS application can disable a specific wsdl:binding extension that has a defined WebServiceFeature interface by using the appropriate annotation that is associated with that feature, using an API that accepts the javax.xml.ws.WebServiceFeature interface, or configuring the deployment descriptors.

When the RespectBindingFeature feature is not enabled, which is the default, the runtime environment can choose whether any part of the wsdl:binding is enforced.

## Procedure

1. Develop Java artifacts for your JAX-WS application that includes a Web Services Description Language (WSDL) file that represents your web services application.
   a. If you are starting with a WSDL file, develop Java artifacts from a WSDL file by using the wsimport command to generate the required JAX-WS portable artifacts.
   b. If you are starting with JavaBeans components, develop Java artifacts for JAX-WS applications and generate a WSDL file using the wsgen command.
2. If you want to enable RespectBindingFeature on your endpoint implementation class, use one of the following methods:
   - Use the @RespectBinding annotation on the endpoint.

     To enable RespectBinding on an endpoint, use the @RespectBinding (javax.xml.ws.RespectBinding) annotation on the endpoint. The @RespectBinding annotation has only one parameter, `enabled`.

This parameter is optional. The enabled parameter has a Boolean value and indicates if RespectBindingFeature is enabled for the JAX-WS endpoint.

The following example snippet illustrates adding the @RespectBinding annotation for the JAX-WS `MyServiceImpl` endpoint:

```
@RespectBinding(enabled=true))
@WebService
public class MyServiceImpl {
...
}
```

- Use the `<respect-binding>` deployment descriptor element.

  You can use the `<respect-binding>` element within the `<port-component>` element in the webservices.xml deployment descriptor as an alternative to using the @RespectBinding annotation on the service endpoint implementation class; for example:

```
<port-component>
     <port-component-name>MyPort1</port-component-name>
     <respect-binding>
         <enabled>true</enabled>
     </respect-binding>
     <service-impl-bean>
         <servlet-link>MyPort1ImplBean</servlet-link>
     </service-impl-bean>
</port-component>
```

3. If you want to enable RespectBindingFeature on your client, use one of the following methods:
   - Enable RespectBindingFeature on a dispatch client; for example:

```
RespectBindingFeature respectBinding = new RespectBindingFeature();
Service svc = Service.create(serviceName);
svc.addPort(portName, SOAPBinding.SOAP11_HTTP_BINDING, endpointUrl);
Dispatch<Source> dsp = svc.createDispatch(portName, Source.class, Service.Mode.PAYLOAD, respectBinding);
```

   - Enable RespectBindingFeature on a dynamic proxy client; for example:

```
// Create a dynamic proxy with RespectBinding enabled.
  Service svc = Service.create(serviceName);
  RespectBindingFeature respectBinding = new RespectBindingFeature();
  RespectBindingSample proxy = svc.getPort(portName, RespectBindingSample.class, respectBinding);
```

   - Enable RespectBindingFeature on your client using the @RespectBinding annotation; for example:

```
public class MyClientApplication {

               // Enable RespectBinding for a port-component-ref resource injection.
                   @RespectBinding(enabled=true)
                   @WebServiceRef(MyService.class)
                   private MyPortType myPort;
               ...
}
```

   - Enable RespectBindingFeature on your client using deployment descriptor elements within a port-component-ref element; for example:

```
<service-ref>
    <service-ref-name>service/MyPortComponentRef</service-ref-name>
    <service-interface>com.example.MyService</service-ref-interface>
    <port-component-ref>
        <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
        <respect-binding>
            <enabled>true</enabled>
        </respect-binding>
    </port-component-ref>
</service-ref>
```

## Results

By implementing the feature, RespectBindingFeature, you have specified to enforce adherence of the contents of a WSDL binding that is associated with an endpoint for your JAX-WS application.

# Developing a webservices.xml deployment descriptor for JAX-WS applications

*Deployment descriptors* are standard text files, formatted using XML and packaged in a web services application. You can optionally use the webservices.xml deployment descriptor to augment or override application metadata specified in annotations within Java API for XML-Based Web Services (JAX-WS) web services.

## About this task

Similar to Java API for XML-based RPC (JAX-RPC) Web services, you can use deployment descriptors to describe JAX-WS web services. For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

A JAX-WS web service requires that you annotate your Java class with the `javax.jws.WebService` annotation or the `javax.jws.WebServiceProvider` annotation for Provider endpoints. You can use server-side deployment descriptors to override corresponding attributes of the annotation or to enhance information in annotations. There is a defined relationship between the deployment descriptor elements and the @WebService and @WebServiceProvider annotations. Refer to section 5.3 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification, Version 1.2 for detailed information regarding the deployment descriptor elements and the mapping to the @WebService and @WebServiceProvider annotation attributes. There are also elements in the `webservice.xml` deployment descriptor that map to other annotations. For example, the deployment descriptor element <protocol-binding> maps to the @BindingType annotation, and the deployment descriptor element <enable-mtom> maps to the @MTOM annotation. For more information regarding the web services deployment descriptor elements, see section 7.1 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification.

## Procedure

Use assembly tools to generate the `webservice.xml` deployment descriptor.

## Results

You have deployment descriptor templates that you can use to override JAX-WS annotation attributes or specify attributes that are not defined by the annotation.

## Example

In the following example, the service implementation class for a JAX-WS web service includes the @WebService annotation:

```
@WebService(wsdlLocation="http://myhost.com/location/of/the/wsdl/ExampleService.wsdl")
```

The associated `webservices.xml` deployment descriptor specifies a different filename for the WSDL document as follows:

```
<webservices>
<webservice-description>
<webservice-description-name>ExampleService</webservice-description-name>
<wsdl-file>META-INF/wsdl/ExampleService.wsdl</wsdl-file>
...
</webservice-description>
</webservices>
```

The value that is specified in the deployment descriptor, `META-INF/wsdl/ExampleService.wsdl`, overrides the annotation value.

## What to do next

Configure the `webservice.xml` deployment descriptor. After you configure the deployment descriptors, you must assemble the Web services application for deployment.

## Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

## Default product locations (distributed)

The following file paths are default locations. You can install the product and other components or create profiles in any directory where you have write access. Multiple installations of WebSphere Application Server - Express products or components require multiple locations. Default values for installation actions by root and nonroot users are given. If no nonroot values are specified, then the default directory values are applicable to both root and nonroot users.

*app_client_root*

*Table 214. Default installation root directories for the Application Client for IBM WebSphere Application Server.*

*This table shows the default installation root directories for the Application Client for IBM WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppClient` (Java EE Application client only)<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\Program Files\IBM\WebSphere\AppClient` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\IBM\WebSphere\AppClient` |

*app_server_root*

*Table 215. Default installation directories for WebSphere Application Server.*

*This table shows the default installation directories for WebSphere Application Server - Express.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppServer`<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppServer`<br>Windows `C:\Program Files\IBM\WebSphere\AppServer` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppServer`<br>Windows *user_home*`\IBM\WebSphere\AppServer` |

*component_root*

The component installation root directory is any installation root directory described in this topic. Some programs are for use across multiple components—in particular, the Web Server Plug-ins, the Application Client, and the IBM HTTP Server. All of these components are part of the product package.

*gskit_root*

IBM Global Security Kit (GSKit) can now be installed by any user. GSKit is installed locally inside the installing product's directory structure and is no longer installed in a global location on the target system. The following list shows the default installation root directory for Version 8 of the GSKit, where *product_root* is the root directory of the product that is installing GSKit, for example IBM HTTP Server or the web server plug-in.

AIX HP-UX Linux Solaris

*product_root*`/gsk8`

Windows

*product_root*`\gsk8`

*profile_root*

*Table 216. Default profile directories.*

*This table shows the default directories for a profile named profile_name on each distributed operating system.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/AppServer/profiles/*profile_name*<br>HP-UX Linux Solaris /opt/IBM/WebSphere/AppServer/profiles/*profile_name*<br>Windows C:\Program Files\IBM\WebSphere\AppServer\profiles*profile_name* |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/AppServer/profiles<br>Windows *user_home*\IBM\WebSphere\AppServer\profiles |

*plugins_root*

*Table 217. Default installation root directories for the Web Server Plug-ins.*

*This table shows the default installation root directories for the Web Server Plug-ins for WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/Plugins<br>HP-UX Linux Solaris /opt/IBM/WebSphere/Plugins<br>Windows C:\Program Files\IBM\WebSphere\Plugins |

| Root | AIX /usr/IBM/WebSphere/Toolbox<br>HP-UX Linux Solaris /opt/IBM/WebSphere/Toolbox<br>Windows C:\Program Files\IBM\WebSphere\Toolbox |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/Toolbox<br>Windows C:\IBM\WebSphere\Toolbox |

*web_server_root*

*Table 219. Default installation root directories for the IBM HTTP Server.*

*This table shows the default installation root directories for the IBM HTTP Server.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/HTTPServer`<br>HP-UX Linux Solaris `/opt/IBM/HTTPServer`<br>Windows `C:\Program Files\IBM\HTTPServer` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/HTTPServer`<br>Windows `C:\IBM\HTTPServer` |

# Completing the JavaBeans implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) web service, you must complete the JavaBeans implementation to assemble a web application archive (WAR) file. The resulting WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

## Before you begin

Generate Java artifacts for JAX-WS applications and optionally generate a WSDL file using the wsgen command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS web services.

## About this task

For JAX-WS applications, complete the JavaBeans implementation by writing your business application.

## Procedure

1. Write the JavaBeans implementation. The JavaBeans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

## Results

You have now written your JavaBeans implementation to complete your web service application.

## What to do next

After completing the JavaBeans implementation, assemble your web services application.

# Completing the EJB implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file. The resulting JAR file contains the Enterprise JavaBeans implementation and the supported classes created from the tooling.

## Before you begin

Generate Java artifacts for JAX-WS applications and optionally generate a WSDL file using the **wsgen** command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS web services.

### About this task

For JAX-WS applications, complete the enterprise beans implementation by writing your business application.

### Procedure

1. Write the enterprise beans implementation. The enterprise beans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

### Results

You have now written your enterprise beans implementation to complete your web service application.

### What to do next

After completing the enterprise beans implementation, assemble your web services application.

---

# Developing JAX-WS clients

# Developing a JAX-WS client from a WSDL file

Java API for XML-Based Web Services (JAX-WS) tooling supports generating Java artifacts you need to develop static JAX-WS web services clients when starting with a Web Services Description Language (WSDL) file.

### Before you begin

When you use a top-down development approach to developing JAX-WS web services by starting with a WSDL file, you must obtain the Uniform Resource Locator (URL) for the WSDL file.

Windows If the WSDL file is a local file, the URL looks like this example: file:*drive:**path**file_name*.wsdl.

Linux AIX HP-UX Solaris If the WSDL file is a local file, the URL looks like this example: file:/*path*/*file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

### About this task

The static client programming model for JAX-WS is the called the dynamic proxy client. The dynamic proxy client invokes a web service based on a service endpoint interface that is provided. After you create the proxy, the client application can invoke methods on the proxy just like a standard implementation of those interfaces. For JAX-WS web service clients using the dynamic proxy programming model, use the JAX-WS tool, wsimport, to process a WSDL file and generate portable Java artifacts that are used to create a web service client. Create the following portable Java artifacts using the wsimport tool:

- Service endpoint interface (SEI)
- Service class
- Exception class that is mapped from the wsdl:fault class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types

**Note:** The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

**Note:** WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The wsimport, wsgen, schemagen and xjc command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

In addition to using the tools from the command-line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsImport` Ant task from within the Ant build environment to invoke the wsimport tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

## Procedure

Run the wsimport command to generate the portable client artifacts. The wsimport tool is located in the *app_server_root*\bin\ directory.

Windows

*app_server_root*\bin**wsimport.bat** ***wsdl_URL***

AIX HP-UX Linux Solaris

*app_server_root*/bin/**wsimport.sh** ***wsdl_URL***

(Optional) Use the following options with the wsimport command:

- Use the **-verbose** option to see a list of generated files when you run the command.
- Use the **-keep** option to keep generated Java files.
- Use the **-wsdlLocation** option to specify the location of the WSDL file.

  **Note:** A best practice for ensuring that you produce a JAX-WS web services client enterprise archive (EAR) file that is portable to other systems is to package the WSDL document within the application module such as a web services client Java archive (JAR) file or a web application archive (WAR) file. You can specify a relative URI for the location of your WSDL file by using the `-wsdllocation` annotation attribute. For example, if your `MyService.wsdl` file is located in the `META-INF/wsdl/ directory`, then run the wsimport tool and use the `-wsdllocation` option to specify the value to be used for the location of the WSDL file. This ensures that the generated artifacts contain the correct `-wsdllocation` information needed when the application is loaded into the administrative console; for example:

```
wsimport -keep -wsdllocation /META-INF/wsdl/MyService.wsdl
```

- Use the **-b** option if you are using WSDL or schema customizations to specify external binding files that contain your customizations.

  You can customize the bindings in your WSDL file to enable asynchronous mappings or attachment files. To generate asynchronous interfaces, add the client-side only customization `enableAsyncMapping` binding declaration to the `wsdl:definitions` element or in an external binding file that is defined in the WSDL file. Use the `enableMIMEContent` binding declaration in your custom client or server binding file to enable or disable the default mime:content mapping rules. For additional information on custom binding declarations, see chapter 8 the JAX-WS specification.

Read about the wsimport command to learn more about this command and additional options that you can specify.

## Results

You have the generated Java artifacts to create a JAX-WS client that can invoke JAX-WS web services. To learn more about the usage, syntax, and parameters for the wsimport command, see the wsimport command for JAX-WS applications documentation.

## Example

The following example illustrates how the wsimport command is used to process the sample `ping.wsdl` file to generate portable artifacts.

1. Copy the following `ping.wsdl` file to a temporary directory.

```
<?xml version="1.0" encoding="UTF-8"?>
<!--
 * This program can be used, run, copied, modified and distributed
 * without royalty for the purpose of developing, using, marketing, or distributing.
 -->
<wsdl:definitions xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
 xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
 xmlns:tns="http://com/ibm/was/wssample/sei/ping/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema" name="PingService"
 targetNamespace="http://com/ibm/was/wssample/sei/ping/">
 <wsdl:types>
  <xsd:schema
   targetNamespace="http://com/ibm/was/wssample/sei/ping/"
   xmlns:xsd="http://www.w3.org/2001/XMLSchema">

   <xsd:element name="pingStringInput">
    <xsd:complexType>
     <xsd:sequence>
      <xsd:element name="pingInput" type="xsd:string" />
     </xsd:sequence>
    </xsd:complexType>
   </xsd:element>
  </xsd:schema>
 </wsdl:types>
 <wsdl:message name="pingOperationRequest">
  <wsdl:part element="tns:pingStringInput" name="parameter" />
 </wsdl:message>
 <wsdl:portType name="PingServicePortType">
  <wsdl:operation name="pingOperation">
   <wsdl:input message="tns:pingOperationRequest" />

  </wsdl:operation>
 </wsdl:portType>
 <wsdl:binding name="PingSOAP" type="tns:PingServicePortType">
  <soap:binding style="document"
   transport="http://schemas.xmlsoap.org/soap/http" />
  <wsdl:operation name="pingOperation">
   <soap:operation soapAction="pingOperation" style="document" />
   <wsdl:input>
    <soap:body use="literal" />
   </wsdl:input>
  </wsdl:operation>
 </wsdl:binding>
 <wsdl:service name="PingService">
  <wsdl:port binding="tns:PingSOAP" name="PingServicePort">
   <soap:address
    location="http://localhost:9080/WSSampleSei/PingService" />
  </wsdl:port>
 </wsdl:service>
</wsdl:definitions>
```

2. Run the wsimport command from the *app_server_root*\bin\ directory.

Windows

```
app_server_root\bin\wsimport.bat -keep -verbose ping.wsdl
```

Linux AIX HP-UX Solaris Operating systems such as AIX or Linux *source* the script to the parent shell to inherit the exported variables by running the following command:

```
. ./setupCmdLine.sh  (Notice the space between the periods.)
```

from the . */app_server_root*>/bin directory. Run the following wsimport command:

```
app_server_root/bin/wsimport.sh -keep -verbose ping.wsdl
```

After generating the template files from the wsimport command, the following files are generated:

```
com\ibm\was\wssample\sei\ping\ObjectFactory.java
com\ibm\was\wssample\sei\ping\package-info.java
com\ibm\was\wssample\sei\ping\PingServicePortType.java
com\ibm\was\wssample\sei\ping\PingService.java
com\ibm\was\wssample\sei\ping\PingStringInput.java
```

The `ObjectFactory.java`, `PingService.java`, and `PingServicePortType.java` files are the generated Java class files to use when you package the Java artifacts with your client implementation inside a Java archive (JAR) or a web application archive (WAR) file.

### What to do next

Complete the client implementation.

## Developing deployment descriptors for a JAX-WS client

Deployment descriptors are standard text files, formatted using XML and packaged in a web services application. You can optionally use the Web Services for Java Platform, Enterprise Edition (Java EE) specification (JSR 109) service reference deployment descriptor to augment or override application metadata specified in annotations within Java API for XML-Based Web Services (JAX-WS) web services client.

### Before you begin

You must first generate the web services client artifacts from a Web Services Description Language (WSDL) file using the wsimport command.

### About this task

You can add `service-ref` entries within the `application-client.xml`, `web.xml`, or `ejb-jar.xml` Java EE deployment descriptors. A `service-ref` entry represents a reference to a web service that is used by a Java EE component in Web, Enterprise JavaBeans (EJB) or application client containers. A `service-ref` entry has a JNDI name that is used to lookup the service. Specifying the `service-ref` entry enables the client applications to locate the service using a JNDI lookup and you can also use these service references for resource injection.

For each `service-ref` entry found in one of the deployment descriptors, the corresponding service object is bound into the JNDI namespace and the port information is included, if specified. The JAX-WS client can now perform a JNDI lookup to retrieve either a JAX-WS service or port instance.

When defining a `service-ref` that represents a JAX-WS service, use the `javax.xml.ws.Service` subclass that is generated by the wsimport tool as the `service-interface` value. This is the class that contains the @WebServiceClient annotation. When defining a `service-ref` that represents a JAX-WS port, the `service-interface` value is still the javax.xml.ws.Service subclass generated by the wsimport tool, and the `service-ref-type` value specifies the service endpoint interface (SEI) class used by the port. The SEI class is also generated by wsimport, and it is annotated with the @WebService annotation.

### Procedure

1. Define the `service-ref` entry in your `application-client.xml`, `web.xml`, or `ejb-jar.xml` deployment descriptors.

For example, suppose a web application archive (WAR) file contains a WEB-INF/web.xml deployment descriptor that includes the following service-ref entries:

```
<service-ref>
  <service-ref-name>service/ExampleService</service-ref-name>
  <service-interface>com.ibm.sample.ExampleService</service-interface>
</service-ref>

<service-ref>
  <service-ref-name>service/ExamplePort</service-ref-name>
  <service-interface>com.ibm.sample.ExampleService</service-interface>
  <service-ref-type>com.ibm.sample.ExamplePort</service-ref-type>
</service-ref>

<service-ref>
  <service-ref-name>service/ExamplePortInjected</service-ref-name>
  <service-interface>com.ibm.sample.ExampleService</service-interface>
  <service-ref-type>com.ibm.sample.ExamplePort</service-ref-type>

  <injection-target>
    <injection-target-class>com.ibm.sample.J2EEClient</injection-target-class>
    <injection-target-name>injectedPort</injection-target-name>
  </injection-target>
</service-ref>
```

In this example, com.ibm.sample.ExampleService is a generated JAX-WS service class and this class must be a subclass of javax.xml.ws.Service. Additionally, the ExampleService.getPort() method returns an instance of com.ibm.sample.ExamplePort.

2. Use the deployment descriptors within your web services client application to customize your application. The following code fragments are examples of how your client application can use the service-ref entries within the WAR module:

```
import javax.xml.ws.Service;
import com.ibm.sample.ExampleService;
import com.ibm.sample.ExamplePort;

// Create an InitialContext object for doing JNDI lookups.
InitialContext ic = new InitialContext();

// Client obtains an instance of the generic service class using JNDI.
Service genericService =
(Service) ic.lookup("java:comp/env/service/ExampleService");

// Client obtains an instance of the generated service class using JNDI.
ExampleService exampleService =
(ExampleService) ic.lookup("java:comp/env/service/ExampleService");

// Client obtains an instance of the port using JNDI.
ExamplePort ExamplePort =
(ExamplePort) ic.lookup("java:comp/env/service/ExamplePort");

// The container injects an instance of ExamplePort based on the client deployment descriptor
private ExamplePort injectedPort;
```

## Results

You can now use the service references that were defined in the deployment descriptor within your client application. Additionally, you can use deployment descriptors to augment or override information specified by @WebServiceRef or @Resource annotations.

**Note:**

The <lookup-name> deployment descriptor element is new in Java EE 6, and is used to indirectly refer to an already-defined service reference. When the <lookup-name> element is used, only the <service-ref-name> element may also be specified, and no other child elements of <service-ref> may be defined.

The following example shows a service-ref entry within a WEB-INF/web.xml file which defines a reference to a JAX-WS service, as well as a service-ref entry within the same web.xml file which defines an indirect reference to the first service-ref:

```
<service-ref>
  <service-ref-name>service/ExampleService</service-ref-name>
  <service-interface>com.ibm.sample.ExampleService</service-interface>
  <service-ref-type>com.ibm.sample.ExampleServicePortType</service-ref-type>
```

```
  <wsdl-file>WEB-INF/wsdl/ExampleService.wsdl</wsdl-file>
</service-ref>

<service-ref>
  <service-ref-name>service/ExampleService2</service-ref>
  <lookup-name>java:comp/env/service/ExampleService</lookup-name>
</service-ref>
```

Assuming the above service-refs are defined in the WEB-INF/web.xml file, the client application could perform a JNDI lookup using the name java:comp/env/service/ExampleService2, and the result would be a reference to the ExampleService service defined in the WSDL document WEB-INF/wsdl/ExampleService.wsdl, as defined in the first service-ref.

### What to do next

Complete the client implementation by writing your client application code that is used to invoke the web service.

## Developing a dynamic client using JAX-WS APIs

Java API for XML-Based Web Services (JAX-WS) provides support for the dynamic invocation of service endpoint operations.

### About this task

JAX-WS provides a new dynamic Dispatch client API that is more generic and offers more flexibility than the existing Java API for XML-based RPC (JAX-RPC)-based Dynamic Invocation Interface (DII). The Dispatch client interface, javax.xml.ws.Dispatch, is an XML messaging oriented client that is intended for advanced XML developers who prefer to work at the XML level using XML constructs. To write a Dispatch client, you must have expertise with the Dispatch client APIs, the supported object types, and knowledge of the message representations for the associated Web Services Description Language (WSDL) file.

The Dispatch API can send data in either PAYLOAD or MESSAGE mode. When using the PAYLOAD mode, the Dispatch client is only responsible for providing the contents of the <soap:Body> and JAX-WS includes the input payload in a <soap:Envelope> element. When using the MESSAGE mode, the Dispatch client is responsible for providing the entire SOAP envelope.

The Dispatch client API requires application clients to construct messages or payloads as XML and requires a detailed knowledge of the message or message payload. The Dispatch client can use HTTP bindings when using Source objects, Java Architecture for XML Binding (JAXB) objects, or data source objects. The Dispatch client supports the following types of objects:

- javax.xml.transform.Source: Use Source objects to enable clients to use XML APIs directly. You can use Source objects with SOAP and HTTP bindings.
- JAXB objects: Use JAXB objects so that clients can use JAXB objects that are generated from an XML schema to create and manipulate XML with JAX-WS applications. JAXB objects can only be used with SOAP and HTTP bindings.
- javax.xml.soap.SOAPMessage: Use SOAPMessage objects so that clients can work with SOAP messages. You can only use SOAPMessage objects with SOAP version 1.1 or SOAP version 1.2 bindings.
- javax.activation.DataSource: Use DataSource objects so that clients can work with Multipurpose Internet Mail Extension (MIME) messages. Use DataSource only with HTTP bindings.

The Dispatch API uses the concept of generics that are introduced in Java SE Runtime Environment (JRE) 6. For each of the invoke() methods on the Dispatch interface, generics are used to determine the return type.

### Procedure

1. Determine if you want your dynamic client to send data in PAYLOAD or MESSAGE mode.

2. Create a service instance and add at least one port to it. The port carries the protocol binding and service endpoint address information.
3. Create a Dispatch<T> object using either the Service.Mode.PAYLOAD method or the Service.Mode.MESSAGE method.
4. Configure the request context properties on the javax.xml.ws.BindingProvider interface. Use the request context to specify additional properties such as enabling HTTP authentication or specifying the endpoint address.
5. Optional: Set the jaxws.response.throwExceptionIfSOAPFault property on the RequestContext option for the Dispatch API to `Boolean.TRUE` if you do not want the JAX-WS runtime to throw a SOAPFaultException.

   The following example illustrates how to specify this property on the RequestContext option for the Dispatch API

```
Dispatch<OMElement> dispatch = service.createDispatch(
portName, OMElement.class, Mode.MESSAGE);
BindingProvider bp = (BindingProvider)dispatch;
bp.getRequestContext().put(
"jaxws.response.throwExceptionIfSOAPFault", Boolean.FALSE);
```

6. Compose the client request message for the dynamic client.
7. Invoke the service endpoint with the Dispatch client either synchronously or asynchronously.
8. Process the response message from the service.

## Results

You have developed a dynamic JAX-WS client using the Dispatch API. Refer to Chapter 4, section 3 of the JAX-WS 2.0 specification for more information on using a Dispatch client.

**Note:** JAX-WS dynamic ports, which are those added using the service method addPort, might have additional memory requirements starting in WebSphere Application Server Version 8.0. In previous releases, a single instance of a dynamic port could be shared across multiple service instances. In version 8, dynamic ports are now scoped to the instance of the service that added them. If a JAX-WS client has multiple service instances which refer to a dynamic port of the same name, those instances are no longer shared. This can potentially increase the memory requirements for that client. The memory used by dynamic ports is released when the service instance goes out of scope. However, if you encounter issues related to increased memory usage, it is possible to revert the behavior so that dynamic ports are again shared across service instances. To do this, set the system property `jaxws.share.dynamic.ports.enable` to the value `true`. However, note that doing so can cause some other issues, such as having policy set attachments incorrectly applied across shared dynamic ports. If you set this flag to `true` and encounter some of these issues, then you should remove the flag setting.

In previous releases, if a SOAP Action was not provided by the Dispatch client application, the correct SOAP Action was not sent on the outbound message. Instead, the SOAP action was set to an anonymous operation. Starting in WebSphere Application Server Version 8, if the SOAP Action is not provided by the Dispatch client application, the JAX-WS runtime environment parses the outgoing message. It determines the operation being invoked and uses that information to determine the appropriate value for the SOAP Action. The operation resolution of the outbound message is based on the SOAP Body and the message encoding, for example, Doc/Lit/Bare, Doc/Lit/Wrapped. Since this parsing can be expensive, a property can be set. To always disable the parsing, set the property at the System level. To disable parsing on a per-message basis, set the property on the JAX-WS Request Message Context. The property is defined as a constant `org.apache.axis2.jaxws.Constants.DISPATCH_CLIENT_OUTBOUND_RESOLUTION` with a String value of `jaxws.dispatch.outbound.operation.resolution.enable`. The default value of the property is null which is interpreted as the String `true`, which enables the outbound operation resolution. Setting the property to `false` disables the outbound operation resolution. If parsing is disabled, then the SOAP Action in the outbound message is set to an anonymous operation as in previous releases. If the client provides a SOAP Action through the JAX-WS `javax.xml.ws.BindingProvider` properties,

SOAPACTION_USE_PROPERTY and SOAPACTION_URI_PROPERTY, then that SOAP Action is used. Therefore, parsing of the outbound message does not occur regardless of the setting of the property. Setting a SOAP Action explicitly by the client is considered a best practice, particularly for performance on the service-provider. This practice prevents the inbound message from being parsed, to be routed to the correct endpoint operation.

### Example

The following example illustrates the steps to create a Dispatch client and invoke a sample EchoService service endpoint.

```
String endpointUrl = ...;

QName serviceName = new QName("http://com/ibm/was/wssample/echo/",
 "EchoService");
QName portName = new QName("http://com/ibm/was/wssample/echo/",
 "EchoServicePort");

/** Create a service and add at least one port to it. **/
Service service = Service.create(serviceName);
service.addPort(portName, SOAPBinding.SOAP11HTTP_BINDING, endpointUrl);

/** Create a Dispatch instance from a service.**/
Dispatch<SOAPMessage> dispatch = service.createDispatch(portName,
SOAPMessage.class, Service.Mode.MESSAGE);

/** Create SOAPMessage request. **/
// compose a request message
MessageFactory mf = MessageFactory.newInstance(SOAPConstants.SOAP_1_1_PROTOCOL);

// Create a message.  This example works with the SOAPPART.
SOAPMessage request = mf.createMessage();
SOAPPart part = request.getSOAPPart();

// Obtain the SOAPEnvelope and header and body elements.
SOAPEnvelope env = part.getEnvelope();
SOAPHeader header = env.getHeader();
SOAPBody body = env.getBody();

// Construct the message payload.
SOAPElement operation = body.addChildElement("invoke", "ns1",
 "http://com/ibm/was/wssample/echo/");
SOAPElement value = operation.addChildElement("arg0");
value.addTextNode("ping");
request.saveChanges();

/** Invoke the service endpoint. **/
SOAPMessage response = dispatch.invoke(request);

/** Process the response. **/
```

## Invoking JAX-WS web services asynchronously

Java API for XML-Based Web Services (JAX-WS) provides support for invoking web services using an asynchronous client invocation. JAX-WS provides support for both a callback and polling model when calling web services asynchronously. Both the callback model and the polling model are available on the Dispatch client and the Dynamic Proxy client.

### Before you begin

Develop a JAX-WS Dynamic Proxy or Dispatch client. When developing Dynamic Proxy clients, after you generate the portable client artifacts from a Web Services Description Language (WSDL) file using the **wsimport** command, the generated service endpoint interface (SEI) does not have asynchronous methods included in the interface. Use JAX-WS bindings to add the asynchronous callback or polling methods on the interface for the Dynamic Proxy client. To enable asynchronous mappings, you can add the jaxws:enableAsyncMapping binding declaration to the WSDL file. For more information on adding binding customizations to generate an asynchronous interface, see chapter 8 of the JAX-WS specification.

**Note:** When you run the wsimport tool and enable asynchronous invocation through the use of the JAX-WS enableAsyncMapping binding declaration, ensure that the corresponding response message your WSDL file does not contain parts. When a response message does not contain parts, the request acts as a two-way request, but the actual response that is sent back is empty.

The wsimport tool does not correctly handle a void response. To avoid this scenario, you can remove the output message from the operation which makes your operation a one-way operation or you can add a <wsdl:part> to your message. For more information on the usage, syntax and parameters for the wsimport tool, see the wsimport command for JAX-WS applications documentation.

## About this task

An asynchronous invocation of a web service sends a request to the service endpoint and then immediately returns control to the client program without waiting for the response to return from the service. JAX-WS asynchronous web service clients consume web services using either the callback approach or the polling approach. Using a polling model, a client can issue a request and receive a response object that is polled to determine if the server has responded. When the server responds, the actual response is retrieved. Using the callback model, the client provides a callback handler to accept and process the inbound response object. The `handleResponse()` method of the handler is called when the result is available. Both the polling and callback models enable the client to focus on continuing to process work without waiting for a response to return, while providing for a more dynamic and efficient model to invoke web services. Polling invocations are valid from Enterprise JavaBeans (EJB) clients or Java Platform, Enterprise Edition (Java EE) application clients. Callback invocations are valid only from Java EE application clients.

**Using the callback asynchronous invocation model**

To implement an asynchronous invocation that uses the callback model, the client provides an `AsyncHandler` callback handler to accept and process the inbound response object. The client callback handler implements the `javax.xml.ws.AsyncHandler` interface, which contains the application code that is run when an asynchronous response is received from the server. The `javax.xml.ws.AsyncHandler` interface contains the `handleResponse(java.xml.ws.Response)` method that is called after the run time has received and processed the asynchronous response from the server. The response is delivered to the callback handler in the form of a `javax.xml.ws.Response` object. The response object returns the response content when the `get()` method is called. Additionally, if an error was received, then an exception is returned to the client during that call. The response method is then invoked according to the threading model used by the executor method, `java.util.concurrent.Executor` on the client's `java.xml.ws.Service` instance that was used to create the Dynamic Proxy or Dispatch client instance. The executor is used to invoke any asynchronous callbacks registered by the application. Use the `setExecutor` and `getExecutor` methods to modify and retrieve the executor configured for your service.

**Using the polling asynchronous invocation model**

Using the polling model, a client can issue a request and receive a response object that can subsequently be polled to determine if the server has responded. When the server responds, the actual response can then be retrieved. The response object returns the response content when the `get()` method is called. The client receives an object of type `javax.xml.ws.Response` from the `invokeAsync` method. That Response object is used to monitor the status of the request to the server, determine when the operation has completed, and to retrieve the response results.

**Using an asynchronous message exchange**

By default, asynchronous client invocations do not have asynchronous behavior of the message exchange pattern on the wire. The programming model is asynchronous; however, the exchange of request or response messages with the server is not asynchronous. To use an asynchronous message exchange, the `com.ibm.websphere.webservices.use.async.mep` property must be set on the client request context with a boolean value of `true`. When this property is enabled, the messages exchanged between the client and server are different from messages exchanged synchronously. With an asynchronous exchange, the request and response messages have WS-Addressing headers added that provide additional routing information for the messages. Another major difference between asynchronous and synchronous message exchange is that the response is delivered to an asynchronous listener that then delivers that response back to the client. For asynchronous exchanges, there is no timeout that is sent to notify the client to stop

listening for a response. To force the client to stop waiting for a response, issue a `Response.cancel()` method on the object returned from a polling invocation or a `Future.cancel()` method on the object returned from a callback invocation. The cancel response does not affect the server when processing a request.

**Note:** Windows The location of the asynchronous listener is sent to the server, so that the service can reply to the client. On Windows operating systems, the local host name is used by default, because it is compatible with Dynamic Host Configuration Protocol (DHCP). However, if the server cannot resolve the host name, the client application does not receive replies from the target service. For example, a client application is hosted on the workstation myhost.bar.com. In the following SOAP message header, the client application sends the short name myhost as its host details. Unless the target server can resolve myhost to myhost.bar.com, subsequent replies do not reach the client application:

```
<soapenv:Header>
  <wsa:To>http://target.bar.com:81/LiteSecurityService/SecurityService</wsa:To>
  <wsa:ReplyTo>
    <wsa:Address>http://myhost:2146/axis2/services/LiteSecurityService.
      WSRMServicePort/AnonOutInOp?IBMwebservicesID=922A5DC38A337C4CEF1168347862705
    </wsa:Address>
  </wsa:ReplyTo>
  <wsa:MessageID>urn:uuid:922A5DC38A337C4CEF1168347862403</wsa:MessageID>
  <wsa:Action>getEndpointReference</wsa:Action>
</soapenv:Header>
```

To resolve this issue, configure the client to send the location details for the asynchronous listener in IP format, by adding the following system property to the Java virtual machine. Note that by transmitting the IP address, you lose the benefits of DHCP.

```
-Dcom.ibm.websphere.webservices.transportEPRInIPAddr=yes
```

## Procedure

1. Determine if you want to implement the callback method or the polling method for the client to asynchronously invoke the web service.
2. (Optional) Configure the client request context. Add the

```
com.ibm.websphere.webservices.use.async.mep
```

property to the request context to enable asynchronous messaging for the web services client. Using this property requires that the service endpoint supports WS-Addressing which is supported by default for the application server. The following example demonstrates how to set this property:

```
Map<String, Object> rc = ((BindingProvider) port).getRequestContext();
 rc.put("com.ibm.websphere.webservices.use.async.mep", Boolean.TRUE);
```

3. To implement the asynchronous callback method, perform the following steps.
   a. Find the asynchronous callback method on the SEI or `javax.xml.ws.Dispatch` interface. For an SEI, the method name ends in *Async* and has one more parameter than the synchronous method of type `javax.xml.ws.AsyncHandler`. The `invokeAsync(Object, AsyncHandler)` method is the one that is used on the Dispatch interface.
   b. (Optional) Add the `service.setExecutor` methods to the client application. Adding the executor methods gives the client control of the scheduling methods for processing the response. You can also choose to use the `java.current.Executors` class factory to obtain packaged executors or implement your own executor class. See the JAX-WS specification for more information on using executor class methods with your client.
   c. Implement the `javax.xml.ws.AsyncHandler` interface. The `javax.xml.ws.AsyncHandler` interface only has the `handleResponse(javax.xml.ws.Response)` method. The method must contain the logic for processing the response or possibly an exception. The method is called after the client run time has received and processed the asynchronous response from the server.
   d. Invoke the asynchronous callback method with the parameter data and the callback handler.
   e. The `handleResponse(Response)` method is invoked on the callback object when the response is available. The `Response.get()` method is called within this method to deliver the response.
4. To implement the polling method,

a. Find the asynchronous polling method on the SEI or `javax.xml.ws.Dispatch` interface. For an SEI, the method name ends in *Async* and has a return type of `javax.xml.ws.Response`. The `invokeAsync(Object)` method is used on the Dispatch interface.

b. Invoke the asynchronous polling method with the parameter data.

c. The client receives the object type, `javax.xml.ws.Response`, that is used to monitor the status of the request to the server. The `isDone()` method indicates whether the invocation has completed. When the `isDone()` method returns a value of `true`, call the `get()` method to retrieve the response object.

5. Use the `cancel()` method for the callback or polling method if the client needs to stop waiting for a response from the service. If the `cancel()` method is invoked by the client, the endpoint continues to process the request. However, the wait and response processing for the client is stopped.

## Results

You have enabled your JAX-WS web service client to asynchronously invoke and consume web services. See the JAX-WS specification for additional information regarding the asynchronous client APIs.

## Example

The following example illustrates a web service interface with methods for asynchronous requests from the client.

```
@WebService

public interface CreditRatingService {
       // Synchronous operation.
       Score getCreditScore(Customer     customer);
       // Asynchronous operation with polling.
       Response<Score> getCreditScoreAsync(Customer customer);
       // Asynchronous operation with callback.
       Future<?> getQuoteAsync(Customer customer,
              AsyncHandler<Score> handler);
}
```

### Using the callback method

The callback method requires a callback handler that is shown in the following example. When using the callback procedure, after a request is made, the callback handler is responsible for handling the response. The response value is a response or possibly an exception. The `Future<?>` method represents the result of an asynchronous computation and is checked to see if the computation is complete. When you want the application to find out if the request is completed, invoke the `Future.isDone()` method. Note that the `Future.get()` method does not provide a meaningful response and is not similar to the `Response.get()` method.

```
CreditRatingService svc = ...;

Future<?> invocation = svc.getCreditScoreAsync(customerTom,
       new AsyncHandler<Score>() {
              public void handleResponse (
                     Response<Score> response)
                 {
                    score = response.get();
                    // process the request...
                 }
    }
);
```

### Using the polling method

The following example illustrates an asynchronous polling client:

```
CreditRatingService svc = ...;
Response<Score> response = svc.getCreditScoreAsync(customerTom);

while (!response.isDone()) {
       // Do something while we wait.
}

score = response.get();
```

# Implementing extensions to JAX-WS web services clients

WebSphere Application Server provides extensions to web services clients using the Java API for XML-based Web Services (JAX-WS) programming model.

## About this task

You can customize web services by using the following extensions to the JAX-WS client programming model.

## Procedure

- Set the **JAXWS_OUTBOUND_SOAP_HEADERS** and **JAXWS_INBOUND_SOAP_HEADERS** properties on the request context of the Dispatch or Proxy object to enable a JAX-WS web services client to send or retrieve implicit SOAP headers.

  An implicit SOAP header is a SOAP header that is not explicitly defined in the WSDL file. An implicit SOAP header file fits one of the following descriptions:

  – A message part that is declared as a SOAP header in the binding in the WSDL file, but the message definition is not referenced by a portType within a WSDL file.

  – An element that is not contained in the WSDL file.

  Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

  To learn how to modify your client code to send or retrieve transport headers, see the information on sending implicit SOAP headers with JAX-WS or receiving implicit SOAP headers with JAX-WS.

- Set the **REQUEST_TRANSPORT_PROPERTIES** and **RESPONSE_TRANSPORT_PROPERTIES** properties to enable a web services client to send or retrieve transport headers.

  Set the properties on the BindingProvider instance.

  By modifying your client code to send or retrieve transport headers, you can send or receive specific information within the transport headers of outgoing requests or incoming responses from the server. For requests or responses that use the HTTP transport, the information is sent or retrieved in an HTTP header. Similarly, for a request or response that uses the Java Message Service (JMS) transport, the information is sent or retrieved in a JMS message property.

  To learn how to modify your client code to send or retrieve transport headers, see the information on sending transport headers with JAX-WS or retrieving transport headers with JAX-WS.

  To learn how to enable a web services client to send or retrieve transport headers, see the transport header properties best practices information.

## Example: Using JAX-WS properties to manipulate SOAP headers in a JAX-WS handler

WebSphere Application Server provides extensions to the Java API for XML-Based Web Services (JAX-WS) and Web Services for Java Platform, Enterprise Edition (Java EE) client programming models, including the jaxws.binding.soap.headers.outbound and jaxws.binding.soap.headers.inbound properties. This example shows how to use these two properties to manipulate SOAP headers in a JAX-WS handler.

The following programming example illustrates how to set two request SOAP headers and retrieve one response SOAP header within a JAX-WS handler context:

```
1  //Create the hashmaps for the outbound soap headers
2  Map<QName, List<String>> outboundHeaders=messageContext.get("jaxws.binding.soap.headers.outbound");
3
4  //Add "AtmUuid1" and "AtmUuid2" to the outbound map
5  List<String> list1 = new ArrayList<String>();
6  list1.add("<AtmUuid1 xmlns=\"com.rotbank.security\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid1>");
7  List<String> list2 = new ArrayList<String>();
8  list2.add("<AtmUuid2 xmlns=\"com.rotbank.security\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid2>"
9  outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid1"), list1);
10 outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid2"), list2);
11 // Set the outbound map on the MessageContext object, which is passed into the JAX-WS handler method
12 messageContext.put("jaxws.binding.soap.headers.outbound", outboundHeaders);
```

On line 2, retrieve the outbound SOAP header map from the MessageContext parameter, which is passed into the JAX-WS handler method.

On lines 5-10, the AtmUuid1 and AtmUuid2 headers elements are added to the outbound map.

On line 12, the outbound map is set on the JAX-WS handler context, which causes the AtmUuid1 and AtmUuid2 headers to be added to the request message. This code is not necessary because the outboundHeaders map is a live map.

JAX-WS handler methods might also retrieve specific headers from the map and remove headers or entire lists of headers, if desired.

## Sending implicit SOAP headers with JAX-WS

You can enable an existing Java API for XML-Based Web Services (JAX-WS) web services client to send values in implicit SOAP headers. By modifying your client code to send implicit SOAP headers, you can send specific information within an outgoing web service request.

### Before you begin

To complete this task, you need a web services client that you can enable to send implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

Using JAX-WS, there is no restriction on types of headers that you can manipulate.

### About this task

The client application sets properties on the Dispatch or Proxy object to send and receive implicit SOAP headers.

### Procedure

1. Create a java.util.HashMap<QName, List<String>> object.
2. Add an entry to the HashMap object for each implicit SOAP header that the client wants to send. The HashMap entry key is the QName of the SOAP header. The HashMap entry value is a List<String> object, and each String is the XML text of the entire SOAP header element. By using List<String> object, you can add multiple SOAP header elements that each have the same QName object.
3. Set the HashMap object as a property on the request context of the Dispatch or Proxy object. The property name is com.ibm.wsspi.websvcs.Constants.JAXWS_OUTBOUND_SOAP_HEADERS. The value of the property is the HashMap.
4. Issue the remote method calls using the Dispatch or Proxy object. The headers within the HashMap object are sent in the outgoing message.

   A WebServiceException error can occur if any of the following are true:

   - The HashMap object contains a key that is not a QName object or if the HashMap object contains a value that is not a List<String> object.
   - The String representing an SOAP header is not a compliant XML message.
   - The HashMap contains a key that represents a SOAP header that is declared protected by the owning component.

### Results

You have a JAX-WS web services client that is configured to send implicit SOAP headers.

### Example

The following programming example illustrates how to set two request SOAP headers and retrieve one response SOAP header within a JAX-WS web services request and response context:

```
1  //Create the hashmaps for the outbound soap headers
2  Map<QName, List<String>> outboundHeaders=new HashMap<QName, List<String>>();
3
4  //Add "AtmUuid1" and "AtmUuid2" to the outbound map
5  List<String> list1 = new ArrayList<String>();
6  list1.add("<AtmUuid1 xmlns=\"com.rotbank.security\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid1>");
7  List<String> list2 = new ArrayList<String>();
8  list2.add("<AtmUuid2 xmlns=\"com.rotbank.security\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid2>"
9  outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid1"), list1);
10 outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid2"), list2);
11 // Set the outbound map on the request context
12 dispatch.getRequestContext().put("jaxws.binding.soap.headers.outbound");
13 // Invoke the remote operation
14 dispatch.invoke(parm1);
15 // Get the inbound header map from the response context
16 Map<QName,List<String>> inboundMap = dispatch.getResponseContext().get("jaxws.binding.soap.headers.outbound");
17 List<String> serverUuidList = inboundMap.get(new QName("com.rotbank.security","ServerUuid"));
18 String text = serverUiidList.get(0);
19 //Note: text now equals a XML object that contains a SOAP header:
21//"<y:ServerUuid xmlns:y=\"com.rotbank.security\"><:uuid>ROTB-0A03519322FSA01
22  </y:uuid></y:ServerUuid.");
```

On line 2, create the outbound SOAP header map.

On lines 5-10, the AtmUuid1 and AtmUuid2 headers elements are added to the outbound map.

On line 12, the outbound map is set on the request context, which causes the AtmUuid1 and AtmUuid2 headers to be added to the request message when the operation is invoked.

On line 14, invoke the remote operation.

On line 15, obtain the outbound header map.

On lines 17-18, the ServerUuid header is retrieved from the response Map. The Map accesses the SOAP header from the response message.

## Receiving implicit SOAP headers with JAX-WS

You can enable an existing Java API for XML-Based Web Services (JAX-WS) web services client to receive values from implicit SOAP headers. By modifying your client code to receive implicit SOAP headers, you can receive specific information within an incoming web service response.

### Before you begin

To complete this task, you need a web services client that you can enable to receive implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

Using JAX-WS, there is no restriction on types of headers that you can manipulate.

### About this task

The client application sets properties on the Dispatch or Proxy object to send and receive implicit SOAP headers.

### Procedure

1. Issue a remote method call with the Dispatch or Proxy object.
2. Using the property name, com.ibm.wsspi.websvcs.Constants.JAXWS_INBOUND_SOAP_HEADERS, retrieve the Map<QName, List<String>> from the ResponseContext of the Dispatch or Proxy object.
3. From the Map<QName, List<String>> value, retrieve a List<String> using the QName of the SOAP header. If the List<String> value is present, that value contains zero or more String objects that contain the XML text of the SOAP headers for the corresponding QName.

### Results

You have a JAX-WS web services client that can receive values from implicit SOAP headers.

## Transport header properties best practices

You can set the REQUEST_TRANSPORT_PROPERTIES property and RESPONSE_TRANSPORT_PROPERTIES property on a Java API for XML-based RPC (JAX-RPC) client Stub, a Call instance, or a Java API for XML-Based Web services (JAX-WS) BindingProvider's RequestContext instance to enable a web services client to send or retrieve transport headers.

**Note:** Use these best practices to enable a Web services client to send or retrieve transport headers.

### REQUEST_TRANSPORT_PROPERTIES best practices

#### Transport headers that require multiple values

Some transport headers such as the HTTP Cookie header and the Cookie2 header contain multiple embedded values. For headers that contain multiple values, the header value must be written in the following way:

- Each name=value pair embedded within the header value must be separated by a semi-colon (;).
- Each *name* and its value must be separated by an equal (=) sign.

The following is an example of how the header value must be written:

```
name1=value1;name2=value2;name3=value3
```

#### Map values

The values contained in the user's Map might be parsed before being added to the outgoing request if the outgoing request already contains a header identifier that matches one in the Map. For certain transport headers that contain multiple embedded values, the header values in the Map are parsed into individual name=value components. A semi-colon (;) separates the components, for example, name1=value1;name2=value2. Each name=value is appended to the outgoing header unless:

- **The outgoing request header contains a *name* value**.

  In this case, the name=value from the Map is silently ignored, preventing a client from overwriting or modifying values for the *name* value that are already set in the outgoing request header by either the server or the web services engine.
- **The user's header value contains multiple *name* values**.

  When the user's header value contains multiple *name* values, the first occurrence of the *name* value is used and the others are silently ignored. For example, if the user's header value contains

name1=value1;name2=value2;name1=value3, where there are two occurrences of name1, the first value, name1=value1, is used. The other value, name1=value3, is silently ignored.

## RESPONSE_TRANSPORT_PROPERTIES best practices

### Map values

Only the Map keys are used; the Map values are ignored. The values are filled in this Map by retrieving the transport headers, which correspond to the Map keys from the incoming response message. An empty Map causes all of the transport headers and the associated values to be retrieved from the incoming response message.

## HTTP headers that are processed under special consideration

The following are HTTP headers that are given special consideration when sending and retrieving HTTP responses and requests.

The values in these headers can be set in a variety of ways. For example, some header values are sent based on settings in a deployment descriptor or binding file. In these cases, the value set through REQUEST_TRANSPORT_PROPERTIES overrides the values set any other way.

*Table 220. HTTP request and response header values. Values to specify for HTTP headers when sending and retrieving HTTP responses and requests.*

| Header | Send request | Retrieve response |
|---|---|---|
| **Transfer-encoding** | • The transfer-encoding header is ignored for HTTP 1.0.<br>• When using HTTP 1.1, the transfer-encoding header is set to `chunked` if the value is `chunked`. | There is no special processing. |
| **Connection** | • The connection header is ignored for HTTP 1.0.<br>• When using HTTP 1.1, the following values are set:<br>– The connection header is set to "close" if the value is set to "close".<br>– The connection header is set to "keep-alive" if the value is set to "keep-alive".<br>– All other value settings are ignored. | There is no special processing. |
| **Expect** | • The expect header is ignored for HTTP 1.0.<br>• When using HTTP 1.1, the following values are set:<br>– The connection header is set to "100-continue" if the value is set to "100-continue".<br>– All other value settings are ignored. | There is no special processing. |
| **Host** | Ignored | There is no special processing. |
| **Content-type** | Ignored | There is no special processing. |
| **SOAPAction** | Ignored | There is no special processing. |
| **Content-length** | Ignored | There is no special processing. |
| **Cookie**<br><br>The following is a String constant: com.ibm.websphere.webservices.Constants .HTTP_HEADER_COOKIE | The value is sent on the header if it is structured correctly. See the information in this article for Header value format and Map values. | There is no special processing. |

*Table 220. HTTP request and response header values (continued). Values to specify for HTTP headers when sending and retrieving HTTP responses and requests.*

| | | |
|---|---|---|
| **Cookie2**<br><br>The following is a String constant:<br>com.ibm.websphere.webservices.Constants<br>.HTTP_HEADER_COOKIE2 | See the information in the "Cookie" entry. | There is no special processing. |
| **Set-cookie**<br><br>The following is a String constant:<br>com.ibm.websphere.webservices.Constants<br>.HTTP_HEADER_SET_COOKIE | There is no special processing. | If the property MAINTAIN_SESSION is set to `true`, the entire value is saved into SessionContext.CONTEXT_PROPERTY and is sent on subsequent requests in the Cookie header. See the Cookie entry in this table for more information. |
| **Set-cookie2**<br><br>The following is a String constant:<br>com.ibm.websphere.webservices.Constants<br>.HTTP_HEADER_SET_COOKIE2 | There is no special processing. | If the property MAINTAIN_SESSION is set to `true`, the entire value is saved into SessionContext.CONTEXT_PROPERTY and is sent on subsequent requests in the Cookie header. See the Cookie entry in this table for more information. |

### Example client code

The following is an example of how you can code a web services client to send and retrieve transport header values:

```
public class MyApplicationClass {
    // Inject an instance of the service's port-type.
    @WebServiceRef(EchoService.class)
    private EchoPortType port;

    // This method will invoke the web service operation and send and receive transport headers.
    public void invokeService() {

        // Set up the Map that will contain the request headers.
        Map<String, Object>requestHeaders = new HashMap<String, Object>();
        requestHeaders.put("Cookie", "ClientAuthenticationToken=FFEEBBCC");
        requestHeaders.put("MyHeaderFlag", new Boolean(true));

        // Set the Map as a property on the RequestContext.
        BindingProvider bp = (BindingProvider) port;
        bp.getRequestContext().put(com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES, requestHeaders);

        // Set up the Map to retrieve transport headers from the response message.
        Map<String, Object>responseHeaders = new HashMap<String, Object>();
        responseHeaders.put("Set-Cookie", null);
        responseHeaders.put("MyHeaderFlag, null);

        // Invoke the web services operation.
        String result = port.echoString("Hello, world!");

        // Retrieve the headers from the response.
        String cookieValue = responseHeaders.get("Set-Cookie");
        String headerFlag = responseHeaders.get("MyHeaderFlag");
    }
}
```

## Sending transport headers with JAX-WS

You can enable an existing Java API for XML-Based Web Services (JAX-WS) web services client to send application-defined information along with your web services requests by using transport headers. In addition, you can enable a JAX-WS Web services endpoint to send application-defined information along with the Web services response message by using transport headers.

### Before you begin

You need a JAX-WS web services client that you can enable to send transport headers.

Sending transport headers is supported in JAX-WS Web services clients, and is supported for the HTTP and JMS transports. The web services client must call the JAX-WS APIs directly and not through any intermediary layers, such as a gateway function.

## About this task

When using the JAX-WS programming model, the client must set a property on the BindingProvider's RequestContext object to send values in transport headers with the Web services request message. After you set the property, the values are set in all the requests for subsequent remote method invocations against the BindingProvider object until the associated property is set to null or the BindingProvider object is discarded.

To send values in the transport headers on outbound requests from a JAX-WS Web services client application, modify the client code as follows:

## Procedure

1. Create a java.util.Map object that contains the transport headers.
2. Add an entry to the Map object for each transport header that you want the client to send.
   a. Set the Map entry key to a string that exactly matches the transport header identifier. You can define the header identifier with a reserved header name, such as Cookie in the case of HTTP, or the header identifier can be user-defined, such as `MyTransportHeader`. Certain header identifiers are processed in a unique manner, but no other checks are made as to the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as HTTP_HEADER_SET_COOKIE in the com.ibm.websphere.webservices.Constants class.
   b. Set the Map entry value to the value of the transport header. The type of this value can be one of the following data types:
      - java.lang.String
      - java.lang.Integer
      - java.lang.Short
      - java.lang.Long
      - java.lang.Float
      - java.lang.Double
      - java.lang.Byte
      - java.lang.Boolean

      **Note:** When using transport headers with HTTP, all non-String header values are converted to java.lang.String before being set on the HTTP message.
3. Set the Map object on the BindingProvider's RequestContext using the com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES property. When the REQUEST_TRANSPORT_PROPERTIES property value is set, that Map is used on subsequent invocations to set the header values in the outgoing requests. If the REQUEST_TRANSPORT_PROPERTIES property value is set to null, no transport properties are sent in outgoing requests. To learn more about these properties, see the transport header properties documentation.
4. Issue remote method calls against the BindingProvider instance. The headers and the associated values from the Map are added to the outgoing request for each method invocation. If the invocation uses HTTP, then the transport headers are sent as HTTP headers within the HTTP request. If the invocation uses JMS, then the transport headers are sent as JMS message properties.

   If the Constants.REQUEST_TRANSPORT_PROPERTIES property is not set correctly, you might experience API usage errors that result in a WebServiceException error. The following requirements must be met, or the process fails:
   a. The Constants.REQUEST_TRANSPORT_PROPERTIES property value that is set on the BindingProvider's RequestContext must be a java.util.Map object or null.
   b. Each key in the Map must be a java.util.String data type.

c. Each value in the Map must be one of the following data types:
   - java.lang.String
   - java.lang.Integer
   - java.lang.Short
   - java.lang.Long
   - java.lang.Float
   - java.lang.Double
   - java.lang.Byte
   - java.lang.Boolean

## Results

You have a JAX-WS web services client that is configured to send transport headers in Web services request messages.

## Example

Here is a short programming example that illustrates how request transport headers are sent by a JAX-WS Web services client application:

```
public class MyApplicationClass {
    // Inject an instance of the service's port-type.
    @WebServiceRef(EchoService.class)
    private EchoPortType port;

    // This method will invoke  the web service operation and send transport headers on the request.
    public void invokeService() {

        // Set up the Map that will contain the request headers.
        Map<String, Object> requestHeaders = new HashMap<String, Object>();
        requestHeaders.put("MyHeader1", "This is a string value");
        requestHeaders.put("MyHeader2", new Integer(33));
        requestHeaders.put("MyHeader3", new Boolean(true));

        // Set the Map as a property on the RequestContext.
        BindingProvider bp = (BindingProvider) port;
        bp.getRequestContext().put(com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES, requestHeaders);

        // Invoke the web services operation.
        String result = port.echoString("Hello, world!");
    }
}
```

### *Sending response transport headers from a JAX-WS endpoint:*
### Before you begin

You need a JAX-WS Web services endpoint implementation class that you can enable to send transport headers.

Sending response transport headers from a JAX-WS endpoint is similar to sending request transport headers from a JAX-WS client. It is supported for the HTTP and JMS transports.

#### About this task

When using the JAX-WS programming model, the endpoint implement class must set a property on the MessageContext to send values in transport headers with the Web services response message.

#### Procedure

1. Create a java.util.Map object that contains the transport headers.
2. Add an entry (key and value) to the Map object for each transport header that you want to send in the response message. This is similar to the procedure for the client above.

3. Retrieve the MessageContext (instance of `javax.xml.ws.handler.MessageContext`) associated with the invocation of the endpoint.
4. Set the Map object on the MessageContext using the com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES property.

### Results

You have a JAX-WS Web services endpoint implementation class that is configured to send transport headers in Web services response messages.

### Example

Here is a short programming example that illustrates how response transport headers are sent by a JAX-WS Web services endpoint implementation class:

```
@WebService
public class EchoServiceImpl implements EchoServicePortType {

    // Inject an instance of WebServiceContext so we can retrieve
    // the MessageContext for each invocation of this endpoint.
    @Resource
    WebServiceContext ctxt;

    /**
     * Default constructor.
     */
    public EchoServiceImpl() {
        ....
    }

    public String echoString(String input) {
        String result = "Echo result: " + input;

        // Retrieve the MessageContext from the injected WebServiceContext.
        MessageContext mc = ctxt.getMessageContext();

        // Send some headers back in the response message.
        Map<String, Object> responseHeaders = new HashMap<String, Object>();
        responseHeaders.put("MyHeader1", "This is a string response value");
        responseHeaders.put("MyHeader2", new Integer(33));
        responseHeaders.put("MyHeader3", new Boolean(false));

        // Set the response header Map on the MessageContext.
        mc.put(com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES, responseHeaders);

        return result;
    }
}
```

## Retrieving transport headers with JAX-WS

You can enable a Java API for XML-Based Web Services (JAX-WS) web services client to retrieve values from transport headers. For a request that uses HTTP, the transport headers are retrieved from HTTP headers found in the HTTP response message. For a request that uses Java Message Service (JMS), the transport headers are retrieved from the JMS message properties found on the JMS response message.

### Before you begin

You need a JAX-WS web services client that you can enable to retrieve transport headers.

Retrieving transport headers is supported only by Web services clients, and is supported for the HTTP and JMS transports. The web services client must call the JAX-WS APIs directly and not through any intermediary layers, such as a gateway function.

## About this task

When using the JAX-WS programming model, the client must set a property on the BindingProvider's RequestContext object to retrieve values from the transport headers. After you set the property, values are read from responses for the subsequent method invocations against that BindingProvider object until the associated property is set to null or the BindingProvider object is discarded.

To retrieve values from the transport headers on inbound responses, modify the client code as follows:

## Procedure

1. Create a java.util.Map object that will hold the transport headers retrieved from the response message. To retrieve all the transport headers from a response message, leave this Map empty.
2. (Optional) Add an entry to the Map for each header that you want to retrieve from the incoming response message.
   a. Set the Map entry key to a string that exactly matches the transport header identifier. You can specify the header identifier with a reserved header name, such as Cookie in the case of HTTP, or the header identifier can be user-defined, such as `MyTransportHeader`. Certain header identifiers are processed in a unique manner, but no other checks are made to confirm the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as HTTP_HEADER_SET_COOKIE in the com.ibm.websphere.webservices.Constants class. The Map entry value is ignored and does not need to be set. An empty Map, for example, one that is non-null, but does not contain any keys, causes all the transport headers in the response to be retrieved.
3. Set the Map object on the BindingProvider's RequestContext using the com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES property. When the Map is set, the RESPONSE_TRANSPORT_PROPERTIES property is used in subsequent invocations to retrieve the headers from the responses. If you set the property to null, no headers are retrieved from the response. To learn more about these properties, see the transport header properties documentation.
4. Invoke remote method calls against the BindingProvider instance. The values from the specified transport headers are retrieved from the response message and placed in the Map.

   If the property is not set correctly, you might experience API usage errors that result in a WebServiceException error. The following requirements must be met, or the process fails:
   - The Constants.RESPONSE_TRANSPORT_PROPERTIES property value that is set on the BindingProvider's RequestContext instance must be either null or an instance of java.util.Map.
   - All the Map keys must be of the java.lang.String data type, and the keys must not be null.
   - The Map may be empty, which means that it contains no entries at all. In this case, all the transport headers will be retrieved from the response message.

## Results

You have a JAX-WS web service that can receive transport headers from incoming response messages.

## Example

Here is a short programming example that illustrates how response transport headers are retrieved by a JAX-WS Web services client application:

```
public class MyApplicationClass {
    // Inject an instance of the service's port-type.
    @WebServiceRef(EchoService.class)
    private EchoPortType port;

    // This method will invoke  the web service operation and retrieve transport headers on the request.
    public void invokeService() {
```

```
        // Set up the Map to retrieive our response headers.
        Map<String, Object> responseHeaders = new HashMap<String, Object>;
        responseHeaders.put("MyHeader1", null);
        responseHeaders.put("MyHeader2", null);
        responseHeaders.put("MyHeader3", null);

        // Set the Map as a property on the RequestContext.
        BindingProvider bp = (BindingProvider) port;
        bp.getRequestContext().put(com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES, responseHeaders);

        // Invoke the web services operation.
        String result = port.echoString("Hello, world!");

        // Now retrieve our response headers.
        Object header1 = responseHeaders.get("MyHeader1");
        Object header2 = responseHeaders.get("MyHeader2");
        Object header3 = responseHeaders.get("MyHeader3");

    }
}
```

# Developing JAX-RPC web services

## Setting up a development environment for web services

The application server provides command-line tools to develop web services clients and implementations that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. You must set up your development environment before you start developing web services.

### Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information on installing the application server, read about installing your application server environment.

### About this task

Set up a web services development environment by completing the following actions.

### Procedure

1. Set up the environment.

   Windows Run the `setupCmdLine.bat` command from the *`/profile_root/<application_server>`*`/bin` directory.

   Linux AIX HP-UX Solaris Operating systems such as AIX or Linux ***source*** the script to the parent shell to inherit the exported variables by running this command:

```
. ./setupCmdLine.sh  (Notice the space between the periods.)
```

   from the `.` *`/profile_root/<application_server>`*`/bin` directory.

   You can set `WAS_USER_SCRIPT` to *`profile_root`*`\<`*`application_server`*`>\bin\setupCmdLine.bat`, which has the same effect as running the setupCmdLine command.

2. Configure the path. You can add the WebSphere and Java `bin` directories to your path by typing:

   Windows

```
set PATH=%WAS_PATH%;%PATH%
```

   AIX HP-UX Solaris Linux

```
export PATH=$WAS_PATH:$PATH
```

### Results

You have set up an environment so that you can develop Web services.

### What to do next

Implement web services applications. See the task overview for implementing web services applications information to learn about how to develop and implement a Java EE web service.

## Developing a service endpoint interface from JavaBeans for JAX-RPC applications

You must develop a service endpoint interface if you are developing a JAX-RPC web service from a JavaBeans implementation.

### Before you begin

You need to set up a development environment for web services and access an existing Java bean web application archive (WAR) file. See the setting up a development environment for web services information.

### About this task

This task is a required step in developing a JAX-RPC Web service from a Java bean.

The service endpoint interface defines the methods for particular Java API for XML-based RPC (JAX-RPC) web services. The JavaBeans implementation must implement methods with the same signature as the methods on the service endpoint interface. A number of restrictions apply on which types to use as parameters and results of service endpoint interface methods. These restrictions are documented in the JAX-RPC specification.

You can also create a service endpoint interface by using assembly tools.

Develop a service endpoint interface for a JavaBeans implementation by following the actions listed:

### Procedure

1. Create a Java interface that contains the methods to include in the service endpoint interface. If you start with an existing Java interface, remove any methods that do not conform to the JAX-RPC specification.
2. Compile the interface.

   Use the name of the service endpoint interface class in the javac command for the class to compile.

   Windows Use the javac commands.

   Linux AIX HP-UX Solaris On operating systems such as AIX or Linux, see the developing thin application client code information.

### Results

You have developed a service endpoint interface that you can use to develop web services.

### Example

The following example depicts the AddressBook interface:

```
package addr;
public interface AddressBook {
    /**
     * Retrieve an entry from the AddressBook.
     *
     *@param name the name of the entry to look up.
     *@return the AddressBook entry matching name or null if none.
```

```
     *@throws java.rmi.RemoteException if communications failure.
     */
    public addr.Address getAddressFromName(java.lang.String name);
}
```

Use the `AddressBook` interface to create the service endpoint interface:
1. Make a copy of the `AddressBook.java` interface and name it `AddressBook_SEI.java`. Use this copy as a template for the service endpoint interface.
2. Compile the interface.

### What to do next

Continue to gather the artifacts that are required to develop a web service, including the Web Services Description Language (WSDL) file. You need to develop a WSDL file because it is the engine of a web service. Without a WSDL file, you do not have a web service. See the developing a WSDL file for JAX-RPC applications information.

## Developing a service endpoint interface from enterprise beans for JAX-RPC applications

You can develop a service endpoint interface from an Enterprise JavaBeans (EJB) for JAX-RPC web services.

### Before you begin

Set up a development environment for web services. To learn more, see the setting up a development environment for web services information.

Set up a development environment for web services.

This task is a required step in developing a Java API for XML-based RPC (JAX-RPC) web service from an enterprise bean.

The service endpoint interface defines the web services methods. The enterprise beans that implements the web service must implement methods having the same signature as the methods of the service endpoint interface. A number of restrictions exist on which types to use as parameters and results of service endpoint interface methods. These restrictions are documented in the Java API for XML-based remote procedure call (JAX-RPC) specification. See the web services specifications and API documentation to review the JAX-RPC specification along with a complete list of the supported standards and specifications.

The easiest method for creating the service endpoint interface for an EJB web service implementation is from the EJB remote interface.

You can also create a service endpoint interface by using assembly tools..

### About this task

Develop a service endpoint interface by following the steps provided in this task section.

### Procedure

1. Create a Java interface that contains the methods that you want to include in the service endpoint interface. If you start with an existing Java interface, remove any methods that do not conform to the JAX-RPC specification.
2. Compile the interface.

   Use the name of the service endpoint interface class in the javac command for the class to compile.

Windows Use the javac commands.

Linux AIX HP-UX Solaris On operating systems such as AIX or Linux, see the developing stand-alone thin client applications documentation.

### Results

You have a service endpoint interface that you can use to develop a web service.

### Example

This example uses the EJB remote interface, `AddressBook_RI`, to create a service endpoint interface for an EJB implementation that is used as a web service. The following code example illustrates the AddressBook_RI remote interface.

```
package addr;
public interface AddressBook_RI extends javax.ejb.EJBObject {
    /**
     * Retrieve an entry from the AddressBook.
     *
     *@param name the name of the entry to look up.
     *@return the AddressBook entry matching name or null if none.
     *@throws java.rmi.RemoteException if communications failure.
     */
    public addr.Address getAddressFromName(java.lang.String name)
     throws java.rmi.RemoteException;
}
```

Use the following steps to create the service endpoint interface with the `AddressBook_RI` remote interface:

1. Locate a remote interface that has already been created, like the `AddressBook_RI.java` remote interface.
2. Make a copy of the `AddressBook.java` remote interface and use it as a template for the service endpoint interface.
3. Compile the `AddressBook.java` service endpoint interface.

### What to do next

Continue gathering the artifacts that are required to develop a web service, including the Web Services Description Language (WSDL) file. You need to develop a WSDL file because it is the engine of a web service; without a WSDL file, you have no web service.

## Developing a WSDL file for JAX-RPC applications

You can develop a Web Services Description Language (WSDL) file to describe the characteristics of your Java API for XML-based RPC (JAX-RPC) web services application including where the service resides and how to invoke the service using an XML format.

### Before you begin

Depending on your development path, develop a service endpoint interface from a JavaBeans implementation or develop a service endpoint interface from an enterprise bean implementation.

### About this task

You need a WSDL file to use web services. You can develop your own WSDL file or get one from a web services provider through email, downloading, or through a Uniform Resource Locator (URL). This documentation assumes you are creating your own.

Develop a WSDL file by following the actions listed:

## Procedure

1. Configure the service endpoint interface class and referenced classes into your CLASSPATH variable.
   - On Windows systems, set `CLASSPATH="%CLASSPATH%;<`*list your application Java archive (JAR) files and classes*`>"`.
   - On UNIX and Linux systems, export `CLASSPATH="$CLASSPATH:<`*list your application JAR files and classes*`>"`.
2. Run the Java2WSDL *seiInterface* command. A WSDL file named *`seiInterface`*`.wsdl` is created.
   - Move the WSDL file to the `META-INF/wsdl` subdirectory if you are using Enterprise JavaBeans (EJB).
   - Move the WSDL file to the `WEB-INF/wsdl` subdirectory if you are using JavaBeans.
3. Edit the generated WSDL file and inspect the part names. The WSDL parts have names like `arg_0_0`. Modify the WSDL file to use the actual names of the Java parameters.
4. (Optional) Use the Java2WSDL command tool to generate the correct part names of WSDL file. You can automatically generate and set the correct part names by using the Java2WSDL command tool. Generating and setting the part names is done by providing additional information to the Java2WSDL command tool in the form of a Java implementation class that implements the same methods as the service endpoint interface and is compiled with debug information turned on. Parameter names are stored in the `.class` file with the debug information. If your implementation class is compiled with debug on, you can use the `Java2WSDL -implClass` *`seiImpl seiInterface`* command to generate a WSDL file with the proper part names.

## Results

A WSDL file that defines the web services described by the service endpoint interface.

## Example

This example uses the JAR file name `AddressBook.jar` that contains a class named `AddressBook.class` class file.

You must add the `AddressBook.jar` file to your CLASSPATH to create the WSDL file. The JAR file contains an EJB implementation class that is compiled with debugging information turned on. Run the `Java2WSDL -implClass addr.AddressBookBean addr.AddressBook` command to create the file, `AddressBook.wsdl`.

## What to do next

Depending on your development path, develop web services deployment descriptor templates for JavaBeans or develop web services deployment descriptor templates for an enterprise beans implementation.

## Java2WSDL command for JAX-RPC applications

The Java2WSDL command-line tool maps Java classes to a WSDL file for Java API for XML-based RPC (JAX-RPC) applications.

The Java2WSDL command maps a Java class to a Web Services Description Language (WSDL) file by following the Java API for XML-based Remote Procedure Call (JAX-RPC) 1.1 specification.

The Java2WSDL command accepts a Java class as input and produces a WSDL file that represents the input class. If a file exists at the output location, it is overwritten. The WSDL file that is generated by the Java2WSDL command contains WSDL and XML schema constructs that are automatically derived from the input class. You can override these default values with command-line arguments.

The Java2WSDL command is protocol independent; when you run the Java2WSDL command, you can specify command-line options that generate both SOAP and non-SOAP protocol bindings in the WSDL file. For each binding that can be generated, the **Java2WSDL** command has a binding generator to generate the WSDL for that binding.

## Command line syntax and arguments

The command line syntax is:

```
Java2WSDL [argument...] class
```

The following command-line arguments are supported:

## Required arguments

- class

  Represents the fully qualified name of one of the following Java classes:
  - Stateless session Enterprise JavaBeans (EJB) remote interface that extends the javax.ejb.EJBObject class
  - Service endpoint interface that extends the java.rmi.Remote class
  - Java beans

  The Java2WSDL command locates the class in the CLASSPATH variable.

## Important arguments

- -location *location*

  Provides the published location or the Uniform Resource Locator (URL) of the service. If this information is not provided, a warning is issued that indicates that the final published location is not determined yet. The service location is typically overridden when the web service is deployed.

  The name after the last backslash is the name of the service port, unless the name is overridden by the -servicePortName argument. The service port address location attribute is assigned the specified value. Multiple endpoint addresses can be specified. Using the -location option is recommended only if a single binding type is required. If multiple binding types are requested, protocol binding-specific location properties are passed over the command line using the -x flag.

  The following example illustrates how to produce both SOAP over HTTP, and SOAP over Java Message Service (JMS) bindings :

```
java2wsdl -bindingTypes http,jms \
  -x http.location=http://your.server.name:9080/StockQuoteService/services/StockQuote \
  -x jms.location= \
 jms:/queue?destination=jms/MyQueue&connectionFactory=jms/MyCF&targetService=StockQuote
```

  Use the -location option to determine to which port the -location option value applies by requiring the endpoint URLs to be specified through the binding-specific property values.
- -output *wsdl-uri*

  Indicates the path and file name of the output WSDL file. If not specified, the default `class.wsdl` file is written into the current directory.
- -input *wsdl-uri*

  Specifies the input WSDL file that is used to build an output WSDL file. Information from an existing WSDL file, is specified in this option and is used with the input Java class to generate the output.
- -bindingTypes

  Specifies the list of binding types write to the output WSDL file. Each binding generator in the Java2WSDL command supports specific binding types. The valid binding type values are `http` (SOAP over HTTP), `jms` (SOAP over JMS) and `ejb` (local or remote EJB invocation). For example, the following command can be used to generate SOAP over HTTP, EJB bindings for the my.pkg.MySEI Service Endpoint Interface and the my.pkg.MyEJBClass implementation class :

```
java2wsdl -bindingTypes http,ejb -implClass my.pkg.MyEJBClass my.pkg.MySEI
```

The following command is an example of using the -bindingTypes option to generate SOAP over HTTP and SOAP over JMS bindings:

```
java2wsdl -bindingTypes http,jms -implClass my.pkg.MyEJBClass my.pkg.MySEI
```

- -style RPC | DOCUMENT

  Specifies the WSDL style to use in the generated WSDL file. To learn more, see the Mapping between Java language, WSDL and XML for JAX-RPC applications information. This argument is used with the -use argument.

  If RPC is specified with -use ENCODED, a `style=rpc/use=encoded` WSDL file is generated. If RPC is specified with the -use LITERAL option, a `style=rpc/use=literal` WSDL file is generated. If DOCUMENT is specified with the -use LITERAL option, a `style=document/use=literal` WSDL file is generated.
- -use LITERAL | ENCODED

  Specifies which style and use combinations are generated into the WSDL file when used with the -style argument. The combinations are rpc and encoded, rpc and literal, or doc and literal. This setting applies to all SOAP bindings. To learn more, see the Mapping between Java language, WSDL and XML for JAX-RPC applications information.
- -transport http | jms

  Generates SOAP bindings for either HTTP (default) or JMS. If JMS is specified, the characters `jms` are appended to the WSDL file name to prevent overwriting an existing WSDL file for another transport. The transport option can be specified only once.

  This option is deprecated. The -bindingTypes option replaces the -transport option, so that you can generate bindings that are non-SOAP specific.
- -portTypeName *name*

  Specifies the name to use for the portType element. If not specified, the binding name is the port type name.
- -bindingName *name*

  Specifies the name to use for the binding element. If not specified, the binding name is the port type name.
- -serviceElementName *name*

  Specifies the name of the service element.
- -servicePortName *name*

  Specifies the name of the service. If not specified, the service name is derived from the -location argument.
- -namespace *targetNamespace*

  Indicates the target namespace for the WSDL file being generated. To learn about the algorithm that is used to obtain the default namespace, see the Mapping between Java language, WSDL and XML for JAX-RPC applications information.
- -PkgtoNS *package namespace*

  Specifies the mapping of a Java package to a namespace. If a package does not have a namespace, the Java2WSDL command generates a namespace name. You can repeat the -PkgtoNS argument to specify mappings for multiple packages.
- -extraClasses *classes*

  Specifies other classes that are represented in the WSDL file.
- -implClass *impl-class*

  The Java2WSDL command uses method parameter names to construct the WSDL file message part names. The command automatically obtains the message names from the debug information in the class. If the class is compiled without debug information, or if the class is an interface, the method parameter names are not available. In this case, you can use the -implClass argument to provide an alternative class from which to obtain method parameter names. The impl-class does not need to implement the class if the class is an interface, but it must implement the same methods as the class.
- -verbose

  Displays verbose messages.

- -help

  Displays the help message.
- -helpX

  Displays the help message for extended options and for various options that are supported by binding generators.

### Other arguments

- -wrapped *boolean*

  Specifies whether to generate the WSDL file according to wrapped rules. This option is valid if `use` is literal only. The option defaults to `true`.
- -stopClasses *parent* [, *parent*]

  The Java2WSDL command searches inherited classes and interfaces to construct the list of methods for WSDL file operations if the -all argument is specified.

  The Java2WSDL command searches inherited classes and interfaces when generating extended complexTypes. The search stops when a class or an interface is found within a package that begins with `java` or `javax`. You can use the -stopClasses argument to define additional classes that cause the search to stop.
- -methods *argument*

  Specifies a list of method names from the Service Endpoint Interface that must be exposed in the output WSDL file. The list is separated by spaces or commas.
- -soapAction

  Valid arguments are:
  - DEFAULT

    Sets the soapAction field according to the deployment information.
  - NONE

    Sets the soapAction field to double quotes ("").
  - OPERATION

    Sets the soapAction field to the operation name.
- -outputImpl *impl-wsdl*

  Specifies if you want an interface and implementation WSDL file emitted.
- -locationImport *location-uri*

  Specifies the location of the interface WSDL file if you use the -outputImpl argument.
- -namespaceImpl *namespace*

  Specifies the target namespace for the implementation WSDL file, if you use the -outputImpl argument.
- -MIMEStyle <*style*>

  Specifies the Multipurpose Internet Mail Extensions (MIME)- type used to map to Web Services-Interoperability (WS-I) SOAP with attachments reference (wsi:swaRef) for the binding element.

  <*style*> can be one of the following:
  - WSDL11 (default): Exclusively map MIME types using WSDL 1.1 standards. If the MIME type cannot map to WSDL 1.1 standards, the command fails.
  - AXIS: Map MIME types using AXIS standards, for example image becomes axis:image.
  - swaRef: Map MIME types using WSDL 1.1 standards with two caveats:
    - DataHandler maps to the wsi:swaRef element instead of an application and octet-stream
    - If mapping is illegal through WSDL 1.1, map to the wsi:swaRef element
- -propertiesFile *argument*

  Sets existing options, such as -extraClasses, with a properties file instead of with a command line. The following example illustrates the use of this argument:

```
extraClasses=com.ibm.Class1, com.sun.Class2,org.apache.Class3
```

- -voidReturn

  Valid arguments are:
  - ONEWAY

    Methods with void returns are one-way. This argument is the default for a JMS transport.
  - TWOWAY

    Methods with void returns are two-way. This argument is the default for an HTTP transport.
- -debug

  Displays debug messages.
- -property or -x

  You can use the -x option to pass command-line options to various binding generators. Use the -x option multiple times on the command line to specify a set of property values to pass to each binding generator method called by the Java2WSDL command. You can also use a single -x option to specify multiple properties by separating them with a comma, for example:

```
java2wsdl -x prop1=value1 -x prop2=value2
```

  is equivalent to:

```
java2wsdl -x prop1=value1,prop2=value2
```

  The -x option provides flexibility to specify each command-line option for each binding generator individually, if required. The value specified in the -x option overrides the value that is specified in the equivalent command-line option if both are specified.

## Mapping between Java language, WSDL and XML for JAX-RPC applications

Data for Java API for XML-based Remote Procedure Call (JAX-RPC) applications flows as extensible Markup Language (XML). JAX-RPC applications use mappings to describe the data conversion between the Java language and extensible Markup Language (XML) technologies, including XML Schema, Web Services Description Language (WSDL) and SOAP that are supported by the application server.

For JAX-RPC applications, most of the mappings between the Java language and XML are specified by the JAX-RPC specification. Some mappings that are optional or unspecified in JAX-RPC are also supported. Review the JAX-RPC specification for a complete list of APIs. For a complete list of the supported standards and specifications, see the web services specifications and API documentation.

### Notational conventions

*Table 221. Namespace conventions. Describes the namespace prefixes and the corresponding namespace used in namespace conventions.*

| Namespace prefix | Namespace |
|---|---|
| xsd | http://www.w3.org/2001/XMLSchema |
| xsi | http://www.w3.org/2001/XMLSchema-instance |
| soapenc | http://schemas.xmlsoap.org/soap/encoding/ |
| wsdl | http://schemas.xmlsoap.org/wsdl/ |
| wsdlsoap | http://schemas.xmlsoap.org/wsdl/soap/ |
| ns | user-defined namespace |
| apache | http://xml.apache.org/xml-soap |
| wasws | http://websphere.ibm.com/webservices/ |

### Detailed mapping information

The following sections identify the supported mappings, including:
- Java-to-WSDL mapping
- WSDL-to-Java mapping
- Mapping between WSDL and SOAP messages

## Java-to-WSDL mapping

This section summarizes the Java-to-WSDL mapping rules. The Java-to-WSDL mapping rules are used by the Java2WSDL command for *bottom-up processing*. In bottom-up processing, an existing Java service implementation is used to create a WSDL file defining the web service. The generated WSDL file can require additional manual editing for the following reasons:

- Not all Java classes and constructs have mappings to WSDL files. For example, Java classes that do not comply with the Java bean specification rules might not map to a WSDL construct.
- Some Java classes and constructs have multiple mappings to a WSDL file. For example, a java.lang.String class can map to either an xsd:string or soapenc:string construct. The Java2WSDL command chooses one of these mappings, but you must edit the WSDL file if a different mapping is required.
- Multiple ways exist to generate WSDL constructs. For example, you can generate the wsdl:part in wsdl:message with a type or element attribute. The Java2WSDL command makes an informed choice based on the -style and -use option settings.
- The WSDL file describes the instance data elements sent in the SOAP message. If you want to modify the names or format used in the message, the WSDL file must be edited. For example, the Java2WSDL command maps a Java bean property as an XML element. In some circumstances, you might want to change the WSDL file to map the Java bean property as an XML attribute.
- The WSDL file requires editing if header or attachment support is desired.
- The WSDL file requires editing if a multipart WSDL file, using the wsdl:import construct, is desired.

For simple services, the generated WSDL file is sufficient. For complicated services, the generated WSDL file is a good starting point. Read about the Java2WSDL command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

### General issues

- **Package to namespace mapping**

  The JAX-RPC specification does not indicate the default mapping of Java package names to XML namespaces. The JAX-RPC specification does specify that each Java package must map to a single XML namespace. Likewise, each XML namespace must map to a single Java package. A default mapping algorithm is provided that constructs the namespace by reversing the names of the Java package and adding an `http://` prefix. For example, a package named, com.ibm.webservice, is mapped to the XML namespace `http://webservice.ibm.com`.

  You can override the default mapping between XML namespaces and Java package names by using the -NStoPkg and -PkgtoNS options of the WSDL2Java and Java2WSDL commands.
- **Identifier mapping**

  Java identifiers are mapped directly to WSDL and XML identifiers.

  Java bean property names are mapped to XML identifiers. For example, a Java bean, with getInfo and setInfo methods, maps to an XML construct with the name, `info`.

  The service endpoint interface method parameter names, if available, are mapped directly to the WSDL and XML identifiers. See the information for the WSDL2Java command -implClass option to learn more.
- **WSDL construction summary**

*Table 222. Mapping of Java to WSDL or an XML construct. Describes the mapping from a Java construct to the related WSDL and XML construct.*

| Java construct | WSDL and XML construct |
|---|---|
| Service endpoint interface | wsdl:portType |
| Method | wsdl:operation |
| Parameters | wsdl:input, wsdl:message, wsdl:part |
| Return | wsdl:output, wsdl:message, wsdl:part |
| Throws | wsdl:fault, wsdl:message, wsdl:part |
| Primitive types | xsd and soapenc simple types |
| Java beans | xsd:complexType |

*Table 222. Mapping of Java to WSDL or an XML construct (continued). Describes the mapping from a Java construct to the related WSDL and XML construct.*

| | |
|---|---|
| Java bean properties | Nested xsd:elements of xsd:complexType |
| Arrays | JAX-RPC defined xsd:complexType or xsd:element with a maxOccurs="unbounded" attribute |
| User defined exceptions | `xsd:complexType` |

- **Binding** and **service** construction

  A wsdl:binding that conforms to the generated wsdl:portType is generated. A wsdl:service containing a port that references the generated wsdl:binding is generated. The names of the binding and service are controlled by the Java2WSDL command.
- **Style** and **use**

  Use the -style and -use options to generate different kinds of WSDL files. The four supported combinations are:
  – -style DOCUMENT -use LITERAL
  – -style RPC -use LITERAL
  – -style DOCUMENT -use LITERAL -wrapped false
  – -style RPC -use ENCODED

  The following is a brief description of each combination.
  – **DOCUMENT LITERAL**

    The Java2WSDL command generates a Web Services - Interoperability (WS-I) specification compliant document-literal WSDL file. The wsdl:binding is generated with embedded style="document" and use="literal" attributes. An xsd:element is generated for each service endpoint interface method to describe the request message. A similar xsd:element is generated for each service endpoint interface method to describe the response message.
  – **RPC LITERAL**

    The Java2WSDL command generates a WS-I compliant rpc-literal WSDL file. The wsdl:binding is generated with embedded style="rpc" and use="literal" attributes. The wsdl:message constructs are generated for the inputs and outputs of each service endpoint interface method. The parameters of the method are described by the part elements within the wsdl:message constructs.
  – **DOCUMENT LITERAL not wrapped**

    The Java2WSDL command generates a document-literal WSDL file according to the JAX-RPC specification. This WSDL file is not compliant with .NET. The main difference between DOCUMENT LITERAL and DOCUMENT LITERAL not wrapped is the use of wsdl:message constructs to define the request and response messages.
  – **RPC ENCODED**

    The Java2WSDL command generates an rpc-encoded WSDL file according to the JAX-RPC specification. This WSDL file is not compliant with the WS-I specification. The wsdl:binding is generated with embedded style="rpc" and use="encoded" attributes. Certain soapenc mappings are used to represent types and arrays.

**Mapping of standard XML types from Java types**

Many Java types map directly to standard XML types. For example, a java.lang.String maps to an xsd:string. These mappings are described in the JAX-RPC specification.

**Generation of wsdl:types**

Java types that cannot be mapped directly to standard XML types are generated in the `wsdl:types` section. A Java class that matches the Java bean pattern is mapped to an `xsd:complexType`. Review the JAX-RPC specification for a description of all the mapping rules. The following example illustrates the mapping for a sample base and derived Java classes.

**Java:**

```
public abstract class Base {
     public Base() {}
     public int a;                        // mapped
     private int b;                       // mapped via setter/getter
     private int c;                       // not mapped
     private int[] d;                     // mapped via indexed setter/getter
```

```
    public int getB() { return b;}        // map property b
    public void setB(int b) {this.b = b;}

    public int[] getD() { return d;}      // map indexed property d
    public void setD(int[] d) {this.d = d;}
    public int getD(int index) { return d[index];}
    public void setB(int index, int value) {this.d[index] = value;}

    public void someMethod() {...}        // not mapped
  }

  public class Derived extends Base {
    public int x;                         // mapped
    private int y;                        // not mapped
  }
```

**Mapped to:**

```
<xsd:complexType name="Base" abstract="true">
 <xsd:sequence>
  <xsd:element name="a" type="xsd:int"/>
  <xsd:element name="b" type="xsd:int"/>
  <xsd:element name="d" minOccurs="0" maxOccurs="unbounded" type="xsd:int"/>
 </xsd:sequence>
</xsd:complexType>

<xsd:complexType name="Derived">
 <xsd:complexContent>
  <xsd:extension base="ns:Base">
   <xsd:sequence>
    <xsd:element name="x" type="xsd:int"/>
   </xsd:sequence>
  </xsd:extension>
 </xsd:complexContent>
</xsd:complexType>
```

- **Unsupported classes**

  If a class cannot be mapped to an XML type, the Java2WSDL command issues a message and an xsd:anyType reference is generated in the WSDL file. In these situations, modify the web service implementation to use the JAX-RPC compliant classes.

## WSDL-to-Java mapping

The WSDL2Java command generates Java classes using information described in the WSDL file.

### General issues

- **Mapping of a namespace to a package**

  JAX-RPC does not specify the mapping of XML namespaces to Java package names. JAX-RPC does specify that each Java package map to a single XML namespace. Likewise, each XML namespace must map to a single Java package. A default mapping algorithm omits any protocol from the XML namespace and reverses the names. For example, an XML namespace `http://websphere.ibm.com` becomes a Java package with the name com.ibm.websphere.

  The default mapping of an XML namespace to a Java package disregards the context-root. If two namespaces are the same up to the first slash, they map to the same Java package. For example, the XML namespaces `http://websphere.ibm.com/foo` and `http://websphere.ibm.com/bar` map to the com.ibm.websphere Java package. You can override the default mapping between XML namespaces and Java package names by using the -NStoPkg and -PkgtoNS options of the WSDL2Java and Java2WSDL commands.

  **Identifier mapping**

  XML names are much richer than Java identifiers. They can include characters that are not permitted in Java identifiers. See Appendix 20 of the JAX-RPC specification for the rules to map an XML name to a Java identifier.

- **Java construction summary**

  The following table summarizes the XML to Java construction. See the JAX-RPC specification for a description of these mappings.

*Table 223. Mapping of a WSDL or an XML construct to Java. Describes the mapping between constructions for XML and Java.*

| WSDL and XML construction | Java construction |
|---|---|
| xsd:complexType | Java bean class, Java exception class, or Java array |
| nested xsd:element/xsd:attribute | Java bean property |
| xsd:simpleType (enumeration) | JAX-RPC enumeration class |
| wsdl:message The method parameter signature typically is determined by the wsdl:message. | Service endpoint interface method signature |
| wsdl:portType | Service endpoint interface |
| wsdl:operation | Service endpoint interface method |
| wsdl:binding | Stub |
| wsdl:service | Service interface |
| wsdl:port | Port accessor method in Service interface |

- **Mapping standard XML types**
  - **JAX-RPC simple XML types mapping**

    Many XML types are mapped directly to Java types. See the JAX-RPC specification for a description of these mappings.

    **Mapping the XML types defined in the wsdl:types section**

    The WSDL2Java command generates Java types for the XML schema constructs that are defined in the wsdl:types section. The XML schema language is broader than the required or optional subset defined in the JAX-RPC specification. The WSDL2Java command supports the required mappings and most of the optional mappings, as well as some XML schema mappings that are not included in the JAX-RPC specification. The WSDL2Java command ignores some constructs that it does not support. For example, the command does not support the default attribute. If an xsd:element is defined with the default attribute, the default attribute is ignored. In some cases, the command maps unsupported constructs to the Java interface, javax.xml.soap.SOAPElement.

    The standard Java bean mapping is defined in section 4.2.3 of the JAX-RPC specification. The xsd:complexType defines the type. The nested xsd:elements within the xsd:sequence or xsd:all groups are mapped to Java bean properties. For example:

**XML:**

```
<xsd:complexType name="Sample">
  <xsd:sequence>
  <xsd:element name="a" type="xsd:string"/>
  <xsd:element name="b" maxOccurs="unbounded" type="xsd:string"/>
 </xsd:sequence>
</xsd:complexType>
```

**Java:**

```
public class Sample {
     // ..
     public Sample() {}

     // Bean Property a
     public String getA()             {...}
     public void   setA(String value) {...}

     // Indexed Bean Property b
     public String[] getB()           {...}
     public String   getB(int index)  {...}
     public void     setB(String[] values) {...}
     public void     setB(int index, String value) {...}

  }
```

  - **Mapping of the wsdl:portType construct**

    The wsdl:portType construct is mapped to the service endpoint interface. The name of the wsdl:portType construct is mapped to the name of the class of the service endpoint interface.

  - **Mapping of the wsdl:operation construct**

    A wsdl:operation construct within a wsdl:portType is mapped to a method of the service endpoint interface. The name of the wsdl:operation is mapped to the name of the method. The wsdl:operation

contains wsdl:input and wsdl:output elements that reference the request and response wsdl:message constructs using the message attribute. The wsdl:operation can contain a wsdl:fault element that references a wsdl:message describing the fault. These faults are mapped to Java classes that extend the exception, java.lang.Exception as discussed in section 4.3.6 of the JAX-RPC specification.

- **Effect of document literal wrapped format**

  If the WSDL file uses the document literal wrapped format, the method parameters are mapped from the wrapper xsd:element. The document literal wrapped and literal format is automatically detected by the WSDL2Java command. The following criteria must be met:
  - The WSDL file must have style="document" in its wsdl:binding construct.
  - The input and output constructs of the operations within the wsdl:binding must contain soap:body elements that contain use="literal".
  - The wsdl:message referenced by the wsdl:operation input construct must have a single part.
  - The part must use the element attribute to reference an xsd:element.
  - The referenced xsd:element, or wrapper element, must have the same name as the wsdl:operation.
  - The wrapper element must not contain any xsd:attributes.

  In such cases, each parameter name is mapped from a nested xsd:element contained within wrapper element. The type of the parameter is mapped from the type of the nested xsd:element. For example:

**WSDL:**

```
<xsd:element name="myMethod">
 <xsd:complexType>
  <xsd:sequence>
   <xsd:element name="param1" type="xsd:string"/>
   <xsd:element name="param2" type="xsd:int"/>
  </xsd:sequence>
 </xsd:complexType>
</xsd:element>
...
<wsdl:message name="response"/>
 <part name="parameters" element="ns:myMethod"/>
</wsdl:message name="response"/>

<wsdl:message name="response"/>
...
<wsdl:operation name="myMethod">
 <input name="input" message="request"/>
 <output name="output" message="response"/>
</wsdl:operation>
```

**Java:**

```
void myMethod(String param1, int param2) ...
```

- **Parameter mapping**

  If the document and literal wrapped format is not detected, the parameter mapping follows the normal JAX-RPC mapping rules set in section 4.3.4 of the JAX-RPC specification.

  Each parameter is defined by a wsdl:message part referenced from the input and output elements.
  - A wsdl:part in the request wsdl:message is mapped to an input parameter.
  - A wsdl:part in the response wsdl:message is mapped to the return value. If multiple wsdl:parts exist in the response message, they are mapped to output parameters.
    - A Holder class is generated for each output parameter, as discussed in section 4.3.5 of the JAX-RPC specification.
  - A wsdl:part that is both the request and response wsdl:message is mapped to an inout parameter.
    - A Holder class is generated for each inout parameter, as discussed in section 4.3.5 of the JAX-RPC specification.
    - The wsdl:operation parameterOrder attribute defines the order of the parameters.

**XML:**

```
<wsdl:message name="request">
 <part name="param1" type="xsd:string"/>
 <part name="param2" type="xsd:int"/>
</wsdl:message name="response"/>
```

```
<wsdl:message name="response"/>
...
<wsdl:operation name="myMethod" parameterOrder="param1, param2">
 <input name="input" message="request"/>
 <output name="output" message="response"/>
</wsdl:operation>
```

**Java:**

```
void myMethod(String param1, int param2) ...
```

– **Mapping of wsdl:binding**

The WSDL2Java command uses the wsdl:binding information to generate an implementation-specific client-side stub. WebSphere Application Server uses the wsdl:binding information on the server side to properly deserialize the request, invoke the web service, and serialize the response. The information in the wsdl:binding does not affect the generation of the service endpoint interface, except when the document and literal wrapped format is used, or when MIME attachments are present.

- **MIME attachments**

For a WSDL 1.1-compliant WSDL file, the part of an operation message, that is defined in the binding as a MIME attachment, becomes a parameter of the type of the attachment regardless of the part declared. For example:

**XML:**

```
<wsdl:types>
 <schema ...>
  <complexType name="ArrayOfBinary">
   <restriction base="soapenc:Array">
     <attribute ref="soapenc:arrayType" wsdl:arrayType="xsd:binary[]"/>
   </restriction>
  </complexType>
 </schema>
</wsdl:types>

<wsdl:message name="request">
 <part name="param1" type="ns:ArrayOfBinary"/>
<wsdl:message name="response"/>

<wsdl:message name="response"/>
 ...

 <wsdl:operation name="myMethod">
  <input name="input" message="request"/>
  <output name="output" message="response"/>
 </wsdl:operation>
  ...

<binding ...
 <wsdl:operation name="myMethod">
  <input>
   <mime:multipartRelated>
    <mime:part>
     <mime:content part="param1" type="image/jpeg"/>
    </mime:part>
   </mime:multipartRelated>
  </input>
   ...
 </wsdl:operation>
```

**Java:**

```
void myMethod(java.awt.Image param1) ...
```

The JAX-RPC specification requires support for the following MIME types:

*Table 224. Mapping of MIME type and Java type. Describes the mapping between MIME types and Java types.*

| MIME type | Java type |
|---|---|
| image/gif | java.awt.Image |
| image/jpeg | java.awt.Image |
| text/plain | java.lang.String |
| multipart/* | javax.mail.internet.MimeMultipart |
| text/xml | javax.xml.transform.Source |
| application/xml | javax.xml.transform.Source |

– **Mapping of wsdl:service**

The wsdl:service element is mapped to a generated service interface. The generated service interface contains methods to access each of the ports in the wsdl:service element. The generated service interface is discussed in sections 4.3.9, 4.3.10, and 4.3.11 of the JAX-RPC specification.

In addition, the wsdl:service element is mapped to the implementation-specific ServiceLocator class, which is an implementation of the generated service interface.

Read about the WSDL2Java command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

## Mapping between WSDL and SOAP messages

The WSDL file defines the format of the SOAP message that are transmitted through network connections. The WSDL2Java command and the WebSphere Application Server runtime use the information in the WSDL file to ensure that the SOAP message is properly serialized and deserialized.

### DOCUMENT versus RPC, LITERAL versus ENCODED

If a wsdl:binding element indicates that a message is sent using an RPC format, the SOAP message contains an element defining the operation. If a wsdl:binding element indicates that the message is sent using a document format, the SOAP message does not contain the operation element.

If the wsdl:part element is defined using the type attribute, the name and type of the part are used in the message. If the wsdl:part element is defined using the element attribute, the name and type of the element are used in the message. The element attribute is not supported by the JAX-RPC specification when use="encoded".

If a wsdl:binding element indicates that a message is encoded, the values in the message are sent with xsi:type information. If a wsdl:binding element indicates that a message is literal, the values in the message are typically not sent with xsi:type information. For example:

**DOCUMENT/LITERAL**
**WSDL:**

```
<xsd:element name="c" type="xsd:int"/>
<xsd:element name="method">
 <xsd:complexType>
  <xsd:sequence>
   <xsd:element name="a" type="xsd:string"/>
   <xsd:element ref="ns:c"/>
  </xsd:sequence>
 </xsd:complexType>
</xsd:element>
...
  <wsdl:message name="request">
    <part name="parameters" element="ns:method"/>
  </wsdl:message>
 ...
 <wsdl:operation name="method">
  <input message="request"/>
 ...
```

**Message:**

```
<soap:body>
  <ns:method>
   <a>ABC</a>
   <c>123</a>
  <ns:method>
</soap:body>
```

**RPC/ENCODED**
**WSDL:**

```
<xsd:element name="c" type="xsd:int"/>

...
  <wsdl:message name="request">
    <part name="a" type="xsd:string"/>
    <part name="b" element="ns:c"/>
  </wsdl:message>
 ...
 <wsdl:operation name="method">
    <input message="request"/>
 ...
```

```
Message:
<soap:body>
  <ns:method>
   <a xsi:type="xsd:string">ABC</a>
   <element attribute is not permitted in rpc/encoded mode>
  </ns:method>
 </soap:body>
DOCUMENT/LITERAL  not wrapped
WSDL:
<xsd:element name="c" type="xsd:int"/>

...
  <wsdl:message name="request">
    <part name="a" type="xsd:string"/>
    <part name="b" element="ns:c"/>
  </wsdl:message>
 ...
 <wsdl:operation name="method">
    <input message="request"/>

...

Message:
<soap:body>
  <a>ABC</a>
  <c>123</a>
</soap:body>
```

## Developing JAX-RPC web services deployment descriptor templates for a JavaBeans implementation

*Deployment descriptors* are standard text files, formatted using XML and packaged in a web services application. Deployment descriptors are required to deploy Java API for XML-based RPC (JAX-RPC) web services that are developed using Web Services for Java Platform, Enterprise Edition (Java EE) technology.

### Before you begin

Develop a Web Services Description Language (WSDL) file.

You need a WSDL file to use web services. You can develop your own WSDL file or get one from a web services provider through email, downloading, or through a Uniform Resource Locator (URL). This documentation assumes you are creating your own. See the developing a WSDL file for JAX-RPC applications information.

### About this task

Completing this task creates the deployment descriptors used to describe how to map the service implementation to a JavaBeans component for Java API for XML-based RPC (JAX-RPC) applications.

To develop the deployment descriptor templates from a WSDL file, you must obtain the web address of the WSDL file.

If the WSDL file is a local file and you are running on the Windows platform, the web address looks like this example: `file:drive:\path\file_name.wsdl`. If you are using the Linux or Unix platform, the Web address looks like this example: `file:/path/file_name.wsdl`. You can also specify local files using the absolute or relative file system path.

When the web service is a JavaBeans implementation in a web module, the `webservices.xml`,`ibm-webservices-bnd.xmi` and `ibm-webservices.ext.xmi` deployment descriptors and the JAX-RPC mapping file are generated in the `WEB-INF` subdirectory.

### Procedure

Run the **WSDL2Java -verbose -role develop-server -container web -genJava no *wsdlURL*** command to generate the server deployment descriptor templates and mapping file into the `WEB-INF` subdirectory. If the **-verbose** option is specified, a list of all the generated files is displayed when the command runs.

## Results

You have deployment descriptor templates that are required to implement or use JAX-RPC web services.

## Example

The following example uses a WSDL file named `AddressBookJ2WB.wsdl`:

Generate the template files:

```
WSDL2Java -verbose -role develop-server -container web -genJava no AddressBookJ2WB.wsdl
```

The deployment descriptor templates and mapping file are generated into the `WEB-INF` subdirectory:

```
Parsing XML file: AddressBookJ2WB.wsdl
Generating: WEB-INF\webservices.xml
Generating: WEB-INF\ibm-webservices-bnd.xmi
Generating: WEB-INF\ibm-webservices-ext.xmi
Generating: WEB-INF\AddressBookJ2WB_mapping.xml
```

## What to do next

Now, you need to configure the `webservices.xml` deployment descriptor and configure the `ibm-webservices-bnd.xmi` deployment descriptor so that application server can process the incoming web services. After you configure the deployment descriptors, you must assemble the web services application for deployment. See the information on configuring the `webservices.xml` deployment descriptor for JAX-RPC web services and configuring the `ibm-webservices-bnd.xmi` deployment descriptor for JAX-RPC web services.

### *WSDL2Java command for JAX-RPC applications:*

Run the WSDL2Java command-line tool against the WSDL file to create Java APIs and deployment descriptor templates.

A Web Services Description Language (WSDL) file describes a Web service. The Java API for XML-based Remote Procedure Call (JAX-RPC) 1.1 specification defines a Java API mapping that interacts with the web service. The Web Services for Java Platform, Enterprise Edition (Java EE) specification defines deployment descriptors that deploy a web service in a Java EE environment. The WSDL2Java command is run against the WSDL file to create Java APIs and deployment descriptor templates according to these specifications.

**Note:** It is a best practice to use absolute namespaces within your WSDL or schema. By default, the WSDL2Java tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. However, if you have an established WSDL or schema that relies on relative namespaces, under specific conditions you can use the allowRelativeNamespace property to disable the relative namespace restrictions in the WSDL2Java tool. For additional information, see the property description.

You can convert any relative namespaces to absolute namespaces. The following is an example of a relative namespace:

```
targetNamespace="MyRelNamespace"
```

. You can change the relative namespace in this example to an absolute namespace by adding the protocol and base URI information:

```
targetNamespace="http://www.sample.com/MyRelNamespace"
```

.

### Command-line syntax

The command-line syntax is:

```
WSDL2Java [arguments] WSDL-URI
```

### Required arguments

- WSDL-URI

  Specifies the location of the input WSDL file using a Universal Resource Identifier (URI). You can also use a regular file path if the WSDL file is on the local file system.

### Important arguments

- -role *Java EE role*

  Specifies the Java EE development role that identifies which files to generate. Valid arguments include:
  - client

    A combination of the develop-client and deploy-client arguments.
  - deploy-client

    Generates binding files for client deployment.
  - deploy-server

    Generates binding files for server deployment.
  - develop-client (default)

    Generates files for client development.
  - develop-server

    Generates files for server development.
  - server

    A combination of the develop-server and deploy-server arguments.
- -container *Java EE-container*

  Indicates the Java EE container to use. Valid arguments include:
  - client

    Indicates client container.
  - ejb

    Indicates an Enterprise JavaBeans (EJB) container.
  - none

    Indicates no container.
  - web

    Indicates a web container.

  For client roles (see the -role option), the default argument is `none`. For server roles, the container must be `ejb` or `web`. The same container option must be used for both development and deployment.
- -output *directory*

  Sets the root directory for emitted files.
- -inputMappingFile mapping file

  Specifies the file name of the Web Services for Java EE mapping file.
- -introspect

  Uses existing Java beans with a new web service API.

  In some scenarios, it is good to use existing Java classes instead of generating new classes. The -introspect option directs the WSDL2Java command to examine existing Java classes when generating classes. The existing classes are validated against the JAX-RPC specification. For example:

  Suppose you have an existing Java bean

```
public class Bean {
 public Date x;
}
```

The WSDL file defines *x* as `xsd:dateTime`. Without the -introspect option, the WSDL2Java command generates a Java bean that is similar to the following example:

```
public class Bean {
 private Calendar x;
 public void setx(Calendar value) (x=value;)
 public Calendar getX() { return x;)
}
```

The WSDL2Java command uses the -introspect option to examine the original Java bean and to generate classes that are compatible with existing Java beans.

- -classpath *paths*

  Defines an alternative class path to search for Java classes.
- -noDataBinding

  Disables the binding of XML types to Java types. Instead, each XML type is mapped to a `javax.xml.soap.SOAPElement` interface defined by the SOAP with Attachments API for Java (SAAJ) specification.

  The Java API for XML Web Services (JAX-WS) programming model supports SAAJ 1.2 and 1.3.

  The JAX-RPC programming model supports SAAJ 1.2.

  The Java programming models define Java mappings for a subset of XML types. Several XML types cannot be mapped to Java beans or primitives. In this situation, the WSDL2Java command maps the type to an SAAJ `SOAPElement`. A SAAJ SOAPElement is a generic representation of the element in the message. The methods on the `SOAPElement` can be used to examine the element and its children.

  In some scenarios, it might be more appropriate to use the generic `SOAPElement` mapping exclusively. To learn more about the use of `SOAPElement`, see the information on SOAP with Attachments API for Java interface and custom data binders for JAX-RPC applications.

  For a complete list of the supported standards and specifications, see the web services specifications and API documentation.
- -help

  Displays a help message and exits.
- -helpX

  Displays a help message for extended options. The options include:
- -verbose

  Displays processing information, including the names of the generated files.
- -NStoPkg *namespace=package*

  By default, package names are automatically derived from the namespace strings in the WSDL file. For example, if the namespace is of the form *http://x.y.com* or *urn:x.y.com*, the corresponding package is *com.y.x*.

  You can provide your own mapping by using the -NStoPkg argument, which you can repeat as often as necessary, once for each unique namespace mapping. For example, if a namespace in the WSDL file is called `urn:AddressFetcher2`, and you want files generated from the objects in this namespace to reside in the samples.addr package, provide the -NStoPkg "http://urn:AddressFetcher2/"=samples.addr argument to the WSDL2Java command.
- -timeout *seconds*

  Specifies how long the WSDL2Java command waits, in seconds, for the WSDL-URI to respond before giving up. The default is 45 seconds; -1 disables the timeout.
- -genResolver

  Generates an absolute-import resolver class. The purpose of this class is to record the contents of the imported WSDL files that are used by the WSDL URI. This class is used by the run time and can also be used for future WSDL2Java command runs. This flexibility is desirable when the imported WSDL files are remote and possibly inaccessible. When an import resolver is used, the possibility that a remote WSDL file has different contents at run time that it did during development is eliminated. The generated class is named `_AbsoluteImportResolver.java`. Compile and package this class with the other Java classes that are generated by the WSDL2Java command.
- -useResolver *resolver-class*

Specifies an absolute-import resolver class to use during parsing. This class must be created during a previous run of the WSDL2Java command that uses the -genResolver option. The class must be available in the CLASSPATH variable.

- -deployScope *argument*

  Indicates how to deploy the server implementation. Valid arguments include:
  - Application

    Uses one instance of the implementation class for all requests.
  - Request

    Creates a new instance of the implementation class for each request.
  - Session

    Creates a new instance of the implementation class for each session.

**Other arguments**

- -user *id*

  Specifies the login user name to access the WSDL URI.
- -password *password*

  Specifies the login user password to access the WSDL URI.
- -all

  Generates Java files for all types, even those that are not referenced.
- -allowRelativeNamespace *true or false*

  Specifies whether to disable the relative namespace restrictions. If you specify `-allowRelativeNamespace=true`, the relative namespace restrictions are disabled.

  **Note:** Only use this property if you have an established WSDL file or schema that relies on a relative namespaces and you are seeking to interoperate with a defined set of vendors that permit the use of relative namespaces.
- -debug

  Prints debugging information.
- -genJava *argument*

  Generates Java files. Valid arguments include:
  - IfNotExists, default
  - Overwrite
  - No
- -javaSearch *argument*

  The -javaSearch option is used with the -genJava option. If the -genJava IfNotExists, use the -javaSearch option to determine how file existence is detected.
  - File (default): Looks for a file in the output directory
  - Classpath: Looks for a class in the CLASSPATH variable
  - Both: Looks for a file in the output directory or in a class in the CLASSPATH variable
- -genXML *argument*

  Generates the `.xml` and `.xmi` files. Valid arguments are:
  - IfNotExists, default
  - Overwrite
  - No
- -genImplSer *true or false*

  Indicates that each generated Java bean implements the java.io.Serializable. The default is `false`.
- -genEquals *true or false*

  Indicates that each generated Java bean have `equals` and `hashCode` methods. The default is false.
- -noWrappedOperations

Disables wrapped operations detection. Java beans for the request and response messages are generated.

- -noWrappedArrays

  Disables wrapped array detection.
- -fileNStoPkg *file name*

  Specifies the file of the namespace to package mappings. The default is NStoPKG.properties.
- service *wsdl service name*

  Generates files for the installed WSDL service only.
- -testCase

  Generates the template for a JUnit test case for testing web services. JUnit is a simple framework to write repeatable tests.

## Developing JAX-RPC web services deployment descriptor templates for an enterprise bean implementation

You can develop deployment descriptor templates for an Enterprise JavaBeans (EJB) implementation that is enabled for Java API for XML-based RPC (JAX-RPC) web services.

### Before you begin

You need to create a service endpoint interface and develop a Web Services Description Language (WSDL) file before you can develop the deployment descriptor templates because the service endpoint interface and the WSDL file are artifacts that are used to create the templates.

### About this task

Completing this task creates deployment descriptor templates that describe how to map the service implementation to a Enterprise JavaBeans (EJB). This task is a required step in developing a web service from an enterprise bean.

To develop the deployment descriptor templates from a WSDL file, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use.

Windows If the WSDL file is a local file, the URL looks like this example: file:*drive:**path**file_name*.wsdl.

Linux AIX HP-UX Solaris If the WSDL file is a local file, the URL looks like this example: file:/*path*/*file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

When the web service implementation contains an enterprise bean in an EJB module, the webservices.xml, ibm-webservices-bnd.xmi and ibm-webservices-ext.xmi deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file are generated in the META-INF subdirectory.

### Procedure

Run the WSDL2Java -verbose -role develop-server -container ejb -genJava no *wsdlURL* command to generate the server deployment descriptor templates and mapping file into the META-INF subdirectory. If the -verbose option is specified, a list of all generated files displays when the command runs.

### Results

You have deployment descriptor templates that are required to implement a web service.

### Example

The following example uses the `AddressBookJ2WE.wsdl` WSDL file:

1. Generate the template files with the following command syntax:

```
WSDL2Java -verbose -role develop-server -container ejb -genJava no AddressBookJ2WE.wsdl
```

   The deployment descriptor templates are generated into the `META-INF` subdirectory as follows:

```
Parsing XML file: AddressBookJ2WE.wsdl
Generating: META-INF\webservices.xml
Generating: META-INF\ibm-webservices-bnd.xmi
Generating: META-INF\ibm-webservices-ext.xmi
Generating: META-INF\AddressBookJ2WE_mapping.xml
```

### What to do next

Continue to complete the steps that are necessary to develop a JAX-RPC web service from an enterprise bean. The next step is to complete the EJB implementation. When you complete the EJB implementation, you assemble an enterprise bean Java archive (JAR) file that contains the enterprise bean and supporting classes created from a WSDL file. To learn more, see the completing the EJB implementation for JAX-RPC applications information.

## Completing the JavaBeans implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) web service, you must complete the JavaBeans implementation to assemble a Java archive (JAR) file or a web application archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

### Before you begin

Develop web services deployment descriptor templates for a JavaBeans implementation using the WSDL2java command-line tool. You need to complete this step to create the deployment descriptor templates that are configured to map the service implementation to the JavaBeans implementation.

### About this task

For JAX-RPC applications, complete the JavaBeans implementation by writing your business application.

### Procedure

1. Edit the JavaBeans implementation template, *binding*`Impl.java`. The *binding* is the name of the <wsdl:binding> element in the WSDL file. The JavaBeans implementation is generated by the WSDL2java command-line tool.
   a. Complete the implementation of the methods in the template.
   b. (Optional) Make changes if necessary.
   c. (Optional) Change the class name if the binding name is not acceptable.
2. Compile all the Java classes.
3. Assemble a Web archive (WAR) file. Assemble all the Java classes into a WAR file using web module assembly tools. Include all of the classes generated from running the WSDL2java command tool for JAX-RPC web service applications when developing implementation templates and bindings from a WSDL file.

### Results

You have now enabled the JavaBeans-based business application for JAX-RPC web services. You have a JAR file or a WAR file containing the JavaBeans implementation and supported classes created from the WSDL file.

### What to do next

If you are developing a JAX-RPC web services application from JavaBeans, you need to configure the `webservices.xml` deployment descriptor and configure the `ibm-webservices-bnd.xmi` deployment descriptor so that the application server can process the incoming web services requests.

## Completing the EJB implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file or a web application archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the Enterprise JavaBeans (EJB) implementation and the supported classes created from the tooling.

### Before you begin

Develop EJB implementation templates and bindings from a WSDL file for JAX-RPC web services using the wsdl2java command-line tool. The deployment descriptor templates that are generated from a Web Services Description Language (WSDL) file are required to complete the EJB implementation in the web services development process.

### About this task

For JAX-RPC applications, complete the enterprise beans implementation by writing your business application.

### Procedure

1. Inspect the EJB remote interface template, *portType*`_RI.java`. If necessary, modify the template. The value *portType* is the name of the `<wsdl:portType>` element in the WSDL file.
2. Edit the *binding*`Impl.java` EJB implementation template. Where *binding* is the name of the `<wsdl:binding>` element in the WSDL file.
3. Complete the implementation of the methods in the template.
4. (Optional) Make changes if necessary.
5. (Optional) Change the class name if the binding name is not acceptable.
6. Compile all the Java classes.
7. Assemble an EJB Java archive (JAR) file. Assemble all the Java classes into an enterprise bean JAR file using assembly tools. Include all of the classes generated from running the WSDL2Java command tool when developing implementation templates and bindings from a WSDL file.

### Results

You have enabled an enterprise beans business application for JAX-RPC web services. You now have an enterprise bean JAR file containing an EJB and supporting classes created from web services artifacts.

### What to do next

Now that you have gathered the required artifacts for developing a JAX-RPC web service with an enterprise bean, you need to, configure the `webservices.xml` deployment descriptor.

# Configuring the webservices.xml deployment descriptor for JAX-RPC web services

You can configure the `webservices.xml` deployment descriptor with an assembly tool.

## Before you begin

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer information.

Before you can configure the `ibm-webservices-bnd.xml` deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

## About this task

For JAX-RPC web services, this task is one of the required steps in developing a web service. You need to configure the deployment descriptors so that the application server can process the incoming web services requests.

If you are developing a web service from JavaBeans, you can develop web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file. Then, you complete the JavaBeans implementation. To learn more, read about developing JavaBeans deployment descriptor templates from a WSDL file and completing the JavaBeans implementation.

If you are developing a web service from an enterprise bean, you can develop web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file. Then, you complete the EJB implementation. To learn more, read about developing web services EJB deployment descriptor templates from a WSDL file and completing the EJB implementation.

When the JavaBeans implementation is complete, the web module web application archive (WAR) file is assembled. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. These archive files contain the `webservices.xml` deployment descriptor. The archive files must be assembled before you can configure the `webservices.xml` deployment descriptor.

The assembly tools provide a graphical interface for developing code artifacts, assembling the code artifacts into various archives (modules) and configuring compliant deployment descriptors for Java Platform, Enterprise Edition (Java EE ).

Configure the `webservices.xml` deployment descriptor by following the steps provided in this task section.

## Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

### Results

You have a webservices.xml deployment descriptor that is configured.

### What to do next

For JAX-RPC web services, you must configure the ibm-webservices-bnd.xmi deployment descriptor. To learn more, see the configuring the ibm-webservices-bnd.xmi deployment descriptor for JAX-RPC web services information.

## Configuring the webservices.xml deployment descriptor for handler classes

You can use an assembly tool to configure the webservices.xml deployment descriptor for user-provided handler classes.

### Before you begin

You can configure deployment descriptors with assembly tools provided with the application server.

A *handler class* is a class that is written to modify a SOAP message that represents a remote procedure call (RPC) request or response. Handlers can be associated with a web service or a web service client.

Similar to Java API for XML-based RPC (JAX-RPC) web services, you can use deployment descriptors to describe Java API for XML Web Services (JAX-WS) web services. For JAX-WS web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

To complete this task, you need an enterprise archive (EAR) file for the applications that you want to configure. For some handler use, such as logging or tracing, only the server or client application require configuration. For other handler use, including sending information in the SOAP headers, the client and server applications must be configured with symmetrical handlers.

### About this task

The modules in the EAR file contain the handler classes to configure. These classes implement the javax.xml.rpc.handler.Handler interface. For more information on writing handler classes, see chapter 6 of the Web Services for Java EE specification. See chapter 9 in the JAX-WS specification or chapter 12 in the JAX-RPC specification for additional information on the handler framework for your programming model. The application modules must contain the webservices.xml deployment descriptor. See the web services specifications and API information to review the JAX-RPC specification along with a complete list of the supported standards and specifications.

### Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate

files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.

4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

# Configuring the ibm-webservices-bnd.xmi deployment descriptor for JAX-RPC web services

Use assembly tools to configure the `ibm-webservices-bnd.xml` deployment descriptor. This file stores binding information that is associated with the endpoints defined with the `webservices.xml` deployment descriptor file.

## Before you begin

**Note:** The `ibm-webservices-bnd.xmi` deployment descriptor is for Java API for XML-based RPC (JAX-RPC) based web services application. It is not used for Java API for XML-Based Web Services (JAX-WS) enabled applications.

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer information.

Before you can configure the `ibm-webservices-bnd.xml` deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

## About this task

This task is one of the steps in developing a web service. You need to configure the deployment descriptors so that WebSphere Application Server can process the incoming web services requests.

Depending on if you are developing a web service from JavaBeans or an enterprise bean:

- Develop web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file.
- Develop web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file.

Then, complete the EJB implementation or complete the JavaBeans implementation. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. When the JavaBeans implementation is complete, the web module web application archive (WAR) file is assembled. These archive files contain the `webservices.xml` deployment descriptor. The archive files must be assembled before you can configure the `webservices.xml` deployment descriptor.

Configure the `webservices.xml` deployment descriptor by following the steps provided in this task section.

## Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

## Results

The ibm-webservices-bnd.xmi deployment descriptor is configured for the web service implementation module.

## What to do next

If you are developing a web service from JavaBeans, assemble a WAR file that is enabled for web services from Java code. See the assembling a WAR file that is enabled for web services from Java code information.

If you are developing a web service from an enterprise bean, assemble a JAR file that is enabled for web services from an enterprise bean. To learn more about assembling the artifacts that are required to enable the EJB module for web services into the JAR file, see the assembling a JAR file that is enabled for web services from an enterprise bean information.

## JAX-RPC web services enabled module - deployment descriptor settings (ibm-webservices-bnd.xmi file)

The ibm-webservices-bnd.xmi file is a deployment descriptor for a Java API for XML-based RPC (JAX-RPC) web services-enabled web module or an Enterprise JavaBeans (EJB) module. This file contains information for the web services run time that is required by WebSphere Application Server..

You can edit these properties using an assembly tool. See Configuring the ibm-webservices-bnd.xmi deployment descriptor for JAX-RPC web services for instructions.

The following user-defined assembly properties are supported:

- **wsDescNameLink**

  Attribute of the wsdescBindings element that specifies the link to the corresponding <webservice-description-name> element in the webservices.xml file.
- **pc-name-link**

  Attribute of the pcBindings element that specifies the link to the <port-component-name> element in the webservices.xml file.
- **scope**

  Attribute of the pcBindings element that specifies when new instances of implementation beans are created. Possible values are request, session, and application.

You can change scope value for a deployed web service using the administrative console. Click **Enterprise Applications** > *application* > **Web modules** or **EJB modules** > *module* > **Web Services Implementation Scope**.

### Bindings file examples

The following examples demonstrate the spelling and position of the various attributes. You cannot cut and paste these examples because they do not contain the required ID attributes. If you add elements to a binding file template generated by the WSDL2Java command, you must confirm that each element has an ID attribute with a unique string value. Review the template xmi files generated by the WSDL2Java command for examples of ID strings. Read about the WSDL2Java command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

```
<com.ibm.etools.webservice.wsbnd:WSBinding xmi:version="2.0" xmlns:xmi=
"http://www.omg.org/XMI" xmlns:com.ibm.etools.webservice.wsbnd=
"http://www.ibm.com/websphere/appserver/schemas/5.0.2/wsbnd.xmi">
 <wsdescBindings wsDescNameLink="AddressBookService">
  <pcBindings pcNameLink="AddressBook" scope="Application"/>
 </wsdescBindings>
</com.ibm.etools.webservice.wsbnd:WSBinding>
```

# Developing JAX-RPC web services with WSDL files (top down)

## Setting up a development environment for web services

The application server provides command-line tools to develop web services clients and implementations that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. You must set up your development environment before you start developing web services.

### Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information on installing the application server, read about installing your application server environment.

### About this task

Set up a web services development environment by completing the following actions.

### Procedure

1. Set up the environment.

   Windows Run the `setupCmdLine.bat` command from the *`/profile_root/<application_server>/bin`* directory.

   Linux AIX HP-UX Solaris Operating systems such as AIX or Linux ***source*** the script to the parent shell to inherit the exported variables by running this command:

```
. ./setupCmdLine.sh  (Notice the space between the periods.)
```

   from the *`. /profile_root/<application_server>/bin`* directory.

   You can set `WAS_USER_SCRIPT` to *`profile_root`*`\<application_server>\bin\setupCmdLine.bat`, which has the same effect as running the setupCmdLine command.

2. Configure the path. You can add the WebSphere and Java `bin` directories to your path by typing:

   Windows

```
set PATH=%WAS_PATH%;%PATH%
```

   AIX HP-UX Solaris Linux

```
export PATH=$WAS_PATH:$PATH
```

### Results

You have set up an environment so that you can develop Web services.

### What to do next

Implement web services applications. See the task overview for implementing web services applications information to learn about how to develop and implement a Java EE web service.

## Developing Java artifacts for JAX-RPC applications from a WSDL file

You can develop Java artifacts from a Web Services Description Language (WSDL) file for JAX-RPC applications from a WSDL file by using the WSDL2Java command-line tool to create Java implementation templates and bindings.

### Before you begin

To develop the JavaBeans implementation templates and bindings from a WSDL file, you must obtain the Uniform Resource Locator (URL) of the WSDL file.

Windows If the WSDL file is a local file, the URL looks like this example: file:*drive:**path**file_name*.wsdl.

Linux AIX HP-UX Solaris If the WSDL file is a local file, the URL looks like this example: file:/*path*/*file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

Implementation templates are generated using the -role develop-server option of the WSDL2Java command. The WSDL2Java command also generates bindings and deployment descriptors.

## About this task

Develop JavaBeans implementation templates and bindings from a WSDL file by issuing the proper command.

**Note:** It is a best practice to use absolute namespaces within your WSDL or schema. By default, the WSDL2Java tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. You can convert any relative namespaces to absolute namespaces. To learn more about the use of namespaces with the WSDL2Java tool, see the WSDL2Java command for JAX-RPC applications documentation.

## Procedure

Run the `WSDL2Java -verbose -role develop-server -container web` *wsdlURL* command. Since the -verbose option is specified, a list of all the generated files is displayed when the command runs.

## Results

You have templates for the implementation and deployment descriptors required to implement a web service, as well as bindings files. These templates are partially filled with information from the WSDL file.

## Example

The following example uses the AddressBook JavaBeans implementation and the `AddressBook.wsdl` WSDL file. After generating the template files from the `WSDL2Java -verbose -role develop-server -container web AddressBook.wsdl` command, the following files are generated:

```
Parsing XML file:  file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file:  AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookSoapBindingImpl.java..
WSWS3282I: Info: Generating WEB-INF\webservices.xml.
WSWS3282I: Info: Generating WEB-INF\ibm-webservices-bnd.xmi.
WSWS3282I: Info: Generating WEB-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating WEB-INF\ibm-webservices-ext.xmi.
```

The `AddressBookSOAPBindingImpl.java` file is the template for the implementation bean. It is named after the port in the WSDL file. Generally, this class is renamed to a more meaningful name.

## What to do next

Complete the JavaBeans implementation for JAX-RPC applications.

# Developing EJB implementation templates and bindings from a WSDL file for JAX-RPC web services

You can develop Enterprise JavaBeans (EJB) implementation deployment descriptor templates and bindings from a Web Services Description Language (WSDL) file for a JAX-RPC application.

## Before you begin

To develop EJB implementation templates and bindings from a WSDL file for a Java API for XML-based RPC (JAX-RPC) web service, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use.

Windows If the WSDL file is a local file, the URL looks like the following example: file:*drive:**path**file_name*.wsdl.

Linux AIX HP-UX Solaris If the WSDL file is a local file, the URL looks like the following example: file:/*path*/*file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

## About this task

This task is one a required step in developing a web service from an enterprise bean.

Implementation templates are generated using the `-role develop-server` option of the WSDL2Java command.

Templates are generated for an EJB implementation for the following components:
- enterprise bean
- EJB remote interface
- EJB Home

The WSDL2Java command also generates bindings and deployment descriptors.

**Note:** It is a best practice to use absolute namespaces within your WSDL or schema. By default, the WSDL2Java tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. You can convert any relative namespaces to absolute namespaces. To learn more about the use of namespaces with the WSDL2Java tool, see the WSDL2Java command for JAX-RPC applications documentation.

## Procedure

Run the `WSDL2Java -verbose -role develop-server -container ejb` *wsdlURL* command. Because the verbose option is specified, a list of all the generated files is displayed when the command runs.

## Results

You have templates for the implementation and deployment descriptors required to implement web services, as well as bindings files. These templates are partially completed with information from the WSDL file.

### Example

The following example uses the enterprise bean AddressBook enterprise bean and the `AddressBook.wsdl` file. After generating the template files from the `WSDL2Java -verbose -role develop-server -container EJB AddressBook.wsdl` command, the following files are generated:

```
Parsing XML file:  file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file:  AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookSoapBindingImpl.java.
WSWS3282I: Info: Generating addr\AddressBook_RI.java.
WSWS3282I: Info: Generating addr\AddressBookHome.java.
WSWS3282I: Info: Generating META-INF\webservices.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservices-bnd.xmi.
WSWS3282I: Info: Generating META-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservices-ext.xmi.
```

### What to do next

Complete the EJB implementation. When you complete the EJB implementation, an EJB Java archive (JAR) file that contains an EJB and supporting classes is created from a WSDL file.

## Completing the JavaBeans implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) web service, you must complete the JavaBeans implementation to assemble a Java archive (JAR) file or a web application archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

### Before you begin

Develop web services deployment descriptor templates for a JavaBeans implementation using the WSDL2java command-line tool. You need to complete this step to create the deployment descriptor templates that are configured to map the service implementation to the JavaBeans implementation.

### About this task

For JAX-RPC applications, complete the JavaBeans implementation by writing your business application.

### Procedure

1. Edit the JavaBeans implementation template, *binding*`Impl.java`. The *binding* is the name of the <wsdl:binding> element in the WSDL file. The JavaBeans implementation is generated by the WSDL2java command-line tool.
   a. Complete the implementation of the methods in the template.
   b. (Optional) Make changes if necessary.
   c. (Optional) Change the class name if the binding name is not acceptable.
2. Compile all the Java classes.
3. Assemble a Web archive (WAR) file. Assemble all the Java classes into a WAR file using web module assembly tools. Include all of the classes generated from running the WSDL2java command tool for JAX-RPC web service applications when developing implementation templates and bindings from a WSDL file.

### Results

You have now enabled the JavaBeans-based business application for JAX-RPC web services. You have a JAR file or a WAR file containing the JavaBeans implementation and supported classes created from the WSDL file.

### What to do next

If you are developing a JAX-RPC web services application from JavaBeans, you need to configure the `webservices.xml` deployment descriptor and configure the `ibm-webservices-bnd.xmi` deployment descriptor so that the application server can process the incoming web services requests.

## Completing the EJB implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file or a web application archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the Enterprise JavaBeans (EJB) implementation and the supported classes created from the tooling.

### Before you begin

Develop EJB implementation templates and bindings from a WSDL file for JAX-RPC web services using the wsdl2java command-line tool. The deployment descriptor templates that are generated from a Web Services Description Language (WSDL) file are required to complete the EJB implementation in the web services development process.

### About this task

For JAX-RPC applications, complete the enterprise beans implementation by writing your business application.

### Procedure

1. Inspect the EJB remote interface template, *portType*`_RI.java`. If necessary, modify the template. The value *portType* is the name of the `<wsdl:portType>` element in the WSDL file.
2. Edit the *binding*`Impl.java` EJB implementation template. Where *binding* is the name of the `<wsdl:binding>` element in the WSDL file.
3. Complete the implementation of the methods in the template.
4. (Optional) Make changes if necessary.
5. (Optional) Change the class name if the binding name is not acceptable.
6. Compile all the Java classes.
7. Assemble an EJB Java archive (JAR) file. Assemble all the Java classes into an enterprise bean JAR file using assembly tools. Include all of the classes generated from running the WSDL2Java command tool when developing implementation templates and bindings from a WSDL file.

### Results

You have enabled an enterprise beans business application for JAX-RPC web services. You now have an enterprise bean JAR file containing an EJB and supporting classes created from web services artifacts.

### What to do next

Now that you have gathered the required artifacts for developing a JAX-RPC web service with an enterprise bean, you need to, configure the `webservices.xml` deployment descriptor.

# Configuring the webservices.xml deployment descriptor for JAX-RPC web services

You can configure the webservices.xml deployment descriptor with an assembly tool.

## Before you begin

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer information.

Before you can configure the ibm-webservices-bnd.xml deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

## About this task

For JAX-RPC web services, this task is one of the required steps in developing a web service. You need to configure the deployment descriptors so that the application server can process the incoming web services requests.

If you are developing a web service from JavaBeans, you can develop web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file. Then, you complete the JavaBeans implementation. To learn more, read about developing JavaBeans deployment descriptor templates from a WSDL file and completing the JavaBeans implementation.

If you are developing a web service from an enterprise bean, you can develop web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file. Then, you complete the EJB implementation. To learn more, read about developing web services EJB deployment descriptor templates from a WSDL file and completing the EJB implementation.

When the JavaBeans implementation is complete, the web module web application archive (WAR) file is assembled. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. These archive files contain the webservices.xml deployment descriptor. The archive files must be assembled before you can configure the webservices.xml deployment descriptor.

The assembly tools provide a graphical interface for developing code artifacts, assembling the code artifacts into various archives (modules) and configuring compliant deployment descriptors for Java Platform, Enterprise Edition (Java EE ).

Configure the webservices.xml deployment descriptor by following the steps provided in this task section.

## Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

## Results

You have a webservices.xml deployment descriptor that is configured.

## What to do next

For JAX-RPC web services, you must configure the ibm-webservices-bnd.xmi deployment descriptor. To learn more, see the configuring the ibm-webservices-bnd.xmi deployment descriptor for JAX-RPC web services information.

# Configuring the webservices.xml deployment descriptor for handler classes

You can use an assembly tool to configure the webservices.xml deployment descriptor for user-provided handler classes.

## Before you begin

You can configure deployment descriptors with assembly tools provided with the application server.

A *handler class* is a class that is written to modify a SOAP message that represents a remote procedure call (RPC) request or response. Handlers can be associated with a web service or a web service client.

Similar to Java API for XML-based RPC (JAX-RPC) web services, you can use deployment descriptors to describe Java API for XML Web Services (JAX-WS) web services. For JAX-WS web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

To complete this task, you need an enterprise archive (EAR) file for the applications that you want to configure. For some handler use, such as logging or tracing, only the server or client application require configuration. For other handler use, including sending information in the SOAP headers, the client and server applications must be configured with symmetrical handlers.

## About this task

The modules in the EAR file contain the handler classes to configure. These classes implement the javax.xml.rpc.handler.Handler interface. For more information on writing handler classes, see chapter 6 of the Web Services for Java EE specification. See chapter 9 in the JAX-WS specification or chapter 12 in the JAX-RPC specification for additional information on the handler framework for your programming model. The application modules must contain the webservices.xml deployment descriptor. See the web services specifications and API information to review the JAX-RPC specification along with a complete list of the supported standards and specifications.

## Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate

files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.

4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

# Configuring the ibm-webservices-bnd.xmi deployment descriptor for JAX-RPC web services

Use assembly tools to configure the `ibm-webservices-bnd.xml` deployment descriptor. This file stores binding information that is associated with the endpoints defined with the `webservices.xml` deployment descriptor file.

## Before you begin

**Note:** The `ibm-webservices-bnd.xmi` deployment descriptor is for Java API for XML-based RPC (JAX-RPC) based web services application. It is not used for Java API for XML-Based Web Services (JAX-WS) enabled applications.

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer information.

Before you can configure the `ibm-webservices-bnd.xml` deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

## About this task

This task is one of the steps in developing a web service. You need to configure the deployment descriptors so that WebSphere Application Server can process the incoming web services requests.

Depending on if you are developing a web service from JavaBeans or an enterprise bean:

- Develop web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file.
- Develop web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file.

Then, complete the EJB implementation or complete the JavaBeans implementation. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. When the JavaBeans implementation is complete, the web module web application archive (WAR) file is assembled. These archive files contain the `webservices.xml` deployment descriptor. The archive files must be assembled before you can configure the `webservices.xml` deployment descriptor.

Configure the `webservices.xml` deployment descriptor by following the steps provided in this task section.

## Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

## Results

The ibm-webservices-bnd.xmi deployment descriptor is configured for the web service implementation module.

## What to do next

If you are developing a web service from JavaBeans, assemble a WAR file that is enabled for web services from Java code. See the assembling a WAR file that is enabled for web services from Java code information.

If you are developing a web service from an enterprise bean, assemble a JAR file that is enabled for web services from an enterprise bean. To learn more about assembling the artifacts that are required to enable the EJB module for web services into the JAR file, see the assembling a JAR file that is enabled for web services from an enterprise bean information.

## JAX-RPC web services enabled module - deployment descriptor settings (ibm-webservices-bnd.xmi file)

The ibm-webservices-bnd.xmi file is a deployment descriptor for a Java API for XML-based RPC (JAX-RPC) web services-enabled web module or an Enterprise JavaBeans (EJB) module. This file contains information for the web services run time that is required by WebSphere Application Server..

You can edit these properties using an assembly tool. See Configuring the ibm-webservices-bnd.xmi deployment descriptor for JAX-RPC web services for instructions.

The following user-defined assembly properties are supported:

- **wsDescNameLink**

  Attribute of the wsdescBindings element that specifies the link to the corresponding <webservice-description-name> element in the webservices.xml file.
- **pc-name-link**

  Attribute of the pcBindings element that specifies the link to the <port-component-name> element in the webservices.xml file.
- **scope**

  Attribute of the pcBindings element that specifies when new instances of implementation beans are created. Possible values are request, session, and application.

You can change scope value for a deployed web service using the administrative console. Click **Enterprise Applications** > *application* > **Web modules** or **EJB modules** > *module* > **Web Services Implementation Scope**.

### Bindings file examples

The following examples demonstrate the spelling and position of the various attributes. You cannot cut and paste these examples because they do not contain the required ID attributes. If you add elements to a binding file template generated by the WSDL2Java command, you must confirm that each element has an ID attribute with a unique string value. Review the template xmi files generated by the WSDL2Java command for examples of ID strings. Read about the WSDL2Java command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

```
<com.ibm.etools.webservice.wsbnd:WSBinding xmi:version="2.0" xmlns:xmi=
"http://www.omg.org/XMI" xmlns:com.ibm.etools.webservice.wsbnd=
"http://www.ibm.com/websphere/appserver/schemas/5.0.2/wsbnd.xmi">
 <wsdescBindings wsDescNameLink="AddressBookService">
  <pcBindings pcNameLink="AddressBook" scope="Application"/>
 </wsdescBindings>
</com.ibm.etools.webservice.wsbnd:WSBinding>
```

# Developing JAX-RPC web services clients

## Developing client bindings from a WSDL file for a JAX-RPC Web services client

You can develop client bindings from a Web Services Description (WSDL) file for a JAX-RPC web services client.

### Before you begin

To develop the client bindings from a WSDL file for JAX-RPC web service applications, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use. You need bindings and deployment descriptors in order for a client to use a web service.

Windows If the WSDL file is a local file, the URL looks like the following example: file:*drive:**path**file_name*.wsdl.

Linux AIX HP-UX Solaris If the WSDL file is a local file, the URL looks like the following example: file:/*path*/*file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

Client bindings are generated using the `-role develop-client` option in combination with the `-container` option of the WSDL2Java command. The `-container` option takes the following parameters:

- **-container client**

  Generates bindings and deployment descriptors for a client residing in the application client container.
- **-container ejb**

  Generates bindings and deployment descriptors for a client that is an enterprise bean in the Enterprise JavaBeans (EJB) module.
- **-container web**

  Generates bindings and deployment descriptors for a client residing in the web container.

### About this task

Develop client bindings from a WSDL file by running the appropriate command.

**Note:** It is a best practice to use absolute namespaces within your WSDL or schema. By default, the WSDL2Java tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. You can convert any relative namespaces to absolute namespaces. To learn more about the use of namespaces with the WSDL2Java tool, see the WSDL2Java command for JAX-RPC applications documentation.

### Procedure

Run the `WSDL2Java -verbose -role develop-client -container` *type wsdlURL* command, where *type* is **ejb** for an enterprise EJB client, `web` for a JavaBeans client, or `client` for an application client.
You can use the following combinations in the command-line:

- -container `web`
- -container `ejb`
- -container `client`

Because the verbose option is specified, a list of all generated files is displayed when the command runs.

### Results

You have the bindings and deployment descriptors needed by a client to use a web service.

### Example

The following example uses the AddressBook enterprise bean the `AddressBook.wsdl` WSDL file. After generating the bindings from the `WSDL2Java -verbose -role develop-client -container client AddressBook.wsdl` command, the following files are generated:

```
Parsing XML file:  file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file:  AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookService.java.
WSWS3282I: Info: Generating META-INF\ibm-webservicesclient-bnd.xmi.
WSWS3282I: Info: Generating META-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservicesclient-ext.xmi.
```

### What to do next

Complete the client implementation by writing your client application and then assembling the client artifacts.

.

## Changing SOAP message encoding to support WSI-Basic Profile

Support for Universal Transformation Format (UTF)-16 encoding is required by the WS-I Basic Profile 1.0. WebSphere Application Server conforms to the WS-I Basic Profile 1.1. UTF-16 is a kind of unicode encoding scheme using 16-bit values to store Universal Character Set (UCS) characters. UTF-8 is the most common encoding that is used on the Internet and UTF-16 encoding is typically used for Java and Windows product applications. You can change the encoding in a SOAP message from UTF-8 to UTF-16.

### Before you begin

To learn more about the requirements of the Web Services-Interoperability Basic Profile (WS-I), including UTF-16, see Web Services-Interoperability Basic Profile information.

### About this task

Support for UTF-16 encoding is required by WS-I Basic Profile. The application server only supports UTF-8 and UTF-16 encoding of SOAP messages.

You can change the character encoding in one of two ways:

### Procedure

- Use a property on the Stub for users to set.

  This choice applies to the client only.

  For a client, the encoding is specified in the SOAP request. The SOAP engine serializes the request and sends it to the web service engine. The web service engine receives the request and deserializes the message to Java objects, which are returned to you in a response.

  When the web service engine on the server receives the serialized request, a raw message in the form of an input stream, is passed to the parser, which understands Byte Order Mark (BOM). BOM is mandatory for UTF-16 encoding and it can be used in UTF-8. The message is deserialized to a Java

objects and a service invocation is made. For two-way invocation, the engine needs to serialize the message using a specific encoding and send it back to the caller. The following example shows you how to use a property on the Stub to change the character set:

```
javax.xml.rpc.Stub stub=service.getPort("MyPortType");
((javax.xml.rpc.Stub)stub).setProperty(com.ibm.wsspi.webservices.Constants.MESSAGE_CHARACTER_SET_ENCODING,"UTF-16");
stub.invokeMethod();
```

In this code example, **com.ibm.wsspi.webservices.Constants.MESSAGE_CHARACTER_SET_ENCODING** = *"com.ibm.wsspi.webservices.xmlcharset";*

- Use a handler to change the character set through SOAP with Attachments API for Java (SAAJ).

  If you are using a handler, the SOAP message is transformed to a SAAJ format from other possible forms, such as an input stream. In such cases as a handleRequest method on the client side and a handleResponse method on the server side, the web services engine transforms from a SAAJ format back to the stream with appropriate character encoding. This transformation or change is called a *roundtrip transformation*. The following is an example of how you can use a handler to specify the character encoding through SAAJ:

```
handleResponse(MessageContext mc) {
 SOAPMessageContext smc = (SOAPMessageContext) context;
 javax.xml.soap.SOAPMessage msg = smc.getMessage();
 msg.setProperty (javax.xml.soap.SOAPMessage.CHARACTER_SET_ENCODING, "UTF-16");
 }
}
```

### Results

You have modified the character encoding from UTF-8 to UTF-16 in the web service SOAP message.

## Configuring the JAX-RPC web services client deployment descriptor with an assembly tool

You can configure JAX-RPC web services client deployment descriptor with an assembly tool.

### Before you begin

You can configure deployment descriptors with assembly tools provided with WebSphere Application Server.

Also, you need an enterprise JavaBeans (EJB) Java archive (JAR) file, web application archive (WAR) file or an application client file that you can import into the assembly tool.

Assemble the client JAR file into an EAR file or assemble the client WAR file into an EAR file. To learn more, see the information on assembling a web services-enabled client JAR file into an EAR file or assembling a web services-enabled client WAR file into an EAR file.

### About this task

Complete this task if you are developing a managed client that runs in the Java EE client container. This task is done after you assemble the EJB or web module.

### Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) or Java Archive (JAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to assembly tools. To migrate

files, import your WAR or JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.

4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

### Results

You have a client deployment descriptor that is configured.

### What to do next

Test the web services client. See the testing web services-enabled clients information to learn more about how to test an unmanaged client Java archive (JAR) file and an unmanaged client application.

## Configuring the JAX-RPC client deployment descriptor for handler classes

You can configure the JAX-RPC client deployment descriptor for user-provided handler classes.

### Before you begin

You need an enterprise archive (EAR) file for the applications that you want to configure. For some handler use, such as logging or tracing, only the server or client application needs to be configured. For other handler use, including sending information in SOAP headers, the client and server applications must be configured with symmetrical handlers.

The modules in the EAR file should contain the handler classes to configure. These classes implement the `javax.xml.rpc.handler.Handler` interface. For more information on writing handler classes, see chapter 6 of the Web Services for Java Platform, Enterprise Edition (Java EE) specification and chapter 12 of the Java API for XML-based remote procedure call (JAX-RPC) specification. The application modules must contain the `webservices.xml` (for server) and the client deployment descriptors.

For a complete list of the supported standards and specifications, see the web services specifications and API documentation.

### About this task

Configure a handler in the client deployment descriptor by following the steps provided:

### Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) or Java archive (JAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. Read about importing WAR or JAR files using an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about creating web services handlers in the Rational Application Developer information.

### Results

You have a client deployment descriptor that is configured.

## What to do next

Test the web services client. See the testing web services-enabled clients information to learn more about how to test an unmanaged client Java archive (JAR) file and an unmanaged client application.

## Handler class properties with JAX-RPC

This article describes handler class properties using Java API for XML-based RPC (JAX-RPC).

You can configure the following handler class properties with assembly tools provided with WebSphere Application Server. See Configuring the `webservices.xml` deployment descriptor for Handler classes or Configuring the client deployment descriptors for Handler classes for instructions on how to configure the properties.

You can configure the following handler class properties with assembly tools provided with WebSphere Application Server. For instructions on how to configure the handler class properties, read about configuring the `webservices.xml` deployment descriptor for handler classes or configuring the client deployment descriptors for handler classes.

***Description:***

Standard Java Platform, Enterprise Edition (Java EE) technology descriptor field.

***Display name:***

Standard Java EE technology descriptor field.

***Small icon:***

Standard Java EE technology descriptor field.

***Large icon:***

Standard Java EE technology descriptor field.

***Handler name:***

The name of the handler. This name must be unique within the module.

***Handler class:***

The fully qualified name of the handler class. Initially, it is set by an assembly tool.

***Initial parameters:***

Property names and values available to the handler.

***SOAP headers:***

Qualified names (Qnames) of the SOAP headers that are processed by this handler.

See section 12.2.2 of the Java API for XML-based remote procedure call (JAX-RPC) specification, available through the web services specifications and APIs information, for more information about setting this property.

***SOAP roles:***

URIs containing the SOAP actor names for which the handler acts in the role.

See section 12.2.2 of the Java API for XML-based remote procedure call (JAX-RPC) specification, available through the web services specifications and APIs information, for more information about setting this property.

## Example: Configuring handler classes for web services deployment descriptors

This scenario explains how to add a client and server handler class to a sample application, `WebServicesSamples.ear`. The handler classes display messages when given a request or response to handle.

The code for the client handler class is illustrated in the following example:

```
package samples;

public class ClientHandler implements javax.xml.rpc.handler.Handler {
    public ClientHandler() { }

public boolean handleRequest(javax.xml.rpc.handler.MessageContext context) {
    System.out.println("ClientHandler: In handleRequest");
    return true; }

public boolean handleResponse(javax.xml.rpc.handler.MessageContext context) {
    System.out.println("ClientHandler: In handleResponse");
    return true; }

public boolean handleFault(javax.xml.rpc.handler.MessageContext context) {
    System.out.println("ClientHandler: In handleFault");
    return true;  }

public void init(javax.xml.rpc.handler.HandlerInfo config) {}

public void destroy() {}

public javax.xml.namespace.QName[] getHeaders() {
    return null; }
}
```

The code for the server handler class is illustrated in the following example:

```
package sample;
public class ServerHandler implements javax.xml.rpc.handler.Handler {
    public ServerHandler() { }

public boolean handleRequest(javax.xml.rpc.handler.MessageContext context) {
    System.out.println("ServerHandler: In handleRequest");
    return true; }

public boolean handleResponse(javax.xml.rpc.handler.MessageContext context) {
    System.out.println("ServerHandler: In handleResponse");
    return true; }

public boolean handleFault(javax.xml.rpc.handler.MessageContext context) {
    System.out.println("ServerHandler: In handleFault");
    return true; }

public void init(javax.xml.rpc.handler.HandlerInfo config) {}

public void destroy() {}

public javax.xml.namespace.QName[] getHeaders() {
    return null;  }
}
```

1. Compile these classes using:

   Windows `%JAVA_HOME%\bin\java -extdirs %WAS_EXT_DIRS% ClientHandler.java ServerHandler.java`

   Linux AIX HP-UX Solaris `$JAVA_HOME/bin/java -extdirs $WAS_EXT_DIRS ClientHandler.java ServerHandler.java`

2. Open an assembly tool and import the two sample enterprise archive (EAR) files:
   - Windows `...\installableApps\WebServicesSamples.ear`

     Linux AIX HP-UX Solaris `.../installableApps/WebServicesSamples.ear`

- Windows ...\installableApps\ApplicationClients.ear
  Linux AIX HP-UX Solaris .../installableApps/ApplicationClients.ear

3. Import the compiled handler classes into the projects for the sample modules:
   - Import sample.ClientHandler into the **appClientModule** directory of the **AddressBookClient** project.
   - Import sample.ServerHandler into the **ejbModule** directory of the **AddressBookW2JE** project.
4. Configure the client deployment descriptor for handler classes.

   This topic explains how to configure the client deployment descriptor for user-provided handler classes.
5. Configure the webservices.xml deployment descriptor for handler classes.

   This topic explains how to configure the webservices.xml deployment descriptor for user-provided handler classes.
6. Save your changes and export the EAR files.
7. Uninstall the WebServicesSamples.ear application from your server if it is already installed.
8. Install the new WebServicesSamples.ear application.
9. Start the server.
10. Run the client:

    ```
    launchClient ApplicationClients.ear -CCjar=AddressBookClient.jar
    ```

    When the client runs, the console output looks like the following example. The messages from the handlers are shown in bold.

```
IBM WebSphere Application Server

com.ibm.websphere.samples.webservices.addr.AddressBookClient
>> Querying address for 'Purdue Boilermaker' using port
AddressBookW2JE
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
       1 University Drive
       West Lafayette, IN 47907
       Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port
AddressBookJ2WE
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
       2 University Drive
       West Lafayette, IN 47907
       Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port
AddressBookJ2WB
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
       3 University Drive
       West Lafayette, IN 47907
       Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port AddressBookW2JB
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
       4 University Drive
       West Lafayette, IN 47907
       Phone: (765) 555-4900
```

For the client, the handler class is configured for each service reference, not for each port. The AddressBook sample has four ports, but only one service reference, therefore the ClientHandler handles requests and responses on all ports.

When the server log file is examined, it contains the following data:

```
[9/24/03 16:39:22:661 CDT] 4deec1c6 WebGroup      I SRVE0180I:
[HTTP router for AddressBookW2JE.jar] [/AddressBookW2JE] [Servlet.LOG]:
AddressBook: init
[9/24/03 16:39:23:161 CDT] 4deec1c6 SystemOut     O ServerHandler: In handleRequest
[9/24/03 16:39:23:211 CDT] 4deec1c6 SystemOut     O ServerHandler: In handleResponse
```

#### Results

The deployment descriptors for handler classes are configured. Deployment descriptors are required so that so that WebSphere Application Server can process the incoming web services requests.

#### What to do next

Deploy the EAR file that has been configured and enabled for web services. Then you can test the application to make sure it runs within the WebSphere Application Server environment.

# Configuring the JAX-RPC web services client bindings in the ibm-webservicesclient-bnd.xmi deployment descriptor

You can configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor file with assembly tools.

## Before you begin

You can configure deployment descriptors with assembly tools provided with the application server.

You must configure the assembly tool before you can use it. Read about configuring the assembly tool in the Rational Application Developer documentation.

## About this task

Now that you have assembled the client module, complete this step to configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor. Deployment descriptors are required so that so that WebSphere Application Server can process the incoming web services requests.

Configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor file with the following steps provided:

## Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. Switch to the Java EE Perspective.
   a. Click **Window** > **Open Perspective** > **Other** > **Java EE**.
3. Open the Project Explorer.
   a. Click **Window** > **Show View** > **Other** > **Project Explorer**.
4. Locate the deployment descriptor file for the module. Hint: Deployment Descriptor: *<module>*
5. Double-click the deployment descriptor file to open the Deployment Descriptor editor.
   a. Select the **WS Binding** tab at the bottom of the editor window to open the Web Services Client Bindings editor.
6. Verify the serviceRefLink element settings.
   a. Open the **Web Services Client Bindings** editor.
   b. Click the **Services References** tab.
   c. Click **Add**.
   d. Select the service references defined in the client deployment descriptor file from the list.
7. Verify the deployedWSDLFile element settings.

a. Open the **Web Services Client Bindings** editor.
b. Select the service reference.
c. Expand the **Service Reference Details** section.
d. Click **Browse** that is located to the right of the Deployed WSDL file field.
e. Select the new Web Services Description Language (WSDL) file.
f. Click **OK**.

You can also change the deployedWSDLFile element of a deployed web service using the administrative console. Click **Enterprise Applications** > ***application*** > **Web module or EJB module** > ***module*** > **Web services client bindings**.

8. Verify the `defaultMappings` element settings.
   a. Open the **Web services client bindings** editor.
   b. Click **Default mappings**.
   c. Click **Add**.
   d. Edit the entries in the newly added row to establish a mapping between a *portType* and a *port* in the WSDL file. Only one entry is supported for each *portType*.
   e. Click **OK**.

   You can also change the defaultMappings element of a deployed web service using the administrative console. Click **Enterprise Applications** > ***application*** > **Web module or EJB module** > ***module*** > **Web services client bindings**.
9. Access the web services client Port bindings editor through the **Port qualified name binding details** section at the bottom of the editor pane.
10. Verify the syncTimeout element settings.
    a. Create a Port qualified name bindings for the port.
    b. Open the **Web services client bindings** editor.
    c. Confirm that a service reference is selected in either the **Component-scoped references** or the **Service references** section.
    d. Expand the **Port qualified name binding** section.
    e. Click **Add**. The **Add port qualified name binding** dialog opens.
    f. Type the *namespace* of the WSDL file port you want to configure, in the **Port namespace link** field.
    g. Type the *local_name* of the WSDL file port you want to configure in the **Port local name link** field. The name displayed in the **Port qualified name binding** list is the local name of the WSDL file port.
    h. Click **OK**.
    a. Configure the syncTimeout property by locating the Synchronization timeout field and enter the desired value. The default is 300 seconds.
11. Verify the basicAuth element settings.
    a. Locate the **HTTP basic authentication** field in the **Port qualified name binding details** section.
    b. Type the desired value in the User ID and Password fields.
    c. Click **OK**.
12. Verify the sslConfig element settings.
    a. Locate the **SSL configuration** field in the **Port qualified name binding details** section.
    b. Type the desired value in the **Name** field.
    c. Click **OK**.
13. After editing the properties, type `ctrl-s` on your keyboard to save the changes.

## Results

You have configured the ibm-webservicesclient-bnd.xmi deployment descriptor. If you have configured all of the client deployment descriptors, test the web services client. If you have not configured all of the client deployment descriptors, complete the configurations and then test the web services client.

## ibm-webservicesclient-bnd.xmi assembly properties for JAX-RPC applications

The ibm-webservicesclient-bnd.xmi deployment descriptor file contains information for the web services run time that is WebSphere product-specific. This deployment descriptor file is used with Java API for XML-based RPC (JAX-RPC) web services. This binding file is not applicable for Java API for XML-Based Web Services (JAX-WS) web services.

You can configure deployment descriptors with assembly tools provided with WebSphere Application Server. Read about configuring the JAX-RPC web services client bindings in the ibm-webservicesclient-bnd.xmi deployment descriptor to learn more about configuring this deployment descriptor.

### Assembly properties

The following user-definable assembly properties are supported:

- **componentNameLink**

  An attribute of the componentScopedRefs element. When a web service is implemented by an Enterprise JavaBeans (EJB) implementation, each <componentScopedRefs> element contains assembly properties for an individual enterprise bean. The componentNameLink attribute of the <componentScopedRefs> element identifies the enterprise bean that the assembly properties apply to by specifying the <ejb-name>. This property is used only when the web service client is an enterprise bean.
- **serviceRefLink**

  An attribute of the serviceRefs element. Specifies the link to the <service-ref-name> in the <service-ref> element in the client deployment descriptor. The client deployment descriptor is either ejb-jar.xml, web.xml or application-client.xml.
- **deployedWSDLFile**

  An attribute of the serviceRefs element is optional. Permits an alternate Web Services Description Language (WSDL) file to use other than that specified in the <wsdl-file> element of the <service-ref> element in the client deployment descriptor. If an attribute is specified, the alternate WSDL file must be packaged in the same module and must be compatible with the development WSDL file. The deployedWSDLFile property supplies a new WSDL file containing a different endpoint web address than the original WSDL file.
- **defaultMappings** element

  Identifies which port to use for a given portType when one is not selected by the client. This element has the following attributes: portTypeNamespace, portTypeLocalName, portNamespace, portLocalName. These attributes identify which wsdl:port is used for a wsdl:portType.
- **syncTimeout**

  An attribute of the portQnameBindings element. Specifies how long, in seconds, to wait for a response from a synchronous call. The default is 300 seconds.
- **basicAuth**

  An element of the portQnameBindings element. Authenticates a service client to the service endpoint, independent of the underlying transport that includes, HTTP, HTTPS, and Java Message Service (JMS). Set the user ID and password attributes as needed.
- **sslConfig**

  An element of the portQnameBindings element. Specifies the Secure Sockets Layer (SSL) configuration of an HTTPS outbound request. The name attribute is the name of an SSL configuration entry or alias that is defined in the SSL configuration repertoire. This attribute is used only when the client is running in the WebSphere Application Server.

### A bindings file example

The following example demonstrates the spelling and position of the various attributes. You cannot cut and paste these examples because they do not contain the required ID attributes. If you add elements to a binding file template generated by the WSDL2Java command, you must confirm that each element has an ID attribute whose value is a unique string. Review the template `xmi` files generated by the WSDL2Java command for examples of ID strings. Read about the WSDL2Java command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

```
<com.ibm.etools.webservice.wscbnd:ClientBinding xmi:version="2.0"
xmlns:xmi="http://www.omg.org/XMI" xmlns:com.ibm.etools.webservice.wscbnd=
"http://www.ibm.com/websphere/appserver/schemas/5.0.2/wscbnd.xmi">

 <componentScopedRefs componentNameLink="myComponent ref"/>

 <serviceRefs serviceRefLink="myService ref" deployedWSDLFile="META-INF/wsdl/alternate.wsdl">
  <defaultMappings portTypeLocalName="AddressBook" portTypeNamespace="http://www.com.ibm"
portLocalName="AddressBookPort" portNamespace="http://www.com.ibm"/>
   <portQnameBindings portQnameNamespaceLink="http://www.com.ibm"
portQnameLocalNameLink="AddressBookPort" syncTimeout="99">
    <basicAuth userid="myId" password="myPassword"/>
    <sslConfig name="mynode/DefaultSSLSettings"/>
   </portQnameBindings>
  </serviceRefs>
 </com.ibm.etools.webservice.wscbnd:ClientBinding>
```

## Implementing extensions to JAX-RPC web services clients

WebSphere Application Server provides extensions to web services clients using the Java API for XML-based RPC (JAX-RPC) programming model.

### About this task

You can customize web services by using the following extensions to the JAX-RPC client programming model.

### Procedure

- Set the **REQUEST_SOAP_HEADERS** and **RESPONSE_SOAP_HEADERS** properties in a JAX-RPC client Stub to enable a web services client to send or retrieve implicit SOAP headers.

  An implicit SOAP header is a SOAP header that is not explicitly defined in the WSDL file. An implicit SOAP header file fits one of the following descriptions:

  – A message part that is declared as a SOAP header in the binding in the WSDL file, but the message definition is not referenced by a portType within a WSDL file.
  – An element that is not contained in the WSDL file.

  Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

  To learn how to modify your client code to send or retrieve transport headers, see the information on sending implicit SOAP headers with JAX-RPC or receiving implicit SOAP headers with JAX-RPC.
- Set the **REQUEST_TRANSPORT_PROPERTIES** and **RESPONSE_TRANSPORT_PROPERTIES** properties to enable a web services client to send or retrieve transport headers.

  Set the properties on the Stub or Call object.

  By modifying your client code to send or retrieve transport headers, you can send or receive specific information within the transport headers of outgoing requests or incoming responses from the server. For requests or responses that use the HTTP transport, the information is sent or retrieved in an HTTP header. Similarly, for a request or response that uses the Java Message Service (JMS) transport, the information is sent or retrieved in a JMS message property.

  To learn how to modify your client code to send or retrieve transport headers, see the information on sending transport headers with JAX-RPC or retrieving transport headers with JAX-RPC.

To learn how to enable a Web services client to send or retrieve transport headers, see the transport header properties best practices information.

- Implement support for `javax.xml.rpc.ServiceFactory.loadService()` methods.

  The loadService methods create an instance of the generated service implementation class in an implementation-specific manner. The loadService methods are new for JAX-RPC 1.1 and include three signatures:

  – **public.javax.xml.rpc.Service loadService (Class serviceInterface)**

    As documented in the JAX-RPC specification, this method returns the generated service implementation for the service interface. See the web services specifications and API documentation to review the JAX-RPC specification.

  – **public.javax.xml.rpc.Service loadService (URL wsdlDocumentLocation, Class serviceInterface, Properties properties)**

    This method behaves like the loadService (Class serviceInterface) because the following parameters are ignored:

    - wsdlDocumentLocation
    - properties

  – **public.javax.xml.rpc.Service loadService (URL wsdlDocumentLocation, QName serviceName, Properties properties)**

    This method returns the generated service implementation for the specified service by using optional namespace-to-package mapping information.

    - wsdlDocumentLocation - ignored
    - serviceName - QName (namespace, localpart) of the service
    - properties - If this parameter is non-null, it contains namespace-to-package mapping entries. Each Property entry key is a String corresponding to the namespace. Each Property entry value is a String corresponding to the Java package name.

      If the properties argument contains an entry with a key (namespace) that matches the namespace portion of the QName serviceName argument, the entry value (`javaPackage`) is used as the package name when trying to locate the service implementation.

  For more information on these methods, see the JAX-RPC specification.

- Implement the `CustomBinder` interface to provide concrete custom data binders for a specific XML schema type **(JAX-RPC applications only)**.

  Custom data binders are used to map XML schema types with Java objects. Custom data binders provide bindings for XML schema types that are not supported by the current Java API for XML-based Remote Call Procedure (JAX-RPC) specification. WebSphere Application Server provides an extension to the Web Services for Java Platform, Enterprise Edition (Java EE) programming model called the CustomBinder interface that implements these custom bindings for a specific XML schema type. The CustomBinder interface has three properties, in addition to deserialize and serialize methods:

  – QName for the XML schema type
  – QName scope
  – Java type

  The custom data binder defines serialize and deserialize methods to convert between a Java object and a SOAPElement interface. A custom data binder is added to the runtime system and interacts with the web services runtime using a SOAPElement. They are added to the runtime by using custom binding providers. Read about the custom data binders and the custom binding provider to learn more. See the CustomBinder interface documentation to learn more about how you can implement this interface to provide concrete custom data binders for a specific XML schema type.

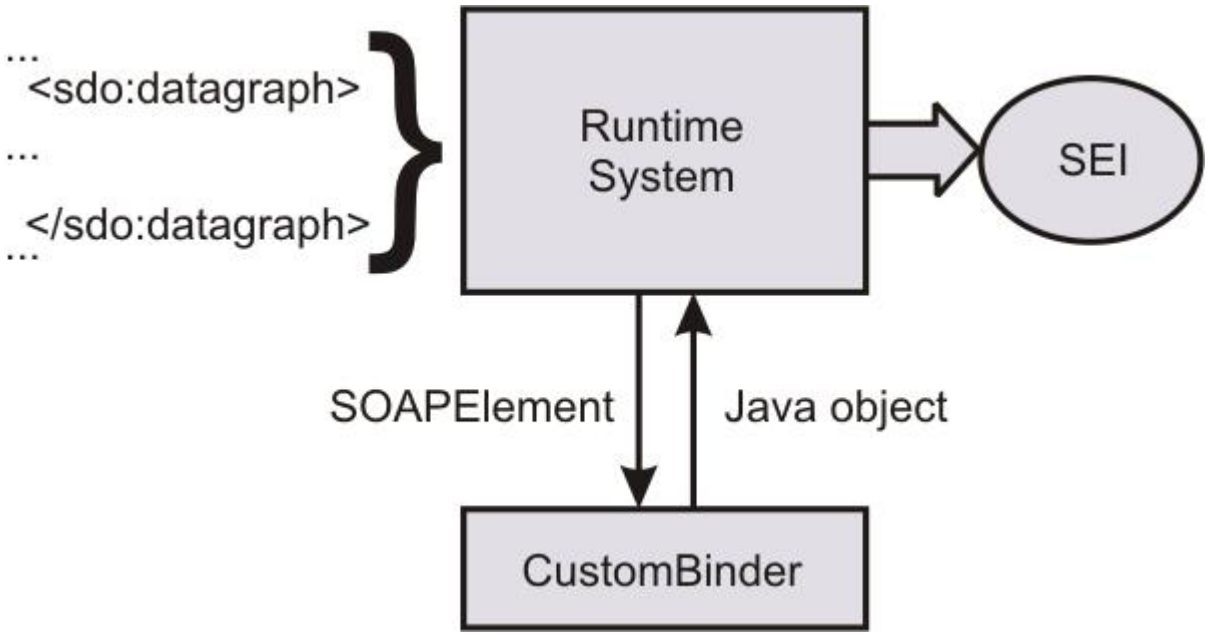
## Custom data binders for JAX-RPC applications

A *custom data binder* is used to map XML schema types with Java objects. Custom data binders provide bindings for XML schema types that are not supported by the current Java API for XML-based Remote Call Procedure (JAX-RPC) specification.

The custom data binder defines serialize and deserialize methods to convert between a Java object and a SOAPElement interface. A custom data binder is added to the runtime system and interacts with the web services run time using a SOAPElement. Unlike conventional deserializers, custom data binders do not rely on the low-level parsing events from the run time to build the Java object, such as Simple API for XML (SAX). Instead, the run time builds the custom data binder by rendering the incoming SOAP message into a SOAPElement. The SOAPElement that contains the message is passed to the customer data binder. For example, if the incoming message contains a Service Data Object (SDO) datagraph, the runtime system processes as follows:

1. The runtime system recognizes the `<sdo:Datagraph>` code.
2. The run time queries the type mapping system to locate the custom data binder for the datagraph data, for example SDOCustomBinder.
3. A SOAPElement is created that represents the incoming SDO datagraph.
4. The run time passes the SOAPElement to the SDOCustomBinder.

Within the deserialized method, the SDOCustomBinder extracts the content from the SOAPElement and builds a concrete DataGraph object with a `commonj.sdo.DataGraph` type.



When a Java object is serialized, a similar process occurs. The run time locates a custom data binder and converts the Java object to a SOAPElement. The runtime serializes the SOAPElement to the raw message that is transported in the output stream.

The following is an example of an XML schema that is defined by the SDO specification:

```
<xsd:schema
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:sdo="commonj.sdo"
  targetNamespace="commonj.sdo">

  <xsd:element name="datagraph" type="sdo:DataGraphType"/>

  <xsd:complexType name="DataGraphType">
  <xsd:complexContent>
    <xsd:extension base="sdo:BaseDataGraphType">
      <xsd:sequence>
        <xsd:any minOccurs="0" maxOccurs="1"
                 namespace="##other" processContents="lax"/>
      </xsd:sequence>
    </xsd:extension>
  </xsd:complexContent>
```

```
  </xsd:complexType>

  <xsd:complexType name="BaseDataGraphType" abstract="true">
  <xsd:sequence>
    <xsd:element name="models" type="sdo:ModelsType" minOccurs="0"/>
    <xsd:element name="xsd" type="sdo:XSDType" minOccurs="0"/>
    <xsd:element name="changeSummary"
                 type="sdo:ChangeSummaryType" minOccurs="0"/>
   </xsd:sequence>
  <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>

  <xsd:complexType name="ModelsType">
  <xsd:sequence>
    <xsd:any minOccurs="0" maxOccurs="unbounded"
             namespace="##other" processContents="lax"/>
  </xsd:sequence>
  </xsd:complexType>

  <xsd:complexType name="XSDType">
  <xsd:sequence>
    <xsd:any minOccurs="0" maxOccurs="unbounded"
        namespace="http://www.w3.org/2001/XMLSchema" processContents="lax"/>
  </xsd:sequence>
  </xsd:complexType>

  <xsd:complexType name="ChangeSummaryType">
  <xsd:sequence>
    <xsd:any minOccurs="0" maxOccurs="unbounded"
             namespace="##any" processContents="lax"/>
  </xsd:sequence>
  <xsd:attribute name="create" type="xsd:string"/>
  <xsd:attribute name="delete" type="xsd:string"/>
  </xsd:complexType>

</xsd:schema>
```

WebSphere Application Server defines the CustomBinder interface that implements concrete custom bindings for a specific XML schema type.

The custom binding provider is used to import the custom bindings into the run time. To learn how to plug your custom data binders into the WSDL2Java command-line tool for development, read about custom binding providers. You can also read about usage patterns for deploying custom data binders to learn more about how to deploy the provider package to your runtime, as well as the roles involved in the custom binding process.

## Custom binding providers for JAX-RPC applications

A *custom binding provider* is the packaging of custom data binder classes with a declarative metadata file. The main purpose of a custom binding provider is to aggregate related custom data binders to support particular user scenarios. The custom binding provider is used to plug the custom data binders into the emitter tools and the run time system so that the emitter tools can generate the appropriate artifacts and the run time system can augment its existing type mapping system to reflect the applied custom data binders and invoke them.

A custom binding provider works with a specific XML schema type, while applications involve a few related XML schema types. You need a mechanism to aggregate and declare various custom data binders to provide a complete binding solution. The concept of the custom binding provider defines a declarative model that can be used to plug in a set of custom data binders to either emitter tools or the run time system.

See the custom data binders information and the information on the CustomBinder interface to learn more about custom data binders and the CustomBinder API included in WebSphere Application Server to define the custom data binders. After you have defined the custom data binders, you are ready to deploy the custom binder package. To learn how to deploy this package, see the information on usage patterns for deploying custom data binders for JAX-RPC applications.

The declarative metadata file, `CustomBindingProvider.xml`, is an XML file that is packaged with the custom provider classes in a single Java archive (JAR) file and located in the `/META-INF/services/directory`. After a provider JAR file is packaged, the binary information and the metadata file located in the JAR file can be used by the WSDL2Java command-line tool and the run time system.

The following example is the XML schema for the `CustomBindingProvider.xml` file. The top level type is the providerType that contains a list of mapping elements. Each mapping element defines the associated custom data binder and properties, including xmlQName, javaName and qnameScope. You can read more about these properties in the information for CustomBinder interface for JAX-RPC applications. The providerType also has an attribute called scope that has a value of *server*, *application* or *module*. The scope attribute is used by the server deployment to resolve the conflict and to realize a custom binding hierarchy.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsd:schema
    targetNamespace=
       "http://www.ibm.com/webservices/customdatabinding/2004/06"
    xmlns:customdatabinding=
        "http://www.ibm.com/webservices/customdatabinding/2004/06"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    elementFormDefault="qualified" attributeFormDefault="qualified">

   <xsd:element name="provider" type="customdatabinding:providerType"/>

   <xsd:complexType name="providerType">
   <xsd:sequence>
     <xsd:element name="description" type="xsd:string" minOccurs="0"/>
     <xsd:element name="mapping" minOccurs="0" maxOccurs="unbounded">
      <xsd:complexType>
        <xsd:sequence>
          <xsd:element name="description" type="xsd:string" minOccurs="0"/>
          <xsd:element name="xmlQName" type="xsd:QName"/>
          <xsd:element name="javaName" type="xsd:string"/>
          <xsd:element name="qnameScope"
                       type="customdatabinding:qnameScopeType"/>
          <xsd:element name="binder" type="xsd:string"/>
        </xsd:sequence>
       /xsd:complexType>
      </xsd:element>
       <xsd:attribute name="scope"
             type="customdatabinding:ProviderScopeType" default="module"/>
       </xsd:sequence>
   </xsd:complexType

  <xsd:simpleType name="qnameScopeType">
      <xsd:restriction base="xsd:string">
         <xsd:enumeration value="simpleType"/>
         <xsd:enumeration value="complexType"/>
         <xsd:enumeration value="element"/>
      </xsd:restriction>
  </xsd:simpleType>

  <xsd:simpleType name="ProviderScopeType">
     <xsd:restriction base="xsd:string">
         <xsd:enumeration value="server"/>
         <xsd:enumeration value="application"/>
         <xsd:enumeration value="module"/>
     </xsd:restriction>
  </xsd:simpleType>
</xsd:schema>
```

The following is an example of the `CustomBindingProvider.xml` file for the SDO DataGraph schema that was introduced in CustomBinder interface. The example displays the mapping between a schema type, DataGraphType, and a Java type, commonj.sdo.DataGraph. The binder that represents this mapping is called `test.sdo.SDODataGraphBinder`.

```
<cdb:provider
 xmlns:cdb="http://www.ibm.com/webservices/customdatabinding/2004/06"
   xmlns:sdo="commonj.sdo">
   <cdb:mapping>
     <cdb:xmlQName>sdo:DataGraphType</cdb:xmlQName>
     <cdb:javaName>commonj.sdo.DataGraph</cdb:javaName>
```

```
     <cdb:qnameScope>complexType</cdb:qnameScope>
     <cdb:binder>test.sdo.SDODataGraphBinder</cdb:binder>
   </cdb:mapping>
</cdb:provider>
```

You need to import your custom data binders into the WSDL2Java command-line tool for development purposes. The custom data binders affect how the development artifacts, including the Service Endpoint Interface and the JSR 109 mapping data, are generated from the Web Services Description Language (WSDL) file. The WSDL2Java command-line tool ships with WebSphere Application Server and uses the custom binder Java archive file, or custom binder package, to generate these the development artifacts.

The following example is a WSDL file that references the SDO DataGraph schema that is introduced in the CustomBinder interface topic.

```
<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions targetNamespace="http://sdo.test"
   xmlns:impl="http://sdo.test"
   xmlns:intf="http://sdo.test"
   xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
   xmlns:wsdlsoap="http://schemas.xmlsoap.org/wsdl/soap/"
   xmlns:xsd="http://www.w3.org/2001/XMLSchema"
   xmlns:sdo="commonj.sdo">

 <wsdl:types>
  <schema elementFormDefault="qualified" targetNamespace="http://sdo.test"
       xmlns="http://www.w3.org/2001/XMLSchema" xmlns:sdo="commonj.sdo">
   <import namespace="commonj.sdo" schemaLocation="sdo.xsd"/>
  </schema>
 </wsdl:types>

 <wsdl:message name="echoResponse">
  <wsdl:part element="sdo:datagraph" name="return"/>
 </wsdl:message>

 <wsdl:message name="echoRequest">
   <wsdl:part element="sdo:datagraph" name="parameter"/>
 </wsdl:message>

 <wsdl:portType name="EchoService">
   <wsdl:operation name="echo">
     <wsdl:input message="impl:echoRequest" name="echoRequest"/>
     <wsdl:output message="impl:echoResponse" name="echoResponse"/>
    </wsdl:operation>
 </wsdl:portType>

 <wsdl:binding name="EchoServiceSoapBinding" type="impl:EchoService">
   <wsdlsoap:binding style="document"
                     transport="http://schemas.xmlsoap.org/soap/http"/>
     <wsdl:operation name="echo">
        <wsdlsoap:operation soapAction=""/>
        <wsdl:input name="echoRequest">
         <wsdlsoap:body use="literal"/>
        </wsdl:input>

       <wsdl:output name="echoResponse">
          <wsdlsoap:body use="literal"/>
       </wsdl:output>
    </wsdl:operation>
  </wsdl:binding>

  <wsdl:service name="EchoServiceService">
     <wsdl:port binding="impl:EchoServiceSoapBinding" name="EchoService">
       <wsdlsoap:address location="http://<uri>"/>
    </wsdl:port>
  </wsdl:service>

</wsdl:definitions>
```

If you run the WSDL2Java command without the custom data binding package, the following Service Endpoint Interface is generated with a parameter type, as dictated by the JAX-RPC specification:

```
public interface EchoService extends java.rmi.Remote {
  public javax.xml.soap.SOAPElement
   echo(javax.xml.soap.SOAPElement parameter)
    throws java.rmi.RemoteException;
}
```

When you run the WSDL2Java command with the custom data binding package, the custom data binders are used to generate the parameter types. To apply the custom data binders, use the -classpath option on the WSDL2Java tool. The tool searches its classpath to locate all the files with the same file path of `/META-INF/services/CustomBindingProvider.xml`. The following is an example how you can use the command to generate a Service Endpoint Interface with the parameter type of `commonj.sdo.Datagraph`:

```
WSDL2Java -role develop-server -container web classpath sdobinder.jar echo.wsdl
```

The Service Endpoint Interface that is generated looks like the following:

```
public interface EchoService extends java.rmi.Remote {
  public commonj.sdo.DataGraph
   echo(commonj.sdo.DataGraph parameter)
    throws java.rmi.RemoteException;
}
```

The custom binder packaged JAR file has to be made available at runtime to make sure the web service client is invoked, regardless if it is a stub-based client or a Dynamic Invocation Interface (DII) client. The same applies to the service.

## CustomBinder interface for JAX-RPC applications

WebSphere Application Server defines a CustomBinder interface that you can implement for Java API for XML-based Remote Call Procedure (JAX-RPC) applications to provide concrete custom data binders for a specific XML schema type.

The CustomBinder interface has three properties, in addition to deserialize and serialize methods. These properties are QName for the XML schema type, the QName scope, and the Java type that the schema type maps to. The properties are accessible through the corresponding getter methods.

### getQName

The getQName method returns the QName of the target XML schema type. Custom data binders only work with the root level schema type.

For anonymous types, the getQName method returns the QName of the containing element.

For named types, the getQName method returns the QName of the complexType or the simpleType.

### getQNameScope

The getQNameScope method returns the binder qnameScope property that indicates whether the schema type is a named type or an anonymous type. The qnameScope property value can be *complexType* for an `<xsd:complexType>`, *simpleType* for an `<xsd:simpleType>` or *element* for an <xsd:element> that is defined with an anonymous type.

In the following schema, data1 is an element that is defined with an anonymous type. The element, data2, is defined using the named type, data2Type.

```
<xsd:element name="data1">
 <xsd:complexType>
  ...
 </xsd:complexType>
</xsd:element>

<xsd:element name= "data2" type="data2Type"/>
<xsd:complexType name="data2Type">
 ...
</xsd:complexType>
```

The anonymous type, data1, has a qNameScope of element and a qName of data1. The type, data2Type, has a qNameScope of complexType and a qName of data2Type.

The element, data2, is not represented in the custom data binder. The custom data binder only processes types and not elements.

### getJavaName

The getJavaName method returns the fully-qualified class name for the Java type that is mapped to the named or anonymous type. The class can be an interface or a concrete class. The object returned from the deserialize method has a type that is compatible with the Java type that is returned by the getJavaName method.

### serialize

The serialize method returns the SOAPElement that the custom data binder builds from the Java object. The Java object is passed from the run time system and is expected to match what is returned from the getJavaName method. The SOAPElement parameter does not have child elements, but it does have a valid QName. This parameter is a reference for the binder to create the final SOAPElement.

In most cases, the binder implementation appends the child elements to the root SOAPElement. The run time system guarantees that the SOAPElement QName is correct. Therefore, the custom data binder for named types keeps the QName of the root element because the binder does not know the enclosing element. The binder implementation for an anonymous type should always include the QName in the returned SOAPElement that matches the defined schema type. WebSphere Application Server does not have concrete methods in the CustomBindingContext parameter.

### deserialize

The deserialize method returns a Java object that the custom data binder builds from the passed root SOAPElement. The object type of the returned Java object must match what is returned from the getJavaName method. Unlike the parameter serialize method, the passed SOAPElement contains the original XML data with the necessary namespace declarations.

The following is an example of an implementation of the SDO DataGraph binder, where the convertToSDO and convertToSAAJ utility methods convert between SOAPElement and an SDO object.

```
package test.sdo.binder;

import javax.xml.namespace.QName;
import javax.xml.soap.SOAPElement;

import com.ibm.wsspi.webservices.binding.CustomBinder;
import com.ibm.wsspi.webservices.binding.CustomBindingContext;

public class DataGraphBinder implements CustomBinder {
 public QName getQName() {
  return new QName("commonj.sdo", "DataGraphyType");
}
public String getJavaName() {
 return CustomBinder.QNAME_SCOPE_COMPLEXTYPE;
}
public String getJavaName() {
 return commonj.sdo.DataGraph.class.getName();
}
public javax.xml.soap.SOAPElement serialize(
  Object bean,
  SOAPElement rootNode,
  CustomBindingContext context)
  throws javax,xml.soap.SOAPException {
 // convertToSAAJ is a utility method to convert
 // the SDO DataGraph to the SOAPElement
 return convertToSAAJ(bean, rootNode);

public Object deserialize(
```

```
  SOAPElement source,
  CustomBindingContext context)
  throws javax.xml.soap.SOAPException {
  // convertToSDO is a utility method to convert
  // the SOAPElement to the SDO DataGraph
  return convertToSDO(source);
 }
}
```

To learn more about custom data binders, see the custom data binders for JAX-RPC applications information. To learn how to plug your custom data binders into the WSDL2Java command-line tool for development, see the custom binding providers for JAX-RPC applications information.

## Usage patterns for deploying custom data binders for JAX-RPC applications

Custom data binders are used to map XML schema types with Java objects. Custom data binders provide bindings for XML schema types that are not supported by the current Java API for XML-based Remote Call Procedure (JAX-RPC) specification. WebSphere Application Server provides an extension to the Web Services for Java Platform, Enterprise Edition (Java EE) programming model called the CustomBinder interface that implements these custom bindings for a specific XML schema type. The custom binding provider is the package for the custom data binders that is imported into the runtime.

To learn more about the CustomBinder API, see the CustomBinder interface for JAX-RPC applications information. For general information about custom binders, see the custom data binders for JAX-RPC applications information. See the custom binding providers for JAX-RPC applications information to review how custom binding providers are packaged for development.

This usage pattern reviews how to deploy the provider package to your runtime, as well as the roles involved in the custom binding process.

### Roles involved in custom data binding

Four roles are involved with custom data binding. These roles that are defined by the Web Services for Java Platform, Enterprise Edition (Java EE) specification are as follows:

- **Custom binding provider** is responsible for implementing the required custom data binders, declaring these binders in a `CustomBindingProvider.xml` file and packaging the binding classes into a Java archive (JAR) file.
- **Application developer** is responsible for applying the custom binding provider JAR file and generating the development artifacts.
- **Application assembler** needs to understand the application requirements in terms of the custom data binding and decides how to package the custom provider JAR file as a part of the application.
- **Application deployer** configures the shared libraries to make custom data binding support available to the applications. This needs to be done if the custom provider JAR file is not packaged with the application. If the application is not deployed, the deployer has to run the web services deployment tools after the application is installed.

### Common usage patterns

The custom binder provider package can be deployed in various ways to provide flexibility beyond the standard JAX-RPC mapping standards. Three primary deployment usage patterns are as follows:

- **Deploy the custom data binders at the server level**

  This pattern ensures that all the applications that are running on the server are affected by the custom data binders and is useful if fundamental XML types are introduced but are not supported by the standard JAX-RPC mapping rules.

  This type of situation occurs frequently for new web services specifications that define new schema types. For example, the WS-Addressing specification defines an EndpointReferenceType schema type that is not supported by the JAX-RPC mapping rules. Because this pattern requires augmenting the

server classpath, it has a significant impact on the server runtime and affects the installed applications. This pattern is most suitable for WebSphere Application Server internal components.

- **Deploy the custom binders for one or more application**

  Use this pattern if you only want specified applications to be affected by the custom data binders and if relevant XML schema types apply to a set of applications. You can share the custom data binders within a set of applications while achieving isolation between different sets of applications.

- **Deploy the custom binders for a specific web module within an application**

  Using this pattern ensures that a specific Web module is affected by the deployed custom data binders. This pattern is useful when fine granularity for custom binding is required. You cannot use this pattern with EJB modules because the module and its referenced library belong to the entire application.

### Usage patterns

This section reviews deploying custom data binders using one of the three patterns:

- **Server level deployment**

  If you deploy the custom data binders at the server level, you need to set the scope attribute of the declared binding provider as *server*. Setting the value to *server* guarantees a higher priority for declared binders if there are conflicts between the server and applications. The custom binding provider JAR file needs to be in the appropriate place to be picked up by the server runtime. Configure the server path and make the custom binding provider JAR file a part of the server classpath. To learn about values used in configuring the server classpath, see the Java virtual machine settings information.

- **Deploying custom data binders for one or more applications**

  To deploy custom data binders for one or more applications, set the scope attribute of the declared custom binding provider as *application*. Setting the value to application guarantees higher priority binders in case of conflicts between the application and the module. If the custom data binders are used by more than one application, configure a shared library for the applications to reference. To learn about values used in configuring the shared libraries path, see the managing shared libraries information.

- **Deploy the custom data binders for a specific web module within an application**

  To deploy custom data binders for a specific web module within an application, set the scope attribute of the declared custom binding provider to the value *module*. The only way to apply the custom data binder for this pattern is to pre-package the custom binding provider JAR file with the web module, for example, place the JAR file in the `/WEB-INF/lib` directory.

## Sending implicit SOAP headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to send values in implicit SOAP headers. By modifying your client code to send implicit SOAP headers, you can send specific information within an outgoing web service request.

### Before you begin

To complete this task, you need a web services client that you can enable to send implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

You cannot manipulate protected SOAP headers. A SOAP header that is declared protected by its owning component, for example, Web Services Security, is not accessible to client applications. An exception

occurs if you try to manipulate protected SOAP headers.

### About this task

The client application sets properties on the Stub or Call object to send and receive implicit SOAP headers.

### Procedure

1. Create a java.util.HashMap object.
2. Add an entry to the HashMap object for each implicit SOAP header that the client wants to send. The HashMap entry key is the QName of the SOAP header. The HashMap entry value is either an SAAJ SOAPElement object or a String that contains the XML text of the entire SOAP header element.
3. Set the HashMap object as a property on the Stub or Call object. The property name is com.ibm.websphere.webservices.Constants.REQUEST_SOAP_HEADERS. The value of the property is the HashMap.
4. Issue the remote method calls using the Stub or Call object. The headers within the HashMap object are sent in the outgoing message.

   A `JAXRPCException` error can occur if any of the following are true:

   - The HashMap object contains a key that is not a QName object or if the HashMap object contains a value that is not a String or a SOAPElement object.
   - The HashMap object contains a key that represents a SOAP header that is declared protected by the owning component.

### Results

You have a JAX-RPC web services client that is configured to send implicit SOAP headers.

### Example

The following programming example illustrates how to send two request SOAP headers and receive one response SOAP header within a web services request and response:

```
1 //Create the request and response hashmaps.
2 HashMap requestHeaders=new HashMap();
3 HashMap responseHeaders=new HashMap();
4
5 //Add "AtmUuid1" and "AtmUuid2" to the request hashmap.
6 requestHeaders.put(new QName("com.rotbank.security", "AtmUuid1"),
7   "<AtmUuid1 xmlns=\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid1>");
8 requestHeaders.put(new QName("com.rotbank.security", "AtmUuid2"),
9  ((IBMSOAPFactory)SOAPFactory.newInstance()).createElementFromXMLString(
10   "x:AtmUuid2 xmlns:x=\"com.rotbank.security\"><x:uuid>ROTB-0A01254385FCA09
     </x:uuid><x:AtmUuid2>"));
11
12 //Add "ServerUuid" to the response hashmap.
13 //If "responseHeaders" is empty, all the SOAP headers are
14 //extracted from the response message.
15 responseHeaders.put(new QName("com.rotbank.security","ServerUuid"), null);
16
17 //Set the properties on the Stub object.
18 stub.setProperty(Constants.REQUEST_SOAP_HEADERS.requestHeaders);
19 stub.setProperty(Constants.RESPONSE_SOAP_HEADERS.responseHeaders);
20
21 //Call the operationon the Stub.
22 stub.foo(parm2, parm2);
23
24 //Retrieve "ServerUuid" from the response hashmap.
25 SOAPElement serverUuid =
26   (SOAPElement) responseHeaders.get(new QName("com.rotbank.security","ServerUuid"));
27
28 //Note: "serverUuid" now equals a SOAPElement object that represents the
29 //following code:
30//"<y:ServerUuid xmlns:y=\"com.rotbank.security\"><:uuid>ROTB-0A03519322FSA01
   </y:uuid></y:ServerUuid.");
```

On lines 2-3, new HashMaps are created that are used for the request and response SOAP headers.

On lines 6-10, the AtmUuid1 and AtmUuid2 headers elements are added to the request HashMap.

On line 15, the ServerUuid header element name, along with a null value, is added to the response HashMap.

On line 18, the request HashMap is set as a property on the Stub object. This causes the AtmUuid1 and AtmUuid2 headers to be added to each request message that is associated with an operation that is invoked on the Stub object.

On line 19, the response HashMap is set as a property on the Stub object. This causes the ServerUuid header to be extracted from each response message that is associated with an operation that is invoked on the Stub object.

On line 22, the web service operation is invoked on the Stub object.

On lines 25-26, the ServerUuid header is retrieved from the response HashMap. The header was extracted from the response message and inserted into the HashMap by the web services engine.

## Receiving implicit SOAP headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to receive values from implicit SOAP headers. By modifying your client code to receive implicit SOAP headers, you can receive specific information within an incoming web service response.

### Before you begin

To complete this task, you need a web services client that you can enable to receive implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

You cannot manipulate protected SOAP headers. A SOAP header that is declared protected by its owning component, for example, Web Services Security, is not accessible to client applications. An exception occurs if you try to manipulate protected SOAP headers.

### About this task

The client application sets properties on the Stub or Call object to send and receive implicit SOAP headers.

### Procedure

1. Create a java.util.HashMap object
2. Add an entry to the HashMap object for each implicit SOAP header that the client wants to receive. The HashMap entry key is the QName of the SOAP header. The HashMap entry value is null.
3. Set the HashMap entry on the Stub or Call object. The property name is com.ibm.websphere.webservices.Constants.RESPONSE_SOAP_HEADERS. The value of the property is the HashMap.

4. Issue remote method calls against the Stub or Call object. The web services engine extracts the specified response headers from the web services response message and inserts them into the HashMap. After the remote method returns, the response headers are accessible from the HashMap object.

   A JAXRPCException error can occur if any of the following are true:

   - The HashMap contains a key that is not a QName.
   - The HashMap contains a key that represents a SOAP header that is declared protected by the owning component.

### Results

You have a JAX-RPC web services client that can receive values from implicit SOAP headers.

## Sending transport headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to send application-defined information along with your Web services requests by using transport headers.

### Before you begin

You need a JAX-RPC web services client that you can enable to send transport headers.

Sending transport headers is supported only by web services clients, and only supported for the HTTP and JMS transports. The web services client must call the JAX-RPC APIs directly and not through any intermediary layers, such as a gateway function. Sending and retrieving transport headers on the web services server is done through non-web services APIs.

### About this task

When using the JAX-RPC programming model, the client must set a property on the Stub or Call object to send values in transport headers. After you set the property, the values are set in all the requests for subsequent remote method invocations against that Stub or Call object until the associated property is set to null or the Stub or Call object is discarded.

To send values in the transport headers on outbound requests, modify the client code as follows:

### Procedure

1. Create a java.util.HashMap object that contains the transport header identifiers.
2. Add an entry to the HashMap object for each transport header that you want the client to send.
   a. Set the HashMap entry key to a string that exactly matches the transport header identifier. You can define the header identifier with a reserved header name, such as Cookie in the case of HTTP, or the header identifier can be user defined, such as `MyTransportHeader`. Certain header identifiers are processed in a unique manner, but no other checks are made as to the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as HTTP_HEADER_SET_COOKIE in the com.ibm.websphere.webservices.Constants class.
   b. Set the HashMap entry value to a string that contains the value of the transport header.
3. Set the HashMap entry on the Stub or Call object using the com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES property. When the REQUEST_TRANSPORT_PROPERTIES property value is set, that HashMap is used on subsequent invocations to set the header values in the outgoing requests. If the REQUEST_TRANSPORT_PROPERTIES property value is set to null, no HashMap is used on subsequent invocations to set header values in outgoing requests. To learn more about these properties, see the transport header properties documentation.

4. Issue remote method calls against the Stub or Call object. The headers and the associated values from the HashMap are added to the outgoing request for each method invocation. If the invocation uses HTTP, then the transport headers are sent as HTTP headers within the HTTP request. If the invocation uses JMS, then the transport headers are sent as JMS message properties.

   If the property is not set correctly, you might experience API usage errors that result in a JAXRPCException error. The following requirements must be met, or the process fails:

   - The property value that is set on the Stub or Call object must be a HashMap object or null.
   - The HashMap must not be empty.
   - Each key in the HashMap must be a String object.
   - Each value in the HashMap must be a String object.

### Results

You have a JAX-RPC web services client that is configured to send transport headers.

## Retrieving transport headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to retrieve values from transport headers. For a request that uses HTTP, the transport headers are retrieved from HTTP headers found in the HTTP response message. For a request that uses Java Message Service (JMS), the transport headers are retrieved from the JMS message properties found on the JMS response message.

### Before you begin

You need a web services client that you can enable to retrieve transport headers.

Retrieving transport headers is supported only by web services clients, and only supported for the HTTP and JMS transports. The web services client must call the JAX-RPC APIs directly and not through any intermediary layers, such as a gateway function. Sending and retrieving transport headers on the web services server is done through non-web services APIs.

### About this task

When using the JAX-RPC programming model, the client must set a property on the Stub or Call object in order to retrieve values from the transport headers. After you set the property, values are read from responses for the subsequent method invocations against that Stub or Call instance until the associated property is set to null or the Stub or Call object is discarded.

To retrieve values from the transport headers on inbound responses, modify the client code.

### Procedure

1. Create a java.util.HashMap object that contains the names of the transport headers to be retrieved from incoming response messages.
2. Add an entry to the HashMap for each header that you want to retrieve a value from every incoming response message.
   a. Set the HashMap entry key to a string that exactly matches the transport header identifier. You can define the header identifier with a reserved header name, such as Cookie in the case of HTTP, or the header identifier can be user-defined, such as `MyTransportHeader`. Certain header identifiers are processed in a unique manner, but no other checks are made to confirm the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as HTTP_HEADER_SET_COOKIE in the com.ibm.websphere.webservices.Constants class.

The HashMap entry value is ignored and does not need to be set. An empty HashMap, for example, one that is non-null, but does not contain any keys, causes all the transport headers in the response to be retrieved.

3. Set the HashMap entry on the Stub or Call object using the com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES property. When the HashMap is set, the RESPONSE_TRANSPORT_PROPERTIES property is used in subsequent invocations to retrieve the headers from the responses. If you set the property to null, no headers are retrieved from the response. To learn more about these properties, see the transport header properties documentation.
4. Issue remote method calls against the Stub or Call object. The values from the specified transport headers are retrieved from the response message and placed in the HashMap.

   If the property is not set correctly, you might experience API usage errors that result in a JAXRPCException error. The following requirements must be met, or the process fails:

   - The property value that is set on the Stub or Call object must be either null or an instance of a HashMap.
   - All the HashMap keys must be a string data type, and the keys must not be null.

### Results

You have a JAX-RPC web service that can receive transport headers from incoming response messages.

# Assembling web services applications

# Assembling web services applications

You can assemble Java-based web services applications using assembly tools.

## Before you begin

You can assemble Java-based web services modules with assembly tools provided with the application server.

## About this task

After you develop your web service application, you are now ready to assemble the application. Assembling a web service application consists of creating the Java Platform, Enterprise Edition (Java EE) modules that you can deploy onto application servers. The modules are created from code artifacts such as web application archives (WAR) files for JavaBeans applications or enterprise beans Java archive (JAR) files for enterprise beans applications. This packaging and configuring of code artifacts into enterprise application modules (EAR files) or standalone web modules is necessary for deploying the modules onto an application server.

## Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. Assemble your web services enabled bean into the appropriate module.
   - For JavaBeans enabled as web services:
     a. “Assembling a WAR file that is enabled for web services from Java code” on page 1588.
     b. “Assembling a web services-enabled WAR file from a WSDL file” on page 1589.
   - For enterprise beans enabled as web services:
     a. “Assembling a JAR file that is enabled for web services from an enterprise bean” on page 1586.
     b. “Assembling a web services-enabled enterprise bean JAR file from a WSDL file” on page 1587.

**Note:** This product supports packaging enterprise beans in WAR files. If you include a web services-enabled enterprise bean JAR file into a WAR file, you must merge any information in the webservices.xml deployment descriptor files that are in the JAR files into the webservices.xml deployment descriptor in the WEB-INF directory of the WAR file. To learn more, see the EJB content in WAR modules information.

**Note:** When developing faults for a JAX-WS application, it is a best practice to always include the fault bean that is generated by the JAX-WS tooling in the packaging of your JAX-WS application. However if your application does not use the fault bean classes that are generated by the JAX-WS tooling (that is, you use a bottom-up development approach starting from Java and you choose not to package the fault bean classes), the application server runtime environment dynamically generates the fault beans. Even so, it is a best practice to always package the fault bean.

3. Assemble the web services enabled module into an enterprise archive (EAR) file.
   - "Assembling a web services-enabled WAR into an EAR file" on page 1592.
   - "Assembling an enterprise bean JAR file into an EAR file" on page 1590.
4. Enable the EAR file for EJB modules that contain web services. When the EAR file contains Enterprise JavaBeans (EJB) modules that contain web services, you must run the endptEnabler command-line tool or an assembly tool before deployment to produce a web services endpoint WAR file. This tool is also used to specify whether the web services are exposed using SOAP over Java Message Service (JMS) or SOAP over HTTP.
5. Assemble a web services-enabled WAR file into an EAR file.

## Results

You have a web services-enabled EAR file that you can deploy onto the application server.

## What to do next

Now you need to deploy the web services-enabled EAR file onto your application server. To learn more, read about deploying web services applications onto application servers

## Assembling a JAR file that is enabled for web services from an enterprise bean

You can assemble a web service-enabled enterprise bean Java archive (JAR) file with an assembly tool using artifacts generated from tooling.

### Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

You need the following artifacts that are generated from the WSDL2Java command-line tool to complete this task:

- An assembled enterprise bean JAR file that is not enabled for web services
- A compiled Java class for the service endpoint interface
- A Web Services Description Language (WSDL) file
- The complete `webservices.xml`, `ibm-webservices-bnd.xmi`, and `ibm-webservices-ext.xmi` deployment descriptor, and Java API for XML-based remote procedure call (JAX-RPC) mapping file.

### About this task

Assemble a web services-enabled enterprise bean JAR file from Java code by following the actions in the steps for this task section.

### Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.

### Results

You have the artifacts required to web service-enable an Enterprise JavaBeans (EJB) module for web services. The artifacts are added to the JAR file. Now you need to configure the deployment descriptors so that you can deploy the web service into the application server run time environment.

### Example

The `AddressBook.jar` JAR file contains the following files after assembly. The files added in this task are in bold. These files include the WSDL file, the deployment descriptors, and the JAX-RPC mapping file.

```
META-INF/MANIFEST.MF
META-INF/ejb-jar.xml
addr/Address.class
addr/AddressBook_RI.class
addr/AddressBookBean.class
addr/AddressBookHome.class
addr/Phone.class
addr/StateType.class
addr/AddressBook.class
META-INF/wsdl/AddressBook.wsdl
META-INF/ibm-webservices-bnd.xmi
META-INF/ibm-webservices-ext.xmi
META-INF/webservices.xml
META-INF/AddressBook_mapping.xml
```

### What to do next

Assemble the EAR file so that you can deploy the EAR file into WebSphere Application Server.

## Assembling a web services-enabled enterprise bean JAR file from a WSDL file

You can assemble a web services-enabled enterprise bean Java archive (JAR) file from a Web Services Description Language (WSDL) file with an assembly tool.

### Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

You need the following artifacts to complete this task:

- An assembled enterprise bean JAR file that contains the Enterprise JavaBeans (EJB) implementation and all classes that generate from the WSDL2Java command-line tool when the role argument is `develop-server` and the container argument is `EJB`.
- A WSDL file
- The complete `webservices.xml`, `ibm-webservices-bnd.xmi` and `ibm-webservices-ext.xmi` deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file.

### About this task

Assemble a web services-enabled enterprise bean JAR file from a WSDL file by following the actions in the steps for this task section.

### Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.

### Results

You have the artifacts required to web service-enable an EJB module for web services. The artifacts are added to the JAR file. Now you need to configure the deployment descriptors so that you can deploy the web service into the application server runtime environment.

### Example

The `AddressBook.jar` JAR file contains the following files after assembly. The files added in this task are in bold. These files include the WSDL file, the deployment descriptors, and the JAX-RPC mapping file.

```
META-INF/MANIFEST.MF
META-INF/ejb-jar.xml
addr/Address.class
addr/AddressBook_RI.class
addr/AddressBookSoapBindingImpl.class
addr/AddressBookHome.class
addr/Phone.class
addr/StateType.class
addr/AddressBook.class
META-INF/wsdl/AddressBook.wsdl
META-INF/ibm-webservices-bnd.xmi
META-INF/ibm-webservices-ext.xmi
META-INF/webservices.xml
META-INF/AddressBook_mapping.xml
```

### What to do next

For JAX-RPC web services, configure the `webservices.xml` deployment descriptor . You need to configure the deployment descriptors for the web service so that WebSphere Application Server can process the incoming web services requests.

## Assembling a WAR file that is enabled for web services from Java code

You can assemble a web application archive (WAR) file that is enabled for web services from Java code with an assembly tool.

### Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

For Java API for XML-Based Web Services (JAX-WS) web service applications, you need the portable artifacts that are generated by the wsgen command-line tool when starting from a service endpoint

implementation to complete this task. The wsgen tool processes a compiled service endpoint implementation class as input and generates the following portable artifacts:

- any additional Java Architecture for XML Binding (JAXB) classes that are required to marshal and unmarshal the message contents. The additional classes include classes that are represented by the @RequestWrapper annotation and the @ResponseWrapper annotation for a wrapped method.
- a WSDL file if the optional *-wsdl* argument is specified. The wsgen command does not automatically generate the WSDL file. The WSDL file is automatically generated when you deploy the service endpoint.

For Java API for XML-based RPC (JAX-RPC) web service applications, you need the following artifacts that are generated by the WSDL2Java command-line tool to complete this task:

- An assembled WAR file that contains the `web.xml` file, but is not enabled for web services.
- The Java class for the service endpoint interface
- A Web Services Description Language (WSDL) file
- The complete `webservices.xml`, `ibm-webservices-bnd.xmi`, and `ibm-webservices-ext.xmi` deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file classes that are generated by the WSDL2Java command.

### About this task

Assemble a web services-enabled WAR file from Java code by following the actions in the steps for this task section.

### Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Import the JavaBeans implementation and the artifacts generated by the command-line tooling into the assembly tool.
4. Migrate WAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.

### Results

The artifacts required to enable the web module for web services are added to the WAR file.

### What to do next

Now you can assemble the WAR file that is enabled for Web services into an EAR file. To learn more, read about assembling a web services-enabled WAR into an EAR file.

## Assembling a web services-enabled WAR file from a WSDL file

You can assemble a web application archive (WAR) file from a Web Services Description Language (WSDL) file that is enabled for web services.

### Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

For Java API for XML-Based Web Services (JAX-WS) web service applications, you need the portable artifacts that are generated by the wsimport command-line tool when starting from a WSDL file to complete this task. The wsimport tool processes a WSDL file as input and generates the following portable artifacts:

- Service Endpoint Interface (SEI)
- Service class
- Exception classes that are mapped from the `wsdl:fault` class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types

You can package the generated artifacts in a web application archive (WAR) file with the WSDL file and schema documents along with the endpoint implementation that you plan to deploy.

For Java API for XML-based RPC (JAX-RPC) web service applications, you need the following artifacts that are generated by the WSDL2Java command-line tool to complete this task:

- An assembled WAR file that contains the Enterprise JavaBeans (EJB) implementation, all the classes that generate from the WSDL2Java command-line tool and the `web.xml` deployment descriptor file.
- A WSDL file
- The complete `webservices.xml`, `ibm-webservices-bnd.xmi`, and `ibm-webservices-ext.xmi` deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file.

### About this task

Assemble a web services-enabled WAR file from a WSDL file by following the actions in the steps for this task section.

### Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Import the JavaBeans implementation and the artifacts generated by the command-line tooling into the assembly tool.
4. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.

### Results

The artifacts required to enable the web module for web services is added to the WAR file.

### What to do next

Now you can assemble the WAR file that is enabled for Web services into an EAR file. To learn more, read about assembling a web services-enabled WAR into an EAR file.

## Assembling an enterprise bean JAR file into an EAR file

You can assemble an enterprise bean Java archive (JAR) file into an enterprise archive (EAR) file with an assembly tool. Assembling the JAR file, and now the EAR file, are required tasks to enable Java code for web services.

## Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

Before assembling a web services-enabled EAR file you must assemble an enterprise bean JAR file that you want to enable for Web services. To learn more about the artifacts that are needed for the assembly of the enterprise bean JAR file, see the information on assembling an enterprise bean JAR file from Java code that is enabled for web services.

**Restriction:** Do not include a pound sign (#) in the name of files that are packaged within an application archive. Due to internal processing, the application server fails to correctly deploy the application when a pound sign is included in a file name within the application archive. When this failure occurs, an exception might occur when the application is being processed. Also, parts of the application might be missing after the application is deployed. To address this issue, rename any file names within the application archive so that they do not contain a pound sign.

## About this task

To assemble a web services-enabled EAR file:

## Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Assemble the web services-enabled JAR file into an EAR file. The EAR file can contain an enterprise bean or application client JAR files, WAR files, web applications, and metadata describing the applications or `application.xml` files.

## Results

A web services-enabled EAR file.

## Example

In the following example, there is an `application.xml` deployment descriptor packaged with a web services-enabled JAR file called `AddressBook.jar` that is packaged into an EAR file called `AddressBook.ear`. The EAR file contains:

```
META-INF/MANIFEST.MF
META-INF/application.xml
AddressBook.jar
```

An example of the `application.xml` deployment descriptor is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE application PUBLIC "-//Sun Microsystems, Inc.//DTD J2EE Application 1.3//EN"
"http://java.sun.com/dtd/application_1_3.dtd">
 <application id="Application_ID">
  <display-name>AddressBookJ2WEE</display-name>
  <description>AddressBook EJB Example from Java</description>
  <module id="EjbModule_1">
   <ejb>AddressBook.jar</ejb>
  </module>
 </application>
```

### What to do next

You can enable an EAR file for EJB modules that contain web services. Then, deploy the EAR file into WebSphere Application Server.

## Assembling a web services-enabled WAR into an EAR file

You can assemble a web services-enabled web application archive (WAR) file into an enterprise archive (EAR) file with an assembly tool.

### Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

**Restriction:** Do not include a pound sign (#) in the name of files that are packaged within an application archive. Due to internal processing, the application server fails to correctly deploy the application when a pound sign is included in a file name within the application archive. When this failure occurs, an exception might occur when the application is being processed. Also, parts of the application might be missing after the application is deployed. To address this issue, rename any file names within the application archive so that they do not contain a pound sign.

### About this task

Assemble a web services-enabled WAR file into an EAR file using the steps provided in this task section.

### Procedure

1. Start an assembly tool. Read about starting the assembly tool in theRational Application Developer documentation.
2. Assemble the web services-enabled WAR file into an EAR file. Assemble the EAR file that contains the JAR or WAR files. The EAR file can contain an enterprise bean or application client JAR files; web applications or WAR files; and metadata describing the applications or `application.xml` files. To learn more about how to assemble the WAR file, see the assembling applications documentation.

### Results

A web services-enabled EAR file.

### Example

In the following example, there is an `application.xml` deployment descriptor packaged with a web services-enabled JAR file called `AddressBook.jar` that is packaged into an EAR file called `AddressBook.ear`. The EAR file contains:

```
META-INF/MANIFEST.MF
META-INF/application.xml
AddressBook.war
```

An example of the `application.xml` deployment descriptor is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE application PUBLIC "-//Sun Microsystems, Inc.//DTD J2EE Application 1.3//EN"
"http://java.sun.com/dtd/application_1_3.dtd">
 <application id="Application_ID">
  <display-name>AddressBook</display-name>
  <description>AddressBook Example from Java bean</description>
  <module id="WebModule_1">
   <web>
    <web-uri>AddressBook.war</web-uri>
```

```
    <context-root>/AddressBook</context-root>
   </web>
  </module>
 </application>
```

### What to do next

Deploy your web services.

## Enabling an EAR file for EJB modules that contain web services

When your enterprise archive (EAR) file contains enterprise JavaBeans (EJB) modules that contain Web services, you must run the endptEnabler command-line tool or an assembly tool before deployment to produce a web services endpoint web application archive (WAR) fiile.

### Before you begin

Assemble an enterprise Java archive (JAR) file that is enabled for web services from an enterprise bean. The enterprise JAR file is an artifact that is required to build the EAR file.

### About this task

You can add router modules to your application that is enabled for web services with either the **endptEnabler** command-line tool or with assembly tools provided with WebSphere Application Server. The tool that you choose to use for this task depends on your preference to work with a command-line tool or a graphical user interface. See the assembly tools documentation to learn how to use assembly tool to accomplish this task.

These tools add one or more router modules to the EAR file for each web service-enabled enterprise JavaBeans (EJB) module contained in the EAR file. A router module provides an endpoint for the web service in a particular EJB module.

You should not modify the contents of the EJB module or the web module that was generated using the **endptEnabler**command-line tool. If you do, an error occurs during run time. The following is an example of the error that displays:

```
"Error]- WSWS3142E: Error: Could not find web services engine.]: javax.servlet.ServletException: WSWS3142E:
Error: Could not find web services engine."
```

Each router module supports a specific transport such as HTTP or Java Message Service (JMS). If no enterprise bean JAR modules are located in the EAR file, it is not necessary to use these tools.

### Procedure

Enable an EAR file with the **endptEnabler** command-line tool. In its interactive mode, the **endptEnabler** command guides you through the required steps to enable one or more services within an application.

### What to do next

Deploy the EAR file into WebSphere Application Server. An assembled EAR file that is enabled for web services is required for deployment.

#### *Enabling an EAR file for web services with the endptEnabler command:*

Use the endptEnabler command-line tool to enable an enterprise archive (EAR) file for Enterprise JavaBeans (EJB) modules that contain web services and to specify whether the web services are exposed using SOAP over Java Message Service (JMS) or SOAP over HTTP.

### Before you begin

Before doing this task, you need to assemble a web services-enabled enterprise Java archive (JAR) into an EAR file.

### About this task

The endptEnabler command-line tool adds one or more router modules to the EAR file for each Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) based Web service-enabled enterprise bean Java archive (JAR) module within the EAR file. A router module provides an endpoint for the web services in a particular enterprise bean JAR module.

Each router module supports a specific transport such as HTTP or JMS. An HTTP router module is a web application archive (WAR) module that provides an HTTP endpoint for each of the web services contained within a particular enterprise bean JAR module. Likewise, a JMS router module is an enterprise bean JAR module that contains a Message Driven Bean (MDB) that serves as the message listener for requests intended for the web service endpoints.

If no enterprise bean JAR modules exist in the EAR file, it is not necessary to use this tool.

### Procedure

1. Invoke the endptEnabler command from the *install_root*\bin directory. Linux HP-UX Solaris AIX For operating systems such as Linux, HP-UX, Solaris, AIX or z/OS, invoke the command from the *install_root*/bin directory.
2. Enter the name of the EAR file, when prompted.
3. Enter various input values as requested by the endptEnabler command. You are prompted for various input values for each enterprise bean JAR module that is enabled for web services in the EAR file. Typically, you accept the defaults for each prompt. To learn about the properties of this command, see the endptEnabler command documentation.
   a. Specify an HTTP router module to transport your EJB-based web service. Use the `-transport http` option to indicate the web service is available using HTTP. One router module is created for each enterprise bean JAR file that contains either JAX-WS or JAX-RPC web services.
   b. Specify an JMS router module to transport your EJB-based web service. Use the `-transport jms` option to indicate the web service is available using JMS. One router module is created for each enterprise bean JAR file that contains either JAX-WS or JAX-RPC web services.

### Results

An HTTP or JMS router module is added to the EAR file for each enterprise bean JAR module within the EAR file that contains web services endpoints. For HTTP, a context-root is configured for the application so that the web service can be invoked through a Web address. The web address used to invoke the web service is:

`http://host[:port]/<context-root>/services/<port-component-name>`

Ensure that you install the HTTP or Java Message Service (JMS) router module that you generated with the endptEnabler command onto the same target as your web services enterprise bean JAR files. These HTTP or JMS router modules are included in your web services application and they need to use the runtime libraries of the application server.

### What to do next

Deploy the EAR file onto your application server. An assembled EAR file that is enabled for web services is required for deployment.

If you are using JMS as a transport for your web service requests, define the various JMS objects such as queues, topics, or connection factories, that will be used by your application prior to installing the application.

*endptEnabler command:*

The **endptEnabler** command is used to enable a set of web services within an enterprise archive (EAR) file. The **endptEnabler** command must run on EAR files containing Enterprise JavaBeans (EJB) modules that are enabled for web services.

Each router module provides a web service endpoint for a particular transport. For example, you can add a HTTP router module so that the web service can receive requests over the HTTP transport. Or, you can add a Java Message Service (JMS) router module so that the web service can receive requests from a JMS queue or topic.

In its interactive mode, the **endptEnabler** command guides you through the required steps to enable one or more services within an application. The **endptEnabler** command makes a backup copy of your original EAR file in the event that you need to remove or add services at a later time. If your EAR file contains an enterprise bean Java archive (JAR) file that is enabled for web services, you must run the **endptEnabler** command before the EAR file is deployed. Otherwise, you do not need to run the command.

**endptEnabler usage syntax**

Invoke the **endptEnabler** command from the WebSphere Application Server `bin` directory. The command syntax is presented in the following example:

```
endptEnabler
    [-verbose|-v]
    [-quiet|-q]
    [-help|-h|-?]
    [-properties|-p properties-filename]
    [-transport|-t default-transports]
    [-enableHttpRouterSecurity]
    [-enableClientCertSecurity]
    [ear-filename]
    [-classpath|-cp]
```

All parameters are optional and described in the following list:

- **-verbose, -v**

  This parameter details and displays progress messages as the endptEnabler tool processes the EAR file. This command-line option is mapped to the verbose global property.
- **-quiet, -q**

  This parameter makes sure that there are no displays of per-module progress messages as the endptEnabler tool processes the EAR file. This command-line option is mapped to the quiet global property.
- **-help, -h, -?**

  This parameter displays a brief help message that explains the various options.
- **-properties, -p <properties-filename>**

  This parameter reads properties from the *properties-filename* properties and controls the behavior of the endptEnabler tool.
- **-transport, -t <default-transports>**

  This parameter specifies the default list of transports for which router modules are created for each enterprise bean JAR file contained in the EAR file. This command-line option is mapped to the defaultTransports global property. The following are examples of this parameter:

  ```
  -transport http (the default)
  -transport jms
  -t http,jms
  ```
- **-enableHttpRouterSecurity**

This parameter enables you to add a security policy for all authenticated users to protect the HTTP router module if all the EJB modules are secured in the enterprise bean JAR file. This command-line option is mapped to the http.enableRouterSecurity global property.

- **-enableClientCertSecurity**

  This parameter enables you to add the following login-config stanza to the `web.xml` file for certificate authentication, instead of basic-auth or form-login. This command-line option is mapped to the http.enableClientCertSecurity global property.

```
<login-config>
  <auth-method>CLIENT-CERT</auth-method>
</login-config>
```

  **Note:** Use the -enableClientCertSecurity parameter with the -enableHttpRouterSecurity parameter.

- **<ear-filename>**

  This parameter specifies the name of the EAR file to be processed.

  If the *ear-filename* parameter is not entered on the command line, the interactive mode is used. In the interactive mode, you are prompted for the EAR file name, the router module names and other important values as the processing occurs. The following dialog is an example of the endptEnabler interactive mode.

  In this dialog, the user input is in fixed width font and the endptEnabler output is in bold.

```
endptEnabler<enter>
WSWS2004I: IBM WebSphere Application Server Release 5
WSWS2005I: Web Services Enterprise Archive Endpoint Enabler Tool.
WSWS2007I: (C) COPYRIGHT International Business Machines Corp. 1997, 2003
WSWS2006I: Please enter the name of your EAR file: AddressBook.ear<enter>

WSWS2003I: Backing up EAR file to: AddressBook.ear~

WSWS2016I: Loading EAR file: AddressBook.ear
WSWS2017I: Found EJB Module: AddressBookEJB.jar

WSWS2029I: Enter http router name for EJB Module AddressBookEJB
[AddressBookEJB_HTTPRouter.war]:<enter>
WSWS2030I: Enter http context root for EJB Module AddressBookEJB
[/AddressBookEJB]:<enter>
WSWS2024I: Adding http router for EJB Module AddressBookEJB.jar.
WSWS2036I: Saving EAR file AddressBook.ear...
WSWS2037I: Finished saving the EAR file.
WSWS2018I: Finished processing EAR file AddressBook.ear.
```

  If the *ear-filename* parameter is entered on the command-line, the non-interactive mode is used. In the non-interactive mode, the router module names and other important values are determined from the user-specified properties or default values.

- **-classpath, -cp**

  This parameter enables you to specify separate JAR files in the class path for the endptEnabler command. Use this parameter if the EJB file references Java types in separate JAR files that do not exist within the EAR file. You can specify multiple values for this parameter. For example:

```
endptEnabler -classpath C:\MyWork\Utility.jar;D:\SharedFiles\Hello.zip;HelloWorld.jar
```

  When you do not specify this parameter, you might encounter an error that is similar to the following message:

```
WSWS2021I: Skipping the enterprise bean module module_name
because it contains no web services.
```

### endptEnabler properties

With the **endptEnabler** command you can control its run-time behavior by specifying a set of properties with the -properties command-line option. These properties are organized in one of two ways: global and

per-module. Global properties affect the overall behavior of the tool as it processes multiple enterprise bean JAR modules within the EAR file. Per-module properties affect the processing of a particular enterprise bean JAR module.

### Global properties

*Table 225. Global properties for the* **endptEnabler** *command. Use these global properties of the endptEnabler command when enabling a set of web services within an enterprise archive (EAR) file.*

| Property name | Description | Default value |
|---|---|---|
| verbose | Displays detailed progress messages. | False |
| quiet | Displays only brief progress messages. | False |
| http.enableRouterSecurity | Enables you to add a security policy for all authenticated users to protect the HTTP router module if all the EJB modules are secured in the enterprise bean JAR file. | False |
| http.enableClientCertSecurity | Enables you to add the following login-config stanza to the `web.xml` file for certificate authentication, instead of basic-auth or form-login:<br>`<login-config>`<br>`  <auth-method>CLIENT-CERT</auth-method>`<br>`</login-config>` | False |
| http.routerModuleNameSuffix | Specifies the suffix used to construct default HTTP router module names. The `.war` extension is added by the **endptEnabler** command. | _HTTPRouter |
| jms.routerModuleNameSuffix | Specifies the suffix used to construct default JMS router module names. The `.jar` extension is added by the **endptEnabler** command. | _JMSRouter |
| jms.defaultDestinationType | Specifies the default destination type to use for all JMS router modules that are added to the EAR file. This type is either queue or topic. | queue |
| defaultTransports | Specifies the default list of transports for which router modules are created. The list can contain the values `http` and `jms`. Multiple values are separated by a comma. Examples are: `http`, `jms` and `http,jms`. | http |

### Per-module properties

The following table describes the per-module properties supported by the **endptEnabler** command. The *ejbJarName* variable refers to the name of an enterprise bean JAR module within the EAR file, without the `.jar` extension.

*Table 226. Per-module properties for the* **endptEnabler** *command. Use these properties of the endptEnabler command that affect the processing of a particular enterprise bean JAR module.*

| Property name | Description | Default value |
|---|---|---|
| `<ejbJarName>.transports` | Lists the transports for which router modules are created for a particular enterprise bean JAR file. The list can contain the values `http` and `jms`. Multiple values are separated by a comma. Examples are: `http`, `jms` and `http,jms`. | http |
| `<ejbJarName>.http.skip` | Specifies the flag which bypasses the addition of an HTTP router module, even if it otherwise is added based on other properties. Valid values are `true` and `false`. | false |
| `<ejbJarName>`<br>`.http.routerModuleName` | Specifies the name of the HTTP router module for a particular enterprise bean JAR file. | *ejbJarName*_HTTPRouter |
| `<ejbJarName>.http.contextRoot` | Specifies the context root associated with the HTTP router module for a particular enterprise bean JAR file. | */ejbJarName* |
| `<ejbJarName>.jms.skip` | Specifies the flag that bypasses the addition of an JMS router module even if it otherwise is added based on other properties. Valid values are `true` and `false`. | false |

*Table 226. Per-module properties for the* **endptEnabler** *command (continued). Use these properties of the endptEnabler command that affect the processing of a particular enterprise bean JAR module.*

| | | |
|---|---|---|
| <ejbJarName>.jms.<br>routerModuleName | Specifies the name of the JMS router module for a particular enterprise bean JAR file. | *ejbJarName*_JMSRouter |
| <ejbJarName>.jms.<br>activationSpecJndiName | Specifies the Java Naming and Directory Interface (JNDI) name of the activation specification that is configured for the Message Driven Bean (MDB) within the JMS router module. | null |
| <ejbJarName>.jms.<br>listenerInputPortName | Specifies the name of the listener port to configure for the MDB within the JMS router module. The listener port is configured only if an activationSpecJndiName property is not specified. | null |
| <ejbJarName>.jms.destinationType | Specifies the JMS destination type associated with the MDB within the JMS router. Valid values are `queue` and `topic`. | queue |
| <ejbJarName>.<port_local_name><br>.http.urlPattern=<br><url_pattern_name> | Specifies the URL pattern for ports. If you have EJB module with the indicated name that has a port with the indicated local name, you can specify the HTTP URL pattern with this property. This property only applies to HTTP router modules. It has no affect on JMS router modules. | null |

### Properties example

Suppose an EAR file contains an enterprise bean JAR file named, `StockQuoteEJB.jar` that contains web services. The following set of properties can be used to control the **endptEnabler** command run-time behavior as it processes the EAR file:

```
StockQuoteEJB.transports=http,jms

StockQuoteEJB.http.routerModuleName=StockQuoteEJB_HTTP

StockQuoteEJB.http.contextRoot=/StockQuote

StockQuoteEJB.jms.routerModuleName=StockQuoteEJB_JMS

StockQuoteEJB.jms.destinationType=queue
```

### endptEnabler examples

The following commands are examples of how the **endptEnabler** command can be used:

```
endptEnabler MyApp.ear

endptEnabler -t jms,http MyApp.ear

endptEnabler -v -properties MyApp.props MyApp.ear

endptEnabler -q -t jms MyApp.ear

endptEnabler -v -t http,jms
```

# Assembling web services-enabled clients

## Assembling a web services-enabled client JAR file into an EAR file

Now that you have generated your application artifacts, you need to assemble these artifacts to create an enterprise archive (EAR) file that is used in the web services application.

## Before you begin

For Java API for XML-Based Web Services (JAX-WS) web service applications, you need the portable artifacts that are generated by the wsimport command-line tool when starting from a WSDL file to complete this task. The wsimport tool processes a WSDL file as input and generates the following portable artifacts:

- Service Endpoint Interface (SEI)
- Service class
- Exception classes that are mapped from the `wsdl:fault` class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types
- An assembled client module that contains the implementation, all of the classes generated by the wsimport command-line tool and the `ejb-jar.xml` deployment descriptor or the `application-client.xml` deployment descriptor. This module can be:
  - An application client module that contains the `META-INF/application-client.xml` file.
  - An Enterprise JavaBeans (EJB) module that contains the `META-INF/ejb-jar.xml` file.

For Java API for XML-based RPC (JAX-RPC) web service applications, you need the following artifacts that are generated from the WSDL2Java command-line tool to complete this task:

- An assembled client module that contains the implementation, all of the classes generated by the WSDL2Java command-line tool and the `ejb-jar.xml` deployment descriptor or the `application-client.xml` deployment descriptor. This module can be:
  - An application client module that contains the `META-INF/application-client.xml` file.
  - An Enterprise JavaBeans (EJB) module that contains the `META-INF/ejb-jar.xml` file.
- The WSDL file that you used to develop the client.
- The templates for the `ibm-webservicesclient-ext.xmi` and `ibm-webservicesclient-bnd.xmi` deployment descriptor, if used.
- A generated Java API for XML-based remote procedure call (JAX-RPC) mapping deployment descriptor.

**Restriction:** Do not include a pound sign (#) in the name of files that are packaged within an application archive. Due to internal processing, the application server fails to correctly deploy the application when a pound sign is included in a file name within the application archive. When this failure occurs, an exception might occur when the application is being processed. Also, parts of the application might be missing after the application is deployed. To address this issue, rename any file names within the application archive so that they do not contain a pound sign.

## About this task

You can use assembly tools included with WebSphere Application Server to assemble web services-enabled client applications.

Assemble the client code and artifacts that enable the application client to access a web service with steps provided:

## Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Import the client implementation and the artifacts generated by the command-line tooling into the assembly tool.

4. Migrate JAR files created with the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.
5. Assemble the JAR file into an enterprise archive (EAR) file using typical assembly techniques if the client runs in a container.

### Results

You have assembled the artifacts required to enable the client application for web services into an EAR file.

### Example

This example of the assembly process uses the `AddressBookClient.jar` JAR file the `AddressBookClient.ear` EAR file:

```
META-INF/MANIFEST.MF
META-INF/application-client.xml
META-INF/wsdl/AddressBook.wsdl
META-INF/AddressBook_mapping.xml

com/ibm/websphere/samples/webservices/addr/Address.class
com/ibm/websphere/samples/webservices/addr/AddressBook.class
com/ibm/websphere/samples/webservices/addr/AddressBookClient.class
com/ibm/websphere/samples/webservices/addr/AddressBookService.class
...other generated classes...
```

After assembling the `AddressBookClient.jar` file into the `AddressBookClient.ear` file, the `AddressBookClient.ear` file contains the following files:

```
META-INF/MANIFEST.MF
AddressBookClient.jar
META-INF/application.xml
```

### What to do next

For Java API for XML-Based Web Services (JAX-WS) applications, you are ready to deploy the web services client application.

For Java API for XML-based RPC (JAX-RPC) applications, you need to configure the client deployment descriptor bindings with an assembly tool so that the client can communicate with a web service that is deployed on a server.

## Assembling a web services-enabled client WAR file into an EAR file

Now that you have generated your application artifacts, you need to assemble these artifacts to create an enterprise archive (EAR) file that is used in the web services application.

### Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

**Restriction:** Do not include a pound sign (#) in the name of files that are packaged within an application archive. Due to internal processing, the application server fails to correctly deploy the application when a pound sign is included in a file name within the application archive. When this failure occurs, an exception might occur when the application is being processed. Also, parts of the application might be missing after the application is deployed. To address this issue, rename any file names within the application archive so that they do not contain a pound sign.

### About this task

Assemble the client code and artifacts that enable the application client to access a web service with steps provided:

### Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate WAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to an assembly tool. Read about importing web application archive (WAR) files using an assembly tool in the Rational Application Developer documentation.

### Results

You have assembled the artifacts required to enable the client application for web services into an EAR file.

### Example

This example of the assembly process uses the `AddressBookWeb.war` WAR file and the `AddressBook.ear` EAR file:

```
WEB-INF/MANIFEST.MF
WEB-INF/web.xml
WEB-INF/wsdl/AddressBook.wsdl
WEB-INF/AddressBook_mapping.xml
WEB-INF/ibm-webservicesclient-ext.xmi (optional)
WEB-INF/ibm-webservicesclient-bnd.xmi
com/ibm/websphere/samples/webservices/addr/Address.class
com/ibm/websphere/samples/webservices/addr/AddressBook.class
com/ibm/websphere/samples/webservices/addr/AddressBookClient.class
com/ibm/websphere/samples/webservices/addr/AddressBookService.class
...other generated classes...
```

After assembling the `AddressBookWeb.war` file into the `AddressBook.ear` file, the `AddressBook.ear` file contains the following files:

```
META-INF/MANIFEST.MF
AddressBookWeb.war
META-INF/application.xml
```

### What to do next

For Java API for XML-Based Web Services (JAX-WS) applications, you are ready to deploy the web services client application.

For Java API for XML-based RPC (JAX-RPC) applications, you need to configure the client deployment descriptor bindings with an assembly tool so that the client can communicate with a web service that is deployed on a server.

# Deploying web services

## Deploying web services applications onto application servers

After assembling the artifacts required to enable the web module for web services into an enterprise archive (EAR) file, you can deploy the EAR file into the application server.

## Before you begin

To deploy Java-based web services, you need an enterprise application, also known as an EAR file that is configured and enabled for web services.

A Java API for XML-Based Web Services (JAX-WS) application does not require additional bindings and deployment descriptors for deployment whereas a Java API for XML-based RPC (JAX-RPC) web services application requires you to add additional bindings and deployment descriptors for application deployment. JAX-WS is much more dynamic, and does not require any of the static data generated by the deployment step required for deploying JAX-RPC applications.

For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

**Note:** In a mixed node cell, you can only target a JAX-WS enabled enterprise beans module to a server using WebSphere Application Server Version 7.0 and later. However, you can target a JAX-WS enabled web application archives (WAR) module to a server using either WebSphere Application Server Version 7.0 and later or WebSphere Application Server Version 6.1 Feature Pack for Web Services

You can use the wsdeploy command with JAX-RPC applications to add WebSphere product-specific deployment classes to a web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file.

To install or deploy a JAX-WS application, you only need to install the JAX-WS enabled EAR file. If your web services application contains only JAX-WS endpoints, you do not need to run the wsdeploy command, as this command is used to process only JAX-RPC endpoints.

Ensure that you have installed the HTTP or Java Message Service (JMS) router module that was generated with the endptEnabler command onto the same target as your web services enterprise bean JAR files. These HTTP or JMS router modules are included in your web services application and they need to use the runtime libraries of the application server.

## About this task

This task is one of the steps in developing and implementing web services.

You can use either the administrative console or the wsadmin scripting tool to deploy an EAR file. If you are installing an application containing web services by using the wsadmin command, specify the `-deployws` option for JAX-RPC applications. If you are installing an application containing web services by using the administrative console, select **Deploy WebServices** in the Install New Application wizard. For more information about installing applications using the administrative console, see the installing enterprise application files with the console information.

If your JAX-RPC web services application was previously deployed with the wsdeploy command, it is not necessary to specify web services deployment during installation.

The following actions deploy the EAR file with the wsadmin command:

## Procedure

1. Start *install_root*`/bin/wsadmin` from a command prompt. Linux AIX HP-UX

   Solaris On operating systems such as AIX or Linux, start *install_root*`/bin/wsadmin.sh`.

2. Deploy the EAR file.
   - For JAX-WS web service applications, enter the `$AdminApp install` *`EARfile`* `"-usedefaultbindings"` command at the wsadmin prompt.
   - For JAX-RPC web service applications, enter the `$AdminApp install` *`EARfile`* `"-usedefaultbindings -deployws"` command at the wsadmin prompt.

## Results

You have a web service installed onto your application server.

**Note:** While installing web services applications that contain a large number of enterprise beans onto the application server, you might receive out of memory errors. If you receive out of memory errors, increase the heap size of your Java Virtual Machine (JVM). Read about tuning the IBM virtual machine for Java documentation to learn more about tuning the application server environment.

## What to do next

You can confirm that the web services application was deployed by entering the web service endpoint URL in a browser, then viewing an informative page. The information page contains the following information:

```
{http://webservice.pli.tc.wssvt.ibm.com}RetireWebServices
Hello! This is an Axis2 web service!
```

The first line of this information is variable, depending on your web service. The URI in the brackets is the namespace and the string that follows, in this example RetireWebServices, is the name of the port used to access the web service.

The next step you might want to consider is to apply security to your web service.

# Provide options to perform the web services deployment settings

Use this page to specify options for web services deployment.

This administrative console page is a step in the application installation and update wizards.

To view this page, you must select **Deploy web services** on the **Select installation options** page.

To view this administrative console page, complete the following steps:

1. Click **Applications** > **New application** > ***application_path*** .
2. Select the option to **Show all installation options and parameters** .
3. Click **Next** to get to the **Step: Select installation options** page.
4. Select **Deploy web service**.
5. Click **Next** to get to the **Step: Provide options to perform the web services deployment** page.

You can specify the web services deployment options on this page only when installing or updating an application that uses web services.

The wsdeploy command is supported by Java API for XML-based RPC (JAX-RPC) applications. The Java API for XML-Based Web Services (JAX-WS) programming model that is implemented by the application server does not support the wsdeploy command. If your web services application contains only JAX-WS endpoints, you do not need to run the wsdeploy command, as this command is used to process only JAX-RPC endpoints.

The options that you specify set parameter values for the wsdeploy command. The wsdeploy command adds product-specific deployment classes to a web services-compatible enterprise archive (EAR) file or an application client Java archive (JAR) file. These classes include:

- Stubs

- Serializers and deserializers
- Implementations of service interfaces

The wsdeploy command is run during installation after you click **Finish** on the **Summary** page of the wizard.

***Deploy web services option - Classpath:***

Specifies entries to add to the CLASSPATH when the generated classes are compiled.

To specify the class paths of multiple entries, you need to separate the entries with a semicolon on Windows platforms and on Linux, Unix, and z/OS platforms, you need to use a colon to separate the entries. This is the same separator that is used with the CLASSPATH environment variable.

This option is the same as the wsdeploy command parameter `-cp` *`class_path`*.

| | |
|---|---|
| **Data type** | String |
| **Default** | null |

***Deploy web services option - Extension Directories:***

Specifies a directory that contains zipped or Java archive (JAR) files. All zipped and JAR files in this directory are added to the CLASSPATH used to compile the generated files.

This option is the same as the wsdeploy command parameter `-jardir` *`directory`*.

| | |
|---|---|
| **Data type** | String |
| **Default** | null |

## wsdeploy command

Use the wsdeploy command to add WebSphere product-specific deployment classes to a web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file.

The wsdeploy command is supported by Java API for XML-based RPC (JAX-RPC) applications. The Java API for XML-Based Web Services (JAX-WS) programming model that is implemented by the application server does not support the wsdeploy command. If your web services application contains only JAX-WS endpoints, you do not need to run the wsdeploy command, as this command is used to process only JAX-RPC endpoints.

The deployment classes that are added by the wsdeploy tool to a web services-compatible EAR file or a JAR file include:
- Stubs
- Serializers and deserializers
- Implementations of service interfaces

This deployment step must be performed at least once, and can be performed more often. Deployment can be performed separately using the wsdeploy command, assembly tools, or when the application is installed. When using the wsadmin command for installation, specify the **-deployws** option.

The wsdeploy command operates as noted in the following list:
- Each module in the enterprise application or JAR file is examined.
- If the module contains web services implementations, indicated by the presence of the `webservices.xml` deployment descriptor, the associated Web Services Description Language (WSDL) files are located and the WSDL2Java command is run with the role deploy-server option.

- If the module contains web services clients, indicated by the presence of the client deployment descriptor, the associated WSDL files are located and the WSDL2Java command is run with the role deploy-client option.
- The files generated by the WSDL2Java command are compiled and repackaged.

See the WSDL2Java command for JAX-RPC applications command information to learn more about the files that are generated for deployment.

When the generated files are compiled, they can reference application-specific classes outside the EAR or JAR file, if the EAR or JAR file is not self-contained. In this case, use either the -jardir or -cp option to specify additional JAR or zip files to be added to CLASSPATH variable when the generated files are compiled.

### wsdeploy command syntax

The command syntax is noted in the following example:

```
wsdeploy Input_filename Output_filename [options]
```

**Required options:**

- ***Input_filename***

  Specifies the path to the EAR or JAR file to deploy.
- ***Output_filename***

  Specifies the path of the deployed EAR or JAR file. If *output_filename* already exists, it is silently overwritten. The *output_filename* can be the same as the *input_filename*.

**Other options:**

- **-jardir** *directory*

  Specifies a directory that contains JAR or zip files. All JAR and zip files in this directory are added to the CLASSPATH used to compile the generated files. This option can be specified zero or more times.
- **-cp** *entries*

  Specifies entries to add to the CLASSPATH when the generated classes are compiled. Multiple entries are separated the same as they are in the CLASSPATH environment variable.
- **-codegen**

  Specifies to generate but not compile deployment code. This option implicitly specifies the -keep option.
- **-debug**

  Includes debugging information when compiling, that is, use javac -g to compile.
- **-help**

  Displays a help message and exit.
- **-ignoreerrors**

  Do not stop deployment if validation or compilation errors are encountered.
- **-keep**

  Do not delete working directories containing generated classes. A message is displayed indicating the name of the working directory that is retained.
- **-novalidate**

  Do not validate the web services deployment descriptors in the input file.
- **-trace**

  Displays processing information, including the names of the generated files.
- **-compliancelevel** *level*

  Sets the JDK level for compiler compliance. Valid values include: 1.4, 5.0, 6.0 (default) and 7.0. This flag is optional.

**Example** The following example illustrates how the options are used with the wsdeploy command:

```
wsdeploy x.ear x_deployed.ear -trace -keep
Processing web service module x_client.jar.
Keeping directory: f:\temp\Base53383.tmp for module: x_client.jar.
Parsing XML file:f:\temp\Base53383.tmp\WarDeploy.wsdl
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java.
Done processing module x_client.jar.
```

**Messages**

- Flag *-f* is not valid.

  Option *f* was not recognized as a valid option.
- Flag *-c* is ambiguous.

  Options can be abbreviated, but the abbreviation must be unique. In this case, the wsdeploy command cannot determine which option was intended.
- Flag *-c* is missing parameter *-p*.

  A required parameter for an option is omitted.
- Missing *p* parameter.

  A required option is omitted.

## JAX-WS application deployment model

The administration function of the product is enhanced to support installing and deploying Java Application Programming Interface (API) for XML Web Services (JAX-WS) applications like any other WebSphere Application Server applications.

A JAX-WS application is packaged as a web application archive (WAR) file or a WAR module within an Enterprise Archive (EAR) file. The JAX-WS application deployment model is similar to the Java API for XML Remote Protocol Call (JAX-RPC) web services application model. The main difference between them is that JAX-RPC web services application requires you to add additional bindings and deployment descriptors for application deployment. A JAX-WS application does not require additional bindings and deployment descriptors for deployment. You can deploy your JAX-WS applications as you would deploy any other WebSphere Application Server application.

JAX-WS web services is a rewrite of JAX-RPC web services. The table compares the web services stack for both JAX-WS and JAX-RPC web services.

| JAX-RPC web services | JAX-WS web services |
|---|---|
| Bindings are proprietary | Bindings are based on the open source Java API for XML Bindings (JAXB) |
| Parsing is proprietary | Parsing is based on the open source Java Specification Request (JSR) 173 |
| No Java annotations support | Support for Java annotations such as `@WebService`, `@WebMethod`, `@WebParam`, `@WebResult`, and `@SOAPBinding` |

| JAX-RPC web services | JAX-WS web services |
| --- | --- |
| During deployment, some deployment descriptor files are created in a JAX-RPC based service and client.<br><br>The following files are created on the services side, when it is an EJB based web service and EJB based module:<br>• webservices.xml<br>• <name_of_service>_mapping.xml<br>• ibm-webservices-bnd.xmi<br>• ibm-webservices-ext.xmi<br><br>When the service is a JavaBeans-based or web module-based service, the following files and deployment descriptors are required:<br>• webservices.xml<br>• <name_of_service>_mapping.xml<br>• In the web.xml file, there is no additional content<br>• ibm-webservices-bnd.xmi<br>• ibm-webservices-ext.xmi<br><br>The web.xml exists in both EJB and JavaBeans based services. However, there is no additional content added to the file during deployment of a Web service application or module. | For JAX-WS web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations. |

**Note:** Starting with WebSphere Application Server Version 7.0 and later, Java EE 5 application modules (web application modules version 2.5 or above, or EJB modules version 3.0 or above) are scanned for annotations to identify JAX-WS services and clients. However, pre-Java EE 5 application modules (web application modules version 2.4 or before, or EJB modules version 2.1 or before) are not scanned for JAX-WS annotations, by default, for performance considerations. In the Version 6.1 Feature Pack for Web Services, the default behavior is to scan pre-Java EE 5 web application modules to identify JAX-WS services and to scan pre-Java EE 5 web application modules and EJB modules for service clients during application installation. Because the default behavior for WebSphere Application Server Version 7.0 and later is to not scan pre-Java EE 5 modules for annotations during application installation or server startup, to preserve backward compatability with the feature pack from previous releases, you must configure either the UseWSFEP61ScanPolicy property in the META-INF/MANIFEST.MF of a web application archive (WAR) file or EJB module or define the Java virtual machine custom property, com.ibm.websphere.webservices.UseWSFEP61ScanPolicy, on servers to request scanning during application installation and server startup. To learn more about annotations scanning, see the JAX-WS annotations information.

## Using a third-party JAX-WS web services engine

In certain situations you might need to set up a third-party JAX-WS web services engine. For example, you must set up a third-party JAX-WS web services engine if you need to deploy applications that use a single runtime across various application servers such as WebSphere Application Server, JBoss, and WebLogic, or if you want to build JAX-WS web services applications using third party JAX-WS run-times such as CXF, Axis2, and Metro.

### Before you begin

Use of a third-party JAX-WS runtime has limitations. It also requires mandatory configuration changes, and in some cases, it requires manual intervention to resolves issues that occur during deployment and when you run the application. These limitations and issues vary based on the third-party JAX-WS runtime you

decide to use. You should understand the limitations for the third-party JAX-WS runtime you are preparing to use before you configure your system to use that implementation.

The following limitations exist regardless of which third-party JAX-WS implementation you use:

- The WebSphere Application Server runtime restricts usage of application modules that use both the JAX-WS implementation provided with WebSphere Application Server, and an external JAX-WS implementation in the same application EAR file. You must use either the JAX-WS implementation provided with WebSphere Application Server or the external implementation in a single application EAR file. This limitation ensures that the runtime WebSphere Application Server does not conflict with the external third-party JAX-WS implementation.
- You must remove any conflicting JAR files from your application library before you deploy an application that uses an external JAX-WS implementation. Most of the external third-party JAX-WS runtimes include some JAR file libraries that are already installed on WebSphere Application Server. This situation causes conflicts in your application library.
- After an application that uses a third-party JAX-WS runtime is deployed on WebSphere Application Server, it is not recognized as a service client or provider. Therefore, you cannot attach application level policy sets to these applications. You must rely on external runtimes support quality of service. Following is a list of WebSphere Application Server features that are not available if you decide to deploy and run application that uses third-party JAX-WS implementations:
  - WS-Security, WS-RM, and WS-Transactions policy sets
  - WSDM
  - JNDI lookup to retrieve JAX-WS Service or Port Instance.

**gotcha:** Even though IBM supports the enablement of third party JAX-WS runtimes to run on WebSphere Application Server, and ensures the successful deployment of applications that use such runtimes, IBM does not provide support for resolving JAR file conflict problems, or any problem that a stack trace indicates is in the third party code.

## About this task

When you deploy an application EAR file with a third-party JAX-WS implementation on WebSphere Application Server, the WebSphere Application Server runtime must ensure the use of the third-party engine, and disable the use of the existing WebSphere Application Server JAX-WS web services engine.

WebSphere Application Server does not claim support for any of the third-party JAX-WS runtimes, but has tested the deployment and execution of applications that use such runtimes.

You must complete the following steps before you can use an external JAX-WS runtime in an application.

## Procedure

1. Set the class loader policy to `Classes loaded with local class loader first (parent last)` at the module level.

   Changing the class loader policy to parent last ensures that the external third-party JAX-WS runtime and their dependent library JAR files are first in the class loader search path, thereby ensuring that the third-party implementation is used instead of the WebSphere Application Server.

   a. In the administrative console, click **Applications > Application Types > WebSphere enterprise applications >** *application_name* **> Class loading and update detection**.

   b. Under Class reloading options, select **Override class reloading settings for web and EJB modules** .

   c. Under Class loader order, select **Class loader order** property to `Classes loaded with local class loader first (parent last)`.

   a. Click **OK**, and then **Save** to save your changes.
2. Turn off web services annotation scanning.

Annotation scanning can be turned off at the application level or at the server level.

To turn off annotation scanning at the application level, set the DisableIBMJAXWSEngine property in the META-INF/MANIFEST.MF of a WAR file or EJB module to true. Example:

```
Manifest-Version: 1.0
DisableIBMJAXWSEngine: true
```

To turn off web services annotation scanning at the server level:

a. In the administrative console, go to the Custom properties page for the Java virtual machine.

   **Servers > Server Types > WebSphere application servers >** *server_name*, and then, under Server Infrastructure, click **Java and process management > Process definition > Java virtual machine > Custom properties**

b. Set the **com.ibm.websphere.webservices.DisableIBMJAXWSEngine** property to `true`

   If this property does not already exist for your configuration, click **New**, and add `com.ibm.websphere.webservices.DisableIBMJAXWSEngine` in the **Name** field and `true` in the **Value** field.

### Results

### What to do next

- Deploy and run an application EAR file with a third-party JAX-WS implementation on WebSphere Application Server.

## Deploying web services client applications

After you have created an enterprise archive (EAR) file for the web services client application, you can deploy the web services client application into the Application Server.

### Before you begin

To deploy a Java-based web services client, you need an enterprise application, also known as an enterprise archive (EAR) file that is configured and enabled for web services.

A Java API for XML-Based Web Services (JAX-WS) application is packaged as a web application archive (WAR) file or a WAR module within an Enterprise Archive (EAR) file. A JAX-WS application does not require additional bindings and deployment descriptors for deployment whereas a Java API for XML-based RPC (JAX-RPC) web services application requires you to add additional bindings and deployment descriptors for application deployment. JAX-WS is much more dynamic, and does not require any of the static data generated by the deployment step required for deploying JAX-RPC applications. For JAX-RPC web services clients, you must configure the client deployment descriptors.

### About this task

You can use either the administrative console or the wsadmin scripting tool to deploy an EAR file. If you are installing an application containing web services by using the wsadmin command, specify the `-deployws` option for JAX-RPC applications.

Use the wsdeploy command only with JAX-RPC applications. The wsdeploy command is not applicable for JAX-WS applications.

If you are installing an application containing web services by using the administrative console, select **Deploy WebServices** in the Install New Application wizard. Read about installing a new application for more information on using the administrative console.

The following actions deploy the EAR file with the wsadmin command:

### Procedure

1. Start *install_root*/bin/wsadmin from a command prompt.

   AIX HP-UX Linux Solaris On operating systems such as AIX or Linux, start *install_root*/bin/wsadmin.sh.
2. Deploy the EAR file.
   - For JAX-WS web service applications, enter the `$AdminApp install` *EARfile* `"-usedefaultbindings"` command at the wsadmin prompt.
   - For JAX-RPC web service applications, enter the `$AdminApp install` *EARfile* `"-usedefaultbindings -deployws"` command at the wsadmin prompt.

### Results

You have a deployed a web service client in the application server runtime environment.

### What to do next

Test the web services client. You can now test a web services-enabled managed client EAR file or an unmanaged client JAR file.

## Making deployed web services applications available to clients

You can publish WSDL files to the file system. If you are a client developer or a system administrator, you can use WSDL files to enable clients to connect to web services.

### Before you begin

The publish WSDL administrative console panel supports both JAX-RPC and JAX-WS services. The publish WSDL panel generates a compression file that contains WSDL files for all modules in an application that contains JAX-WS or JAX-RPC web services. Read about providing the HTTP endpoint URL information to learn how the URL information affects the content of the published WSDL.

To publish a Web Services Description Language (WSDL) file you need an enterprise application, also known as an enterprise archive (EAR) file, that contains a Web services-enabled module and has been deployed into WebSphere Application Server. To learn how to deploy web services, see the deploying web services applications onto application servers information.

### About this task

The purpose of publishing the WSDL file is to provide clients with a description of the web service, including the URL identifying the location of the service.

After installing a web services application, and optionally modifying the endpoint information, you might need WSDL files containing the updated endpoint informations to make deployed web services application to be available to clients.

Before you publish a WSDL file, you can configure web services to specify endpoint information in the form of URL fragments to enable full URL specification of WSDL ports. Refer to the tasks describing configuring endpoint URL information.

The WSDL files for each web services-enabled module are published to the file system location you specify. You can provide these WSDL files to clients that want to invoke your Web services.

You can specify endpoint information for HTTP ports, for Java Message Service (JMS) ports, or you can directly access enterprise beans that are acting as web services.

## Procedure

1. Configure the web services client bindings.
2. Configure the URL endpoint information for HTTP bindings. Do one of the following depending on what kind of bindings you are using:
   - Configure the URL endpoint information for HTTP bindings.
   - Configure the URL endpoint information for JMS bindings.
   - Configure the URL endpoint information to directly access enterprise beans.
3. Externalize or publish the WSDL file out of the application. You can complete this task in the following ways:
   - Publish a WSDL file with the administrative console
   - Publish a WSDL file using a URL.
   - Publish a WSDL file with the wsadmin tool.

## What to do next

Apply security to your web services. To learn more, see the securing web services applications using message level security information.

# Configuring web services client bindings

When a web services application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains deployment information for the web module or Enterprise JavaBeans (EJB) module, including client bindings.

## Before you begin

Deploy a web service into your WebSphere Application Server instance. Read about deploying web services applications onto application servers.

You must know the topology of the URL endpoint address of the web services servers and which web service the client depends upon. You can view the deployment descriptors in the administrative console to find the topology information. To learn more, see the View web services server deployment descriptors information.

## About this task

The client bindings define the Web Services Description Language (WSDL) file name and preferred ports. The relative path of a web service in a module is specified within a compatible WSDL file that contains the actual URL to be used for requests. The address is only needed if the original WSDL file did not contain a URL, or when a different address is needed. For a service endpoint with multiple ports, you need to define an alternative WSDL file name.

The following steps describe how to edit bindings for a web service after these bindings are deployed on a server. When one web service communicates with another web service, you must configure the client bindings to access the downstream web service.

You can also configure client bindings with the wsadmin tool. Read about configuring a web service client deployed WSDL file name with the wsadmin tool.

To configure client bindings through the administrative console:

## Procedure

1. Open the administrative console.

2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Manage Modules** > *module_instance* > **Web services client bindings**.
3. Find the web service you want to update.

   The web services are listed in the **Web Service** field.
4. Select the WSDL file name from the drop down box in the WSDL file name field.
5. Click **Edit** in the Preferred port mappings field to configure the default port to use.
   a. Specify the port type and the preferred ports in the Port type and Preferred ports fields.

      Configuring the preferred port enables you to select an optimal port implementation use non-SOAP protocols. See the RMI-IIOP web services using JAX-RPC information to learn more about using non-SOAP protocols.
   b. Click **Apply** and **OK**.
6. Click **Edit** in the Port information field to configure the request timeout, the overridden endpoint, and the overridden binding namespace for a port.

   Configuring the request timeout accommodates complex topologies that can have multiple cascaded Web services that involve multiple hops or long-running services.

   You can configure Timeout values based on observed behavior of the overall system as integration proceeds. For example, a web service client might time out because of changing network conditions or the performance of an external web service. When you have applications containing web services clients that timeout, you can change the request time out values for the clients.

   You can specify an endpoint URL to override the current endpoint. A client invoking a request on this port uses this endpoint instead of the endpoint specified in the WSDL file. You can specify the **Overridden endpoint URL** value for both Java API for XML-Based Web Services (JAX-WS) clients and Java API for XML-based RPC (JAX-RPC) clients.

   **Note:** The **Overridden endpoint URL** field is applicable for both JAX-WS and JAX-RPC clients. The other fields on this administrative console page are only applicable for JAX-RPC clients.

   a. Click **Apply** and **OK**.

## Results

Your web service client bindings are configured.

## What to do next

Now you can finish any other configurations, start or restart the application, and verify the expected behavior of the web service.

***Web services client bindings:***

The client bindings define the Web Services Description Language (WSDL) file name, preferred ports and other port information. Use this page to specify the client bindings and the port mappings for the web services in a module.

A web service can specify the relative path within the module of a compatible WSDL file containing the actual URL to be used for requests. The relative path only needs to be specified if the original WSDL file does not contain a URL or when a different URL is needed. For a service endpoint with multiple ports defined, a preferred mapping specifies the default port to use for a port type.

To view this administrative console page, complete the following steps:

1. Click **Applications > Application Types > WebSphere enterprise applications > *application_name*** .
2. Click **Manage modules > *URI_file_name* > web services client bindings** .

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

*Web service:*

Identifies the name of this web service. A module can contain one or more web services.

*EJB:*

Identifies the name of the EJB for the EJB modules.

*WSDL file name:*

Specifies the WSDL file name, which is relative to the module. Locate the WSDL file name in the drop down menu.

*Preferred port mappings:*

Specifies and manages the preferred port type mapping for a web service when a particular port type is requested.

Click **Edit** to edit the preferred port mapping information on the **Preferred port mappings** panel.

*Port information:*

Specifies additional configuration information for the ports of this web service.

Click **Edit** to edit the port information on the **Port information** panel. You can set a request timeout, override an endpoint and override a binding namespace for each client port.

*Preferred port mappings:*

Use this page to view and manage a preferred portType mapping for a web service.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

When you have multiple ports that reference the same portType (service endpoint interface), a preferred port specifies the port to use when the `Service.getPort(Class SEI)` method is called with only the service endpoint interface.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Manage Modules** > ***module instance*** > **Web services client bindings** > **Edit** > ***preferred_port_instance***.

*portType:*

Specifies the portType.

The preferred port and the portType values are both of the type `java.xml.namespace.QName`.

*Preferred port:*

Specifies the preferred port to be associated with a particular portType. The `Service.getPort(Class)` method returns the preferred port associated with the specified service endpoint interface class (portType).

The preferred ports available are listed, as well as a value of `None`, which indicates no preferred port is selected.

*Web services client port information:*

Use this page to specify a request timeout, override an endpoint, and override a binding namespace for a web services client port.

A web service can have multiple ports. You can view and configure the port attributes for each defined web service port. The web services are listed on the web services client bindings panel.

To view this page, click **Applications** > **Application Types** > **WebSphere enterprise applications** ***application_name*** > **Manage Modules** > ***module_instance*** > **Web services client bindings** > **Edit** .

This administrative console panel applies to both Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services. The **Overridden endpoint URL** field is the only field supported for JAX-WS clients. The other fields are not applicable for JAX-WS clients.

*Port:*

Specifies the name of a port.

*Request timeout:*

Specifies the time, in seconds, that a web service client waits for a request to complete on this port. If a timeout is not specified, the default request timeout for the client to wait is `300` seconds. If the value is set at `0` (zero), the timeout used is the default value for the underlying transport mechanism. This field is supported only for JAX-RPC clients.

A typical use for this setting is to customize the client's behavior when it is configured to use a JMS transport to access a web service to make it wait longer for an expected completion. Depending upon network conditions, or the nature of a web service implementation, it might be necessary to tune the timeout.

*Overridden endpoint URL:*

Specifies the name of an endpoint that is used to override the current endpoint. A client invoking a request on this port uses this endpoint instead of the endpoint specified in the WSDL file. This field is supported for both JAX-WS and JAX-RPC clients.

If an assembled application contains a web service client that is statically bound, the client is locked into using the implementation (service end point) identified in the WSDL file used during development. Overriding the endpoint is an alternative to configuring the deployed WSDL attribute.

The overridden endpoint URI attribute is specified on a per port basis. It does not require an alternative WSDL file within the module. The overridden endpoint URI takes precedence over the deployed WSDL attribute. The client uses this value for the service end point URI or SOAP address, instead of the value in the static client bindings.

**Note:** You can edit this field if you have managed clients or a mixture of both managed and unmanaged clients. You cannot edit the field if you have unmanaged clients only.

If you do not want a request by an unmanaged JAX-WS client service to be sent to the endpoint URL that is specified in this field, you can specify the `com.ibm.ws.websvcs.unmanaged.client.dontUseOverriddenEndpointUri` Java virtual machine (JVM) system property. For more information about this custom property, read about the Java virtual machine custom properties.

*Overridden binding:*

Specifies the WSDL file binding namespace URI to use with this port, instead of the namespace in the WSDL file. This binding does not need to exist in the WSDL file. A client invoking a request on this port uses this binding instead of the binding specified in the WSDL file. An overridden binding namespace cannot be specified unless an overridden endpoint is specified. This field is supported only for JAX-RPC clients.

## Configuring endpoint URL information for HTTP bindings

Configuring a service endpoint is necessary to connect Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services clients to any web services among the components being assembled or to any external web services.

### Before you begin

You can develop an HTTP accessible Java API for XML-based remote procedure call (JAX-RPC) or Java API for XML Web Services (JAX-WS) web service when you have an existing JavaBeans object to enable as a web service. For additional information, see the using HTTP to transport web services requests information.

You can use either the administrative console or property files to configure and manage HTTP endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

This task describes using the administrative console to configure endpoint URL information for HTTP bindings.

### About this task

You can specify HTTP URL prefixes for web services that are accessed through HTTP by using the Provide HTTP endpoint URL information panel in the administrative console. The HTTP URL prefixes provide location specific information and are used to form complete endpoint URLs that are included within published WSDL files.

**Note:** The Provide HTTP panel in the administrative console displays modules that contain Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services. You can use the Provide HTTP panel to provide URL information for both types of web services, however, the panel does not indicate which type of service that you are working with.

To configure these prefixes with the administrative console:

### Procedure

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Provide HTTP endpoint URL information**.
3. Specify the URL prefixes for the web service.

   In this step you specify the protocol (HTTP or HTTPS), as well as the *host_name* and *port_number* used in the endpoint URL. You can select a prefix from a predefined list, by selecting the default HTTP URL prefix, or you can use a custom HTTP URL prefix.

   a. Select **Default HTTP URL prefix** or **Custom HTTP URL Prefix**.

      If you select the default HTTP URL prefix, a list provides you with a choice of endpoint URL prefixes. The list is a combination of two sets of ports in the module: the virtual host ports and the application server ports. Use a prefix from this list if the application server of the web service is accessed directly. Select a value and also select the check box of the modules to use the prefix.

      If you want to use a custom HTTP URL prefix, type the value in the field. Select the check box to use in the prefix.

If you configure a custom HTTP URL prefix, , you must also configure the custom JVM property, `com.ibm.ws.webservices.enableHTTPPrefix` in the administrative console and set the value to `true`. You must restart the application server after this custom property has been defined so that this property is used by the system. Setting this custom JVM property is required so the custom HTTP endpoint prefix information is correctly displayed in the ?WSDL query that is returned from the browser and the URL field of the WSDL file that is returned to the client. If this custom property is not defined with the value of `true`, the custom HTTP URL prefix is not reflected in the WSDL file that the service returns to the client. To learn how to configure this custom JVM property, see the documentation on configuring additional HTTP transport properties using the JVM custom property panel in the administrative console.

**Note:** The `com.ibm.ws.webservices.enableHTTPPrefix` custom property applies to JAX-RPC web services applications only.

b. Click **Apply**.

The URL prefix, whether default or custom, is copied to the selected module HTTP URL prefix field.

c. Click **OK**. The URL information is saved to your workspace.

## Results

You have specified the partial URL information that is used to form the target endpoint addresses in the WSDL files that are published using the Publish WSDL files panel.

## What to do next

Configure any other URL endpoint information for Java Message Service (JMS) bindings and direct Enterprise JavaBeans (EJB) access. Then publish the WSDL files to make the deployed web services application available to clients.

***Provide HTTP endpoint URL information:***

Use this page to specify endpoint URL prefix information for web services accessed by HTTP. Prefixes are used to form complete endpoint addresses included in published Web Services Description Language (WSDL) files.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Provide HTTP endpoint URL information**.

You can specify a portion of the endpoint URL to be used in each web service module. In a published WSDL file, the URL defining the target endpoint address is found in the location attribute of the port's `soap:address` element.

This administrative console page applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

In addition to the using the administrative console, you can use property files to configure and manage HTTP endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

*Specify endpoint URL prefixes for web services:*

Specifies the *protocol* (either http or https), *host_name*, and *port_number* to be used in the endpoint URL.

You can select a prefix from a predefined list using the **HTTP URL prefix** or **Custom HTTP URL prefix** field.

The URL prefix format is *protocol://host_name:port_number*, for example, `http://myHost:9045`. The actual endpoint URL that is contained in a published WSDL file consists of the prefix followed by the module's context-root and the web service url-pattern, for example, `http://myHost:9045/services/myService`.

*Select default HTTP URL prefix:*

Specifies the drop down list associated with a default list of URL prefixes. This list is the intersection of the set of ports for the module's virtual host and the set of ports for the module's application server. Use items from this list if the web services application server is accessed directly.

To set an HTTP endpoint URL prefix, select **Select default HTTP URL prefix** and select a value from the drop down list. Select the check box of the modules that are to use the prefix and click **Apply**. When you click **Apply**, the entry in the **Select default HTTP URL prefix** or **Select custom HTTP URL prefix** fields, depending on which is selected, is copied into the **HTTP URL prefix** field of any module whose check box is selected.

*Select custom HTTP URL prefix:*

Specifies the *protocol*, *host*, and *port_number* of the intermediate service if the web services in a module are accessed through an intermediate node, for example the web services gateway or an IHS server.

To set a custom HTTP endpoint URL prefix, you must also configure the custom JVM property, `com.ibm.ws.webservices.enableHTTPPrefix` in the administrative console and set the value to `true`. Setting this custom JVM property is required so the custom HTTP URL is correctly populated in the URL field of the WSDL file that is returned to the client. If this custom JVM property is not configured, the custom HTTP URL prefix is not in the URL field in the copy of the WSDL file that the service returns to the client. To learn how to configure this custom JVM property, see the documentation on configuring additional HTTP transport properties using the JVM custom property panel in the administrative console. You must restart the application server after this custom property has been defined so that this property is used by the system.

After the `com.ibm.ws.webservices.enableHTTPPrefix` custom JVM property is configured, select **Select custom HTTP URL prefix** and enter a value. Select the check box of the modules that are to use the prefix and click **Apply**. When you click **Apply**, the entry in the **Select default HTTP URL prefix** or **Select custom HTTP URL prefix** fields, depending on which is selected, is copied into the **HTTP endpoint URL prefix** field of any module whose check box is selected.

**Note:** The `com.ibm.ws.webservices.enableHTTPPrefix` custom property applies to JAX-RPC web services applications only.

## Configuring endpoint URL information for JMS bindings

WebSphere Application Server supports the use of the Java Message Service (JMS) API to transport web services requests, as an alternative to using HTTP.

### Before you begin

The application server supports use of the Java Message Service (JMS) API to transport web services requests, as an alternative to HTTP transport. Read about using the Java Message Service (JMS) to transport web services requests to learn more about how web service clients and servers can communicate through JMS queues and topics instead of through HTTP connections.

You can use either the administrative console or property files to configure and manage JMS endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

This task describes using the administrative console to configure endpoint URL information for JMS bindings.

## About this task

Configuring a service endpoint is necessary to connect web service clients to any web services among the components being assembled or to any external web services. You can configure the endpoint URL information for JMS during application installation

In this task, enter the JMS endpoint URL prefix to use for each web service-enabled Enterprise JavaBeans (EJB) Java archive (JAR) file that belong to the application. The JMS endpoint URLs are included in the Web Services Description Language (WSDL) files published for clients to use.

You can specify HTTP URL prefixes for web services that are accessed through HTTP by using the Provide HTTP endpoint URL information panel in the administrative console. These prefixes are used to form complete endpoint addresses that are included in WSDL files when published.

You can specify JMS URL prefixes by using the Provide JMS and EJB endpoint URL information panel in the administrative console during or after application installation.

This task applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

To configure JMS URL prefixes:

## Procedure

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > ***application_instance*** > **Provide JMS and EJB endpoint URL information**.
3. Locate the list of web services modules that are accessible through JMS transport.
4. Type the JMS URL fragment in the **URL fragment** field. Enter a URL fragment that is a prefix to the initial URL part that is obtained by examining the deployment information of the Web service. See the usage scenario following this task for more information.

   The value that you enter is used to define the location attribute of the port soap:address element within the WSDL file that is published using the *application_name*_ExtendedWSDLFiles.zip or the *application_name*_WSDLFiles.zip file on the Publish WSDL zip files panel.

## Results

You have a web service that is accessible through the JMS transport and configured with JMS bindings.

## Example

Suppose an application called StockQuoteService contains an EJB JAR file that is named StockQuoteEJB, which contains one or more web services that are accessible through the JMS transport.

See the using SOAP over Java Message Service to transport web services information to review the example that defines a queue with the Java Naming and Directory Interface (JNDI) name of jms/StockQuote_Q, and a connection factory with the JNDI name of jms/StockQuote_CF, for your application.

In this example, you specify the following string as the JMS URL prefix within the Provide JMS and EJB endpoint URL information panel:

```
jms:/queue?destination=jms/StockQuote_Q&connectionFactory=jms/StockQuote_CF
```

The WSDL publisher uses this partial URL string to produce the actual JMS URL for each port component that is defined in the module. The `targetService=<port_name>` string is added to the end of the JMS URL, for example:

```
jms:/queue?destination=jms/StockQuote_Q&connectionFactory=jms/StockQuote_CF&targetService=getQuote
```

The published WSDL file is used by clients to invoke the web service.

## What to do next

Publish the WSDL files to make the deployed web services application available to clients.

***Provide JMS and EJB endpoint URL information:***

Use this page to specify Java Message Service (JMS) and Enterprise JavaBeans (EJB) endpoint URL fragments for web services accessed through SOAP and Java Message Service (JMS) or directly as enterprise beans. Fragments are used to form complete endpoint addresses included in published Web Services Description Language (WSDL) files.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Provide JMS and EJB endpoint URL information**.

You can specify a fragment of the endpoint URL to be used in each web service module. In a published WSDL file, the URL defining the target endpoint address is found in the location attribute of the port's `soap:address` element.

If you are using web services modules that are configured to use JMS or configured to access enterprise beans directly, these modules are listed on this panel.

This administrative console page applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

In addition to the using the administrative console, you can use property files to configure and manage JMS and EJB endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

*URL fragment for JMS:*

Specifies a URL fragment for web services accessed through a JMS transport. You can enter a value that is used to define the `soap:address` of a web service. When WSDL files are published, a URL is formed using this fragment and is contained in the WSDL files.

The URL fragment that is entered as a value is a prefix to which the targetService property is appended to form a complete JMS URL endpoint. The default value is obtained by examining the installed service's deployment information, for example, `jms:jndi:jms/MyQueue&jndiConnectionFactoryName=jms/MyCF`.

This information is obtained from the configured JMS endpoint for the web service, which is a Message Driven Bean (MDB) defined by the **endpointEnabler** command-line tool. You can modify the URL fragment, for example, by adding properties. The URL fragment is combined with the targetService property to form the complete URL, for example, `jms:jndi:jms/MyQueue&jndiConnectionFactoryName=jms/MyCF&priority=5&targetService=GetQuote`.

*URL fragment for EJB:*

Specifies a URL fragment for web services accessed through an EJB binding. You can enter a value used to define the location attribute of the port's `generic:address` element of a Web service. This port address

is contained in the WSDL compression file when the compression file is published using the *application_name_ExtendedWSDLFiles*.zip field on the **Publish WSDL zip file** panel.

The URL fragment value entered is a suffix, which is appended to the initial part of the URL obtained by examining the web service's deployment information. For example, the following URL fragment can be obtained from the EJB's deployment information: wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome.

In this case, you can enter the following information in the URL fragment field, jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2809, which results in this endpoint URL, wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome&jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2809.

## Configuring endpoint URL information to directly access enterprise beans

WebSphere Application Server supports directly accessing an enterprise bean as a web service, as an alternative to using HTTP or Java Message Service (JMS) to transport requests between the server and the client. The Enterprise JavaBeans (EJB) module that is used as a web service contains a Web Services Description Language (WSDL) file that contains EJB bindings.

### Before you begin

To learn more about the process of directly accessing an enterprise bean as a web service, see the using WSDL EJB bindings to invoke an EJB from a JAX-RPC web services client.

You can use either the administrative console or property files to configure and manage EJB endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

This task describes using the administrative console to configure endpoint URL information to directly access enterprise beans.

### About this task

Configuring a service endpoint is necessary to connect web service clients to any web services among the components being assembled or to any external web services.

You can specify web address endpoints of the enterprise bean for web services that are accessed directly by EJB bindings using the Provide JMS and EJB endpoint web address information panel in the administrative console.

If you have modules that are configured for using direct EJB access, the modules are listed on the Provide JMS and EJB endpoint web address information panel in the administrative console. The EJB endpoint is only available in the WSDL that is found in the *application_name*_ExtendedWSDLfiles.zip file.

You can specify a fragment of the endpoint web address for the web services in each module.

To configure the web address endpoints of the enterprise bean with the administrative console:

### Procedure

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > ***application_instance*** > **Provide JMS and EJB endpoint URL information**.
3. Locate the list of EJB modules.
4. Select the application module.
5. Type the web address fragment in the **URL fragment** field.

Enter a web address fragment that is a suffix to the initial web address part that is obtained by examining the web service deployment information. See the example following this task for more information.

The value that you enter is used to define the location attribute of the port generic:address element within the WSDL file that is published using the *application_name*_ExtendedWSDLFiles.zip file name link on the Publish WSDL zip files panel. The zip file names are listed as links on the panel.

6. Click **OK**.
7. Click **Save**.

### Results

You have configured endpoints of the enterprise bean for Web services that are accessed directly by EJB bindings.

### Example

The following example illustrates a web address fragment to enter in the URL fragment field.

The following web address information can be obtained from the deployment descriptor of an enterprise bean:

```
wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome
```

Enter the following web address fragment in the URL fragment field:

```
jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2089
```

The results are shown in the following example:

```
wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome&jndiProviderURL=
corbaloc:iiop:myhost.mycompany.com:2089
```

### What to do next

Provide a description of the web service to the service requestor by publishing WSDL files. To learn more, read about making deployed web services applications available to clients.

## Publishing WSDL files using the administrative console

You can publish a Web Services Description Language (WSDL) file using the WebSphere Application Server administrative console.

### Before you begin

Before completing this task, you need to install or deploy the web service. After deployment, configure the URL endpoint tasks for your transport:

- Configure endpoint URL information for HTTP bindings
- Configure endpoint URL information for JMS bindings
- Configure endpoint URL information to directly access enterprise beans

### About this task

By publishing a WSDL file, you are providing clients with a description of the web service, including the URL identifying the location of the service.

The WSDL files in each web services-enabled module are published to the file system location you specify. You can provide these WSDL files in the development and configuration process of the web service clients so they can invoke your web services.

This task applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

To learn about more ways to publish WSDL files, see the making deployed web services applications available to clients information.

To publish an application's WSDL file with the administrative console:

## Procedure

1. Open the administrative console.
2. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
3. Under Web Services Properties, click **Publish WSDL files**. This takes you to the **Publish WSDL zip files** page.
4. Click the WSDL compression file to download. The compression file contains the application's published WSDL files. The compression file `ExtendedWDLFiles.zip` contains EJB binding information. It can also contain JMS or HTTP binding information. The compression file `WSDLFiles.zip` only contains JMS or HTTP binding information.

## What to do next

Apply security to your web services. To learn more, see the securing web services applications using message level security information.

***Publish WSDL compressed files settings:***

Use this page to publish Web Services Description Language (WSDL) files.

This administrative console page applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

The publish WSDL panel generates a compressed file that contains WSDL files for all modules in an application that contains a JAX-WS or JAX-RPC web service. Read about providing the HTTP endpoint URL information to learn how the URL information affects the content of the published WSDL.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Publish WSDL files**.

When you click **OK**, a panel showing one or several compressed file names displays. Each compressed file contains a WSDL file that represents the web services-enabled modules in the application. When you select a compressed file to publish, a dialogue displays from which you can choose where to create the compressed file. Within the published compressed files, the directory structure is *`application_name`*`/`*`module_name`*`/[META-INF|WEB-INF]/wsdl/`*`wsdl_file_name`*.

In a published WSDL file, the location attribute of a port's `soap:address` element contains the endpoint URL through which the web service is accessed. Using the **Provide HTTP endpoint URL information** and the **Provide JMS and EJB endpoint URL information** panels, configure the endpoint URLs to be used for the web services in each module.

*application_name_WSDLFiles.zip:*

Specifies the *`application_name`*`_WSDLFiles.zip` file containing the WSDL that describes web services that are accessible by standard SOAP-based ports.

*application_name_ExtendedWSDLFiles.zip:*

Specifies the *application_name*_ExtendedWSDLFiles.zip file containing the WSDL file that describes the web services available, including SOAP-based and non-SOAP based (for example, EJB) ports.

If there are no web services configured for direct EJB access, this compressed file name is not displayed. Do not use this compressed file if you want to produce a WSDL file compliant to standards.

## Publishing WSDL files using a URL

You can publish a Web Services Description Language (WSDL) file using a URL.

### Before you begin

Before you can publish a WSDL file using a URL, ensure the web services-enabled application is installed and running.

The files referenced by the <wsdl-file> element in the webservices.xml might import other WSDL or XML Schema Definition (XSD) files. Typically, all WSDL or XSD files are initially placed into the META-INF/wsdl directory when using Enterprise JavaBeans (EJB) or the WEB-INF/wsdl directory when using JavaBeans. If your WSDL or XSD files are not placed in one of these directories, the file referenced by the <wsdl-file> and its imported files are copied to the wsdl directory for publishing purposes.

There are two different forms of URL query strings. The first appends /wsdl to the service and returns only HTTP and JMS bindings. The second appends /extwsdl to the service and returns the extended WSDL file, including HTTP, JMS, and EJB bindings. If a WSDL file contains only EJB bindings and the /wsdl query is used, an error message displays in the browser saying there are no HTTP or JMS bindings in the WSDL file. The error message suggests using the /extwsdl query instead. Publishing a WSDL file using a URL requires that the application have a web module; either provided by the application or in the form of an HTTP router module. If an EJB application contains a WSDL file with only JMS or EJB Web service bindings, the endptEnabler command can be used to add an HTTP router module to the application.

**Note:** Only HTTP URLs are supported for publishing.

### About this task

To publish a WSDL file using a URL:

### Procedure

1. Retrieve the outer-most WSDL file. The outer-most WSDL file is the WSDL file defined by the <wsdl-file> element in the webservices.xml file.

   Each web service has an endpoint address, like http://example.com/services/stockquote. You can retrieve the outer-most WSDL file (defined by the <wsdl-file> element within the webservices.xml file) by appending the string "/wsdl" or "/wsdl/" to the endpoint address, for example, http://example.com/services/stockquote/wsdl.
2. Retrieve the imported WSDL files. When the outer-most WSDL file imports other WSDL or XSD files, these imported files can be retrieved by appending the relative path to the URL, which is used to retrieve the outer-most WSDL file. This is also true for WSDL files that import other files. This process is similar to the use of relative hyperlinks in HTML documents. If an HTML document contains a hyperlink to other documents, the relative path is appended to create the URL to access the hyperlinked documents.

### Example

Suppose you have an application with the following directory structure:

```
<module-root>/
 WEB-INF/
  webservices.xml    /* the <wsdl-file> element points to "WEB-INF/wsdl/fooImpl.wsdl"*/
  web.xml
```

```
ibm-webservices-bnd.xml

wsdl/
 fooImpl.wsdl   /* imports foo.wsdl which is an interface wsdl */
 foo.wsdl       /* type definition for the interface */
```

If the SOAP address for the foo service is `http://examples.com:9080/services/foo`, the simple way to retrieve the foo service's outer-most WSDL is with the following form: `http://examples.com:9090/services/foo/wsdl` or `http://examples.com:9090/services/foo/wsdl/`. The URL is redirected to `http://examples.com:9090/services/foo/wsdl/fooImpl.wsdl`, where `fooImpl.wsdl` is the name of the outer-most WSDL file.

Since the `fooImpl.wsdl` file has the import `<import namespace="http://examples.com/foo" location="a/b/foo.wsdl>`, use the URL `http://examples.com:9090/services/foo/wsdl/a/b/foo.wsdl` to obtain the `foo.wsdl` file.

# Running an unmanaged web services JAX-RPC client

WebSphere Application Server Version 8.0 and the Application Client for WebSphere Application Server Version 8.0 provides a thin Java Platform, Standard Edition 6 (Java SE 6) web services client runtime implementation that is based on the Java API for XML-based RPC (JAX-RPC) 1.1 specification. The Thin Client for JAX-RPC with WebSphere Application Server is a stand-alone Java SE 6 client environment that enables running unmanaged JAX-RPC web services client applications in a non-WebSphere environment to invoke web services that are hosted by the application server.

## Before you begin

**Note:** You can use the Thin Client for JAX-RPC with WebSphere Application Server as a stand-alone client run time in a pure Java SE environment, or within an OSGi environment. The Thin Client for JAX-RPC is not supported when running within WebSphere Application Server or WebSphere Application Client environments. In this version of the application server, with the exception of the Administration Thin Client, other Thin Client run times provided with the application server can also reside in the CLASSPATH and coexist with the Thin Client for JAX-RPC.

Before you can set up a JAX-RPC unmanaged client environment you will need to obtain the Thin Client for JAX-RPC Java archive (JAR) file. To obtain the Thin Client for JAX-RPC, you must either install the application server or the application client.

The Thin Client for JAX-RPC JAR file, `com.ibm.ws.webservices.thinclient_8.0.0.jar`, is located in the *app_server_root*`\runtimes` directory. Refer to the license agreements to ensure correct usage and for limitations on copies of the Thin Client for JAX-RPC outside of the WebSphere environment.

The Thin Client for JAX-RPC is supported in the following environments:

- IBM Software Development Kits (SDKs) Version 6.0
- Sun Java Development Kit (JDK) Version 6.0 that are provided by IBM
- non-IBM SDKs Version 6.0 with this limitation:
  - Xerces limitation on non-IBM SDKs

    If you are using a non-IBM SDK, because of dependencies with the Xerces implementation, you will need to download Xerces-J version 2.6.2 and set it in the classpath before attempting to run the Thin Client for JAX-RPC.
  - Equinox 3.6 OSGi runtime environments

## About this task

**Note:** WS-Addressing is not supported for JAX-RPC web services in an unmanaged client environment. If you need to use WS-Addressing, or a web service standard that relies on WS-Addressing, such as

WS-Notification, you must use the Thin Client for Java API for XML-based Web Services (JAX-WS) instead. To learn how to setup and run the Thin Client for JAX-WS, see the Thin Client for JAX-WS documentation.

## Procedure

1. Configure the path. You can add the Java `bin` directories to your path by typing:

   Windows

```
set PATH=<your_JDK_bin_directory>;%PATH%
```

   AIX HP-UX Solaris Linux

```
export PATH=<your_JDK_bin_directory>:$PATH
```

2. Configure the classpath.

   Windows

```
set CLASSPATH=.;<your_web_services_thin_client_install_directory>\com.ibm.ws.webservices.thinclient_8.0.0.jar;
<your_application_jars>;%CLASSPATH%
```

   AIX HP-UX Solaris Linux

```
export CLASSPATH=.:<your_web_services_thin_client_install_directory>/com.ibm.ws.webservices.thinclient_8.0.0.jar:
<your_application_jars>;$CLASSPATH
```

   - If you are using a non-IBM SDK, obtain a Xerces `xml-apis.jar` and `xercesImpl.jar` from the Xerces web site and configure the classpath definition.

     Windows

```
set CLASSPATH=.;<your_Xerces_install_directory>\xml-apis.jar;<your_Xerces_install_directory>
\xercesImpl.jar;%CLASSPATH%
```

     AIX HP-UX Solaris Linux

```
export CLASSPATH=.:<your_Xerces_install_directory>/xml-apis.jar:<your_Xerces_install_directory>
\xercesImpl.jar:$CLASSPATH
```

3. Configure SSL for the client.

   a. Add the following system properties to the Java command:

```
-Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props
```

      You can obtain the `ssl.client.props` file from the WebSphere Application Server installation and modify the file to suit your environment. You must, at a minimum, update the location of the `com.ibm.ssl.keyStore` and `com.ibm.ssl.trustStore` key files in the `ssl.client.props` file to the match location of your target environment. For example, use these SSL configuration settings when running the application with a Sun JRE:

```
com.ibm.ssl.protocol=SSL
com.ibm.ssl.trustManager=SunX509
com.ibm.ssl.keyManager=SunX509
com.ibm.ssl.contextProvider=SunJSSE

com.ibm.ssl.keyStoreType=JKS
com.ibm.ssl.keyStoreProvider=SUN
com.ibm.ssl.keyStore=/home/user1/etc/key.jks

com.ibm.ssl.trustStoreType=JKS
com.ibm.ssl.trustStoreProvider=SUN
com.ibm.ssl.trustStore=/home/user1/etc/trust.jks
```

      The key store file and trust store file must be created using the Java keytool utility before the application runs. The automatic key file generation is not supported with a non-IBM product JRE.

4. Enter the following command to run your client application:

   Windows

```
%JAVA_HOME%/bin/java -Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props <your_client_application>
```

   AIX HP-UX Solaris Linux

```
$JAVA_HOME/bin/java -Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props <your_client_application>
```

### Results

You have set up an unmanaged JAX-RPC client runtime environment that can be used to invoke web services hosted on a WebSphere Application Server.

## Running an unmanaged web services JAX-WS client

WebSphere Application Server provides a thin Java Platform, Standard Edition 6 (Java SE 6) web services client runtime implementation that is based on the Java API for XML-based Web Services (JAX-WS) 2.2 specification. The Thin Client for JAX-WS with WebSphere Application Server is a stand-alone Java SE 6 client environment that enables running unmanaged JAX-WS web services client applications in a non-WebSphere environment to invoke web services that are hosted by the application server.

### Before you begin

**Note:** You can use the Thin Client for JAX-WS with WebSphere Application Server as a stand-alone client run time in a pure Java SE environment, or within an OSGi environment. The Thin Client for JAX-WS is not supported running within WebSphere Application Server or WebSphere Application Client environments. In this version of the application server, with the exception of the Administration Thin Client, other Thin Client run times provided with the application server can also reside in the CLASSPATH and coexist with the Thin Client for JAX-WS.

Before you set up a JAX-WS unmanaged client execution environment, obtain the Thin Client for JAX-WS Java archive (JAR) file. To obtain the Thin Client for JAX-WS, install WebSphere Application Server Version 8.0 or the Application Client for WebSphere Application Server Version 8.0. The Thin Client for JAX-WS JAR file, `com.ibm.jaxws.thinclient_8.0.0.jar`, is located in the *app_server_root*`\runtimes` directory.

Copy the Thin Client for JAX-WS, `com.ibm.jaxws.thinclient_8.0.0.jar` file and the `endorsed_apis_8.0.0.jar` files, to other machines to create a lightweight client environment that enables communications with the product. Copies of the Thin Client for JAX-WS are subject to the same terms and conditions of the license agreement for the WebSphere product where you obtained the Thin Client for JAX-WS. Refer to the license agreements for correct usage and other limitations.

The Thin Client for JAX-WS is supported in the following environments:

- IBM Software Development Kits (SDKs) Version 6.0
- non-IBM SDKs V6.0 with the following limitation:
  - Xerces limitation on non-IBM SDKs

    You must download Xerces-J Version 2.6.2, and add the file to the classpath when setting up the Thin Client for JAX-WS environment.
  - WS-SecurityKerberos on non-IBM SDKs

    WS-SecurityKerberos is not supported with the Sun JDK or other non-IBM SDKs. Applications running in a Thin Client for JAX-WS environment that make use of WS-Security message level protection and use Kerberos security tokens as described in the Web Services Security Kerberos Token Profile 1.1 specification, do not correctly work on non-IBM JDKs. This limitation exists because of a dependancy on the IBM JGSS provider that is only available within IBM SDKs.
- Equinox 3.6 OSGi runtime environments

### About this task

Set up a Thin Client for JAX-WS environment by completing the following steps.

## Procedure

1. Copy the Thin Client for JAX-WS JAR file, `com.ibm.jaxws.thinclient_8.0.0.jar`, to other machines to create a lightweight client environment.
2. Use the Java Endorsed Standards Override Mechanism to override APIs that are available in the JDK on your system.

   Because the Thin Client for JAX-WS with WebSphere Application ServerVersion 8.0 requires APIs that are more current than what is available in JDKs to support JAX-WS 2.2 and JAXB 2.2 implementations, you must override the default JDK APIs in use by your system by using the Java Endorsed Standards Override Mechanism.

   Copy the *app_server_root*`\runtimes\endorsed\endorsed_apis_8.0.0.jar` file into the default directory, `JAVA_JRE\lib\endorsed`. Alternatively, you can use the `java.endorsed.dirs` property to specify a directory of your choice. If you choose to use an alternative directory, it is a best practice to only include the `endorsed_apis` JAR file.
3. Configure the path. Enter the following command to add the Java `bin` directories to your path:

   Windows

```
set PATH=<your_JDK_bin_directory>;%PATH%
```

   AIX HP-UX Solaris Linux

```
export PATH=<your_JDK_bin_directory>:$PATH
```

4. Configure the classpath.
   - Add the Thin Client for JAX-WS JAR file to the classpath definition.

     **Important:** If the Thin Client is to use the Java Message Service (JMS), then **all** the JAR files that are required must be in the classpath for JMS and for the client so that entries exist for all the required files. Otherwise, required files will not be identified as installed and ready for use.

     Windows

```
set CLASSPATH=.;<your_jax-ws_thin_client_install_directory>\com.ibm.jaxws.thinclient_8.0.0.jar;
<your_application_jars>;%CLASSPATH%
```

     AIX HP-UX Solaris Linux

```
export CLASSPATH=.:<your_jax-ws_thin_client_install_directory>/com.ibm.jaxws.thinclient_8.0.0.jar:
<your_application_jars>;$CLASSPATH
```

   - If you are using a non-IBM SDK, obtain a Xerces `xml-apis.jar` file and `xercesImpl.jar` file from the Xerces website, and configure the classpath definition.

     Windows

```
set CLASSPATH=.;<your_Xerces_install_directory>\xml-apis.jar;<your_Xerces_install_directory>
\xercesImpl.jar;%CLASSPATH%
```

     AIX HP-UX Solaris Linux

```
export CLASSPATH=.:<your_Xerces_install_directory>/xml-apis.jar:<your_Xerces_install_directory>
\xercesImpl.jar:$CLASSPATH
```

5. Configure SSL for the client.
   a. Add the following system properties to the Java command:

```
-Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props
```

   You can obtain the `ssl.client.props` file from the WebSphere Application Server installation and modify the file to suit your environment. You must, at a minimum, update the location of the `com.ibm.ssl.keyStore` and `com.ibm.ssl.trustStore` key files in the `ssl.client.props` file to the match location of your target environment. For example, use these SSL configuration settings when running the application with a Sun JRE:

```
com.ibm.ssl.protocol=SSL
com.ibm.ssl.trustManager=SunX509
com.ibm.ssl.keyManager=SunX509
com.ibm.ssl.contextProvider=SunJSSE

com.ibm.ssl.keyStoreType=JKS
com.ibm.ssl.keyStoreProvider=SUN
```

```
com.ibm.ssl.keyStore=/home/user1/etc/key.jks

com.ibm.ssl.trustStoreType=JKS
com.ibm.ssl.trustStoreProvider=SUN
com.ibm.ssl.trustStore=/home/user1/etc/trust.jks
```

The key store file and trust store file must be created using the Java keytool utility before the application runs. The automatic key file generation is not supported with a non-IBM product JRE.

6. Run your client application:
   - Enter the following command if you have copied the `endorsed_apis_8.0.0.jar` file into the `JAVA_JRE\lib\endorsed` default directory; for example:

Windows

```
%JAVA_HOME%\bin\java -Dcom.ibm.SSL.ConfigURL=file:\\\home\sample\ssl.client.props <your_client_application>
```

AIX HP-UX Solaris Linux

```
$JAVA_HOME/bin/java -Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props <your_client_application>
```

   - Enter the following command if you have copied the `endorsed_apis_8.0.0.jar` file into a directory other than the default `JAVA_JRE\lib\endorsed` directory; for example:

Windows

```
%JAVA_HOME%\bin\java
-Djava.endorsed.dirs=<directory_that_includes_endorsed_apis_8.0.0.jar>
-Dcom.ibm.SSL.ConfigURL=file:\\\home\sample\ssl.client.props <your_client_application>
```

AIX HP-UX Solaris Linux

```
$JAVA_HOME/bin/java
-Djava.endorsed.dirs=<directory_that_includes_endorsed_apis_8.0.0.jar>
-Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props <your_client_application>
```

### Results

You have set up an unmanaged JAX-WS client runtime environment to invoke web services hosted on a WebSphere Application Server.

## Testing web services-enabled clients

Once you have developed, assembled, deployed and configured your web service, you can test to confirm your web service runs in the application server environment.

### Before you begin

Before testing your web services Java client to confirm your web service runs in the WebSphere Application Server environment, verify that the server endpoint specified in the client Web Services Description Language (WSDL) file is running and available.

### About this task

Tests are run differently depending on whether the client module is in a Java EE container or if the client is running in the Thin Client for Java API for XML-based RPC (JAX-RPC) with WebSphere Application Server application environment or the Thin Client for Java API for XML-Based Web Services (JAX-WS) with WebSphere Application Server application environment.

### Procedure

1. Test an unmanaged client JAR file by running your application with the **java** command.

Windows For JAX-WS applications:

```
"%JAVA_HOME%\bin\java"
-Djava.endorsed.dirs=<your_jax-ws_thin_client_install_directory>/endorsed_apis_8.0.0.jar
-classpath
"<your_JAX-WS_thin_client_install_directory>\runtimes\com.ibm.jaxws.thinclient_8.0.0.jar;
<list_of_your_application_jars_and_classes>"
<fully_qualified_class_name_to_run> <your_application_parameters>
```

Windows For JAX-RPC applications:

```
"%JAVA_HOME%\bin\java"
-classpath
"<your_JAX-RPC_thin_client_install_directory>\runtimes\com.ibm.ws.webservices.thinclient_8.0.0.jar;
<list_of_your_application_jars_and_classes>"
<fully_qualified_class_name_to_run> <your_application_parameters>
```

AIX HP-UX Linux Solaris For JAX-WS applications:

```
"$JAVA_HOME/bin/java"
-Djava.endorsed.dirs=<your_jax-ws_thin_client_install_directory>/endorsed_apis_8.0.0.jar
-classpath
"<your_JAX-WS_thin_client_install_directory>/runtimes/com.ibm.jaxws.thinclient_8.0.0.jar:
<list_of_your_application_jars_and_classes>"
<fully_qualified_class_name_to_run> <your_application_parameters>
```

Linux For JAX-RPC applications:

```
"$JAVA_HOME/bin/java"
-classpath
"<your_JAX-RPC_thin_client_install_directory>/runtimes/com.ibm.ws.webservices.thinclient_8.0.0.jar:
<list_of_your_application_jars_and_classes>"
<fully_qualified_class_name_to_run> <your_application_parameters>
```

The unmanaged client application runs.

2. Test a managed JAX-RPC client EAR file or an unmanaged JAX-WS client EAR file.
   a. Run your client application with the **launchClient** command. The following example illustrates the use of this command:

```
launchClient clientEar
```

## Results

You have a web services-enabled client that is tested. Now you can add security measures to the web service. Security measures are optional.

# Chapter 34. Developing web services - Addressing (WS-Addressing)

The Web Services Addressing (WS-Addressing) support in this product provides the environment for web services that use the World Wide Web Consortium (W3C) WS-Addressing specifications. This family of specifications provide transport-neutral mechanisms to address web services and to facilitate end-to-end addressing.

## Using the Web Services Addressing APIs: Creating an application that uses endpoint references

This product provides application programming interfaces for applications that have to create endpoint references and use those endpoint references to target web service endpoints.

### Before you begin

The steps described in this task apply to servers and clients that run on WebSphere Application Server.

### About this task

Complete this task if you are a web service developer who needs to create endpoint references within an application, and then use these references to target web service resource instances. For example, a WSRF application developer.

### Procedure

1. Create a web service that is referenced by an endpoint reference, and a client that accesses the web service. For JAX-WS applications, use the instructions in “Creating a JAX-WS web service application that uses Web Services Addressing.” For JAX-RPC applications, use the instructions in “Creating a JAX-RPC web service application that uses Web Services Addressing” on page 1636
2. Optional: You can extend the application that you created in the previous step so that it conforms to the Web Services Resource Framework (WSRF) specifications, by following the instructions in Creating stateful web services by using the Web Services Resource Framework.

## Creating a JAX-WS web service application that uses Web Services Addressing

Web Services Addressing (WS-Addressing) aids interoperability between web services by defining a standard way to address web services and provide addressing information in messages. This task describes the steps that are required to create a JAX-WS web service that is accessed using a WS-Addressing endpoint reference. The task also describes the extra steps that are required to use stateful resources as part of the web service.

### Before you begin

The steps that are described in this task apply to servers and clients that run on WebSphere Application Server.

### About this task

Complete this task if you are creating a JAX-WS web service that uses the WS-Addressing specification. This task uses the JAX-WS WS-Addressing APIs to create the required endpoint reference. Alternatively, you can create endpoint references by using the IBM proprietary WS-Addressing API, and convert them into JAX-WS API objects for use with the rest of the application.

© IBM Corporation 2009

## Procedure

1. Provide a web service interface that returns an endpoint reference to the target service.

   The interface must return an endpoint reference, which it can do by using a factory operation or a separate factory service. The target service can front a resource instance, for example a shopping cart.

2. Implement the web service created in the previous step. For the WS-Addressing portion of the implementation, complete the following steps:

   a. Include annotations to specify WS-Addressing behavior. See “Web Services Addressing annotations” on page 1683 for more details.

   b. Optional: If your interface involves a web service that fronts a resource instance, create or look up the resource instance.

   c. Optional: If you are using a resource instance, obtain the identifier of the resource. The resource identifier is application dependent and might be generated during the creation of the resource instance.

      **Attention:** Do not put sensitive information in the resource identifier, because the identifier is propagated in the SOAP message.

   d. Create an endpoint reference that references the web service by following the instructions in “Creating endpoint references by using the JAX-WS Web Services Addressing API” on page 1634. If you are using a resource instance, pass in the resource identifier as a parameter.

   e. Return the endpoint reference.

3. If your web service uses resource instances, extend the implementation to match incoming messages to the appropriate resource instances. Because you associated the resource identifier with the endpoint reference that you created earlier, any incoming messages targeted at that endpoint reference contain the resource identifier information as a reference parameter in the SOAP header of the message. Because the resource identifier is passed in the SOAP header, you do not have to expose it on the web service interface. When WebSphere Application Server receives the message, it puts this information into the message context on the thread. Extend the implementation to undertake the following actions:

   a. Obtain the resource instance identifier from the message context.

      - If you are using the 2005/08 WS-Addressing namespace, use the REFERENCE_PARAMETERS property of the MessageContext class.
      - If you are using the 2004/08 WS-Addressing namespace, you must use the IBM WS-Addressing API, specifically the EndpointReferenceManager.getReferenceParameterFrom MessageContext(QName resource_id) method.

      Use the following method for the 2005/08 namespace:

```
...
List resourceIDList = (List)getContext().getMessageContext().get(MessageContext.REFERENCE_PARAMETERS);
...
```

      Use the following method for the 2004/08 namespace:

```
...

String resource_identifier =
        EndpointReferenceManager.getReferenceParameterFromMessageContext(PRINTER_ID_PARAM_QNAME);
...
```

   b. Forward the message to the appropriate resource instance.

4. Optional: Configure a proxy client to communicate with the service.

   a. Use the wsimport or xjc tool to generate the artifacts required by the client.

      **Note:** If you want to use the 2004/08 WS-Addressing specification, specify the provided binding file, *app_server_root*/util/SubmissionEndpointReference.xjb, as the -b parameter of the tool. This parameter tells the tool to generate endpoint reference objects by using the SubmissionEndpointReference class that is part of the IBM implementation of the standard JAX-WS API. If you do not specify this bindings file, the resulting endpoint reference objects will not work with the standard JAX-WS API.

b. In the client code, create an instance of the service class.

c. Obtain a proxy object from the service class. There are several ways to use the JAX-WS API to obtain proxy objects. For example, there are several getPort methods on the Service class and one on the EndpointReference class. For more information, refer to the API documentation.

d. Optional: Use the Addressing or SubmissionAddressing feature to enable WS-Addressing support. For example, create a proxy by using a getPort method that accepts web service features as a parameter. If you prefer, you can enable WS-Addressing support by using another method, such as policy sets. For more information see “Enabling Web Services Addressing support for JAX-WS applications” on page 1647.

e. Use the proxy object to invoke the service method that returns the endpoint reference.

The following sample code shows a client invoking a web service to add two numbers together. The web service issues a ticket (the resource identifier) to the client, and requires the client to use this ticket when invoking the web service.

The client creates two proxies. The first proxy obtains the ticket as an endpoint reference from the service. The second proxy uses the AddressingFeature class to enable WS-Addressing for the 2005/08 specification, and invokes the service to add the two numbers together.

```
...
CalculatorService service = new CalculatorService();
// Create the first proxy
Calculator port1 = service.getCalculatorServicePort();
// Obtain the ticket as an endpoint reference from the service
W3CEndpointReference epr = port1.getTicket();

// Create the second proxy, using an addressing feature to enable WS-Addressing
Calculator port2 = epr.getPort(Calculator.class, new AddressingFeature());
// Invoke the service to add the numbers
int answer = port2.add(value0, value1);
System.out.println("The answer is: " + answer);
...
```

**Note:** If the metadata of the endpoint reference conflicts with the information already associated with the outbound message, for example if the proxy object is configured to represent a different interface, a javax.xml.ws.WebServiceException exception is thrown on attempts to invoke the endpoint.

If you want to set message-addressing properties, such as a reply to endpoint, you must use the IBM proprietary WS-Addressing SPI and the BindingProvider class, as described in “Specifying and acquiring message-addressing properties by using the IBM proprietary Web Services Addressing SPIs” on page 1644.

5. Optional: Configure a Dispatch client to communicate with the service. You can configure a client in different ways; the following steps describe one example.

   a. Create an instance of the service.

   b. Add a port to the service object.

   c. Create an instance of the Dispatch class, passing in the endpoint reference.

   d. Create a Dispatch<T> object. Use the Service.createDispatch method with the following parameters:

      - The endpoint reference returned by the service, which represents the resource to forward messages to.
      - An array of web service features. Include one or more WS-Addressing features to enable WS-Addressing. See “Enabling Web Services Addressing support for JAX-WS applications” on page 1647 for more details.

      There are several variations of the Service.createDispatch method; see the API documentation for more details.

   e. Compose the client request message.

   f. Invoke the service endpoint with the Dispatch client.

   The following code shows an example fragment of a Dispatch client that enables 2004/08 WS-Addressing.

```
...
CalculatorService service = new CalculatorService();
Dispatch(<SOAPMessage> dispatch = service.createDispatch(
    endpointReference,
    SOAPMessage.class,
    Service.Mode.MESSAGE,
    new SubmissionAddressingFeature(true));
...
```

## Results

The web service and client are configured to use endpoint references through the WS-Addressing support. For a detailed example that includes code, see “Example: Creating a web service that uses the JAX-WS Web Services Addressing API to access a generic web service resource instance” on page 1642.

## What to do next

- Refer to “Web Services Addressing security” on page 1684 for information about security with WS-Addressing.
- Deploy the application. If you used WS-Addressing annotations or features in the code, you do not have to take any additional steps to enable WS-Addressing support. For more information and for other scenarios that might require additional steps, for example enabling WS-Addressing support by using policy sets, see “Enabling Web Services Addressing support for JAX-WS applications” on page 1647.

# Creating endpoint references by using the JAX-WS Web Services Addressing API

Endpoint references are a primary concept of the Web Services Addressing (WS-Addressing) interoperability protocol, and provide a standard mechanism to encapsulate information about specific web service endpoints. This product provides interfaces for you to create endpoint references by using the standard JAX-WS API.

## About this task

This task is a subtask of “Creating a JAX-WS web service application that uses Web Services Addressing” on page 1631.

Complete this task if you are writing an application that uses the standard JAX-WS WS-Addressing API. Such applications require endpoint references to target web service endpoints. The standard JAX-WS API is designed to create only simple endpoint references, and therefore has the following restrictions:

- You cannot create highly available or workload managed endpoint references.
- You cannot create endpoint references that represent stateful session beans.
- You cannot use classes that are created by using the JAX-WS API with the IBM proprietary WS-Addressing SPI.

You can overcome these restrictions by using the IBM proprietary WS-Addressing API to create the endpoint references and then converting them into standard JAX-WS endpoint references that can be used by the rest of the application.

## Procedure

- If an endpoint needs to create an endpoint reference that represents itself, use the getEndpointReference method of the web service context object, passing in an Element object representing the reference parameters to be associated with the endpoint reference (or a null object if you do not want to specify any reference parameters).

  By default, this method creates a W3CEndpointReference object. If you want to create a SubmissionEndpointReference object, representing an endpoint that conforms to the 2004/08 WS-Addressing specification, pass the endpoint reference type as a parameter. For example, the following code fragment uses the getEndpointReference method to return a W3CEndpointRerence object that has a ticket ID associated with it:

```
...
@WebService(name="Calculator",
            targetNamespace="http://calculator.org")

public class Calculator {
    @Resource
    WebServiceContext wsc;

    ...
    // Create the ticket id
    element = document.createElementNS(
                      "http://calculator.jaxws.axis2.apache.org", "TicketId");
    element.appendChild( document.createTextNode("123456789") );
    ...

    public W3CEndpointReference getEPR() {
        // Get the endpoint reference and associate the ticket id
        // with it as a reference parameter
        W3CEndpointReference epr = (W3CEndpointReference)wsc.getEndpointReference(element);

        return epr;
    }
...
```

The following line of code shows how to create a 2004/08 endpoint reference for the preceding sample:

```
SubmissionEndpointReference epr = (SubmissionEndpointReference)
       wsc.getEndpointReference(SubmissionEndpointReference.class, element);
```

- If an endpoint needs to create an endpoint reference that represents a different endpoint, use either the W3CEndpointReferenceBuilder class or the SubmissionEndpointReferenceBuilder class, depending on the namespace that you want to use.
  1. Create an instance of the appropriate builder class. Use the W3CEndpointReferenceBuilder class if you want to create an endpoint reference that complies with the 2005/08 WS-Addressing specification. Use the SubmissionEndpointReferenceBuilder class if you want to create an endpoint reference that complies with the 2004/08 WS-Addressing specification.
  2. Set the following property or properties of the builder instance according to the location of the endpoint.
     - If the endpoint is in another module in this application, set the serviceName and endpointName properties to appropriate values. You must set the serviceName property before you set the endpointName property, otherwise the application throws an error. The endpoint reference that is returned contains a suitable address for the endpoint, as determined by the implementation.

       **Note:** This behavior differs from the IBM WS-Addressing API, in that creating an endpoint reference using the com.ibm.websphere.wsaddressing.EndpointReferenceManager.createEndpointReference(QName serviceName, String endpointName) method is not restricted to endpoints in the same application.
     - If the endpoint is in another Java EE application, set the address property to point to the endpoint.
  3. Optional: Set other properties of the builder instance as required. For example, if the web service is used to access a resource instance, use the referenceParameter property to associate the identifier of the resource with the endpoint reference. For more information on the properties that you can set, see the API documentation.
  4. Invoke the build method on the builder instance to obtain the endpoint reference.

  For example, the following code fragment uses the W3CEndpointReferenceBuilder class to obtain an endpoint reference that complies with the 2005/08 specification, and points to an endpoint that is in another application:

```
...
@WebService(name="Calculator", targetNamespace="http://calculator.org")
public class Calculator {

    public W3CEndpointReference getEPR() {
        ...
        // Create the builder object
        W3CEndpointReferenceBuilder builder = new
                              W3CEndpointReferenceBuilder();
```

```
        // Modify builder properties
        builder.address(otherServiceURI);

        // Create the endpoint reference from the builder object
        W3CEndpointReference epr = builder.build();
        return epr;
    }
...
```

The following code fragment uses the SubmissionEndpointReferenceBuilder class to obtain an endpoint reference that complies with the 2004/08 specification, and points to an endpoint that is in another module in this application:

```
...
@WebService(name="Calculator", targetNamespace="http://calculator.org")
public class Calculator {

    public W3CEndpointReference getEPR() {
        ...
        // Create the builder object
        SubmissionEndpointReferenceBuilder builder = new
                        SubmissionEndpointReferenceBuilder();

        // Modify builder properties
        builder.serviceName(calculatorService);
        builder.endpointName(calculatorPort);

        // Create the endpoint reference from the builder object
        SubmissionEndpointReference epr = builder.build();
        return epr;
    }
...
```

### Results

You created an endpoint reference for use by your application.

### What to do next

1. If required, convert the endpoint reference to an instance of the com.ibm.websphere.wsaddressing.EndpointReference class, by using the createIBMEndpointReference method. For example, on a client you might want to set the FaultTo message addressing property for outbound messages. You cannot set this property by using the JAX-WS API, so you must convert the endpoint reference representing the FaultTo endpoint to an instance of the com.ibm.websphere.wsaddressing.EndpointReference class, before setting it as a property on the BindingProvider object.
2. Continue with “Creating a JAX-WS web service application that uses Web Services Addressing” on page 1631.

## Creating a JAX-RPC web service application that uses Web Services Addressing

Web Services Addressing (WS-Addressing) aids interoperability between web services by defining a standard way to address web services and provide addressing information in messages. This task describes the steps that are required to create a JAX-RPC web service that is accessed by using a WS-Addressing endpoint reference. The task also describes the extra steps that are required to use stateful resources as part of the web service.

### Before you begin

The steps that are described in this task apply to servers and clients that run on WebSphere Application Server.

### About this task

Complete this task if you are creating a web service that uses the WS-Addressing specification.

## Procedure

1. Provide a web service interface, by creating or generating a Web Services Description Language (WSDL) document for the web service, that returns an endpoint reference to the target service. The interface must return an endpoint reference, which it can do by using a factory operation or a separate factory service. The target service can front a resource instance, for example a shopping cart.
2. Implement the web service created in the previous step. For the WS-Addressing portion of the implementation, complete the following steps:
   a. Create an endpoint reference that references the web service, by following the instructions in "Creating endpoint references by using the IBM proprietary Web Services Addressing API" on page 1640.
   b. Optional: If your interface involves a web service that fronts a resource instance, create or look up the resource instance.
   c. Optional: If you are using a resource instance, obtain the identifier of the resource and associate it with the endpoint reference as a reference parameter, by using the EndpointReference.setReferenceParameter(QName resource_id_name, String value) method. The resource identifier is application-dependent and might be generated during the creation of the resource instance.

      **Attention:** Do not put sensitive information in the resource identifier, because the identifier is propagated in the SOAP message.
      The endpoint reference now targets the resource.
   d. Return the endpoint reference.
3. If your web service uses resource instances, extend the implementation to match incoming messages to the appropriate resource instances. Because you associated the resource identifier with the endpoint reference that you created earlier, any incoming messages targeted at that endpoint reference contain the resource identifier information as a reference parameter in the SOAP header of the message. Because the resource identifier is passed in the SOAP header, you do not have to expose it on the web service interface. When WebSphere Application Server receives the message, it puts this information into the message context on the thread. Extend the implementation to undertake the following actions:
   a. Obtain the resource instance identifier from the message context, by using the EndpointReferenceManager.getReferenceParameterFromMessageContext(QName resource_id_name) method.
   b. Forward the message to the appropriate resource instance.
4. To configure a client to communicate with the service, use the endpoint reference that is produced by the service in the first step to send messages to the endpoint.
   a. Obtain a Stub object (by looking up the service in the Java Naming and Directory Interface (JNDI)), or create an empty Call object.
   b. Associate the endpoint reference with the proxy object. Use the setProperty(String property_name, Object value) method of the Stub or Call object. Use the WS-Addressing constant WSADDRESSING_DESTINATION_EPR as the property name, and the endpoint reference as the value.

      This procedure automatically configures the Stub or Call object, to represent the web service (or resource instance if your interface uses a web service that fronts a resource instance) of the endpoint reference. For Call objects, this process includes the configuration of the interface and endpoint metadata (portType and port elements) that are associated with the endpoint reference.

      **Note:** If the metadata of the endpoint reference conflicts with the information already associated with the outbound message, for example if the Stub object is configured to represent a different interface, a javax.xml.rpc.JAXRPCException exception is thrown on attempts to invoke the endpoint.

   Invocations on the Stub or Call object are now targeted at the web service or resource instance that is defined by the endpoint reference. When an invocation occurs, the product adds appropriate message

addressing properties, such as a reference parameter contained within the endpoint reference that identifies a target resource, to the message header.

## Results

The web service and client are configured to use endpoint references through the WS-Addressing support.

## Providing a web service interface that returns an endpoint reference to the target service

The following examples correspond to steps 1 to 4 in the procedure. The examples show how an IT organization might use web services to manage a network of printers. The organization might represent each printer as a resource that is addressed through an endpoint reference. The following examples show how to code such a service by using the IBM proprietary Web Services Addressing (WS-Addressing) application programming interfaces (APIs) that are provided by WebSphere Application Server, and JAX-WS.

The IT organization implements a PrinterFactory service that offers a CreatePrinter portType element. This portType element accepts a CreatePrinterRequest message to create a resource that represents a logical printer, and responds with an endpoint reference that is a reference to the resource.

The WSDL definition for such a PrinterFactory service might include the following code:

```
<wsdl:definitions targetNamespace="http://example.org/printer" ...
                  xmlns:pr=" http://example.org/printer">
  <wsdl:types>
    ...
    <xsd:schema...>
      <xsd:element name="CreatePrinterRequest"/>
      <xsd:element name="CreatePrinterResponse"
                   type="wsa:EndpointReferenceType"/>
    </xsd:schema>
  </wsdl:types>
  <wsdl:message name="CreatePrinterRequest">
    <wsdl:part name="CreatePrinterRequest"
               element="pr:CreatePrinterRequest" />
  </wsdl:message>
  <wsdl:message name="CreatePrinterResponse">
    <wsdl:part name="CreatePrinterResponse"
               element="pr:CreatePrinterResponse" />
  </wsdl:message>
  <wsdl:portType name="CreatePrinter">
    <wsdl:operation name="createPrinter">
      <wsdl:input name="CreatePrinterRequest"
                  message="pr:CreatePrinterRequest" />
      <wsdl:output name="CreatePrinterResponse"
                   message="pr:CreatePrinterResponse" />
    </wsdl:operation>
  </wsdl:portType>
</wsdl:definitions>
```

The CreatePrinter operation in the previous example returns a wsa:EndpointReference object that represents the newly created Printer resource. The client can use this endpoint reference to send messages to the service instance that represents the printer.

The createPrinter method shown in the following example creates an endpoint reference to the Printer service. The operation then obtains the identifier for the individual printer resource instance, and associates it with the endpoint reference. Finally, the createPrinter method converts the EndpointReference object, which now represents the new printer, into a W3CEndpointReference object, and returns the converted endpoint reference.

```
import com.ibm.websphere.wsaddressing.EndpointReferenceManager;
import com.ibm.websphere.wsaddressing.EndpointReference;
import com.ibm.websphere.wsaddressing.jaxws.EndpointReferenceConverter;
import com.ibm.websphere.wsaddressing.jaxws.W3CEndpointReference;

import javax.xml.namespace.QName;

public class MyClass {

    // Create the printer
    ...
```

```
    // Define the printer resource ID as a static constant as it is required in later steps
    public static final QName PRINTER_ID_PARAM_QNAME = new QName("example.printersample",
                                                        "IBM_WSRF_PRINTERID", "ws-rf-pr" );
    public static final QName PRINTER_SERVICE_QNAME = new QName("example.printer.com", "printer", "...");
    public static final String PRINTER_ENDPOINT_NAME = new String("PrinterService");

    public W3CEndpointReference createPrinter(java.lang.Object createPrinterRequest)
    throws Exception {
     // Create an EndpointReference that targets the appropriate WebService URI and port name.
     EndpointReference epr =  EndpointReferenceManager.createEndpointReference(PRINTER_SERVICE_QNAME,
                                                                    PRINTER_ENDPOINT_NAME);

     // Create or lookup the stateful resource and derive a resource
     // identifier string.
     String resource_identifier = "...";

     // Associate this resource identifier with the EndpointReference as
     // a reference parameter.
     // The choice of name is arbitrary, but should be unique
     // to the service.
     epr.setReferenceParameter(PRINTER_ID_PARAM_QNAME,resource_identifier);
     // The endpoint reference now targets the resource rather than the service.
     ...

     return EndpointReferenceConverter.createW3CEndpointReference(epr);
    }
}
```

Because of the web service implementation described previously, the printer resource instance now has a unique identifier embedded in its endpoint reference. This identifier becomes a reference parameter in the SOAP header of subsequent messages that are targeted at the web service, and can be used by the web service to match incoming messages to the appropriate printer.

When a web service receives a message containing WS-Addressing message-addressing properties, the WebSphere Application Server processes these properties before the message is dispatched to the application endpoint, and sets them into the message context on the thread. The Printer web service application accesses the reference parameters that are associated with the target endpoint from the WebServiceContext object, as illustrated in the following example:

```
import com.ibm.websphere.wsaddressing.EndpointReferenceManager;
...
 // Initialize the reference parameter name
 QName name = new QName(..);
 // Extract the String value.
 String resource_identifier =
        EndpointReferenceManager.getReferenceParameterFromMessageContext(PRINTER_ID_PARAM_QNAME);
```

The web service implementation can forward messages based on the printer identity acquired from the getReferenceParameterFromMessageContext method to the appropriate printer instances.

The client creates a JAX-WS proxy for the printer, and converts the proxy into a BindingProvider object. The client then associates the EndpointReference object obtained previously with the request context of the BindingProvider object, as illustrated in the following example.

```
import javax.xml.ws.BindingProvider;
...

 javax.xml.ws.Service service= ...;
 Printer myPrinterProxy = service.getPort(portName, Printer.class);

 javax.xml.ws.BindingProvider bp = (javax.xml.ws.BindingProvider)myPrinterProxy;

 // Retrieve the request context for the BindingProvider object
 Map myMap = myBindingProvider.getRequestContext();

 // Associate the endpoint reference that represents the new printer to the request context
 // so that the BindingProvider object now represents a specific printer instance.
 myMap.put(WSADDRESSING_DESTINATION_EPR, destinationEpr);

...
```

The BindingProvider object now represents the new printer resource instance, and can be used by the client to send messages to the printer through the Printer web service. When the client invokes the

BindingProvider object, WebSphere Application Server adds appropriate message-addressing properties to the message header, which in this case is a reference parameter contained within the endpoint reference that identifies the target printer resource.

Alternatively, the client can use a JAX-RPC Stub or Call object, which the client configures to represent the new printer. The use of the Call object is illustrated in the following example.

```
import javax.xml.rpc.Call;
...
 :
 // Associate the endpoint reference that represents the new printer with the call.
 call.setProperty(
        "com.ibm.websphere.wsaddressing.WSAConstants.
                              WSADDRESSING_DESTINATION_EPR ", epr);
```

From the perspective of the client, the endpoint reference is opaque. The client cannot interpret the contents of any endpoint reference parameters and should not try to use them in any way. Clients cannot directly create instances of endpoint references because the reference parameters are private to the service provider; clients must obtain endpoint references from the service provider, for example through a provider factory service, and then use them to direct web service operations to the endpoint that is represented by the endpoint reference, as shown.

## What to do next

- Refer to “Web Services Addressing security” on page 1684 for information about security with WS-Addressing.
- Deploy the application. For this scenario, you do not have to take any additional steps to enable the WS-Addressing support in WebSphere Application Server because you specified a WS-Addressing property on the client. For more information, and for other scenarios that might require additional steps, see “Enabling Web Services Addressing support for JAX-RPC applications” on page 1689.

## Creating endpoint references by using the IBM proprietary Web Services Addressing API

Endpoint references are a primary concept of the Web Services Addressing (WS-Addressing) interoperability protocol, and provide a standard mechanism to encapsulate information about specific Web service endpoints. This product provides interfaces for you to create endpoint references by using the IBM proprietary implementation of the WS-Addressing standard.

### About this task

This task is a subtask of “Creating a JAX-RPC web service application that uses Web Services Addressing” on page 1636.

Complete this task if you are writing an application that uses the IBM proprietary WS-Addressing API. Such applications require endpoint references to target web service endpoints. When you are writing the application, you might not know the address of the endpoint, because the address can change when the application is deployed. By using the IBM proprietary API, you can either specify the endpoint address, or allow the product to generate it for you at run time.

If you want to use endpoint reference objects from the standard JAX-WS API instead of the IBM proprietary equivalents, but want the extra functions provided by the IBM proprietary API, create the endpoint references by using the methods described in this task and then convert them by using the supplied converter classes. For example, you might want to undertake such a conversion if you have a JAX-WS service application and you are creating endpoint references that represent stateful session beans, or that have an affinity to a particular server, or are workload managed. You cannot create such endpoint references by using the JAX-WS API.

## Procedure

- To create an endpoint reference with an address that you specify directly, use the WS-Addressing EndpointReferenceManager.createEndpointReference(URI address) method of the system programming interface (SPI) provided. This method is useful in test scenarios, where the address of the service does not change.
- To create an endpoint reference with an address that is automatically generated by the product, complete the following steps:
  1. If you created the web service deployment descriptor file, webservices.xml, manually, ensure that the webservice-description-name in the file is the same as the local part of the Web Services Description Language (WSDL) service name. If you generated the webservices.xml file by using the tools provided, the names match by default. This match is required for the generation of the correct URI for the endpoint reference.
  2. Create the endpoint reference by using the method that is appropriate for the object that the reference will represent.
     - If you are creating an endpoint reference to represent a stateful session bean that maintains in-memory state, create the endpoint reference using the EndpointReferenceManager.createEndpointReference(QName serviceName, String endpointName, Remote statefulSessionBean) method of the application programming interface (API) provided. This method ensures that requests are targeted at the specific server that hosts the stateful session bean instance, and are not workload-managed.
     - If you are creating an endpoint reference to represent any other object, create the endpoint reference by using the EndpointReferenceManager.createEndpointReference(QName serviceName, String endpointName) method of the API. The combination of service name and endpoint name must be unique in the server. If there is more than one web service application with the same service name and endpoint name, the application server cannot generate a unique URI object for the endpoint. If you cannot ensure that the combination of service name and endpoint name is unique, use an SPI method to create the endpoint reference.

     When the application invokes either of the previous two methods, the product generates the address URI for the endpoint reference, and puts the service name and endpoint name into the metadata of the newly created endpoint reference.

     **Note:** If you configured a virtual host for the server on which the endpoint is created, the URI of the endpoint reference refers to the virtual host of the HTTP server configuration. You can use the administrative console to override this setting and provide your own HTTP endpoint URL information. The methods described previously will use the overridden value to generate the address URI for the endpoint reference.

## Results

You created an endpoint reference for use by your application.

## What to do next

1. If you want to convert the endpoint references from IBM proprietary WS-Addressing objects to standard JAX-WS WS-Addressing objects, use one of the following methods of the com.ibm.websphere.wsaddressing.jaxws21.EndpointReferenceConverter class, depending on the namespace of the endpoint reference:
   - createW3CEndpointReference(EndpointReference epr): use this method if the EndpointReference object uses the 2005/08 specification. This method creates a W3CEndpointReference object.
   - createSubmissionEndpointReference(EndpointReference epr): use this method if the EndpointReference object uses the 2004/08 specification. This method creates a SubmissionEndpointReference object.

2. Continue with “Creating a JAX-RPC web service application that uses Web Services Addressing” on page 1636, or if you converted the endpoint reference to the standard JAX-WS API, continue with “Creating a JAX-WS web service application that uses Web Services Addressing” on page 1631.

# Example: Creating a web service that uses the JAX-WS Web Services Addressing API to access a generic web service resource instance

Consider an IT organization that has a network of printers that it wants to manage using web services. The organization might represent each printer as a resource that is addressed through an endpoint reference. This example shows how to code such a service by using the JAX-WS Web Services Addressing (WS-Addressing) application programming interfaces (APIs) that are provided by WebSphere Application Server.

## Providing a web service interface that returns an endpoint reference to the target service

The IT organization implements a PrinterFactory service that offers a CreatePrinter portType element. This portType element accepts a CreatePrinterRequest message to create a resource that represents a logical printer, and responds with an endpoint reference that is a reference to the resource.

The WSDL definition for such a PrinterFactory service might include the following code:

```
<wsdl:definitions targetNamespace="http://example.org/printer" ...
                  xmlns:pr=" http://example.org/printer">
  <wsdl:types>
    ...
    <xsd:schema...>
      <xsd:element name="CreatePrinterRequest"/>
      <xsd:element name="CreatePrinterResponse"
                   type="wsa:EndpointReferenceType"/>
    </xsd:schema>
  </wsdl:types>
  <wsdl:message name="CreatePrinterRequest">
    <wsdl:part name="CreatePrinterRequest"
               element="pr:CreatePrinterRequest" />
  </wsdl:message>
  <wsdl:message name="CreatePrinterResponse">
    <wsdl:part name="CreatePrinterResponse"
               element="pr:CreatePrinterResponse" />
  </wsdl:message>
  <wsdl:portType name="CreatePrinter">
    <wsdl:operation name="createPrinter">
      <wsdl:input name="CreatePrinterRequest"
                  message="pr:CreatePrinterRequest" />
      <wsdl:output name="CreatePrinterResponse"
                   message="pr:CreatePrinterResponse" />
    </wsdl:operation>
  </wsdl:portType>
</wsdl:definitions>
```

The CreatePrinter operation in the previous example returns a wsa:EndpointReference object that represents the newly created Printer resource. The client can use this endpoint reference to send messages to the service instance that represents the printer.

## Implementing the web service interface

The createPrinter method shown in the following example obtains the identifier for the individual printer resource instance. The operation then creates an endpoint reference to the Printer service, and associates the printer ID with the endpoint reference. Finally, the createPrinter method returns the endpoint reference.

```
import javax.xml.ws.wsaddressing.W3CEndpointReference;
import javax.xml.ws.wsaddressing.W3CEndpointReferenceBuilder;

import javax.xml.namespace.QName;

import org.w3c.dom.Document;
import org.w3c.dom.Element;

public class MyClass {

  // Create the printer
  ...
```

```
  //Define the printer resource ID as a static constant as it is required in later steps
    public static final QName PRINTER_SERVICE_QNAME = new QName("example.printer.com", "printer", "...");
    public static final QName PRINTER_ENDPOINT_NAME = new QName("example.printer.com", "PrinterService", "...");

    public W3CEndpointReference createPrinter(java.lang.Object createPrinterRequest)
    {
     Document document = ...;

     // Create or lookup the stateful resource and derive a resource
     // identifier string.
     String resource_identifier = "...";

     // Associate this resource identifier with the EndpointReference as
     // a reference parameter.
     // The choice of name is arbitrary, but should be unique
     // to the service.
     Element element = document.createElementNS("example.printersample",
             "IBM_WSRF_PRINTERID");
     element.appendChild( document.createTextNode(resource_identifier) );
     ...

     // Create an EndpointReference that targets the appropriate WebService URI and port name.
     // Alternatively, the getEndpointReference() method of the MessageContext can be used.
     W3CEndpointReferenceBuilder builder = new W3CEndpointReferenceBuilder();
     builder.serviceName(PRINTER_SERVICE_QNAME);
     builder.endpointName(PRINTER_ENDPOINT_NAME);
     builder.referenceParameter(element);

     // The endpoint reference now targets the resource rather than the service.
     return builder.build();
    }
}
```

## Extending the target service to match incoming messages to web service resource instances

Because of the web service implementation described previously, the printer resource instance now has a unique identifier embedded in its endpoint reference. This identifier becomes a reference parameter in the SOAP header of subsequent messages that are targeted at the web service, and can be used by the web service to match incoming messages to the appropriate printer.

When a web service receives a message containing WS-Addressing message addressing properties, the WebSphere Application Server processes these properties before the message is dispatched to the application endpoint, and sets them into the message context on the thread. The Printer web service application accesses the reference parameters that are associated with the target endpoint from the WebServiceContext object, as illustrated in the following example:

```
@Resource
private WebServiceContext context;
...
List list = (List) context.getMessageContext().get(MessageContext.REFERENCE_PARAMETERS);
```

If your application uses the 2004/08 version of the WS-Addressing specification, use the IBM proprietary API to retrieve the message parameters, as illustrated in the following example.

```
import com.ibm.websphere.wsaddressing.EndpointReferenceManager;
...
 // Initialize the reference parameter name
 QName name = new QName(..);
 // Extract the String value.
 String resource_identifier =
        EndpointReferenceManager.getReferenceParameterFromMessageContext(PRINTER_ID_PARAM_QNAME);
```

The web service implementation can forward messages based on the printer ID to the appropriate printer instances.

## Using endpoint references to send messages to an endpoint

The client uses the endpoint reference returned from the service to create a JAX-WS proxy for the printer, as illustrated in the following example.

```
javax.xml.ws.Service jaxwsServiceObject= ...;
W3CEndpointReference epr = ...;
...
Printer myPrinterProxy = jaxwsServiceObject.getPort(epr, Printer.class, new AddressingFeature());
```

The proxy object now represents the new printer resource instance, and can be used by the client to send messages to the printer through the Printer Web service. When the client invokes the service, WebSphere Application Server adds appropriate message addressing properties to the message header, which in this case is a reference parameter contained within the endpoint reference that identifies the target printer resource.

From the perspective of the client, the endpoint reference is opaque. The client cannot interpret the contents of any endpoint reference parameters and should not try to use them in any way. Clients cannot directly create instances of endpoint references because the reference parameters are private to the service provider; clients must obtain endpoint references from the service provider, for example through a provider factory service, and then use them to direct web service operations to the endpoint that is represented by the endpoint reference, as shown.

# Using the IBM proprietary Web Services Addressing SPIs: Performing more advanced Web Services Addressing tasks

This product provides proprietary system programming interfaces for more advanced Web Services Addressing (WS-Addressing) tasks, which involve the WS-Addressing message-addressing properties that are passed in the SOAP header of a web service message. You can also use the SPIs to choose a WS-Addressing specification level other than the default used by the product.

## Before you begin

You cannot use the standard JAX-WS API classes with these proprietary SPIs. However, you can convert endpoint references created using the standard JAX-WS API classes to instances of the com.ibm.websphere.wsaddressing.EndpointReference class, by using the com.ibm.websphere.wsaddressing.jaxws21.EndpointReferenceConverter class. You can then use these converted endpoint references with the SPIs.

The steps described in this task apply to servers and clients that run on WebSphere Application Server.

## About this task

Complete this task to specify or acquire WS-Addressing message-addressing properties, or if you have an application that needs to interoperate with a client or endpoint that is not using the default WS-Addressing specification supported by this product.

## Procedure

- To manipulate message-addressing properties, follow the instructions in “Specifying and acquiring message-addressing properties by using the IBM proprietary Web Services Addressing SPIs”
- To interoperate with the pre-W3C specification of WS-Addressing, with the namespace http://schemas.xmlsoap.org/ws/2004/08/addressing, refer to “Interoperating with Web Services Addressing endpoints that do not support the default specification supported by WebSphere Application Server” on page 1646.

# Specifying and acquiring message-addressing properties by using the IBM proprietary Web Services Addressing SPIs

Using the proprietary Web Services Addressing (WS-Addressing) system programming interfaces (SPIs), you can add WS-Addressing message addressing properties (MAPs) to the SOAP headers of an outbound client message, through properties on the JAX-WS BindingProvider request context, or the JAX-RPC Stub or Call object. When the target endpoint receives the message, the SPI enables the endpoint to acquire the MAPs through properties on the message context.

## About this task

There are no equivalent SPIs in the JAX-WS standard. If you want to set message-addressing properties in a client that uses JAX-WS endpoint references, you must convert the endpoint references to the IBM proprietary classes, before using them with these SPIs.

Complete this task if you are a web service developer that uses the WS-Addressing support, or a system programmer that uses the IBM proprietary WS-Addressing SPIs to specify message addressing properties, such as fault or reply endpoint references, on web services messages.

The properties that you can set or retrieve are described, with the Java type of property instances, in IBM proprietary Web Services Addressing SPIs. Most properties are of type com.ibm.websphere.wsaddressing.EndpointReference, for example destination, reply, or fault endpoint references. The relationship property is a java.util.Set object that contains instances of the com.ibm.wsspi.wsaddressing.Relationship class. Use relationships when you want to specify an association between messages; for example, in a response message you might want to specify the ID of the message to which you are replying. The action property is an AttributedURI object that identifies a specific method or operation within the target endpoint.

**Attention:** The destination endpoint reference and action properties are required for the message to be WS-Addressing compliant.

## Procedure

1. On the client, obtain the endpoint reference from the service and associate it with your BindingProvider object request context, or your Stub or Call object, as described in “Creating a JAX-RPC web service application that uses Web Services Addressing” on page 1636.
2. Create instances of the required properties. For example, if you want to specify an endpoint reference for the target service to send replies to, create an instance of the com.ibm.websphere.wsaddressing.EndpointReference class, to use as the WSADDRESSING_REPLYTO_EPR property.
3. Set the required properties by associating them with the BindingProvider object request context, or the Stub or Call object. If you are using a Stub or Call object, use the setProperty(String property_name, Object value) method. Note that unlike the endpoint reference required for the first step, these endpoint references do not have to be converted to another type, because they are passed in the header of the SOAP message rather than the body. The following example sets a destination endpoint reference and a reply endpoint reference on a BindingProvider object request context:

```
import javax.xml.ws.BindingProvider;
...
 javax.xml.ws.Service jaxwsServiceObject=...;
 Printer myPrinterProxy = jaxwsServiceObject.getPort(portName, Printer.class);

 javax.xml.ws.BindingProvider myBindingProvider = (javax.xml.ws.BindingProvider)myPrinterProxy;

 // Retrieve the request context for the BindingProvider object
 Map myMap = myBindingProvider.getRequestContext();

 // Associate the endpoint reference for the web service. This property is required for the message
 // to be WS-Addressing compliant.
  myMap.put(WSADDRESSING_DESTINATION_EPR, destinationEpr);

 // Associate the endpoint reference that represents the reply to the request context
 myMap.put(WSADDRESSING_REPLYTO_EPR, replyToEpr);
```

   When an invocation occurs on the BindingProvider, Stub, or Call object, the product adds the appropriate MAPs to the message header.
4. On the server, retrieve the MAPs from the inbound message through the javax.xml.ws.WebServiceContext or javax.xml.rpc.handler.MessageContext object that is currently on the thread. When WebSphere Application Server receives the message, it puts the MAP information into the message context on the thread, making it available to the service. You can retrieve the message context by, for example, using the session context of the endpoint enterprise bean. For more

information about message contexts, refer to the JSR-109 standard. The following example retrieves the reply endpoint reference by using the web service context:

```
import javax.xml.ws.handler.MessageContext;
import javax.xml.ws.WebServiceContext;
...

  // Obtain the message context from the WebService context
  private WebServiceContext wsContext;
  MessageContext context = wsContext.getMessageContext();

  // Retrieve the reply endpoint reference
  replyToEpr = context.getProperty(WSADDRESSING_INBOUND_REPLYTO_EPR);
```

# Interoperating with Web Services Addressing endpoints that do not support the default specification supported by WebSphere Application Server

A target web service endpoint might not support the same Web Services Addressing (WS-Addressing) namespace as this product. In most cases, you do not have to undertake any extra actions to interoperate with such endpoints, however some scenarios require additional steps in the implementation of your web service.

## About this task

WebSphere Application Server supports the default WS-Addressing 2005/08 namespace http://www.w3.org/2005/08/addressing. Complete this task to interoperate with endpoints that support other namespaces. This task specifically describes interoperation with endpoints that are hosted on a node that supports only the 2004/08 namespace: http://schemas.xmlsoap.org/ws/2004/08/addressing.

If you are using the standard JAX-WS API, ensure that you use the appropriate feature, annotation or endpoint reference class for the 2004/08 namespace.

If you are sending to or receiving messages from an endpoint that supports only the 2004/08 namespace, you do not have to undertake any additional steps for interoperability. This product recognizes and understands incoming WS-Addressing messages that conform to the 2004/08 specification, and outbound messages automatically adhere to the namespace of their destination endpoint reference. If you are sending a request, all WS-Addressing elements, such as reply endpoint or fault endpoint elements, must use the same namespace as the message. Any discrepancy results in a JAX-WS or JAX-RPC configuration error.

If you are interacting in a different way with an endpoint that supports only the 2004/08 namespace, such as exporting endpoint references in the message header or body, and you are not using the JAX-WS standard API, you must undertake additional steps as detailed below.

## Procedure

- If you are generating a web service for use by a client that supports only the 2004/08 specification, update the WS-Addressing namespace in the Web Services Description Language (WSDL) document for your web service, by changing `http://www.w3.org/2006/05/addressing/wsdl` to `http://schemas.xmlsoap.org/ws/2004/08/addressing`.

  **Note:** Only the WS-Addressing WSDL Action extensibility element is recognized by pre-W3C WS-Addressing clients.
- If you are creating endpoint references at run time for export to an endpoint that supports the 2004/08 namespace only, perform the following steps:
  1. Create the endpoint reference to export.
  2. Associate the appropriate namespace with the endpoint reference, by using the setNamespace method. The following example illustrates the association of the 2004/08 namespace with an endpoint reference:

```
import com.ibm.wsspi.wsaddressing.EndpointReference;
import com.ibm.wsspi.wsaddressing.NamespaceNotSupportedException;
import com.ibm.wsspi.wsaddressing.WSAConstants;

:

EndpointReference epr = ...

try
{
    epr.setNamespace(WSAConstants.WSADDRESSING_NAMESPACE_2004_08);
} catch (NamespaceNotSupportedException e)
{
    // Error handling code here
}
```

When you pass the endpoint reference to the target endpoint, in either the SOAP body or the SOAP header of a message, the endpoint reference is appropriately serialized into SOAP elements according to its namespace.

- To establish the namespace of an inbound request, use the IBM proprietary WS-Addressing system programming interface (SPI) to retrieve the WSADDRESSING_INBOUND_NAMESPACE property from the inbound message context. This property specifies the Core WS-Addressing specification namespace of the incoming message.

  **Note:** This procedure uses the IBM proprietary WS-Addressing API. There is no equivalent procedure in the JAX-WS API.

  You can retrieve the message context by, for example, using the session context of the endpoint enterprise bean. For more information about message contexts, refer to the JSR-109 specification. The following code example shows how you can establish the namespace of an incoming message on the receiving endpoint:

```
import com.ibm.wsspi.wsaddressing.WSAConstants;
import javax.xml.rpc.handler.MessageContext;

:
  // If the endpoint is implemented as an enterprise bean, you can use its session context
  // to obtain the message context
  private SessionContext sessionContext;
  MessageContext context = sessionContext.getMessageContext();

  try
  {
    String namespace = (String)msgContext.getProperty(WSAConstants.WSADDRESSING_INBOUND_NAMESPACE);
  } catch (IllegalArgumentException e)
  {
    // Error handling code here
  }
```

# Enabling Web Services Addressing support for JAX-WS applications

The Web Services Addressing (WS-Addressing) support provides mechanisms to address web services and provide addressing information in messages. For JAX-WS applications, you can enable WS-Addressing support in several different ways, such as configuring policy sets or using annotations in code.

## About this task

Perform this task to enable the WS-Addressing support, either as a service provider or as a client of a service provided by another party.

For service providers, WS-Addressing support is enabled by default, so you do not have to undertake any actions to enable support. However, you can use the enabling mechanisms to modify other WS-Addressing behavior for the service, such as whether WS-Addressing information is required, and what is included in the generated WSDL document.

- Modify the behavior of the WS-Addressing support after the application is deployed by attaching a policy set to the application. Within the policy set, you can configure the WS-Addressing policy type to specify whether WS-Addressing information is required in incoming messages, and whether to use synchronous or asynchronous messaging. You can communicate the WS-Addressing policy configuration to other

servers and clients that support WS-Policy, by enabling policy sharing on the server, and by applying the provider policy on the client. This method overrides other methods.

- Use deployment descriptor elements within a `port-component` element.
- Modify the behavior of the WS-Addressing support during development of the service by using the Addressing or SubmissionAddressing annotations in the service code. Within each annotation you can specify whether WS-Addressing is enabled on the server, whether the server requires WS-Addressing information in incoming messages and the message exchange pattern the server will use. The presence of the Addressing annotation in the code adds a UsingAddressing element and a WS-Policy assertion to any WSDL document that is generated for the service.
- Modify the behavior of the WS-Addressing support during development of the service by either adding UsingAddressing elements or WS-Policy assertions into the WSDL document. If you do provide your own WSDL document, instead of relying on the JAX-WS runtime environment to generate one, and your WSDL document is being consumed by non JAX-WS 2.2 clients, you may wish to include the UsingAddressing element as such clients will not process WS-Policy assertions.

For service clients, WS-Addressing support is disabled by default. Use one of the following methods to enable WS-Addressing support. The following list is in descending order of precedence, because you can apply multiple methods. For example the deployment descriptor method overrides the use of annotations or features, but is itself overridden by the use of policy sets.

- Attach a policy set to the client artifact and perform one of the following actions:
  - Specify in the policy that WS-Addressing is mandatory.
  - Apply both client and provider policies. In this situation, WS-Addressing support is enabled on the client only if policy sharing is enabled on the service provider and the policy configuration for the provider specifies that WS-Addressing is mandatory.

  This method overrides other methods.
- Set the **com.ibm.websphere.webservices.use.async.mep** property on the client request context.
- Use the IBM proprietary WS-Addressing SPI to add message-addressing properties to the message request context.
- Use deployment descriptor elements within a `port-component-ref` element.
- Use the Addressing annotation in combination with the WebServiceRef annotation in the client code (when you are using an injected Web services proxy reference).
- Use addressing features in the client code. Properties set by using this method override those set in the WSDL document for the service.
- Use WS-Policy assertions in the WSDL document to specify WS-Addressing support. If you add Addressing annotations to your client application code, the generated WSDL document will contain WS-Policy assertions.
- Specify the UsingAddressing element in the WSDL document for the service. If the service uses the Addressing annotation and you generate the WSDL document from the code, the UsingAddressing element already exists.

The following tables summarize the behavior of the WS-Addressing support. Use this table to determine whether a request message is accepted for client settings that do not involve policy configuration.

This is a complex table containing spanned column headings. There is a header column on the left entitled "Client settings" which specifies whether WS-Addressing support is enabled on the client and also which messaging style is configured. The second main column shows the policy settings on the provider, with two sub-columns for whether WS-Addressing is optional or mandatory. Both of these sub-columns are further sub-divided into three sub-columns for messaging style (synchronous, asynchronous, or both). The third main column shows the WSDL settings on the provider, with two sub-columns for whether WS-Addressing is optional or mandatory.

*Table 227. How client and provider settings interact to determine whether a request message is accepted. The preceding paragraph describes this table.*

| Client settings | Provider policy settings | | | | | | Provider WSDL settings (UsingAddressing `required` attribute) | |
|---|---|---|---|---|---|---|---|---|
| | WS-Addressing is optional | | | WS-Addressing is mandatory[1] | | | | |
| | Synchronous and asynchronous | Synchronous only | Asynchronous only | Synchronous and asynchronous | Synchronous only | Asynchronous only | `false` (WS-Addressing is optional) | `true` (WS-Addressing is mandatory[1]) |
| WS-Addressing support enabled and messaging style synchronous | Message accepted | Message accepted | Fault | Message accepted | Message accepted | Fault | Message accepted | Message accepted |
| WS-Addressing support enabled and messaging style asynchronous | Message accepted | Fault | Message accepted | Message accepted | Fault | Message accepted | Message accepted | Message accepted |
| WS-Addressing support not enabled and messaging style synchronous | Message accepted | Message accepted | Message accepted[2] | Fault | Fault | Fault | Message accepted | Fault |
| WS-Addressing support not enabled and messaging style asynchronous[3] | Fault | Fault | Fault | Fault | Fault | Fault | Fault | Fault |

**Notes:**

1. If WS-Addressing is mandatory, all requests without WS-Addressing headers are rejected.
2. The messaging style is only enforced if WS-Addressing headers are present in the request.
3. Asynchronous messaging is not possible without WS-Addressing headers.

Use the following table to determine whether a request message is accepted when the client and provider both have a WS-Addressing policy configuration; the client has provider and client policies applied; and policy sharing is enabled on the server.

This is a complex table containing spanned column headings. There is a header column on the left entitled "Client settings" which specifies whether WS-Addressing support is optional or mandatory on the client and also which messaging style is configured. The second main column shows the policy settings on the provider, with two sub-columns for whether WS-Addressing is optional or mandatory. Both of these sub-columns are further sub-divided into three sub-columns for messaging style (synchronous and asynchronous, synchronous only, or asynchronous only).

*Table 228. How client and provider policy settings interact to determine whether a request message is accepted. The preceding paragraph describes this table.*

| | Provider policy settings | | | | | |
|---|---|---|---|---|---|---|
| | WS-Addressing is optional | | | WS-Addressing is mandatory | | |
| **Client policy settings** | **Synchronous and asynchronous** | **Synchronous only** | **Asynchronous only** | **Synchronous and asynchronous** | **Synchronous only** | **Asynchronous only** |
| WS-Addressing optional and messaging style synchronous and asynchronous | Message accepted | Message accepted | Message accepted | Message accepted | Message accepted | Message accepted |
| WS-Addressing optional and messaging style synchronous only | Message accepted | Message accepted | Message accepted[1] | Message accepted | Message accepted | Fault |
| WS-Addressing optional and messaging style asynchronous only[2] | Fault | Fault | Fault | Message accepted | Fault | Message accepted |
| WS-Addressing mandatory and messaging style synchronous and asynchronous | Message accepted | Message accepted | Message accepted | Message accepted | Message accepted | Message accepted |
| WS-Addressing mandatory and messaging style synchronous only | Message accepted | Message accepted | Fault | Message accepted | Message accepted | Fault |
| WS-Addressing mandatory and messaging style asynchronous only | Message accepted | Fault | Message accepted | Message accepted | Fault | Message accepted |

**Notes:**

1. The messaging style is only enforced if WS-Addressing headers are present in the request.
2. Asynchronous messaging is not possible without WS-Addressing headers.

If the provider and client policies are not shared, the client does not send WS-Addressing headers (unless you enable WS-Addressing on the client by another method). In this situation, if the provider policy specifies that WS-Addressing is mandatory, the server generates a fault regardless of the messaging style.

## Procedure

- To modify the behavior of the WS-Addressing support by creating or modifying policy sets on either the service provider or client, see the topic: “Enabling Web Services Addressing support for JAX-WS applications using policy sets” on page 1651.
- Set the **com.ibm.websphere.webservices.use.async.mep** property on the client request context when using WebSphere Application Server clients to enable WS-Addressing support. See the topic: “Invoking JAX-WS web services asynchronously” on page 1510 for more information.
- To modify the behavior of the WS-Addressing support by using the deployment descriptor of the service or client application, see the topic: “Enabling Web Services Addressing support for JAX-WS applications using deployment descriptors” on page 1678.
- To modify the behavior of the WS-Addressing support programmatically by using addressing annotations in the service application, or on the client with an injected web service proxy reference, see the topic: “Enabling Web Services Addressing support for JAX-WS applications using addressing annotations” on page 1679.
- To enable WS-Addressing support programmatically on the client by creating an instance of an addressing feature class, see the topic: “Enabling Web Services Addressing support for JAX-WS applications using addressing features” on page 1680.

- To modify the behavior of the WS-Addressing support during the development of a client or service application by adding WS-Policy assertions into the WSDL file, see the topic: “Enabling Web Services Addressing support for JAX-WS applications using WS-Policy” on page 1681.

### Results

WS-Addressing properties are now included in the SOAP message header, and are processed by the server on receipt of the message.

## Enabling Web Services Addressing support for JAX-WS applications using policy sets

For JAX-WS applications, you can enable WS-Addressing support after you deploy an application to the server, by creating or modifying policy sets, and attaching those policy sets to either a service or client application.

### About this task

You can also configure the WS-Addressing support using other methods, for example in the code of the application, however this method overrides all other methods. Note that WS-Addressing support is enabled by default for service providers.

### Procedure

1. Ensure that you have a policy set that contains the WS-Addressing policy type. If you have to create a new policy set, or add the WS-Addressing policy to an existing policy set, refer to Managing policy sets using the administrative console for instructions.
2. Configure the WS-Addressing policy type according to the instructions in “Configuring the WS-Addressing policy” on page 1659. Use the two settings to specify whether WS-Addressing is mandatory, and whether to use a synchronous or asynchronous message exchange pattern. The default settings are that WS-Addressing is not mandatory, and that both synchronous and asynchronous messaging patterns are used.
3. Attach the policy set to a web service provider or client artifact, according to the instructions in “Attaching a policy set to a service artifact” on page 1661.
4. Optional: If you want to communicate the WS-Addressing policy settings to other servers and clients, configure policy sharing as described in “Configuring a service provider to share its policy configuration” on page 1662 or “Configuring the client policy to use a service provider policy” on page 1670. If policy sharing is enabled and the server and client cannot agree a policy, normal WS-Policy behavior applies (a policy error is produced).

### Results

WS-Addressing properties are now included in the SOAP message header, and are processed by the server on receipt of the message.

## Creating policy sets using the administrative console

You can use the administrative console to either create a policy set by specifying all the necessary information or by copying an existing policy set that you rename. You can use policy sets, or assertions that define services, to simplify your web services configuration because policy sets group security and other web services settings into reusable units.

### Before you begin

To create a new policy set, you can either specify the information to create a new policy set or you can copy and rename an existing policy set. Using either method, you need basic information about the policy set that you want to create, such as the name, description, policies to include, policy details, attachments,

and binding configurations. If you are creating a policy set by copying an existing policy set, then you should also view the existing policy sets to choose one with properties that are most similar to the one you plan to create.

## About this task

Whether you choose to create a new policy set or copy and rename an existing one, start from the Applications policy sets collection in the administrative console.

## Procedure

1. From the administrative console, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**.
2. If the policy set you are creating is:
   - a new policy set, then click **New**.
   - an existing policy set to be copied and renamed, click the **Select** box beside the name of the policy set to be copied in the **Name** column and click **Copy**.

   Using either method, this action opens the Policy set settings view to specify the required information about the policy set being created or copied.
3. Enter the name of the policy set that you want to create or copy in the **Name** field.
4. Enter a brief description of the policy set in the **Description** field. This is the description that displays in the Application policy sets or the System policy set collection, so it must be meaningful to you and other potential users of this policy set.

   **Note:** If you created a new policy set, it does not contain policies to edit until you add them to the policy set. The policy set is initially empty.

## Results

You have provided the basic information to create a policy set.

## Example

After you have looked at your web services, you might decide that the WS-I RSP default policy set most closely meets your needs. You would go to the administrative console and click **Services > Policy sets > Application policy sets** to access the Application policy sets collection. Locate the WS-I RSP default in the **Name** column of the table and click the box beside it (in the **Select** column). Click **Copy**. This opens the Policy set settings window. You might want to name your policy set by your company or division so you could provide a name like `ABC WS-I RSP` in the Name field. Because you know others in your organization might access and use it, you've chosen a name that is meaningful to those people too. You want to be sure everyone knows exactly what this copy of the WS-I RSP policy is used for, so you add a description in the **Description** field describing it. Now you want to customize the policy set so you edit the policy information by clicking the name of a policy to edit it.

When you identify the requirements of your web service, you might decide that none of the default policy sets meet your needs closely enough to use them as a template so you might decide to create your own policy set. You would first create the policy set with the name you choose to give it. As if you were reusing an existing template, you would go to the administrative console and click **Services > Policy sets > Application policy sets** and click **New**. The Policy set settings window opens but note that the Policy set name field is blank and there are not yet any associated policies in the table. Enter the name and add any policies necessary.

When you add policies to a policy set, the policies are set to their default values. You can then edit the policies to modify any attribute values that need to be changed and save the settings.

## What to do next

If you are creating a new policy set without copying an existing policy set, you need to specify the policy information. If you are copying an existing policy set, you can either accept the default policies associated with the policy set or you can change the policies.

***WS-I RSP default policy sets:***

The Reliable Asynchronous Message Profile (WS-I RSP) default policy sets are based on the Reliable Asynchronous Message Profile specification. The WS-I RSP default policy sets include the WS-I RSP default policy set, the Lightweight Third-Party Authentication (LTPA) WS-I RSP default policy set and the Username WS-I RSP default policy set. You can use these policy sets to simplify your web services configuration.

The WS-I RSP default policy sets are composed of a set of policies to provide reliable and secure web services. The WS-I RSP default policy sets use the WS-Addressing, WS-ReliableMessaging, and WS-Security specifications. Use the WS-I RSP default policy set, the LTPA WS-I RSP default policy set, or the Username WS-Security WS-I RSP default policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WS-I RSP default policy sets include the following policies:

**WS-Addressing policy**
: You can use the WS-Addressing policy to enable the addressing capability of the WS-Addressing specification.

**WS-ReliableMessaging policy**
: You can use the WS-ReliableMessaging policy to specify the quality of service for reliable delivery.

**WS-Security policy**
: The WS-Security policy in the WS-I RSP default policy set provides the following security:
  - Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications.
  - Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications.
  - Traditional RSA cryptography is used to secure a request to a Trust Server to obtain a Secure Context Token (SCT). Thereafter, the conversation is secured using symmetric keys derived from the SCT.

The application server provides additional policy sets that you can use or customize. To use the following default policy sets, you must import the policy sets from the default repository. Read about importing policy sets using the administrative console for more information.

The following WS-I RSP default policy sets exist:

**WS-I RSP default**
: This policy set provides:
  - Reliable message delivery to the intended receiver by enabling WS-ReliableMessaging.
  - Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications.
  - Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications.

**LTPA WS-I RSP default**
This policy set provides the WS-I RSP default policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

**Username WS-I RSP default**
This policy set provides the WS-I RSP default policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

***SecureConversation default policy sets:***

The SecureConversation default policy sets are based on the Web Services Secure Conversation Language (SecureConversation) standard that establishes a secure context, based on shared keys for the client and server to use for a series of messages. This standard provides a framework to define how to secure the message exchange across organizations. The SecureConversation default policy sets include the SecureConversation policy set, the Lightweight Third-Party Authentication (LTPA) SecureConversation policy set, and the Username SecureConversation policy set.

The SecureConversation default policy sets are based on the WS-SecureConversation, the WS-Security, and the WS-Addressing specifications. Use the SecureConversation policy set, the LTPA SecureConversation policy set, or the Username SecureConversation policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WS-SecureConversation specification alone does not provide a complete security solution. The WS-SecureConversation is built on the WS-Security and WS-Trust specifications to provide secure communication across one or more messages. Specifically, this specification defines mechanisms for establishing and sharing security contexts, and deriving keys from established security contexts or any shared secret.

WS-Security focuses on the message authentication model but not in a security context. The WS-SecureConversation specification defines mechanisms for establishing and sharing security contexts, and deriving keys from security contexts, to enable a secure conversation. By using the SOAP extensibility model, modular SOAP-based specifications are designed to be composed with each other to provide a rich messaging environment.

The following SecureConversation default policy sets exist:

**SecureConversation**
This policy set provides:

- Message integrity by digital signature that includes signing the body, timestamp, and WS-Addressing headers using WS-SecureConversation and WS-Security specifications.
- Message confidentiality by encryption that includes encrypting the body, signature and signature confirmation elements, using WS-SecureConversation and WS-Security specifications.

**LTPA SecureConversation**
This policy set provides the SecureConversation policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

**Username SecureConversation**
This policy set provides the SecureConversation policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request

***WS-ReliableMessaging default policy sets:***

The WS-ReliableMessaging default policy sets are pre-configured to provide reliable message exchange between web services. Two of these policy sets (WS-I RSP and WS-I RSP ND) are immediately available, and the rest are readily available for import from a default repository.

With WS-ReliableMessaging, you can make your SOAP over HTTP-based web services reliable without writing custom code. You can use the provided non-editable default policy sets without change, or you can create customized copies of them.

All the default policy sets that include the WS-ReliableMessaging policy also include the WS-Addressing policy. The WS-ReliableMessaging policy provides the ability to deliver a message reliably to its intended receiver. The WS-Addressing policy provides a transport-neutral way to uniformly address web services and messages, and WS-ReliableMessaging uses WS-Addressing to provide asynchronous request and reply capabilities.

**Note:** WS-ReliableMessaging Version 1.1 messaging requires WS-Addressing to be mandatory. If you use a policy set that includes WS-ReliableMessaging and WS-Addressing policies, and the WS-Addressing policy is configured as optional, then WebSphere Application Server overrides the WS-Addressing setting and automatically enables WS-Addressing.

The following default policy sets that include the WS-ReliableMessaging policy are immediately available, as described in Viewing policy sets using the administrative console:

**WS-I RSP**
: This policy set enables WS-ReliableMessaging Version 1.1 and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent. Message integrity is provided by digitally signing the body, the time stamp, and the WS-Addressing headers. Message confidentiality is provided by encrypting the body and the signature. This policy set follows the WS-SecureConversation and WS-Security specifications.

**WS-I RSP ND**
: This is the network deployment version of the WS-I RSP policy set. This policy set provides the WS-I RSP default policy set and adds a *managed non-persistent* quality of service. This in-memory quality of service option uses a messaging engine to manage the sequence state, and messages are written to disk if memory is low. This quality of service allows for the re-sending of messages that are lost in the network, and can also recover from server failure. However, state is discarded after a messaging engine restart so in this case you will lose messages.

The following additional default policy sets that include the WS-ReliableMessaging policy are readily available for import, as described in Importing policy sets using the administrative console:

**LTPA WS-I RSP**
: This policy set provides the WS-I RSP default policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

**Username WS-I RSP**
: This policy set provides the WS-I RSP default policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

**WSReliableMessaging 1_0**
: This policy set enables both WS-ReliableMessaging Version 1.0 and WS-Addressing and uses the

minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

You can use this policy set with .NET-based web services.

**WSReliableMessaging default**
This policy set enables both WS-ReliableMessaging Version 1.1 and WS-Addressing and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

**WSReliableMessaging persistent**
This policy set enables both WS-ReliableMessaging and WS-Addressing and uses the maximum quality of service, *managed persistent*. This quality of service supports asynchronous web service invocations and uses a service integration messaging engine and message store to manage the sequence state. Messages are processed within transactions, are persisted at the web service requester server and at the web service provider server, and are recoverable in the event of server failure. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

Because this policy set specifies managed persistent quality of service, you have to define bindings to the service integration bus and messaging engine that you want to use to manage the WS-ReliableMessaging state. You can attach and bind a WS-ReliableMessaging policy set to a web service application by using the administrative console or the wsadmin tool.

***WSAddressing default policy set:***

The WSAddressing default policy set provides a transport-neutral way to uniformly address web services and messages.

The WSAddressing default policy set is based on the WS-Addressing specification. The WS-Addressing standard uses endpoint references and message addressing properties to facilitate the addressing of web services in a standard and interoperable way.

Use the WSAddressing default policy set as provided with the application server. To customize the policy set, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

To learn more about the WS-Addressing standard, read about Web Services Addressing support.

***Web Services Security default policy sets:***

The Web Services Security default policy sets are based on the WS-Security 1.0 and Web Services Addressing (WS-Addressing) specifications. The Web Services Security default policy sets include the WSSecurity default policy set, the Lightweight Third-Party Authentication (LTPA) WSSecurity policy set, the Username WSSecurity policy set, and the Kerberos V5 HTTPS default policy set. These default policy sets are used to build secure web services.

The Web Services Security default policy sets use the WS-Security 1.0 specification enhancements to SOAP messaging to provide quality of protection through message integrity, message confidentiality, and single message authentication. Providing quality of protection means to prevent the following potential threats to SOAP messages:

- The message being modified or read by antagonists.

- An antagonist sending messages to a service that are formed correctly, but lack the appropriate security claims to be processed.

The WS-Addressing specification defines XML 1.0 and XML Namespaces elements to identify web services endpoints and to secure end-to-end endpoint identification in messages.

You can use the WSSecurity default policy set, the LTPA WSSecurity policy set, the Username WSSecurity policy set, or the Kerberos V5 HTTPS default policy set as provided with the application server. To customize the other Web Services Security policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

Features and details of the default Web Services Security policy sets are as follows:

**Kerberos V5 HTTPS default**

This policy set provides message authentication with a Kerberos Version 5 token. Message integrity and confidentiality are provided by Secure Sockets Layer (SSL) transport security. This policy set follows the OASIS Kerberos Token Profile V1.1 and WS-Security specifications.

When you use this policy set, configure the basic authentication data and custom properties such as the com.ibm.wsspi.wssecurity.krbtoken.targetServiceName and com.ibm.wsspi.wssecurity.krbtoken.targetServiceHost custom properties in the client bindings. For more information, see the Authentication generator or consumer token settings and Protection token settings (generator or consumer) topics.

**LTPA WSSecurity default**

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.
- A Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

**Username SecureConversation**

This policy set provides:

- Message integrity through digital signature that includes signing the body, time stamp, and WS-Addressing headers using WS-SecureConversation and WS-Security specifications
- Message confidentiality through encryption that includes encrypting the body, signature and signature confirmation elements, using WS-SecureConversation and WS-Security specifications
- A username token included in the request message to authenticate the client to the service. The username token is encrypted in the request

**Username WSSecurity default**

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.
- A username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

**WSSecurity default**

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.

***WSTransaction default policy sets:***

The WSTransaction default policy sets are based on the WS-Transaction specification and provide transactional integrity for web services. The WSTransaction default policy sets include the WSTransaction policy set and the SSL WSTransaction policy set.

You can use the WSTransaction default policy sets to make your SOAP over HTTP-based web services interoperable and coordinate atomic transactions or business activities without writing custom code. Use the WSTransaction policy set or the SSL WSTransaction policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WSTransaction default policy sets are:

**WSTransaction**
: Use this policy set to coordinate distributed transactional work atomically and interoperably, by using the WS-AtomicTransaction specification. Also, use this policy set to coordinate loosely coupled business processes that are distributed across the heterogenous web service environment, with the ability to compensate actions if a failure occurs in the business activity, by using the WS-BusinessActivity specification.

**SSL WSTransaction**
: Use this policy set to coordinate distributed transactional work atomically, interoperably and securely, by using the WS-AtomicTransaction specification and SSL Transport security. Also, use this policy set to coordinate loosely coupled business processes, with the ability to compensate actions if a failure occurs in the business activity, securely, by using the WS-BusinessActivity specification and SSL Transport security.

***WSHTTPS default policy set:***

The WSHTTPS default policy set provides SSL transport security for the HTTP protocol with web services applications.

The WSHTTPS default policy set is provided with the application server and it contains the HTTP transport policy, the SSL transport policy and the WS-Addressing policy.

You can use the WSHTTPS default policy set as provided with the application server. You cannot edit the WSHTTPS default policy set. You can create a copy of the default policy set and then configure custom policy settings and bindings to meet your needs. Alternatively, you can create a new policy set and specify the policies for it.

***Copy of default policy set and bindings settings:***

Use this page to copy a policy set that you select from a list of available policy sets.

To view this administrative console page:

1. Click **Services > Policy sets > Application policy sets**.
2. Select the policy set that you want to copy, and click **Copy**.
3. Enter a name for the copy of the policy set in the **Name** field.
4. [Optional] Enter a description for the copy of the policy set in the **Description** field.

*Name:*

Specifies the name of the policy set. Use this field to enter a name for the copy of the policy set.

*Description:*

Specifies a description of the policy set that you want to copy.

*Transfer attachments:*

If the policy set that you want to copy is attached to one or more applications, services, or endpoints, then the check box option for **Attach this policy set in place of the original for all attached applications, services, endpoints, and operations**, is available. The default setting for this check box is cleared. You can perform the following actions:

1. Select the **Attach this policy set in place of the original for all attached applications, services, endpoints, and operations** check box to move the attachments to a new policy set. Selecting the check box detaches the original policy set and attaches the replacement policy set in its place.
2. Select **Copy bindings** if you want to copy the bindings of the policy set that is currently attached.
3. [Optional] Select **Restore default bindings** if you want to restore the default bindings.

## Configuring the WS-Addressing policy

When working with policy sets in the administrative console, you can add and configure policies to enable standard addressing of web services.

### Before you begin

You can specify policies for custom policy sets. The provided default policy sets cannot be edited. You must create a copy of the default policy set or create a completely new policy set in order to specify the policies for it.

### About this task

Adding a WS-Addressing policy enables the support for WS-Addressing. This support provides a standard way to address Web services and include addressing information in messages. Adding a WS-Addressing policy is equivalent to configuring the WSDL file for the web service to specify that WS-Addressing should be used.

To specify or configure the policies associated with a policy set, use the administrative console.

### Procedure

1. In the navigation pane of the administrative console, click **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name*** > **[Policies] WS-Addressing**. The WS-Addressing settings pane is displayed.
2. Select **WS-Addressing is mandatory** to specify that WS-Addressing information must be included in SOAP message headers. For servers, this setting means that the server returns a fault if it receives a message that does not contain a WS-Addressing header. For clients, this setting means that WS-Addressing headers are always added to SOAP messages. If you have enabled WS-Policy, this requirement is communicated between servers and clients that support WS-Policy.
3. In the **Messaging style** box, select the message exchange pattern to use:
   - **Synchronous and asynchronous**. The targeting of response messages is not restricted.
   - **Synchronous only**. Response messages must be targeted at the WS-Addressing anonymous URI.
   - **Asynchronous only**. Response messages must not be targeted at the WS-Addressing anonymous URI.
4. Click **OK**.
5. Save your changes to the master configuration.

## Results

After you have included the WS-Addressing policy in a policy set, the associated policy set uses this policy to address web services.

***WS-Addressing policy settings:***

Use this page to define the appropriate WS-Addressing policy assertions for this policy set.

To view this administrative console page, click **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name*** > **[Policy] WS-Addressing**, when the policy set includes the WS-Addressing policy type.

You can configure the WS-Addressing policy type for both client-side and provider-side policy sets. If you enable WS-Policy, this configuration is communicated between servers and clients that support WS-Policy.

*WS-Addressing is mandatory:*

Specifies whether a WS-Addressing SOAP header is included on messages.

**Data type** Check box
**Default** Cleared
**Range**

**Cleared**
WS-Addressing is not mandatory. Servers will not generate a fault if they receive a message that does not contain a WS-Addressing header. Clients might not include WS-Addressing headers in SOAP messages, for example, if WS-Policy is enabled and the server does not specify that WS-Addressing is mandatory.

**Selected**
WS-Addressing is mandatory. Servers return a fault if they receive a message that does not contain a WS-Addressing header. Clients always include WS-Addressing headers in SOAP messages.

*Messaging style:*

Specifies the messaging style supported by this policy set.

Use the radio buttons to configure the messaging style.

- Select **Synchronous and asynchronous** to specify that there is no restriction on the targeting of response messages.
- Select **Synchronous only** to specify that response messages must be targeted at the WS-Addressing anonymous URI. You might want to use this messaging style in the following situations:
  - The SOAP headers are not signed, and WS-Security is not enabled. Specifying the synchronous message exchange pattern prevents the server sending messages to a third party, thereby preventing the server from potentially taking part in a Denial of Service attack.
  - Clients with a NAT device between themselves and the endpoint. In this configuration, non-anonymous URIs cannot be routed. Use this setting to prevent the client from sending a message containing a ReplyTo endpoint reference with a non-anonymous URI.
- Select **Asynchronous only** to specify that response messages must not be targeted at the WS-Addressing anonymous URI. This setting does not mean that all non-anonymous URIs are

supported, therefore a server can return a fault if it receives a response endpoint reference that it cannot process. You might want to use this messaging style if the endpoint has a very long-running invocation time, and you do not want to hold the connection open while waiting for a response.

The following table shows how the messaging style options correspond to WS-Policy assertions.

*Table 229. WS-Addressing messaging style and WS-Policy. This table provides a mapping between messaging style options and WS-Policy assertions.*

| Messaging style | WS-Policy mapping |
|---|---|
| Synchronous and asynchronous | wsam:AnonymousResponses or wsam:NonAnonymousResponses |
| Synchronous only | wsam:AnonymousResponses |
| Asynchronous only | wsam:NonAnonymousResponses |

**Required** No
**Data type** Radio button

## Attaching a policy set to a service artifact

Attach a policy set to a service artifact, such as an application, service, endpoint or operation, to define the quality of services that are supported. Policy sets can define the policies for WS-Addressing, WS-Security, WS-ReliableMessaging, WS-Transaction, HTTP transport, Java Messaging Service (JMS) transport, and Secure Sockets Layer (SSL) transport.

### Before you begin

Before you can start this task, you must deploy an application containing web services. Also, if none of the default policy sets contain the necessary policy definitions, then you must create a custom policy set with the necessary definitions.

### About this task

Develop a web service that contains each of the necessary artifacts, and deploy your web services application into your application server instance. Now you can attach policy sets to your service artifacts, such as an application, service, or endpoint.

To attach a policy set to a service artifact, perform the following steps:

### Procedure

1. Open the administrative console.
2. To attach a policy set to a service provider, click **Applications > Enterprise applications** > ***application_name*** > **Service provider policy sets and bindings**.

   To attach a policy set to a service client, click **Applications > Enterprise applications** > ***application_name*** > **Service client policy sets and bindings**.
3. Select the check box for the service artifact.
4. Select **Attach** to display a list of available policy sets to attach. Select a policy set from the list.
5. Click **Save**, to save your changes to the master configuration.
6. [Optional] To see what attachments are defined for a given policy set, select **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name*** > **Attached applications**.

### Results

When you finish these steps, a policy set is attached to the service artifact.

### Example

If you have the application, `app1` and you want to attach the policy set, `WSSecurity default`, then perform the following steps:

1. Locate the `app1` application in the **Applications** > **Enterprise applications** collection.
2. Click the **app1** application.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** link.
4. Select the check box for the service artifact where the policy set is to be attached.
5. Click **Attach**. Select **WSSecurity default** policy set.
6. Click **Save**, to save your changes to the master configuration.

### What to do next

You can create custom bindings for policy set attachments. Read about creating custom bindings for policy set attachments.

You can configure the service client or service provider to share their policies. Read about using WS-Policy to exchange policies in a standard format.

## Configuring a service provider to share its policy configuration

A WebSphere Application Server service provider can share its policy configuration in published Web Services Description Language (WSDL), or WSDL that is obtained by using an HTTP GET request or the Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request.

### Before you begin

You have developed a web services service provider that contains all the necessary artifacts and deployed your web services application into your application server instance. You have attached the policy sets and managed the associated bindings.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the topic about learning about WS-Policy.

### About this task

You can make the policy configuration of a Java API for XML-Based Web Services (JAX-WS) service endpoint available to share in the following ways:

- Include the policy configuration of the service provider in the WSDL. The WSDL is then available to publish, or to obtain by using an HTTP GET request.
- Enable the Web Services Metadata Exchange (WS-MetadataExchange) protocol so that the policy configuration of the service provider is included in the WSDL and is available to a WS-MetadataExchange GetMetadata request. An advantage of using the WS-MetadataExchange protocol is that you can apply message-level security to WS-MetadataExchange GetMetadata requests by using a suitable system policy set.

If the service provider application uses multipart WSDL, all the WSDL must be local to the web service application. For more information about multipart WSDL, see the topic about WSDL.

You must configure a service provider to share its policy configuration because by default the policy configuration is not available in its WSDL. You can configure the service provider to include the policy configuration in its WSDL, to use WS-MetadataExchange so that the policy configuration is available, or both. This topic describes how to configure a service provider to share its policy configuration by using the

administrative console. You can also configure a service provider to share its policy configuration by using wsadmin commands or Rational Application Developer tools.

You can configure a service provider to share its policy configuration at application or service level. The policy configuration that is represented by the policy sets attached to any lower levels will also be shared. Policy sets that are attached at lower levels override the policy set configuration attached at a higher level.

## Procedure

1. From the navigation pane of the administrative console, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***service_provider_application_instance*** > **[Web services properties] Service provider policy sets and bindings**.
2. In the row for the application or service where the provider policy that you want to share is attached, click the link in the Policy sharing column. The link is either **Enabled** or **Disabled**. The Policy Sharing pane is displayed.
3. To include the policy configuration of the service provider in its WSDL so that it can be either published or obtained by using an HTTP GET request, select **Exported WSDL**.
4. To enable WS-MetadataExchange and make the policy configuration of the service provider available to a WS-MetadataExchange GetMetada request, select **WS-MetadataExchange request**.
5. Optional: If you select **WS-MetadataExchange request** and you want to use message-level security, select **Attach a system policy set to the WS-MetadataExchange**, then select a suitable policy set and binding from the drop-down lists. See Configuring security for a WS-MetadataExchange request.
6. Click **OK** and save your changes to the master configuration.

## Results

The policy configuration of the service provider is available to its clients. The WSDL of the service provider contains the current policy configuration in WS-PolicyAttachments format so that it is available to other clients, service registries, or services that support the Web Services Policy (WS-Policy) specification. The link in the Policy Sharing column on the Service provider policy sets and bindings pane changes to **Enabled**.

If the policy configuration cannot be shared, an error that describes the problem is written to the service provider error log, and the following policy is attached to the WSDL of the service provider:

```
<wsp:Policy>
<wsp:ExactlyOne>
</wsp:ExactlyOne>
</wsp:Policy>
```

This policy notifies the client that there is no acceptable policy configuration for the service. Other aspects of the WSDL are unaffected.

A service provider might not be able to share its policy configuration because the configuration cannot be expressed in the standard WS-PolicyAttachments format. One reason might be because multiple incompatible policies are defined for a particular attach point. Another reason might be because there is not enough binding information to generate the standard policy. Policy configuration might include bootstrap policy, for example, the policy to access a WS-Trust service, so the bootstrap policy must also be expressed in WS-PolicyAttachments format.

### *Configuring a service provider to share its policy configuration using wsadmin scripting:*

A WebSphere Application Server service provider can share its policy configuration in published Web Services Description Language (WSDL), or WSDL that is obtained by using an HTTP GET request or the Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request.

### Before you begin

You have developed a web services service provider that contains all the necessary artifacts and deployed your web services application into your application server instance. You have attached the policy sets and managed the associated bindings.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the topic about learning about WS-Policy.

### About this task

You can make the policy configuration of a Java API for XML-Based Web Services (JAX-WS) service endpoint available to share in the following ways:

- Include the policy configuration of the service provider in the WSDL. The WSDL is then available to publish, or to obtain by using an HTTP GET request.
- Enable the Web Services Metadata Exchange (WS-MetadataExchange) protocol so that the policy configuration of the service provider is included in the WSDL and is available to a WS-MetadataExchange GetMetadata request. An advantage of using the WS-MetadataExchange protocol is that you can apply message-level security to WS-MetadataExchange GetMetadata requests by using a suitable system policy set.

If the service provider application uses multipart WSDL, all the WSDL must be local to the web service application. For more information about multipart WSDL, see the topic about WSDL.

You must configure a service provider to share its policy configuration because by default the policy configuration is not available in its WSDL. You can configure the service provider to include the policy configuration in its WSDL, to use WS-MetadataExchange so that the policy configuration is available, or both. This topic describes how to configure a service provider to share its policy configuration by using wsadmin commands. You can also use the administrative console or Rational Application Developer tools.

You can configure a service provider to share its policy configuration at application or service level. The policy configuration that is represented by the policy sets attached to any lower levels will also be shared. Policy sets that are attached at lower levels override the policy set configuration attached at a higher level.

### Procedure

1. Start the wsadmin scripting client if it is not already running.
2. Use the SetProviderPolicySharingInfo command. For example:

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WebServiceProviderApplication
-resource WebService:/WebServiceProvider.war:{http://example_path/}Service1
-sharePolicyMethods [httpGet ]]')
```

3. Save your changes to the master configuration.

   To save your configuration changes, enter the following command:

```
AdminConfig.save()
```

### Results

The policy configuration of the service provider is available to its clients. The WSDL of the service provider contains the current policy configuration in WS-PolicyAttachments format so that it is available to other clients, service registries, or services that support the Web Services Policy (WS-Policy) specification.

If the policy configuration cannot be shared, an error that describes the problem is written to the service provider error log, and the following policy is attached to the WSDL of the service provider:

```
<wsp:Policy>
<wsp:ExactlyOne>
</wsp:ExactlyOne>
</wsp:Policy>
```

This policy notifies the client that there is no acceptable policy configuration for the service. Other aspects of the WSDL are unaffected.

A service provider might not be able to share its policy configuration because the configuration cannot be expressed in the standard WS-PolicyAttachments format. One reason might be because multiple incompatible policies are defined for a particular attach point. Another reason might be because there is not enough binding information to generate the standard policy. Policy configuration might include bootstrap policy, for example, the policy to access a WS-Trust service, so the bootstrap policy must also be expressed in WS-PolicyAttachments format.

**What to do next**

Optionally, you can publish the WSDL files.

*setProviderPolicySharingInfo command:*

Use the setProviderPolicySharingInfo command to set how an application or service that is a web service provider can share its policy configuration with other clients, service registries, or services that support the WS-Policy specification. You can set or remove this information about how a provider policy is shared.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available policy set management administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('PolicySetManagement')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

**Purpose**

Use the setProviderPolicySharingInfo command to set how an application, or a service in an application, shares its policy configuration with clients, service registries, or services that support the WS-Policy specification. The policy configuration is shared in WS-PolicyAttachments format.

The policy configuration of the resource can be shared with clients through a WS-MetadataExchange request, through Web Services Description Language (WSDL) exported by a ?WSDL HTTP Get request, or through both methods.

**Target object**

None.

**Required parameters**

**-applicationName**
The name of the application for which you want to set how the provider policy is shared. (String)

**-resource**
The name of the resource for which you want to set how the provider policy is shared. For all resources in an application, specify `WebService:/`. For a service in an application, specify `WebService:/module:{namespace}service_name`. Endpoints or operations inherit the settings of the parent application or service. (String)

### Optional parameters

**-sharePolicyMethods**
Specifies how the policy configuration of the resource can be shared. (String array)

Enter either or both of the following values:

**httpGet**
The resource can share its policy configuration through WSDL that is obtained by a `?WSDL` HTTP Get request.

**wsMex**
The resource can share its policy configuration through a WS-MetadataExchange request.

**-wsMexProperties**
Specifies that message-level security is required for WS-MetadataExchange requests and specifies the settings that provide the message-level security. (Properties)

Enter the following values, following each value with the setting that you require for that value:

**wsMexPolicySetName**
The name of the system policy set that specifies message-level security when the resource shares its policy configuration through a WS-MetadataExchange request. Specify a system policy set that contains only WS-Security policies, only WS-Addressing policies, or both. The default policy set is SystemWSSecurityDefault.

**wsMexPolicySetBinding**
The name of the general binding for the policy set attachment when the resource shares its policy configuration through a WS-MetadataExchange request. Specify a general binding that is scoped to the global domain, or scoped to the security domain of this service. If you do not specify this property, the default binding is used.

This parameter is valid only when you specify wsMex for the **sharePolicyMethods** parameter.

**-remove**
Specifies whether the information about how the provider policy is shared is removed from the resource. (Boolean)

This parameter takes the following values:

**true** The information about how the provider policy is shared is removed from the resource.

**false** This value is the default. The information about how the provider policy is shared is not removed from the resource.

### Examples

The following example removes the information about how the provider policy is shared from the WSSampleServices application:

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WSSampleServices
-resource WebService:/ -remove true]')
```

The following example enables policy sharing, using WSDL exported by a `?WSDL` HTTP Get request, for the EchoService service in the WSSampleServices application:

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WSSampleServices
-resource WebService:/WSSampleServicesSei.war:{http://example_path/}EchoService
-sharePolicyMethods [httpGet ]]')
```

The following example enables policy sharing, using a WS-MetadataExchange request with message-level security, for the WSSampleServices application. Message level security is provided by the SystemWSSecurityDefault policy set and the “Provider sample” general binding.

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WSSampleServices
-resource WebService:/ -sharePolicyMethods [wsMex ]
-wsMexProperties [ [wsMexPolicySetName [SystemWSSecurityDefault]]
[wsMexPolicySetBinding [Provider sample]] ]]')
```

*getProviderPolicySharingInfo command:*

Use the getProviderPolicySharingInfo command to find out whether an application or service that is a web service provider can share its policy configuration, and list the properties that apply to sharing that configuration.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available policy set management administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('PolicySetManagement')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

**Purpose**

Use the getProviderPolicySharingInfo command to find out how a web services application, or a service in a Web services application, shares its policy configuration with clients, service registries, or services that support the WS-Policy specification. The policy configuration is shared in WS-PolicyAttachments format.

The command returns properties that show whether the policy configuration of the resource can be shared with clients through a WS-MetadataExchange request or through Web Services Description Language (WSDL) that is obtained by a `?WSDL` HTTP Get request.

**Target object**

None.

**Required parameters**

**`-applicationName`**
The name of the application for which you want to find out how it shares its policy configuration. The application must be a service provider. (String)

**Optional parameters**

**`-resource`**
The name of the resource for which you want to find out how it shares its policy configuration. If you specify this parameter, only the properties for that resource are returned. To retrieve information for the

application, specify `WebService:/`. Alternatively, you can specify a service, endpoint or operation. However, policy sets are attached only at the application or service level, so the properties returned for an endpoint or operation are the settings that are inherited from the service. (String)

### Return value

Returns a list of properties that include the resource name and that show whether the policy configuration of the resource can be shared. The following properties can be returned:

**wsMexPolicySetName**
The name of the policy set that specifies message-level security when the resource shares its policy configuration through a WS-MetadataExchange request. This property is returned if the value of the **sharePolicyMethods** property is wsMex and a policy set to provide message-level security was specified.

**wsMexPolicySetBinding**
The name of the binding that is applied when the resource shares its policy configuration through a WS-MetadataExchange request. This property is returned if the value of the **sharePolicyMethods** property is wsMex and a binding to provide message-level security was specified.

**resource**
The resource that you specified.

**directSetting**
How the properties apply to the resource. Valid values for this property are:

**true**
The properties apply directly to the resource.

**false**
The properties are inherited from the parent application or service.

**sharePolicyMethods**
How the policy configuration of the resource can be shared. Valid values for this property are:

**httpGet**
The resource shares its policy configuration through an HTTP Get request.

**wsMex**
The resource shares its policy configuration through a WS-MetadataExchange request.

### Example

The following command displays the policy sharing configuration properties for the EchoService service in the WSSampleServices application. The provider is configured to share its policy through an HTTP Get request, and a WS-MetadataExchange request with message-level security. Message-level security for the WS-MetadataExchange request is provided by using the SystemWSSecurityDefault policy set and the “Provider sample” general binding.

```
AdminTask.getProviderPolicySharingInfo(['-applicationName', 'WSSampleServices',
'-resource', 'WebService:/SampleServicesSei.war:{http://example_path/}EchoService'])
.
.
[ [wsMexPolicySetName SystemWSSecurityDefault] [wsMexPolicySetBinding [Provider sample]]
[resource WebService:/SampleServicesSei.war:{http://example_path/}EchoService/]
[directSetting true] [sharePolicyMethods [httpGet wsMex]] ]
```

### *Policy sharing settings:*

Use this pane to view and change whether the policy configuration of a web services service provider is shared. You can configure the service provider to include the policy configuration in its Web Services

Description Language (WSDL) so that it can be accessed using an HTTP Get request, or published. You can also make the policy configuration available to a Web Services Metadata Exchange (WS-MetadataExchange) request.

To view this administrative console page for an application or service, complete the following steps. The application must be a web services service provider.

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***service_provider_application_name*** > **[Web Services Properties] Service provider policy sets and bindings**.
2. Select the link in the Policy Sharing column for the application or service you require. The link is available if the application or service has a policy set attached.

To view this administrative console page for a service, complete the following steps.

1. Click **Services** > **Service providers** > ***service_name***.
2. Select the link in the Policy Sharing column for the service. The link is available if the service has a policy set attached.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

*Exported WSDL:*

Select **Exported WSDL** to include the policy configuration of the service provider in the WSDL. The policy configuration is in WS-PolicyAttachments format in the WSDL so that it is then available to other clients, service registries, or services that support the Web Services Policy (WS-Policy) specification. The policy configuration will be available in published WSDL, or a client can use an HTTP Get request that is targeted at the target URL followed by `?WSDL` to obtain the provider policy.

*WS-MetadataExchange request:*

Select **WS-MetadataExchange** to make the policy configuration of the service provider available to a WS-MetadataExchange GetMetadata request. The policy configuration is in WS-PolicyAttachments format in the WSDL so that it is then available to other clients, service registries or services that support the Web Services Policy (WS-Policy) specification and the WS-MetadataExchange GetMetadata request.

When **WS-MetadataExchange** is selected, the **Attach a system policy set to the WS-MetadataExchange** option is available.

*Attach a system policy set to the WS-MetadataExchange:*

Select **Attach a system policy set to the WS-MetadataExchange** to set message-level security for the WS-MetadataExchange request. By default, this option is not selected and the transport policy of the application is used. This option is available only when **WS-MetadataExchange** is selected.

When **Attach a system policy set to the WS-MetadataExchange** is selected, the **Policy set** and **Binding** lists are available.

*Policy set:*

Select the policy set you require from the list to provide message-level security for the WS-MetadataExchange request. You can select from system policy sets that contain only WS-Security policies, only WS-Addressing policies, or both. The default policy set is SystemWSSecurityDefault.

System policy sets are used for system messages that are not business-related, for example, messages that apply qualities of service (QoS), including the messages that are defined in the WS-MetadataExchange protocol.

Note that any transport policy of the application is always used.

This option is available only when **Attach a system policy set to the WS-MetadataExchange** is selected.

*Binding:*

Select the binding you require from the list to provide message-level security for the WS-MetadataExchange request. You can select from general bindings that are scoped to the global domain, or scoped to the security domain of this service.

This option is available only when **Attach a system policy set to the WS-MetadataExchange** is selected.

## Configuring the client policy to use a service provider policy

An application that is a web service client can obtain the policy configuration of a web service provider and use this information to establish a policy configuration that is acceptable to both the client and the service provider.

### Before you begin

You have developed a web service client that contains all the necessary artifacts, and deployed your web services application into your application server instance. If you require them, you have attached the policy sets and managed the associated bindings.

The service provider must publish its policy in its Web Services Description Language (WSDL) and that policy must contain its policy configuration at run time in WS-PolicyAttachments format. The client must be able to support those provider policies.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the WS-Policy topic.

### About this task

You can administer the client to configure itself dynamically at run time, based on the policy of the service provider in the standard WS-PolicyAttachments format. You can administer the client to apply dynamically the provider policy at the application or service or service reference level. By default, endpoints and operations inherit their policy configuration from the relevant service. However, it is possible to configure a service reference to override the service, in which case the endpoints and operations inherit their policy configuration from the service reference.

If the provider policy uses multipart WSDL, you can use an HTTP GET request to obtain the policy of the provider, but you cannot use the WS-MetadataExchange protocol. For more information about multipart WSDL, see the topic about WSDL.

Policy intersection is the comparison of a client policy and a provider policy to determine whether they are compatible, and the calculation of a new policy, known as the effective policy, that complies with both their requirements and capabilities.

This topic describes how to configure the client policy to use a service provider policy by using the administrative console. You can also configure the client policy to use a service provider policy by using wsadmin commands.

## Procedure

1. From the navigation panel of the administrative console, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***service_client_application_instance*** > **[Web services properties] Service client policy sets and bindings**.
2. In the row for the application or service where you want to apply the policy, click the link in the Policies Applied column. The Policies Applied panel is displayed.
3. Select one of the following options from the drop-down list:
   - Provider policy only. Configure the client based solely on the policy of the service provider. This option is available when a client policy set is not attached.
   - Client and provider policy. Configure the client based on both the client policy set and the policy of the service provider. This option is available when a client policy set is attached.

   The other options in the list do not apply to this task.
4. Use the radio buttons to select which method to employ to obtain the provider policy: an HTTP GET request (see step 5) or a WS-MetadataExchange request (see step 6).
5. Optional: To obtain the provider policy by using an HTTP GET request, click **HTTP GET request**. By default, the HTTP GET request is targeted at the URL for the service endpoint followed by `?WSDL`. For example:

```
http://myhost:9080/WSSampleSei/EchoService?WSDL
```

   When the policy set attach point is at the application level you cannot change this value.
   a. Optional: If you are applying a policy to a service and the provider policy is located at the service endpoint, ensure that **Use the default request target** is selected.
   b. Optional: If you are applying a policy to a service and the provider policy is not located at the service endpoint, click **Specify request target**, then enter the URL for the location of the provider policy in the field. For example, you might change the target of the HTTP GET request if the provider policy is located in a repository.
   c. Optional: If you select **HTTP GET request** as the method to be used to obtain the provider policy and if you select **Specify request target** and you want to configure transport-level security, select **Attach a system policy set to the HTTP GET request**, then select a suitable policy set and binding from the drop-down lists. Select the policy set you require from the Policy set list to provide transport-level security for the HTTP GET request. Select from system policy sets that contain solely HTTP transport policies, solely SSL transport policies, or both; the policy set cannot contain other policy types. Select the binding you require from the Binding list for the HTTP GET request. You can select from general bindings that are scoped to the global domain or scoped to the security domain of this service.
6. Optional: To obtain the provider policy by using a Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request, click **WS-MetadataExchange request**.
   a. Optional: If you select **WS-MetadataExchange request** and want to use message-level security, select **Attach a system policy set to the WS-MetadataExchange request**, then select a suitable policy set and binding from the drop-down lists. See Configuring security for a WS-MetadataExchange request.
7. Click **OK**.
8. Save your changes to the master configuration.

## Results

The web application client-side policy is calculated when it is required at run time, based either on the policy of the service provider, or on the client policy set and the policy of the service provider, depending on which option you selected. This calculated policy is known as the “effective policy” and is cached as a runtime configuration. The effective policy is used for subsequent outbound web service requests to the endpoint or operation for which the dynamic policy calculation was performed. The policy set configuration of the client does not change.

The provider policy that the client holds for a service is refreshed the first time that the web service is invoked after the application is loaded. After that, the provider policy is refreshed when the application restarts, or if the application explicitly invokes a refresh. When the provider policy is refreshed, the effective policy is recalculated.

***Configuring the client policy to use a service provider policy by using wsadmin scripting:***

An application that is a web service client can obtain the policy configuration of a web service provider and use this information to establish a policy configuration that is acceptable to both the client and the service provider.

**Before you begin**

You have developed a web service client that contains all the necessary artifacts, and deployed your web services application into your application server instance. If you require them, you have attached the policy sets and managed the associated bindings.

The service provider must publish its policy in its Web Services Description Language (WSDL) and that policy must contain its policy configuration at run time in WS-PolicyAttachments format. The client must be able to support those provider policies.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the WS-Policy topic.

**About this task**

You can administer the client to configure itself dynamically at run time, based on the policy of the service provider in the standard WS-PolicyAttachments format. You can administer the client to dynamically apply the provider policy at the application or service or service reference level.

**Note:** If you specify client dynamic policy control at the service reference level, you must use the new name-value paired list format of the resource string. If you are not specifying client dynamic policy control at service reference level, you can use either format.

*Table 230. How to specify policy control at different levels of the application. For each applicable level of the application, the table lists the relevant string format command and name-value pair format command needed to specify policy control and summarizes the associated behavior.*

| Level | String format | Name-value pair list format (NEW) | Behavior |
|---|---|---|---|
| Type | "WebService:/" | "type=WebService:/" | Indicates all artifacts in the application |
| Service | "WebService:/*myModule*:{*namespace*}*myService*" | "type=WebService:/,module=*myModule*,service={*namespace*}*myService*" | Indicates all artifacts within the web service |
| Endpoint (under this service) | "WebService:/*myModule*:{*namespace*}*myService*/*endpointA*" | "type=WebService:/ ,module=*myModule*,service={*namespace*}*myService*,endpoint=*endpointA*" | Indicates all operations for this endpoint (under the service) |
| Operation (under this service) | "WebService:/*myModule*:{*namespace*}*myService*/*endpointA*/*operation1*" | "type=WebService:/ ,module=*myModule*,service={*namespace*}*myService*,endpoint=*endpointA*, operation=*operation1*" | Indicates a specific single operation (under the service) |
| Service reference | [Not possible] | "type=WebService:/ ,module=*myModule*,service={*namespace*}*myService*,serviceRef=*myServiceRef*" | Indicates all artifacts within the web service reference |
| Endpoint (under this service reference) | [Not possible] | "type=WebService:/ ,module=*myModule*,service={*namespace*}*myService*,serviceRef=*myServiceRef*, endpoint=*endpointA*" | Indicates all operations for this endpoint (under the service reference) |
| Operation (under this service reference) | [Not possible] | "type=WebService:/ ,module=*myModule*,service={*namespace*}*myService*,serviceRef=*myServiceRef*, endpoint=*endpointA*,operation=*operation1*" | Indicates a specific single operation (under the service reference) |

If the provider policy uses multipart WSDL, you can use an HTTP GET request to obtain the policy of the provider, but you cannot use the WS-MetadataExchange protocol. For more information about multipart WSDL, see the topic about WSDL.

Policy intersection is the comparison of a client policy and a provider policy to determine whether they are compatible, and the calculation of a new policy, known as the effective policy, that complies with both their requirements and capabilities.

This topic describes how to configure the client policy to use a service provider policy by using wsadmin commands. You can also configure the client policy to use a service provider policy by using the administrative console.

**Procedure**

1. Start the wsadmin scripting client if it is not already running.
2. Use the SetClientDynamicPolicyControl command. For example:

```
AdminTask.setClientDynamicPolicyControl('[-applicationName WebServiceClientApplication
-resource WebService:/ClientApplication.war:{http://example_path/}Service1
-acquireProviderPolicyMethod [httpGet ]
-httpGetProperties [httpGetTargetURI http://example_path]]')
```

3. Save your changes to the master configuration.

   To save your configuration changes, enter the following command:

```
AdminConfig.save()
```

**Results**

The web application client-side policy is calculated when it is required at run time, based either on the policy of the service provider, or on the client policy set and the policy of the service provider, depending on which option you selected. This calculated policy is known as the “effective policy” and is cached as a runtime configuration. The effective policy is used for subsequent outbound web service requests to the endpoint or operation for which the dynamic policy calculation was performed. The policy set configuration of the client does not change.

The provider policy that the client holds for a service is refreshed the first time that the web service is invoked after the application is loaded. After that, the provider policy is refreshed when the application restarts, or if the application explicitly invokes a refresh. When the provider policy is refreshed, the effective policy is recalculated.

***Configuring the client policy to use a service provider policy from a registry:***

An application that is a web service client can obtain the policy configuration of a web service provider from a registry, such as WebSphere Service Registry and Repository (WSRR), and use this information to establish a policy configuration that is acceptable to both the client and the service provider.

**Before you begin**

You have developed a web service client that contains all the necessary artifacts, and deployed your web services application into your application server instance. If you require them, you have attached the policy sets and managed the associated bindings.

The Web Services Description Language (WSDL) for the policy of the service provider, and its corresponding policies and policy attachments, are stored in a registry such as WSRR. That policy must contain its policy configuration in WS-PolicyAttachments format. The client must be able to support those provider policies.

The registry must support the use of HTTP GET requests to publish WSDL that contains WS-Policy attachments, for example WSRR Version 6.2 or later.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the WS-Policy topic.

### About this task

You can administer the client to configure itself dynamically at run time, based on the policy of a service provider that is held in a registry. You can administer the client at the service or service reference level to dynamically apply the provider policy that it obtains from a registry. By default, endpoints and operations inherit their policy configuration from the relevant service. However, it is possible to configure a service reference to override the service, in which case the endpoints and operations inherit their policy configuration from the service reference. You cannot administer the client to apply dynamically the provider policy that it obtains from a registry at the application level.

You can configure the client policy to use a service provider policy that is stored in a registry by using the administrative console. You can also configure the client policy to use a service provider policy that is stored in a registry by using wsadmin commands.

### Procedure

1. From the navigation pane of the administrative console, click **Applications** > **Application Types** > **WebSphere enterprise applications**.
2. Click the web service client application that you want to configure.
3. Click **[Web services properties] Service client policy sets and bindings**.
4. In the row for the service where you want to apply the policy, click the link in the Policies Applied column. You cannot apply the policy at application level. The Policies Applied pane is displayed.
5. Select one of the following options from the drop-down list:
   - Provider policy only. Configure the client based solely on the policy of the service provider. This option is available when a client policy set is not attached.
   - Client and provider policy. Configure the client based on both the client policy set and the policy of the service provider. This option is available when a client policy set is attached.

   The other options in the list do not apply to this task.
6. Click **HTTP GET request**.
7. Click **Specify request target**, then enter the URL for the location of the provider policy in the field, that is, the address in the repository for the WSDL and policy. For information about using WSRR to retrieve a WSDL document with embedded policies, and therefore obtain the required URL, see the WSRR documentation. The following example shows a typical URL:

```
https://www.wsrr.host/WSRR/6.2/PolicyService/
WSDL?bsrURI=3b9b493b-278f-4f64.ba3f.dabd30da3f7e
```

8. Click **OK**.
9. Optional: If there is a secure connection that uses the Secure Sockets Layer (SSL) protocol between the client and the registry, ensure that trust is established between the application server and the registry server. To access the registry, the client uses the SSL transport policy that is part of its service-level application policy. For example, for WSRR, you can enter the URL for the WSRR server in a browser window. If the WSRR server is not already trusted, a message is displayed stating that the security certificate is not trusted. To establish trust, use the following steps:
   a. Retrieve and store the X509 certificate from the WSRR server. Use the options on the message to view details of the certificate and save those details to a file, using distinguished encoding rules (DER) encoded binary format.
   b. Find out the key store that the client uses, that is, the key store that is shown by the SSL security transport bindings of the client application policy set. See Configuring the SSL transport policy. For example, the key store might be the default trust store for the node.
   c. Add the signer certificate that you saved in step a. to the key store that the client uses. See Adding a signer certificate to a keystore.
10. Optional: To access the registry, the client uses the transport policy that is part of its service-level application policy. If the registry requires authentication using the HTTP protocol, configure a valid

user name and password as part of the application-level transport policy binding configuration. It is advisable to secure any authorization credentials, because they are used for interactions with both the web service endpoint and the registry.

a. Ensure that the client has a policy set that contains the HTTP transport policy attached to the application or service level. See the relevant steps in Managing policy sets and bindings for service clients at the application level using the administrative console .
b. Configure the HTTP transport client bindings for the binding named Client sample and enter the user name and password that the registry requires to authenticate outbound service requests. See the relevant steps in Configuring the HTTP transport policy.

11. Save your changes to the master configuration.

**Results**

The web application client-side policy is calculated when it is required at run time, based either on the policy of the service provider, or on the client policy set and the policy of the service provider, depending on which option you selected. This calculated policy is known as the “effective policy” and is cached as a runtime configuration. The effective policy is used for subsequent outbound web service requests to the endpoint or operation for which the dynamic policy calculation was performed. The policy set configuration of the client does not change.

The provider policy that the client holds for a service is refreshed the first time that the web service is invoked after the application is loaded. After that, the provider policy is refreshed when the application restarts, or if the application explicitly invokes a refresh. When the provider policy is refreshed, the effective policy is recalculated.

***Policies applied settings:***

Use this panel to view and change whether the policy configuration of a WebSphere Application Server service client is configured dynamically, based on the policies supported by its service provider. You can view or change how the client obtains the policy of the service provider; the client can use an HTTP GET request or a Web Services Metadata Exchange (WS-MetadataExchange) request. You can specify a policy set and binding to provide message-level security for WS-MetadataExchange requests or to specify HTTP transport and SSL transport configuration for HTTP GET requests.

To view this administrative console page for an application or service, complete the following steps. The application must be a web services service client.

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***service_client_application_name*** > **[Web Services Properties] Service client policy sets and bindings**.
2. Select the link in the **Policies Applied** column for the application or service you require.

To view this administrative console page for a service, complete the following steps:

1. Click **Services** > **Service clients** > ***service_name***.
2. Select the link in the **Policies Applied** column for the service. The link is available if the service or the parent application has a policy set attached.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

*Apply the following policies:*

Specifies whether the client policy is based on the policy of the service provider, and how that policy is used.

Select from the following options:

- Client policy only. Configure the client based solely on the client policy set. Do not use the policy of the service provider. This option is available when a client policy set is attached to the resource.
- Client and provider policy. Configure the client based on both the client policy set and the policy of the service provider. This option is available when a client policy set is attached to the resource.
- Inherit application attachment. Inherit the setting of the parent application. This option is available for a service when a client policy set is not attached to the service. If there is a policy set attached to the parent application, the inherited properties are displayed on this panel, but you cannot change them. If there is no policy set attached to the parent application, when you return to the Service clients policy sets and bindings panel, the Policies applied column shows a value of **None**.
- Provider policy only. Configure the client based solely on the policy of the service provider. This option is available when a client policy set is not attached to the resource.

*HTTP GET request:*

Click **HTTP GET request** to obtain the policy of the service provider by using an HTTP GET request. The policy configuration must be in WS-PolicyAttachments format in the WSDL of the service provider.

This option is available when **Apply the following policies** is set to Client and provider policy or Provider policy only.

By default, the HTTP GET request is targeted at the URL for each service endpoint followed by ?WSDL.

*Use the default request target:*

When you apply a policy to a service, click **Use the default request target** to target the HTTP GET request at the URL for each service endpoint followed by ?WSDL.

If the attach point is for the service, then you can either select this default request target or you can choose to specify an alternative request target using the **Specify request target** option.

If the attach point is for the application then the default request target will be used.

*Specify request target:*

When you apply a policy to a service, click **Specify request target** to change the target for acquiring provider policy using an HTTP GET request. Enter the URL for the location of the provider policy in the field.

This option is available when **HTTP GET request** is selected and you apply a policy to a service.

When you apply a policy to an application, this option is not available.

*Attach a system policy set to the HTTP GET request:*

Select **Attach a system policy set to the HTTP GET request** to set HTTP transport and SSL transport configuration for the HTTP GET request. This option is available when **HTTP GET request** is selected as the method to be used to obtain the provider policy and when **Specify request target** is selected and completed.

If you do not specify a policy set you will inherit the HTTP transport and SSL transport configuration from the application.

*Policy set (for the HTTP GET request):*

Select the policy set you require from the list to provide HTTP transport and SSL transport configuration for the HTTP GET request. Select from system policy sets that contain solely HTTP transport policies, solely SSL transport policies, or both; the policy set cannot contain other policy types.

This option is available when **Attach a system policy set to the HTTP GET request** is selected and the **Specify request target** is selected and completed.

*Binding (for the HTTP GET request):*

Select the binding you require from the list for the HTTP GET request. You can select from **Global Default Bindings** or **General client/provider policy set bindings**, which are specific to the individual service.

This option is available when **Attach a system policy set to the HTTP GET request** is selected and the **Specify request target** is selected and completed.

The value of **Default** will result in the Global Default Binding being used.

*WS-MetadataExchange request:*

Click **WS-MetadataExchange** to obtain the policy of the service provider by using a WS-MetadataExchange GetMetadata request. The policy configuration must be in WS-PolicyAttachments format in the WSDL of the service provider.

This option is available when **Apply the following policies** is set to Client and provider policy or Provider policy only.

*Attach a system policy set to the WS-MetadataExchange request:*

Select **Attach a system policy set to the WS-MetadataExchange request** to set message-level security for the WS-MetadataExchange request. By default, this option is not selected and the transport policy of the application is used. This option is available when **WS-MetadataExchange request** is selected.

When **Attach a system policy set to the WS-MetadataExchange request** is selected, the **Policy set** and **Binding** lists are available. If you select **Attach a system policy set to the WS-MetadataExchange request**, you must also select a policy set and a binding.

*Policy set (for the WS-MetadataExchange request):*

Select the policy set you require from the list to provide message-level security for the WS-MetadataExchange request. You can select from system policy sets that contain only WS-Security policies, only WS-Addressing policies, or both. The default policy set is SystemWSSecurityDefault.

System policy sets are used for system messages that are not business-related, for example, messages that apply qualities of service (QoS), including the messages that are defined in the WS-MetadataExchange protocol.

Note that any transport policy of the application is always used.

This option is available when **Attach a system policy set to the WS-MetadataExchange** is selected.

*Binding (for the WS-MetadataExchange request):*

Select the binding you require from the list to provide message level security for the WS-MetadataExchange request. You can select from **Global Default Bindings** or **General client/provider policy set bindings**, which are specific to the individual service.

This option is available when **Attach a system policy set to the WS-MetadataExchange** is selected.

The value of **Default** will result in the Global Default Binding being used.

# Enabling Web Services Addressing support for JAX-WS applications using deployment descriptors

For JAX-WS applications, you can enable WS-Addressing support during the packaging of either a service or client application, by editing the deployment descriptor for that application.

## About this task

To modify WS-Addressing behavior by using deployment descriptors, add an <addressing> element to the deployment descriptor file for the application. The <addressing> element has optional child elements as described in the following table.

The <addressing> element functions in the same way as the Addressing annotation. The child elements of the <addressing> annotation function in the same way as the parameters of the Addressing annotation.

*Table 231. Child elements of the addressing deployment descriptor element. The table lists the different child elements with their possible values and a description of each one.*

| Element name | Possible values | Description |
|---|---|---|
| enabled | true (default)<br>false | Whether WS-Addressing support is enabled. |
| required | true<br>false (default) | Whether WS-Addressing headers are required. |
| responses | All (default)<br>ANONYMOUS<br>NON_ANONYMOUS | Whether to use a synchronous or an asynchronous message exchange pattern. Specify ANONYMOUS to send messages in a synchronous message pattern; use NON_ANONYMOUS to send messages in an asynchronous message exchange pattern. |

## Procedure

- To modify the behavior of the WS-Addressing support in the service application, add the <addressing> element, and optional child elements as required, to the service deployment descriptor under the <port-component> element within the <webservice-description> element. In the following example, the Addressing deployment descriptor fragment specifies that WS-Addressing is enabled and required, and that the asynchronous message exchange pattern is used.

```
<port-component>
     <port-component-name>MyPort1</port-component-name>
        <addressing>
         <enabled>true</enabled>
         <required>true</required>
         <responses>NON_ANONYMOUS</responses>
        </addressing>
        <service-impl-bean>
           <servlet-link>MyPort1ImplBean</servlet-link>
        </service-impl-bean>
</port-component>
```

- To modify the behavior of the WS-Addressing support in the client application, add the <addressing> element, and optional child elements as required, to the client deployment descriptor under the <port-component-ref> element within the <service-ref> element. For example, the following deployment descriptor fragment indicates that WS-Addressing is enabled:

```
<service-ref>
        <service-ref-name>service/MyPortComponentRef</service-ref-name>
        <service-interface>com.example.MyService</service-ref-interface>
        <port-component-ref>
           <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
           <addressing>
              <enabled>true</enabled>
           </addressing>
        </port-component-ref>
</service-ref>
```

## Results

WS-Addressing properties are now included in the SOAP message header, and are processed by the server on receipt of the message.

# Enabling Web Services Addressing support for JAX-WS applications using addressing annotations

For JAX-WS applications, you can enable WS-Addressing support during development of a service application, by using addressing annotations in the code. You can also use this method in a client application that uses an injected web service proxy reference.

## About this task

Use one of the following addressing annotations in your service code:

- Addressing - use this annotation if you want to use the 2005/08 WS-Addressing specification.
- SubmissionAddressing - use this annotation if you want to use the 2004/08 WS-Addressing specification.

On clients, use the Addressing annotation only; the SubmissionAddressing annotation is not supported. You must specify the Addressing annotation in combination with the WebServiceRef annotation. The WebServiceRef annotation specifies a reference to the web service proxy that is injected by the client container.

Annotation settings override settings in the WSDL document. Annotation settings might differ from WSDL settings if you create the WSDL document manually rather than generating it from the code.

Specify up to three optional parameters for each annotation:

*Table 232. Parameters for the addressing annotations. The table lists the different parameters with their possible values and a description of each one.*

| Parameter name | Possible values | Description |
|---|---|---|
| `enabled` | `true` (default)<br>`false` | Whether WS-Addressing support is enabled. |
| `required` | `true`<br>`false` (default) | Whether WS-Addressing headers are required. |
| `responses` | `Responses.All` (default)<br>`Responses.ANONYMOUS`<br>`Responses.NON_ANONYMOUS` | Whether to use a synchronous or an asynchronous message exchange pattern. Specify `Responses.ANONYMOUS` to send messages in a synchronous message pattern; use `Responses.NON_ANONYMOUS` to send messages in an asynchronous message exchange pattern. **Note:** This parameter is not supported on the SubmissionAddressing annotation. |

**Note:** You can use the Addressing annotation only with a SOAP (1.1 or 1.2) over HTTP binding. If you use the class with another binding, such as XML over HTTP, an exception is thrown on clients, and on servers the web service fails to deploy.

## Procedure

- To modify the behavior of the WS-Addressing support programmatically in the service application, use one of the addressing annotations, with optional parameters as required, in the code. In the following example, the Addressing annotation is used with no parameters, so the default settings apply.

```
import javax.xml.ws.soap.Addressing;

@Addressing
@WebService(endpointInterface =
   "org.apache.axis2.jaxws.calculator.Calculator",
   serviceName = "CalculatorService",
   portName = "CalculatorServicePort",
   targetNamespace = "http://calculator.jaxws.axis2.apache.org")
```

In the following example, the SubmissionAddressing annotation is used with parameters that specify that WS-Addressing is enabled and required. The `responses` attribute is not supported on this annotation.

```
import com.ibm.websphere.wsaddressing.jaxws21.SubmissionAddressing;

@SubmissionAddressing(enabled=true, required=true)
@WebService(endpointInterface =
   "org.apache.axis2.jaxws.calculator.Calculator",
   serviceName = "CalculatorService",
   portName = "CalculatorServicePort",
   targetNamespace = "http://calculator.jaxws.axis2.apache.org")
```

- To enable WS-Addressing support on clients that use an injected web service proxy reference, use the Addressing annotation, with optional parameters as required, in combination with the WebServiceRef annotation. The SubmissionAddressing annotation is not supported for this method.

  For example, the following code fragment specifies that WS-Addressing is enabled and that the synchronous message exchange pattern is used:

```
public class MyClientApplication {

            // Enable Addressing for a port-component-ref resource injection.
            @Addressing(enabled=true, responses=Responses.ANONYMOUS)
            @WebServiceRef(MyService.class)
            private MyPortType myPort;
            ...
       }
```

## Results

If you use an addressing annotation in the service application, the server processes any WS-Addressing headers that conform to the relevant specification in inbound SOAP messages. If you specify that WS-Addressing is required, and an inbound SOAP message does not include any WS-Addressing headers, or includes WS-Addressing headers that do not conform to the specification indicated by the annotation, the server returns a fault message. For example, if a client sends a message that includes 2004/08 WS-Addressing headers, and the server requires 2005/08 headers, the server returns a fault message.

If you use the Addressing annotation and generate a WSDL document from the code, a UsingAddressing element and WS-Policy assertions are created in the WSDL document. Clients that use this WSDL document will include WS-Addressing information in their messages. The SubmissionAddressing annotation is not understood by current WSDL generation tools. However, the WSDL document does not distinguish between the 2005/08 specification and the 2004/08 specification, so if you want to generate a WSDL document from code that contains a SubmissionAddressing annotation, use both the Addressing and SubmissionAddressing annotations together.

If you specify the responses attribute, the corresponding message exchange pattern will be used.

# Enabling Web Services Addressing support for JAX-WS applications using addressing features

For JAX-WS applications, you can enable WS-Addressing support during development of a client application, by using addressing features in the code.

## About this task

Use one of the following addressing feature classes in your client code:

- AddressingFeature - use this class if you want to send messages that include WS-Addressing headers that conform to the 2005/08 WS-Addressing specification
- SubmissionAddressingFeature - use this class if you want to send messages that include WS-Addressing headers that conform to the 2004/08 WS-Addressing specification

If you use both feature classes, the specification that is used depends on the type of endpoint reference that you also specify. For example, if you specify a W3CEndpointReference object, the specification that is

used is the 2005/08 specification. If you specify an endpoint reference whose type conflicts with that indicated by the feature class, for example a W3CEndpointReference object with a SubmissionAddressingFeature instance, an error is thrown. If you do not specify an endpoint reference, the default specification is the 2005/08 specification.

Specify up to three optional parameters for each addressing feature instance:

*Table 233. Parameters for the addressing features. The table lists the different addressing feature parameters as well as their possible values and a description of each one.*

| Parameter name | Possible values | Description |
|---|---|---|
| `enabled` | `true` (default)<br>`false` | Whether WS-Addressing support is enabled. |
| `required` | `true`<br>`false` (default) | Whether WS-Addressing headers are required. |
| `responses` | `Responses.All` (default)<br>`Responses.ANONYMOUS`<br>`Responses.NON_ANONYMOUS` | Whether to use a synchronous or an asynchronous message exchange pattern. Specify Responses.ANONYMOUS to send messages in a synchronous message pattern; use Responses.NON_ANONYMOUS to send messages in an asynchronous message exchange pattern.<br>**Note:** This parameter is not supported for the SubmissionAddressingFeature class. |

**Note:** You can use the addressing feature classes only with a SOAP (1.1 or 1.2) over HTTP binding. If you use the class with another binding, such as XML over HTTP, an exception is thrown on clients, and on servers the web service fails to deploy.

### Procedure

Create an instance of one of the addressing feature classes, with parameters as required. For example, to specify that WS-Addressing is enabled and required, and that the 2005/08 specification and the asynchronous message exchange pattern is used, use the following code:

```
AddressingFeature feat = new AddressingFeature(true, true, AddressingFeature.Responses.NON_ANONYMOUS);
```

To specify that WS-Addressing is disabled for the 2004/08 specification, use the following code:

```
SubmissionAddressingFeature feat = new SubmissionAddressingFeature(false);
```

### Results

If you specify that WS-Addressing is enabled, the client includes WS-Addressing headers in SOAP messages. The headers conform to the WS-Addressing specification indicated by the type of feature class used. If the server does not use annotations, or uses policy sets to enable WS-Addressing, the server accepts both the 2005/08 and 2004/08 specifications.

If you specify that WS-Addressing is required and the client receives a message that does not include WS-Addressing headers, the client returns a fault.

If you specify the responses attribute, the corresponding message exchange pattern will be used.

## Enabling Web Services Addressing support for JAX-WS applications using WS-Policy

For JAX-WS applications, you can enable WS-Addressing support during the development of a client or service application by adding WS-Policy assertions into the WSDL document.

## About this task

The JAX-WS 2.2 specification introduces functionality that enables WS-Policy assertions in the application WSDL document to be mapped to and from Java annotations in the code.

There are several ways of enabling WS-Addressing support for JAX-WS applications. The method of using WS-Policy will be effective unless it is overridden by another method with greater precedence, such as if you are using AddressingFeature classes or using Addressing annotations. See the parent topic: Enabling Web Services Addressing support for JAX-WS applications for full details about the order of precedence used by WebSphere Application Server.

**Note:** WebSphere Application Server version 8 supports the JAX-WS 2.2 specification. One of the differences between the JAX-WS 2.1 and JAX-WS 2.2 specifications is that whereas the presence of WS-Policy in an application's WSDL was formerly ignored, if WS-Addressing support is defined within the WS-Policy, this will now be used by WebSphere Application Server in the configuration of the application. As the presence of WS-Policy in an application's WSDL is now checked for WS-Addressing configuration, you may notice a change in behavior in applications formerly run in previous versions of WebSphere Application Server.

If you add an Addressing annotation to your provider code and use the wsgen command-line tool to generate the WSDL document, it will contain WS-Policy assertions specifying the WS-Addressing support. However, if you are looking at the published WSDL document for the provider service, it is possible that policy defined in policy sets is showing, as this would overwrite any annotations defined in the code.

If you are using an existing WSDL document to create Java code, when WebSphere Application Server reads the WSDL, if any WS-Policy assertions specifying WS-Addressing support are present, the generated Java code will contain Addressing annotations.

## Procedure

- To enable WS-Addressing support on clients, use WS-Policy assertions in the code, with optional attributes as required. The `wsam:Addressing` assertion indicates that WS-Addressing is required. If you want to indicate that WS-Addressing is supported but not mandatory, add the `wsp:Optional` attribute. In the following example, WS-Addressing is supported, but is not mandatory and the messaging format to use has not been specified.

```
<wsp:Policy>
    <wsam:Addressing wsp:Optional="true">
        <wsp:Policy/>
    </wsam:Addressing>
</wsp:Policy>
```

  This example is equivalent to the policy set configuration of WS-Addressing being set to non-mandatory and the messaging style being set to synchronous and asynchronous.
- To specify the message exchange pattern to be employed, use the `wsam:AnonymousResponses` assertion for synchronous message exchanges and the `wsam:NonAnonymousResponses` assertion for asynchronous message exchanges. In the following example, WS-Addressing support is set as mandatory and a synchronous message exchange pattern has been specified.

```
<wsp:Policy>
    <wsam:Addressing>
        <wsp:Policy>
            <wsam:AnonymousResponses/>
        </wsp:Policy>
    </wsam:Addressing>
</wsp:Policy>
```

  This example is equivalent to the policy set configuration of WS-Addressing being set to required and the messaging style being set to synchronous only.

  For more information, see the Web Services Addressing 1.0 - Metadata specification document.

### Results

If you add WS-Addressing annotations to the application code specifying that WS-Addressing is enabled, when you generate the WSDL it will contain WS-Policy assertions.

When WS-Policy assertions specifying WS-Addressing support are included in the WSDL, WS-Addressing headers are included in the generated SOAP messages.

If you specify that WS-Addressing is required and an inbound SOAP message is received that does not include any WS-Addressing headers, an exception occurs.

## Web Services Addressing annotations

The WS-Addressing specification provides transport-neutral mechanisms to address web services and to facilitate end-to-end addressing. If you have a JAX-WS application you can use Java annotations in your code to specify WS-Addressing behavior at run time.

You can use WS-Addressing annotations to enable WS-Addressing support, to specify whether WS-Addressing information is required in incoming messages, to control the message exchange pattern the service supports, and to specify actions to be associated with a web service operation or fault response.

The following WS-Addressing annotations are supported in WebSphere Application Server. These annotations are defined in the JAX-WS 2.2 specification unless otherwise stated. The JAX-WS 2.2 specification supersedes and includes functions within the JAX-WS 2.1 specification. See the Java API for XML-Based Web Services 2.2 specification for full details.

**javax.xml.ws.Action**

Specifies the action that is associated with a web service operation.

- When following a bottom-up approach to developing JAX-WS web services, you can generate a WSDL document from Java application code using the wsgen command-line tool. However, for this attribute to be added to the WSDL operation, you must also specify the @Addressing annotation on the implementation class. The result in the generated WSDL document is that the Action annotations will have the `wsam:Action` attribute on the `input message` and `output message` elements of the `wsdl:operation`. Alternatively, if you do not want to use the @Addressing annotation you can supply your own WSDL document with the Action attribute already defined.
- When following a top-down approach to developing JAX-WS web services, you can generate Java application code from an existing WSDL document using the wsimport command-line tool. In such cases, the resulting Java code will contain the correct Action and FaultAction annotations.

If this action is not specified in either code annotations or in the WSDL document, the default action pattern as defined in the Web Services Addressing 1.0 Metadata specification is used. Refer to this specification for full details.

**Note:** Whilst the WebSphere Application Server runtime environment supports the deprecated `wsaw:Action` attribute, if you try to generate Java code from an old WSDL document containing the deprecated `wsaw:Action` attribute, this attribute will be ignored.

**javax.xml.ws.FaultAction**

Specifies the action that is added to a fault response. When you use this annotation with a particular method, the WS-Addressing FaultAction extension attribute is added to the fault element of the WSDL operation that corresponds to that method. For this attribute to be added to the WSDL operation, you must also specify the Addressing annotation on the implementation class. If you do not want to use the Addressing annotation you can supply your own WSDL document with the Action attribute already defined. This annotation must be contained within an Action annotation.

WSDL documents generated from Java application code containing the WS-Addressing FaultAction annotation will have the `wsam:Action` attribute on the `fault message` element of the `wsdl:operation`.

**Note:** To ensure that any custom Exception classes you write are successfully mapped to the generated WSDL document, extend the java.lang.Exception class instead of the java.lang.RuntimeException class.

**javax.xml.ws.soap.Addressing**
Specifies that this service is to enable WS-Addressing support. You can use this annotation only on the service implementation bean; you cannot use it on the service endpoint interface.

**com.ibm.websphere.wsaddressing.jaxws21.SubmissionAddressing**
This annotation is part of the IBM implementation of the JAX-WS specification. This annotation specifies that this service is to enable WS-Addressing support for the 2004/08 WS-Addressing specification. You can use this annotation only on the service implementation bean; you cannot use it on the service endpoint interface.

For more information about the Addressing and SubmissionAddressing annotations, including code examples, see Enabling Web Services Addressing support for JAX-WS applications using addressing annotations.

The following example code uses the Action annotation to define the invoke operation to be invoked (input), and the action that is added to the response message (output). The example also uses the FaultAction annotation to specify the action that is added to a response message if a fault occurs:

```
@WebService(name = "Calculator")
public interface Calculator {
   ...
    @Action(
      input="http://calculator.com/inputAction",
      output="http://calculator.com/outputAction",
      fault = { @FaultAction(className=AddNumbersException.class,
                value="http://calculator.com/faultAction")
      }
   )
   public int add(int value1, int value2) throws AddNumbersException {
      return value1 + value2;
   }
}
```

If you use a tool to generate service artifacts from code, the WSDL tags that are generated from the preceding example are as follows:

```
<definitions targetNamespace="http://example.com/numbers" ...>
   ...
   <portType name="AddPortType">
      <operation name="Add">
         <input message="tns:AddInput" name="Parameters"
                        wsam:Action="http://calculator.com/inputAction"/>
         <output message="tns:AddOutput" name="Result"
                         wsam:Action="http://calculator.com/outputAction"/>
         <fault message="tns:AddNumbersException" name="AddNumbersException"
                         wsam:Action="http://calculator.com/faultAction"/>
      </operation>
    <portType>
     ...
<definitions>
```

## Web Services Addressing security

It is essential that communications that use Web Services Addressing (WS-Addressing) are adequately secured and that a sufficient level of trust is established between the communicating parties. You can achieve secure communications through the signing of WS-Addressing message-addressing properties and the encryption of endpoint references.

Undertake these actions for both the supported addressing namespaces, http://www.w3.org/2005/08/addressing and http://schemas.xmlsoap.org/ws/2004/08/addressing, even if you intend to use only one of those namespaces.

### Signing of WS-Addressing message-addressing properties

You can use an assembly tool to specify the message-addressing properties, and therefore the WS-Addressing message elements, that require signing, or that require signature verification on inbound requests. The receiver of the message might rely on the presence of this verifiable signature to determine that the outbound message originated from a trusted source. Similarly, the lack of a verifiable signature that is associated with the specified inbound message addressing properties causes the rejection of the message with a SOAP fault.

### Encryption of endpoint references

You can encrypt endpoint references as part of the SOAP header or SOAP body. Alternatively, you can remove the need for encryption by not including sensitive information in the address or reference parameters properties of the endpoint reference.

### Use of the synchronous message exchange pattern

This method applies to JAX-WS applications only.

If you do not secure the WS-Addressing information in the SOAP message by using one or more of the previous methods, and you do not have WS-Security enabled, the ReplyTo and FaultTo elements of the SOAP message could be used to send messages to a third party, potentially taking part in a Denial of Service attack. To prevent such attacks, apply a WS-Addressing policy type and configure it to specify synchronous messaging only. You should also enable WS-Policy so that this requirement is communicated to clients.

## Invoking JAX-WS web services asynchronously

Java API for XML-Based Web Services (JAX-WS) provides support for invoking web services using an asynchronous client invocation. JAX-WS provides support for both a callback and polling model when calling web services asynchronously. Both the callback model and the polling model are available on the Dispatch client and the Dynamic Proxy client.

### Before you begin

Develop a JAX-WS Dynamic Proxy or Dispatch client. When developing Dynamic Proxy clients, after you generate the portable client artifacts from a Web Services Description Language (WSDL) file using the **wsimport** command, the generated service endpoint interface (SEI) does not have asynchronous methods included in the interface. Use JAX-WS bindings to add the asynchronous callback or polling methods on the interface for the Dynamic Proxy client. To enable asynchronous mappings, you can add the `jaxws:enableAsyncMapping` binding declaration to the WSDL file. For more information on adding binding customizations to generate an asynchronous interface, see chapter 8 of the JAX-WS specification.

**Note:** When you run the wsimport tool and enable asynchronous invocation through the use of the JAX-WS enableAsyncMapping binding declaration, ensure that the corresponding response message your WSDL file does not contain parts. When a response message does not contain parts, the request acts as a two-way request, but the actual response that is sent back is empty. The wsimport tool does not correctly handle a void response. To avoid this scenario, you can remove the output message from the operation which makes your operation a one-way operation or you can add a `<wsdl:part>` to your message. For more information on the usage, syntax and parameters for the wsimport tool, see the wsimport command for JAX-WS applications documentation.

## About this task

An asynchronous invocation of a web service sends a request to the service endpoint and then immediately returns control to the client program without waiting for the response to return from the service. JAX-WS asynchronous web service clients consume web services using either the callback approach or the polling approach. Using a polling model, a client can issue a request and receive a response object that is polled to determine if the server has responded. When the server responds, the actual response is retrieved. Using the callback model, the client provides a callback handler to accept and process the inbound response object. The `handleResponse()` method of the handler is called when the result is available. Both the polling and callback models enable the client to focus on continuing to process work without waiting for a response to return, while providing for a more dynamic and efficient model to invoke web services. Polling invocations are valid from Enterprise JavaBeans (EJB) clients or Java Platform, Enterprise Edition (Java EE) application clients. Callback invocations are valid only from Java EE application clients.

**Using the callback asynchronous invocation model**

To implement an asynchronous invocation that uses the callback model, the client provides an `AsyncHandler` callback handler to accept and process the inbound response object. The client callback handler implements the `javax.xml.ws.AsyncHandler` interface, which contains the application code that is run when an asynchronous response is received from the server. The `javax.xml.ws.AsyncHandler` interface contains the `handleResponse(java.xml.ws.Response)` method that is called after the run time has received and processed the asynchronous response from the server. The response is delivered to the callback handler in the form of a `javax.xml.ws.Response` object. The response object returns the response content when the `get()` method is called. Additionally, if an error was received, then an exception is returned to the client during that call. The response method is then invoked according to the threading model used by the executor method, `java.util.concurrent.Executor` on the client's `java.xml.ws.Service` instance that was used to create the Dynamic Proxy or Dispatch client instance. The executor is used to invoke any asynchronous callbacks registered by the application. Use the `setExecutor` and `getExecutor` methods to modify and retrieve the executor configured for your service.

**Using the polling asynchronous invocation model**

Using the polling model, a client can issue a request and receive a response object that can subsequently be polled to determine if the server has responded. When the server responds, the actual response can then be retrieved. The response object returns the response content when the `get()` method is called. The client receives an object of type `javax.xml.ws.Response` from the `invokeAsync` method. That Response object is used to monitor the status of the request to the server, determine when the operation has completed, and to retrieve the response results.

**Using an asynchronous message exchange**

By default, asynchronous client invocations do not have asynchronous behavior of the message exchange pattern on the wire. The programming model is asynchronous; however, the exchange of request or response messages with the server is not asynchronous. To use an asynchronous message exchange, the `com.ibm.websphere.webservices.use.async.mep` property must be set on the client request context with a boolean value of `true`. When this property is enabled, the messages exchanged between the client and server are different from messages exchanged synchronously. With an asynchronous exchange, the request and response messages have WS-Addressing headers added that provide additional routing information for the messages. Another major difference between asynchronous and synchronous message exchange is that the response is delivered to an asynchronous listener that then delivers that response back to the client. For asynchronous exchanges, there is no timeout that is sent to notify the client to stop listening for a response. To force the client to stop waiting for a response, issue a `Response.cancel()` method on the object returned from a polling invocation or a `Future.cancel()` method on the object returned from a callback invocation. The cancel response does not affect the server when processing a request.

**Note:** Windows The location of the asynchronous listener is sent to the server, so that the service can reply to the client. On Windows operating systems, the local host name is used by default, because it is compatible with Dynamic Host Configuration Protocol (DHCP). However, if the server cannot resolve the host name, the client application does not receive replies from the target service. For example, a client application is hosted on the workstation myhost.bar.com. In the following SOAP message header, the client application sends the short name myhost as its host details. Unless the target server can resolve myhost to myhost.bar.com, subsequent replies do not reach the client application:

```
<soapenv:Header>
  <wsa:To>http://target.bar.com:81/LiteSecurityService/SecurityService</wsa:To>
  <wsa:ReplyTo>
    <wsa:Address>http://myhost:2146/axis2/services/LiteSecurityService.
      WSRMServicePort/AnonOutInOp?IBMwebservicesID=922A5DC38A337C4CEF1168347862705
    </wsa:Address>
  </wsa:ReplyTo>
  <wsa:MessageID>urn:uuid:922A5DC38A337C4CEF1168347862403</wsa:MessageID>
  <wsa:Action>getEndpointReference</wsa:Action>
</soapenv:Header>
```

To resolve this issue, configure the client to send the location details for the asynchronous listener in IP format, by adding the following system property to the Java virtual machine. Note that by transmitting the IP address, you lose the benefits of DHCP.

```
-Dcom.ibm.websphere.webservices.transportEPRInIPAddr=yes
```

## Procedure

1. Determine if you want to implement the callback method or the polling method for the client to asynchronously invoke the web service.
2. (Optional) Configure the client request context. Add the

```
com.ibm.websphere.webservices.use.async.mep
```

property to the request context to enable asynchronous messaging for the web services client. Using this property requires that the service endpoint supports WS-Addressing which is supported by default for the application server. The following example demonstrates how to set this property:

```
Map<String, Object> rc = ((BindingProvider) port).getRequestContext();
 rc.put("com.ibm.websphere.webservices.use.async.mep", Boolean.TRUE);
```

3. To implement the asynchronous callback method, perform the following steps.
   a. Find the asynchronous callback method on the SEI or `javax.xml.ws.Dispatch` interface. For an SEI, the method name ends in *Async* and has one more parameter than the synchronous method of type `javax.xml.ws.AsyncHandler`. The `invokeAsync(Object, AsyncHandler)` method is the one that is used on the Dispatch interface.
   b. (Optional) Add the `service.setExecutor` methods to the client application. Adding the executor methods gives the client control of the scheduling methods for processing the response. You can also choose to use the `java.current.Executors` class factory to obtain packaged executors or implement your own executor class. See the JAX-WS specification for more information on using executor class methods with your client.
   c. Implement the `javax.xml.ws.AsyncHandler` interface. The `javax.xml.ws.AsyncHandler` interface only has the `handleResponse(javax.xml.ws.Response)` method. The method must contain the logic for processing the response or possibly an exception. The method is called after the client run time has received and processed the asynchronous response from the server.
   d. Invoke the asynchronous callback method with the parameter data and the callback handler.
   e. The `handleResponse(Response)` method is invoked on the callback object when the response is available. The `Response.get()` method is called within this method to deliver the response.
4. To implement the polling method,
   a. Find the asynchronous polling method on the SEI or `javax.xml.ws.Dispatch` interface. For an SEI, the method name ends in *Async* and has a return type of `javax.xml.ws.Response`. The `invokeAsync(Object)` method is used on the Dispatch interface.
   b. Invoke the asynchronous polling method with the parameter data.

c. The client receives the object type, `javax.xml.ws.Response`, that is used to monitor the status of the request to the server. The `isDone()` method indicates whether the invocation has completed. When the `isDone()` method returns a value of `true`, call the `get()` method to retrieve the response object.

5. Use the `cancel()` method for the callback or polling method if the client needs to stop waiting for a response from the service. If the `cancel()` method is invoked by the client, the endpoint continues to process the request. However, the wait and response processing for the client is stopped.

## Results

You have enabled your JAX-WS web service client to asynchronously invoke and consume web services. See the JAX-WS specification for additional information regarding the asynchronous client APIs.

## Example

The following example illustrates a web service interface with methods for asynchronous requests from the client.

```
@WebService

public interface CreditRatingService {
       // Synchronous operation.
       Score getCreditScore(Customer     customer);
       // Asynchronous operation with polling.
       Response<Score> getCreditScoreAsync(Customer customer);
       // Asynchronous operation with callback.
       Future<?> getQuoteAsync(Customer customer,
              AsyncHandler<Score> handler);
}
```

### Using the callback method

The callback method requires a callback handler that is shown in the following example. When using the callback procedure, after a request is made, the callback handler is responsible for handling the response. The response value is a response or possibly an exception. The `Future<?>` method represents the result of an asynchronous computation and is checked to see if the computation is complete. When you want the application to find out if the request is completed, invoke the `Future.isDone()` method. Note that the `Future.get()` method does not provide a meaningful response and is not similar to the `Response.get()` method.

```
CreditRatingService svc = ...;

Future<?> invocation = svc.getCreditScoreAsync(customerTom,
       new AsyncHandler<Score>() {
              public void handleResponse (
                     Response<Score> response)
                  {
                     score = response.get();
                     // process the request...
                  }
    }
);
```

### Using the polling method

The following example illustrates an asynchronous polling client:

```
CreditRatingService svc = ...;
Response<Score> response = svc.getCreditScoreAsync(customerTom);

while (!response.isDone()) {
       // Do something while we wait.
}

score = response.get();
```

# Enabling Web Services Addressing support for JAX-RPC applications

The Web Services Addressing (WS-Addressing) support provides mechanisms to address web services and provide addressing information in messages. To enable the WS-Addressing support for JAX-RPC applications, either configure the Web Services Description Language (WSDL) file for a service that runs on WebSphere Application Server, or use the WS-Addressing application programming interface (API) or system programming interface (SPI) to add WS-Addressing properties in a WebSphere Application Server client.

## About this task

Complete this task to enable the WS-Addressing support, either as a service provider or as a client of a service provided by another party. This task also describes how to disable the WS-Addressing support, which can improve performance for those applications that do not use WS-Addressing or any protocol that depends on the WS-Addressing support.

If you are creating a web service, you can enable the WS-Addressing support during development of the service, by including the UsingAddressing extensibility element in the WSDL binding element for the service. This element contains a **required** attribute that has a value of either false, which specifies that WS-Addressing information is accepted but not required in incoming messages, or true, which specifies that WS-Addressing information is required in incoming messages. The default value is false. Messages from WebSphere Application Server clients always include WS-Addressing information if your service WSDL file includes the UsingAddressing element, regardless of the value of the **required** attribute.

If you are creating a client application to use a service from another provider, you might not have access to the WSDL file for the service, or the service might use a version of WSDL that does not support the UsingAddressing element (if the service is not running on a current version of this product). However, you can still enable WS-Addressing support, during run time, by setting WS-Addressing properties on the JAX-RPC stub or call object that you use to communicate with the service.

The following table summarizes the behavior of the WS-Addressing support in each of the scenarios mentioned previously.

*Table 234. The behavior of the WS-Addressing support in the product. The table details the resulting behavior of different `UsingAddressing` settings when an application server client sends a message.*

| | **The WSDL for the service specifies `UsingAddressing required = "false"`** | **The WSDL for the service specifies** | **The WSDL for the service does not specify UsingAddressing** |
|---|---|---|---|
| **A client sends a message that contains WS-Addressing information** | The WS-Addressing information is processed by the product. | The WS-Addressing information is processed by the product. | The WS-Addressing information is processed by the product. |
| **A non-WebSphere Application Server client sends a message that does not contain WS-Addressing information** | The message is accepted. | The service returns a fault. | The message is accepted. |
| **A WebSphere Application Server client sends a message, without specifying addressing properties** | The message automatically contains the mandatory WS-Addressing information, as defined in the WS-Addressing specification. The information is processed by the product. | The message automatically contains the mandatory WS-Addressing information, as defined in the WS-Addressing specification. The information is processed by the product. | WS-Addressing information is not added. The message is accepted. |

## Procedure

- To enable WS-Addressing support from the server by configuring the WSDL file, complete the following steps:
  1. Ensure that the WSDL file for the service contains the UsingAddressing extensibility element on the binding element. If you generated the WSDL file by using the Java2WSDL tool, this element is

automatically added for you. If you created the WSDL file yourself, for use with the WSDL2Java tool, you must add the extensibility element. The UsingAddressing element has a **required** attribute with a default value of false. For example:

```
<wsdl:binding name="TestServiceSoapBinding" type="intf:TestService">
     <wsaw:UsingAddressing wsdl:required="false"
                           xmlns:wsaw="http://www.w3.org/2006/05/addressing/wsdl"/>

     <wsdlsoap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>

     <wsdl:operation name="invokeInstance">
       ...
     </wsdl:operation>

  </wsdl:binding>
```

This code indicates that the endpoint will process WS-Addressing information, but that this information is not required.

2. Optional: To specify that WS-Addressing information is required, change the value of the **required** attribute to true. If the endpoint receives a message that does not contain the mandatory WS-Addressing elements within the message header, the endpoint returns a fault message, as defined in the WS-Addressing specification.

   WebSphere Application Server clients always send WS-Addressing conformant messages to endpoints with bindings that specify the UsingAddressing element.

- To enable WS-Addressing support from a WebSphere Application Server client, use the IBM proprietary WS-Addressing API or SPI to associate one or more WS-Addressing properties with the JAX-RPC stub or call object that is used to send messages to the endpoint.

  These properties become message-addressing properties (MAPs) in the SOAP message header. If the node that receives the message is a WebSphere Application Server node, it processes the incoming MAPs in accordance with the WS-Addressing specification, even if the service does not have a UsingAddressing element in its WSDL file.

  Use this method when communicating with endpoints that use earlier versions of the WS-Addressing specification (for example: http://schemas.xmlsoap.org/ws/2004/08/addressing) that do not support the UsingAddressing element, or when the WSDL file for the target endpoint is not available to the client.

### Results

WS-Addressing properties are now included in the SOAP message header, and are processed by the server on receipt of the message.

## Disabling Web Services Addressing support

The Web Services Addressing (WS-Addressing) support provides mechanisms to address web services and provide addressing information in messages. WS-Addressing support is disabled by default on clients. The method for disabling WS-Addressing support on servers depends on whether your application is based on JAX-RPC or JAX-WS.

### About this task

You do not have to disable WS-Addressing support even if your application does not require it, because in most cases WS-Addressing support does not have a negative impact on the running of applications. For JAX-RPC applications, disabling WS-Addressing support can be risky as this action also disables support for other specifications such as Web Services Atomic Transactions.

### Procedure

- Disable WS-Addressing support for JAX-WS service providers using one of the following ways:
  - Use both the Addressing and SubmissionAddressing annotations in the service code, with the **enabled** parameter set to false; for example:

```
import javax.xml.ws.soap.Addressing;

@Addressing(enabled=false)
@SubmissionAddressing(enabled=false)
@WebService(...)
```

  - Use the <webservice-description>/<port-component>/<addressing> deployment descriptor element in the deployment descriptor for the service application; for example:

```
<port-component>
   <port-component-name>MyPort1</port-component-name>
   <addressing>
      <enabled>false</enabled>
   </addressing>
   <service-impl-bean>
      <servlet-link>MyPort1ImplBean</servlet-link>
   </service-impl-bean>
</port-component>
```

- You do not have to take any action to disable WS-Addressing support for JAX-WS clients, because WS-Addressing support is disabled by default. However, you can programmatically specify that WS-Addressing is disabled by using one of the following ways:
  - Use both the AddressingFeature and SubmissionAddressingFeature classes in the client code, with the **enabled** parameter set to false; for example:

```
AddressingFeature feat = new AddressingFeature(false);
SubmissionAddressingFeature feat = new AddressingFeature(false);
```

  - Use the Addressing annotation for an injected web services proxy reference; for example:

```
public class MyClientApplication {
   // Disable Addressing for a port-component-ref resource injection.
   @Addressing(enabled=false)
   @WebServiceRef(MyService.class)
   private MyPortType myPort;
   ...
 }
```

  - Use the <service>/<port-component>/<addressing> deployment descriptor; for example:

```
<service-ref>
   <service-ref-name>service/MyPortComponentRef</service-ref-name>
   <service-interface>com.example.MyService</service-ref-interface>
   <port-component-ref>
      <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
      <addressing>
         <enabled>false</enabled>
      </addressing>
   </port-component-ref>
</service-ref>
```

- To disable WS-Addressing support for JAX-RPC service providers or clients, set the **com.ibm.ws.wsaddressingAndDependentsDisabled** system property to true. For example:

```
java -Dcom.ibm.ws.wsaddressingAndDependentsDisabled=true ... application_name
```

  **Attention:** Use this property with care because applications might require WS-Addressing message addressing properties to function correctly. Setting this property also disables support for the following specifications, which depend on the WS-Addressing support: Web Services Atomic Transactions, Web Services Business Agreement, Web Services Notification and Web Services Reliable Messaging.

## Results

By completing this task, you disabled the WS-Addressing support. Disabling WS-Addressing on clients prevents WebSphere Application Server sending WS-Addressing message addressing properties in the SOAP header of outbound web service messages. Disabling WS-Addressing on servers additionally prevents WebSphere Application Server processing WS-Addressing MAPs in incoming SOAP headers.

# Chapter 35. Developing web services - Invocation framework (WSIF)

The Web Services Invocation Framework (WSIF) is a Web Services Description Language (WSDL)-oriented Java™ API. You use this API to invoke web services dynamically, regardless of the service implementation format (for example enterprise bean) or the service access mechanism (for example Java Message Service (JMS)). Using WSIF, you can move away from the usual web services programming model of working directly with the SOAP APIs, towards a model where you interact with representations of the services. You can therefore work with the same programming model regardless of how the service is implemented and accessed.

## Using WSIF to invoke web services

You invoke a web service dynamically by using the WSIF API directly.

### About this task

You specify the location of the Web Services Description Language (WSDL) file for the service, the name of the operation to invoke, and any operation arguments. All other information needed to access the web service (the abstract interface, the binding, and the service endpoint) is available through the WSDL.

This kind of invocation does not require stub classes and does not need a separate compilation cycle.

**Note:** You should not use WSIF for new applications in WebSphere Application Server, unless you are supporting an existing WSIF configuration. You should instead adopt a more recent open standard, such as the Java API for XML-Based Web Services (JAX-WS) programming model.

For more information about using the Web Services Invocation Framework (WSIF) to invoke web services, see the following topics:

### Procedure

- “Linking a WSIF service to the underlying implementation of the service.”
- “Developing a WSIF service” on page 1709.
- “Using complex types” on page 1717.
- “Using WSIF to bind a JNDI reference to a web service” on page 1719.
- “Example: Passing SOAP messages with attachments by using WSIF” on page 1720.
- “Interacting with the Java EE container in WebSphere Application Server” on page 1723.
- “Invoking a WSDL-based web service through the WSIF API” on page 1723.
- “Running WSIF as a client” on page 1729

## Linking a WSIF service to the underlying implementation of the service

A Web Services Invocation Framework (WSIF) service is linked to the underlying service through a WSIF provider. A provider is an implementation of a Web Services Description Language (WSDL) binding that can run a WSDL operation through a binding-specific protocol. Providers implement the interface between the WSIF API and the implementation of a service.

### About this task

Providers are pluggable within the WSIF framework, and are registered according to the namespace of the WSDL extension that they implement. Some providers use the Java Platform, Enterprise Edition (Java EE) programming model to use Java EE services. If a provider is available, but its required class libraries are not, then the provider is disabled.

© IBM Corporation 2009

To use the providers that are supplied with WebSphere Application Server, see the following topics:

## Procedure

- Link a WSIF service to a SOAP over HTTP service.
- Link a WSIF service to a JMS-provided service (SOAP over JMS, or native JMS).
- Link a WSIF service to a local Java application.
- Write the WSDL extension that lets your WSIF service invoke an enterprise bean.

## Linking a WSIF service to a SOAP over HTTP service

The SOAP provider allows WSIF stubs and dynamic clients to invoke SOAP services. Add Web Services Description Language (WSDL) extensions to your web service WSDL file so that the service can use the SOAP provider.

### Before you begin

**Note:** The current WSIF default SOAP provider (the IBM Web Service SOAP provider) does not fully interoperate with services that are running on the former (Apache SOAP) provider. This is because the IBM Web Service SOAP provider is designed to interoperate fully with a JAX-RPC compliant web service, and Apache SOAP cannot provide such a service. For more information see "WSIF SOAP provider: working with existing applications."

### About this task

The Web Services Invocation Framework (WSIF) SOAP provider supports SOAP 1.1 over HTTP.

The SOAP provider is JSR 101/109 compliant and uses Web Services for Java EE for parsing and creating SOAP messages.

The SOAP provider supports:
- SOAP-ENC encoding.
- RPC style and Document style SOAP messages.
- SOAP messages with attachments.

The SOAP provider is not transactional.

The SOAP provider does not support the WSIF synchronous timeout. The SOAP provider uses the default client timeout value that is set for Web Services for Java EE.

To link a WSIF service to a SOAP over HTTP service, you write extensions to the service WSDL file.

### Procedure

- Optional: If you have a web service that you expect multiple clients to use to connect over SOAP, before you deploy the service set up your application deployment descriptor file `dds.xml` to handle multiple connections. For more information, see the troubleshooting tip Using WSIF with multiple clients causes a SOAP parsing error.
- Write the WSDL extension that lets your WSIF service access a SOAP over JMS service.

  **Note:** The WSDL binding extension for SOAP over JMS varies only slightly from the SOAP over HTTP binding.
- Write the WSDL extensions for SOAP attachments.

***WSIF SOAP provider: working with existing applications:***

The current WSIF default SOAP provider (the IBM Web Service SOAP provider) does not fully interoperate with services that are designed to run on the former (Apache SOAP) provider. This is because the IBM Web Service SOAP provider is designed to interoperate fully with a JAX-RPC compliant web service, and Apache SOAP cannot provide such a service.

**About this task**

As a result of the change from the Apache SOAP provider to the IBM Web Service SOAP provider, previous WSIF clients might not work in either of the following cases:

1. The web service uses any of the following parameter types: `xsd:date`, `xsd:dateTime`, `xsd:hexBinary` or `xsd:QName`. For more information, see the **Type Mappings** section of WSIF - Known restrictions.
2. The web service was built upon the Apache SOAP provider.

To get your existing services working again, you have two options:

**Procedure**

- Change the default WSIF SOAP provider back to the former Apache SOAP provider (in which case any future invocations to a JAX-RPC compliant web service will not work if that web service uses parameter types `xsd:date`, `xsd:dateTime`, `xsd:hexBinary` or `xsd:QName`).
- Modify your web services to use the IBM Web Service SOAP provider.

*Changing the default WSIF SOAP provider:*

The WSIF default SOAP provider (the IBM Web Service SOAP provider) is designed to interoperate fully with a JAX-RPC compliant web service, and therefore the default provider does not fully interoperate with services that are running on the former (Apache SOAP) provider. To get your existing services working again, you can either modify your web services to use the current IBM Web Service SOAP provider, or you can change the WSIF default provider back to Apache SOAP as described in this topic.

**About this task**

WSIF uses a properties file named `wsif.properties` to choose what SOAP provider to use. The SOAP provider is a node-wide setting, so all servers on the node must be restarted for any changes to take effect. The `wsif.properties` file is shipped in the `com.ibm.ws.runtime.jar` file that is located in the *app_server_root*`/plugins` directory (where *app_server_root* is the root directory for your installation of IBM WebSphere Application Server), and the “as shipped” properties file is accessed in this location by being put on the class path. However when you make changes to the file, you do not replace the original copy in the `com.ibm.ws.runtime.jar` file. Instead, you save the modified version in the *app_server_root*`/lib/properties` directory.

To change the WSIF default SOAP provider back to Apache SOAP, complete the following steps:

**Procedure**

1. Extract the `wsif.properties` file from the `com.ibm.ws.runtime.jar` file that is located in the *app_server_root*`/plugins` directory (where *app_server_root* is the root directory for your installation of IBM WebSphere Application Server).
2. Open the `wsif.properties` file in a text editor.
3. Remove the leading “#” character from the following lines:

```
# wsif.provider.default.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=1
# wsif.provider.uri.1.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=\
# http://schemas.xmlsoap.org/wsdl/soap/
#
```

After the update, the preceding lines should look like this:

```
wsif.provider.default.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=1
wsif.provider.uri.1.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=\
http://schemas.xmlsoap.org/wsdl/soap/
#
```

4. Save the updated `wsif.properties` file in the *app_server_root*`/lib/properties` directory.
5. Stop then restart all application servers on the node.

**Example**

*Modifying web services to use the IBM Web Service SOAP provider:*

The current WSIF default SOAP provider (the IBM Web Service SOAP provider) is designed to interoperate fully with a JAX-RPC compliant web service, and therefore the current default provider does not fully interoperate with services that are running on the former (Apache SOAP) provider. To get your existing services working again, you can either modify your web services to use the current IBM Web Service SOAP provider as described in this topic, or you can change the WSIF default provider back to Apache SOAP.

**About this task**

To modify an existing web service, use the assembly tool to complete the following steps and thereby generate new deployment artifacts for access to the service from the IBM Web Service provider:

**Procedure**

1. Import into the Workspace the project that contains your existing web services.
2. For every existing SOAP service in the project, repeat the following steps :
   a. From the pop-up menu for *your_service*`.wsdl`, select **Generate Deploy Code**.
   b. In the Generate Deploy Code window, change the **Inbound Binding Type** from `SOAP` to `IBM Web Service`.
   c. Click **Finish**.
3. Export the EAR file that contains all of the deployment artifacts for the IBM Web Service web service.

## Linking a WSIF service to a JMS-provided service

The JMS providers enable a WSIF service to be invoked through either SOAP over JMS, or native JMS. Add Web Services Description Language (WSDL) extensions to your web service WSDL file so that the service can use the JMS providers.

### About this task

The Java Message Service (JMS) is an API for transport technology. The mapping to a JMS destination is defined during deployment and maintained by the container.

The JMS destination endpoint for a web service can be realized in any of the following ways:
- The JMS destination for the queue can be the web service implementation.
- The JMS destination can be (but is not required to be) associated with a message-driven bean by the EJB container, thereby allowing the message-driven bean to be the web service implementation.
- For SOAP over JMS, the JMS destination can unwrap the JMS message and route the SOAP message to a web service that is implemented as a stateless session bean.

The JMS destination endpoint must respect the interaction model expected by the client and defined by the WSDL. It must return a response if one is required.

When the JMS destination endpoint creates the JMS response message the following rules must be followed:
- The response message must be sent to `JMSReplyTo` from the incoming request.

- The JMSCorrelationID value of the response message must be set to the JMSMessageID value from the request message.
- The response must be sent with a deliveryMode value equal to the JMSDeliveryMode value of the request message.
- The response must be sent with a priority value equal to the JMSPriority value of the request message.
- The TimeToLive/JMSExpiration value must be set to a value that equals the JMSExpiration value of the request message.

The client does not see any of these headers. The container receives the JMS message and (for SOAP over JMS) removes the SOAP message to send to the client.

To link a WSIF service to a JMS-provided service, use the following information and code examples:

## Procedure

- Link your WSIF service to a SOAP over JMS service.
- Link a WSIF service to a service provided at a JMS destination.
- Enable a WSIF client to invoke a web service through JMS.

### *Writing the WSDL extension that lets your WSIF service access a SOAP over JMS service:*

You can write a Web Services Description Language (WSDL) extension that enables your Web Services Invocation Framework (WSIF) service to access a SOAP service that uses the Java Message Service (JMS) as its transport mechanism.

#### Before you begin

This topic assumes that you chose and configured a JMS provider when you installed WebSphere Application Server (either the default messaging provider, or another provider such as the WebSphere MQ messaging provider). If not, do so now as described in Choosing a messaging provider.

#### About this task

If a SOAP message contains only XML, it can be carried on the Java Message Service (JMS) transport mechanism with the JMS message body type **TextMessage**. The SOAP message, including the SOAP envelope, is wrapped with a JMS message and put on the appropriate queue. The container receives the JMS message and removes the SOAP message to send to the client.

Use the following procedure, and associated code fragments, to help you to write the Web Services Description Language (WSDL) extension that enables your WSIF service to access a SOAP over JMS service.

**Note:** You can also use this procedure as a guide to writing the WSDL binding extension for SOAP over HTTP, because the SOAP over JMS binding is almost identical to the SOAP over HTTP binding.

#### Procedure

- Select the SOAP over JMS binding.

  You set the transport attribute of the <soap:binding> tag to indicate that JMS is used. If you also set the style attribute to rpc (Remote Procedure Call), then the Web Services Invocation Framework (WSIF) assumes that an operation is invoked on the web service endpoint:

  ```
  <soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/jms"/>
  ```

- Set the JMS address.

  **Note:** See also the alternative method for specifying the JMS address that is given in the next step.

For SOAP over JMS, the <wsdl:port> tag must contain a <jms:address> element. This element provides the information required for a client to connect correctly to the web service by using the JMS programming model. Typically, it is the stubs generated to support the SOAP over JMS binding that act as the JMS client. Alternatively, the web service client can use the JMS programming model directly.

The <jms:address> element takes this form:

```
<jms:address

    destinationStyle="queue"
    jmsVendorURI="http://ibm.com/ns/mqseries"?
    initialContextFactory="com.ibm.NamingFactory"?
    jndiProviderURL="iiop://something:900/wherever"?
    jndiConnectionFactoryName="orange"
    jndiDestinationName="fred">

    <jms:propertyValue name="targetService" type="xsd:string"
                       value="StockQuoteServicePort"/>

</jms:address>
```

where attributes marked with a question mark (?) are optional.

The optional jmsVendorURI attribute is a string that uniquely identifies the JMS implementation. WSIF ignores this URI, which is used by the client developer and perhaps the client implementation to determine if it has access to the correct JMS provider in the client runtime environment.

The optional attributes initialContextFactory and jndiProviderURL can only be omitted if the runtime environment has a default Java Naming and Directory Interface (JNDI) provider configured.

The jndiConnectionFactoryName attribute gives the name of a JMS ConnectionFactory object, which can be looked up within the JNDI context given by the jndiContext attribute. This ConnectionFactory object is used to create a JMS connection to the JMS provider instance that owns the queue. In a simple configuration, the same ConnectionFactory object is used by the server message listener and by the clients. However the server and the clients can use different ConnectionFactory objects, provided that they all create connections to the same JMS provider instance.

The value attribute of the targetService <jms:propertyValue> element is the name of the port component for the target service as defined in the <port-component-name> element of the webservices.xml file for the target service.

- Set the JMS address (alternative method).

  For the SOAP over JMS provider you can instead specify the JMS address using the <soap:address> tag in the following format:

  jms:/[*queue*|*topic*]?<*property*>=<*value*>&<*property*>=<*value*>&...

  where the specification of *queue* or *topic* corresponds to the JMS address destinationStyle attribute.

*Table 235. Properties that are valid for use with the <soap:address> tag.*

*Column 1 specifies the property name, column 2 describes the property, and column 3 specifies the corresponding JMS address value.*

| Property name | Property description | Corresponding JMS address value |
|---|---|---|
| destination | The JNDI name of the destination queue or topic | jndiDestinationName |
| connectionFactory | The JNDI name of the connection factory. | jndiConnectionFactory |
| targetService | The name of the port component of the target service | targetService jms:propertyValue within jms:address |
| JNDI-related properties (optional): | | |
| initialContextFactory | The name of the initial context factory. | initialContextFactory |
| jndiProviderURL | The JNDI provider URL | jndiProviderURL |
| JMS-related properties (optional): | | |

*Table 235. Properties that are valid for use with the <soap:address> tag (continued).*

*Column 1 specifies the property name, column 2 describes the property, and column 3 specifies the corresponding JMS address value.*

| Property name | Property description | Corresponding JMS address value |
|---|---|---|
| deliveryMode | An indication as to whether the request message should be persistent or not. The valid values are DeliveryMode.NON_PERSISTENT (default) and DeliveryMode.PERSISTENT | JMSDeliveryMode |
| password | The password to be used to gain access to the connection factory. | JMSPassword |
| priority | The JMS priority associated with the request message. Valid values are 0 to 9. The default value is 4. | JMSDeliveryMode |
| replyTo | The JNDI destination queue to which reply messages should be sent. | JMSReplyTo |
| timeToLive | The lifetime (in milliseconds) of the request message. A value of 0 indicates an infinite lifetime. | JMSTimeToLive |
| userid | The userid to be used to gain access to the connection factory. | JMSUserid |

Here is an example of this format:

<jms:address> format:

```
<wsdl:port name="StockQuoteServicePort"

        binding="sqi:StockQuoteSoapJMSBinding">

    <jms:address destinationStyle="queue"
        jndiConnectionFactoryName="myQCF"
        jndiDestinationName="myQ"
        initialContextFactory="com.ibm.NamingFactory"
        jndiProviderURL="iiop://something:900/">

        <jms:propertyValue name="targetService"
                           type="xsd:string"
                           value="StockQuoteServicePort"/>

    </jms:address>

</wsdl:port>
```

<soap:address> format:

```
<wsdl:port name="StockQuoteServicePort"
        binding="sqi:StockQuoteSoapJMSBinding">
    <soap:address location="jms:/queue?connectionFactory=myQCF&destination
=myQ&initialContextFactory=com.ibm.NamingFactory&jndiProviderURL
=iiop://something:900/&targetService=StockQuoteServicePort" />

</wsdl:port>
```

- Set the JMS headers and properties.

  You use the <jms:property> tag to set the JMS headers and properties. This tag maps either a message part, or a literal value, into a JMS property:

  ```
  <jms:property name="Priority" {part="requestPriority" | value="fixedValue"}/>
  ```

  If the <jms:property> has a literal value, then it can also be nested within the <jms:address> tag:

  ```
  <jms:property name="Priority" value="fixedValue" />
  ```

  This form of the <jms:property> tag is also used in the native JMS binding.

### Example of a WSDL that defines a SOAP over JMS binding

```
<!-- Example: SOAP over JMS Text Message -->

<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions
        name="StockQuoteInterfaceDefinitions"
```

```
        targetNamespace="urn:StockQuoteInterface"
        xmlns:tns="urn:StockQuoteInterface"
        xmlns:xsd="http://www.w3.org/2000/10/XMLSchema"
        xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
        xmlns:jms="http://schemas.xmlsoap.org/wsdl/jms/"
        xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/">
    <wsdl:message name="GetQuoteInput">
        <part name="symbol" type="xsd:string"/>
    </wsdl:message>
    <wsdl:message name="GetQuoteOutput">
        <part name="value" type="xsd:float"/>
    </wsdl:message>

    <wsdl:portType name="StockQuoteInterface">
        <wsdl:operation name="GetQuote">
            <wsdl:input message="tns:GetQuoteInput"/>
            <wsdl:output message="tns:GetQuoteOutput"/>
        </wsdl:operation>
    </wsdl:portType>

    <wsdl:binding name="StockQuoteSoapJMSBinding" type="tns:StockQuoteInterface">
        <soap:binding style="rpc"
                 transport="http://schemas.xmlsoap.org/soap/jms"/>
        <wsdl:operation name="GetQuote">
            <soap:operation soapAction="urn:StockQuoteInterface#GetQuote"/>
            <wsdl:input>
                <soap:body use="encoded" namespace="urn:StockQuoteService"
                           encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"/>
            </wsdl:input>
            <wsdl:output>
                <soap:body use="encoded" namespace="urn:StockQuoteService"
                     encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"/>
            </wsdl:output>
        </wsdl:operation>
    </wsdl:binding>
    <wsdl:service name="StockQuoteService">
        <wsdl:port name="StockQuoteServicePort"
                       binding="sqi:StockQuoteSoapJMSBinding">
            <jms:address destinationStyle="queue"
                     jndiConnectionFactoryName="myQCF"
                     jndiDestinationName="myQ"
                     initialContextFactory="com.ibm.NamingFactory"
                     jndiProviderURL="iiop://something:900/">

                     <jms:propertyValue name="targetService"
                                        type="xsd:string"
                                        value="StockQuoteServicePort"/>

            </jms:address>

        </wsdl:port>
    </wsdl:service>
</wsdl:definitions>
```

### *Writing the WSDL extensions that let your WSIF service access a service at a JMS destination:*

Using the native Java Message Service (JMS) provider, Web Services Invocation Framework (WSIF) clients can treat a service that is available at a JMS destination as a Web service. Use this information, and associated code fragments, to help you to write the Web Services Description Language (WSDL) extensions.

#### Before you begin

This topic assumes that you chose and configured a JMS provider when you installed WebSphere Application Server (either the default messaging provider, or another provider such as the WebSphere MQ messaging provider). If not, do so now as described in Choosing a messaging provider.

### About this task

The WSDL extensions for JMS are identified with the namespace prefix `jms`. For example, `<jms:binding>`.

The supported operations are either one-way operations (`send` for JMS point-to-point messaging, or `publish` for JMS publish and subscribe messaging) or request-response operations (`send` and `receive` for JMS point-to-point messaging). The WSDL operations therefore specify either an input message only, or an input and an output message.

Operations that describe message interfaces with a native JMS binding do not have fault messages. No assumptions are made about the message schema or the semantics of message properties, therefore no distinction can be made between output and fault messages.

Use the following procedure, and associated code fragments, to help you to write the Web Services Description Language (WSDL) extensions that enable your WSIF service to access an underlying service at a JMS destination.

### Procedure

- Set the JMS message body type.

  You use the `<jms:binding>` extension to specify the JMS message body type:

```
<wsdl:binding ... >
   <jms:binding type="messageBodyType" />
    ...
</wsdl:binding>
```

  where *messageBodyType* is either `ObjectMessage` or `TextMessage`.

- Specify the parts to use for the input and output messages.

  For JMS text messages and JMS object messages created from one or more WSDL message parts, you use the `<jms:input>` and `<jms:output>` extensions to specify the message parts to use for the JMS messages:

```
<wsdl:input ... >
   <jms:input parts="part1 part2 ..." />
</wsdl:input>

<wsdl:output ... >
   <jms:output parts="part1 part2 ..." />
</wsdl:output>
```

  In the next example, the WSDL message has just one part that contains the complete message body. This message body might result from a mapping of some other representation (see the next step “Map the data types”).

```
<wsdl:input ... >
   <jms:input parts="part1" />
</wsdl:input>
```

  If no parts are defined, then all the message parts are used.

- Map the data types.

  You use the `<format>` extensions to map data types:

```
<wsdl:binding ... >
   <jms:binding type="..." />

   <format:typeMapping encoding="Java" style="Java">
      <format:typeMap typeName="..." formatType="targetType"/>
   </format:typemapping>
   ...
</wsdl:binding>
```

The value of *targetType* is dependent on the JMS message body type (see the step “Set the JMS message body type”). For JMS object messages, the target data type implements the java.io.Serializable class. For JMS text messages, the target data type is always java.lang.String.

The `<format>` extensions are also used in other bindings that deal with Java interfaces.

- Set the JMS headers and properties.

  JMS does not make assumptions about message headers. For example, if the JMS provider is MQSeries then each JMS message carries an RFH2 header. However you can access data in this message header indirectly, by getting and setting JMS message properties.

  When you want your application to pass a property into the Web Services Invocation Framework (WSIF) as a part on the WSIF message, you use a `<jms:property>` tag. When you want to hard code a property value into the WSDL, you use a `<jms:propertyValue>` tag. The `<jms:propertyValue>` tag contains a specification of a literal value and its associated XML schema type.

  You can specify `<jms:property>` and `<jms:propertyValue>` extensions within the `<wsdl:input>` tag in the binding operation, and also within the `<jms:address>` tag. For the`<wsdl:output>` tag in the binding operation, you can only specify the `<jms:property>` extension. Property values that are set in the `<jms:property>` tag take precedence over values set in the `<<jms:propertyValue>` tag, and property values that are set in the binding operation (in the `<input>` and `<output>` tags) take precedence over values set in the `<jms:address>` tag.

  Here is an example of the `<jms:property>` and `<jms:propertyValue>` tags nested within the `<input>` and `<output>` tags:

```
<wsdl:input ... >

    <jms:property name="propertyName" part="partName" />

    <jms:propertyValue name="propertyName"
               type="xsdType" value="actualValue" />

</wsdl:input>

<wsdl:output ... >

    <jms:property name="propertyName" part="partName" />

</wsdl:output>
```

  where *propertyName* identifies the JMS property that is associated with the header field, and *partName* identifies the message part that is associated with the property.

  The JMS property identified by *propertyName* can be user-defined, or it can be one of the following predefined header fields:

*Table 236. Predefined JMS message header fields.*

*Column 1 specifies the header field value, and column 2 specifies the data type for that header field value.*

| Value | Java type |
|---|---|
| JMSMessageId | java.lang.String |
| JMSTimeStamp | long |
| JMSCorrelationId | byte [ ] or java.lang.String |
| JMSReplyTo | javax.jms.Destination |
| JMSDestination | javax.jms.Destination |
| JMSDeliveryMode | int |
| JMSRedelivered | boolean |
| JMSType | java.lang.String |
| JMSExpiration | long |

*Table 236. Predefined JMS message header fields (continued).*

*Column 1 specifies the header field value, and column 2 specifies the data type for that header field value.*

| Value | Java type |
|---|---|
| JMSTimeToLive | long |

See the JMS specification for restrictions that apply when setting JMS header field values. Attempts to set restricted values are ignored.

For application-defined JMS message properties, the Java types used in the native JMS binding implementation (used for calls to the corresponding JMS methods) are derived from the XML schema type in the abstract interface (`<wsdl:part>` tag), and from the type mapping information in the format binding (`<format:typemap>` tag).

- Handle transactions.

  Independent of other JMS properties, the asynchronous processing of request-response operations has implications for callers running in a transaction scope. The send request part and the receive response part are separated into two transactions, because the send needs to be committed in order for the request message to become visible. Implementations that process WSDL for asynchronous request-response operations (such as WSIF) must therefore take the following additional actions:
  - They must ensure that the send request transaction returns a correlation ID to the user, and provides a callback with which users can pass in the response message to process the receive response transaction.
  - They might implement their own response message listener in order to recognize the arrival of response messages, and to manage the correlation to the request message.

### Example

Example 1: JMS Text Message

The JMS text message contains a java.lang.String. In this example, the WSDL message contains only one part that represents the whole message body:

```
<wsdl:definitions ... >

   <!-- simple or complex types for input and output message -->
   <wsdl:types> ... </wsdl:types>

   <wsdl:message name="JmsOperationRequest"> ... </wsdl:message>
   <wsdl:message name="JmsOperationResponse"> ... </wsdl:message>

   <wsdl:portType name="JmsPortType">
      <wsdl:operation name="JmsOperation">
         <wsdl:input name="Request"
                     message="tns:JmsOperationRequest"/>
         <wsdl:output name="Response"
                      message="tns:JmsOperationResponse"/>
      </wsdl:operation>
   </wsdl:portType>

   <wsdl:binding name="JmsBinding" type="JmsPortType">
      <jms:binding type="TextMessage" />

      <format:typemapping style="Java" encoding="Java">
         <format:typemap name="xsd:String" formatType="String" />
      </format:typemapping>

      <wsdl:operation name="JmsOperation">
         <wsdl:input message="JmsOperationRequest">
            <jms:input parts="requestMessageBody" />
         </wsdl:input>
         <wsdl:output message="JmsOperationResponse">
```

```
            <jms:output parts="responseMessageBody" />
         </wsdl:output>
      </wsdl:operation>
   </wsdl:binding>

   <wsdl:service name="JmsService">
      <wsdl:port name="JmsPort" binding="JmsBinding">
         <jms:address destinationStyle="queue"
                      jndiConnectionFactoryName="myQCF"
                      jndiDestinationName="myDestination"/>
      </wsdl:port>
   </wsdl:service>

</wsdl:definitions>
```

As an extension to the previous JMS message example, the following example WSDL describes a request-response operation in which specific JMS property values of the request and response message are set for the request message and retrieved from the response message.

The JMS properties in the request message are set according to the values in the input message. Likewise, selected JMS properties of the response message are copied to the corresponding values of the output message. The direction of the mapping is determined by the appearance of the `<jms:property>` tag in the input or output section, respectively.

Example 2: JMS Message with JMS Properties

```
<wsdl:definitions ... >

   <!-- simple or complex types for input and output message -->
   <wsdl:types> ... </wsdl:types>

   <wsdl:message name="JmsOperationRequest">
      <wsdl:part name="myInt" type="xsd:int"/>
      ...
   </wsdl:message>

   <wsdl:message name="JmsOperationResponse">
      <wsdl:part name="myString" type="xsd:String"/>
      ...
   </wsdl:message>

   <wsdl:portType name="JmsPortType">
      <wsdl:operation name="JmsOperation">
         <wsdl:input name="Request"
                     message="tns:JmsOperationRequest"/>
         <wsdl:output name="Response"
                      message="tns:JmsOperationResponse"/>
      </wsdl:operation>
   </wsdl:portType>

   <wsdl:binding name="JmsBinding" type="JmsPortType">
      <!-- the JMS message type might be any of the above -->
      <jms:binding type="..." />

      <format:typemapping style="Java" encoding="Java">
         <format:typemap name="xsd:int" formatType="int" />
         ...
      </format:typemapping>

      <wsdl:operation name="JmsOperation">
         <wsdl:input message="JmsOperationRequest">
            <jms:property message="tns:JmsOperationRequest" parts="myInt" />
            <jms:propertyValue name="myLiteralString"
                          type="xsd:string" value="Hello World" />
            ...
         </wsdl:input>
```

```
         <wsdl:output message="JmsOperationResponse">
            <jms:property message="tns:JmsOperationResponse" parts="myString" />
            ...
         </wsdl:output>
      </wsdl:operation>
   </wsdl:binding>

   <wsdl:service name="JmsService">
      <wsdl:port name="JmsPort" binding="JmsBinding">
         <jms:address destinationStyle="queue"
                      jndiConnectionFactoryName="myQCF"
                      jndiDestinationName="myDestination"/>
    </wsdl:port>
   </wsdl:service>

</wsdl:definitions>
```

### *Enabling a WSIF client to invoke a web service through JMS:*

The ways in which the Web Services Invocation Framework (WSIF) interacts with the Java Message Service (JMS), and the steps to take to enable a service to be invoked through JMS by a WSIF client application.

#### Before you begin

This topic assumes that you chose and configured a JMS provider when you installed WebSphere Application Server (either the default messaging provider, or another provider such as the WebSphere MQ messaging provider). If not, do so now as described in Choosing a messaging provider.

#### About this task

Here are the ways in which WSIF interacts with JMS:
- WSIF only supports input JMS properties.
- WSIF needs two queues when invoking an operation: one for the request message and one for the reply.
- The replyTo queue is by default a temporary queue, which WSIF creates on behalf of the application. You can specify a permanent queue by setting the **JMSReplyTo** property to the JNDI name of a queue.
- WSIF uses the default values for properties set by the JMS implementation.

To enable a service to be invoked through JMS by a WSIF client application, complete the following steps:

#### Procedure

1. Use the administrative console to create and configure a queue connection factory and a queue destination for your chosen messaging provider.

   For more information, see ../ae/tjn0000_.dita, Configuring JMS resources for the WebSphere MQ messaging provider or Managing messaging with a third-party or (deprecated) V5 default messaging provider.

   **Note:** In WebSphere MQ and some other JMS implementations, messages are persistent by default. The WSIF replyTo temporary queue is of type temporary dynamic by default, which means that your JMS provider cannot write a persistent response message to this queue. If you are using the WebSphere MQ messaging provider, create a temporary model queue that is of type permanent dynamic, then pass this model as the **tempmodel** of your queue connection factory. This ensures that persistent messages are written to a temporary replyTo queue that is of type permanent dynamic.
2. Use the administrative console to add the new queue destination to the list of JMS destination names for your application server. Ensure that the **Initial State** is started.

3. Put the JNDI names of the queue destination and queue connection factory, as well as your JNDI configuration, in the Web Services Description Language (WSDL) file.
4. Optional: If your client is running on an application server that has been migrated from WebSphere Application Server Version 5, you might get basic authentication errors and therefore have to modify your security settings. For more information see Web Services Invocation Framework troubleshooting tips.

***JMS message header: The TimeToLive property reference:***

The range of permitted values for the TimeToLive property of a JMS message that WSIF puts onto a queue.

The JMS message header property `JMSTimeToLive` is of type `long`. It sets the time to live of a message put onto a queue, in milliseconds. A value of `0` means live indefinitely.

The factors that determine the time to live of a JMS message are as follows:

- For a one-way (input only) operation, the default time to live is `0`, so the message remains on the queue indefinitely or until the server end-processes the message. The `JMSTimeToLive` value, if specified in the service endpoint URL or the JMS Address, is used for one-way messages. The client never waits for a response to a one-way operation and so it never times out. During a one-way operation, the client fails only if the queue itself is unavailable.
- For a two-way (request and response) operation the `JMSTimeToLive` value, if specified in the service endpoint URL or the JMS Address, is used for two-way messages. When the time to live is not specified, the default value is determined by the client response timeout setting.

## Writing the WSDL extension that lets your WSIF service invoke a method on a local Java object

Using the Web Services Invocation Framework (WSIF) Java provider, WSIF can invoke Java code. This means that, in a thin-client environment such as a Java virtual machine (JVM) or Tomcat test runtime environment, you can define shortcuts to local Java programs. Use this procedure to help you to write the Web Services Description Language (WSDL) extension that links your WSIF service to a local Java application.

### Before you begin

The WSIF Java provider is not intended for use in a Java Platform, Enterprise Edition (Java EE) environment. There is a difference between a client using the WSIF Java provider to invoke a Java component, and implementing a web service as a Java component on the server side.

### About this task

The WSIF Java binding exploits the format binding for type mapping. Using the format binding, your WSDL can define the mapping between XML schema types and Java types.

The WSIFJava provider requires the targeted Java classes to be on the class path of the client. The Java method is invoked synchronously, in-process, in-thread, with the current thread and Object Request Broker (ORB) contexts.

The WSIF Java provider is not transactional.

The WSIF Java provider does not support the WSIF synchronous timeout. The Java provider will not time out waiting for a Java method to complete.

Use the following procedure, and associated code fragments, to help you to specify the WSDL extension that enables your WSIF service to invoke a method on a local Java object.

### Procedure

- Specify the Java binding.

  To use the Java provider, you need the following binding specified in the WSDL file:

```
<!-- Java binding -->
<binding .... >
    <java:binding />
    <format:typeMapping style="Java" encoding="Java"/>?
        <format:typeMap name="qname" formatType="nmtoken"/>*
    </format:typeMapping>
    <operation>*
        <java:operation
            methodName="nmtoken"
            parameterOrder="nmtoken"
            returnPart="nmtoken"?
            methodType="instance|constructor" />
        <input name="nmtoken"? />?
        <output name="nmtoken"? />?
        <fault name="nmtoken"? />?
    </operation>
</binding>
```

  In this example:
  - A question mark (?) means optional, and an asterisk (*) means 0 or more.
  - The `name` attribute of the `<format:typeMap>` element is a qualified name of a simple or complex type used by one of the Java operations.
  - The `formatType` attribute of the `<format:typeMap>` element is the fully qualified class name for the Java class to which the element specified by `name` maps.
  - The `methodName` attribute of the `<java:operation>` element is the name of the method on the Java object that is called by the operation.
  - The `parameterOrder` attribute of the `<java:operation>` element contains a white space-separated list of part names that define the order in which they are passed to the Java object method.
  - The `methodType` attribute of the `<java:operation>` element must be set to either `instance` or `constructor`. The value specifies whether the method that is invoked on the object is an instance method or a constructor for the object.

- Specify the `<java:address>` element.

  The `className` attribute of the `<java:address>` element specifies the fully qualified class name of the object containing the method to invoke:

```
<service ... >
    <port>*
        <java:address
            className="nmtoken"/>
    </port>
</service>
```

## Writing the WSDL extension that lets your WSIF service invoke an enterprise bean

Using the EJB provider, WSIF clients can invoke enterprise beans through Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP). Use this information, and associated code fragments, to help you to write the Web Services Description Language (WSDL) extension that links your WSIF service to a service implemented as an enterprise bean.

### Before you begin

Although you can use the EJB provider for EJB(IIOP)-based web service invocation, it is recommended that you instead invoke RMI-IIOP web services by using JAX-RPC.

The EJB client JAR file must be available in the client runtime environment with the current provider.

The EJB provider does not support the WSIF synchronous timeout. The EJB provider will not time out waiting for a Java method to complete.

## About this task

Your WSIF client can invoke an enterprise bean by using RMI-IIOP, with the current security and transaction contexts. If the EJB provider is invoked within a transaction, the transaction is passed to the onward service and the standard EJB transaction attribute applies.

If there are multiple implementations of the service, it is up to the service providers to make sure that every implementation offers the same semantics. For example, for transactions, the bean deployer must specify `TX_REQUIRES_NEW` to force a new transaction.

Use the following procedure, and associated code fragments, to help you to write the Web Services Description Language (WSDL) extension that enables your WSIF service to invoke an enterprise bean.

## Procedure

- Specify the EJB binding.

```
<!-- EJB binding -->
<binding .... >
    <ejb:binding />
    <format:typeMapping style="Java" encoding="Java"/>?
        <format:typeMap name="qname" formatType="nmtoken"/>*
    </format:typeMapping>
    <operation>*
        <ejb:operation
            methodName="nmtoken"
            parameterOrder="nmtoken"
            returnPart="nmtoken"?
            interface="remote|home" />
        <input name="nmtoken"? />?
        <output name="nmtoken"? />?
        <fault name="nmtoken"? />?
    </operation>
</binding>
```

  In this example:
  - A question mark (?) means optional, and an asterisk (*) means 0 or more.
  - The `name` attribute of the `<format:typeMap>` element is a qualified name of a simple or complex type used by one of the EJB operations.
  - The `formatType` attribute of the `<format:typeMap>` element is the fully qualified class name for the Java class to which the element specified by `name` maps.
  - The `methodName` attribute of the `<ejb:operation>` element is the name of the method on the enterprise bean that is called by the operation.
  - The `parameterOrder` attribute of the `<ejb:operation>` element contains a white space-separated list of part names that define the order in which they are passed to the EJB method.
  - The `interface` attribute of the `<ejb:operation>` element must be set to either `remote` or `home`. The value specifies the interface of the enterprise bean on which the method named by the `methodName` attribute is accessible.

- Specify the `<ejb:address>` element.

```
<service ... >
    <port>*
        <ejb:address
            className="nmtoken"
            jndiName="nmtoken"
            initialContextFactory="nmtoken" ?
            jndiProviderURL="nmtoken" ? />
    </port>
</service>
```

  In this example:
  - The `className` attribute of the `<ejb:address>` element specifies the fully qualified class name of the home interface class of the enterprise bean.

– The `jndiName` attribute of the `<ejb:address>` element specifies the full Java Naming and Directory Interface (JNDI) name that is used to look up the enterprise bean.
– The `initialContextFactory` attribute of the `<ejb:address>` element is optional and specifies the initial context factory class.
– The `jndiProviderURL` attribute of the `<ejb:address>` element is optional and specifies the JNDI provider web address.

# Developing a WSIF service

A Web Services Invocation Framework (WSIF) service is a web service that uses WSIF.

## About this task

To develop a WSIF service, develop the web service (or use an existing web service), then develop the WSIF client based on the Web Services Description Language (WSDL) document for that Web service.

There are also two pre-built WSIF samples available for download from the WebSphere Application Server samples page of the developerWorks website:
- The Address Book sample.
- The Stock Quote sample.

For more information about using the pre-built samples, see the documentation that is included in the developerWorks download package. Note that these samples were written to work with WebSphere Application Server Version 5.

To develop a WSIF service, complete the following steps:

## Procedure

1. Implement the web service.

   Use web services tools to discover, create, and publish the web service. You can develop Java bean, enterprise bean, and URL web services. You can use web service tools to create skeleton Java code and a sample application from a WSDL document. For example, an enterprise bean can be offered as a Web service, and use Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) as the access protocol. Or you can use a Java class as a web service, with native Java invocations as the access protocol.

   You can use the WebSphere Studio Application Developer to create a web service from a Java application, as described in its StockQuote service tutorial. The Java application that you use in this scenario returns the last trading price from the Internet website www.xmltoday.com, given a stock symbol. Using the web service wizard, you generate a binding WSDL document named `StockQuoteService-binding.wsdl` and a service WSDL document named `StockQuoteService-service.wsdl` from the `StockQuoteService.java` bean. You then deploy the web service to a web server, generate a client proxy to the Web service, and generate a sample application that accesses the StockQuoteService through the client proxy. You test the StockQuote web service, publish it by using the IBM UDDI Explorer, and then discover the StockQuote web service in the IBM UDDI Test Registry.
2. Develop the WSIF client.

   Use the following information to help you develop a WSIF client:
   - “Example: Using WSIF to invoke the AddressBook sample web service dynamically” on page 1710 gives example code to show how you define a web service in WSDL.
   - “Linking a WSIF service to the underlying implementation of the service” on page 1693 describes the available providers, and gives example code of how their WSDL extensions are coded.
   - “Invoking a WSDL-based web service through the WSIF API” on page 1723 defines the main interfaces that your client uses to support the invocation of Web services defined in WSDL.

The AddressBook sample is written for synchronous interaction. If you are using a JMS provider, your WSIF client might have to act asynchronously. WSIF provides two main features that meet this requirement:

- A correlation service that assigns identifiers to messages so that the request can match up with the (eventual) response.
- A response handler that picks up the response from the web service at a later time.

For more information, see “WSIFOperation - Asynchronous interactions reference” on page 1727.

## Example: Using WSIF to invoke the AddressBook sample web service dynamically

This is example code for dynamic invocation of the AddressBook sample web service by using WSIF:

```
try {
    String wsdlLocation="clients/addressbook/AddressBookSample.wsdl";

    // The starting point for any dynamic invocation using wsif is a
    // WSIFServiceFactory. Create one through the newInstance
    // method.
    WSIFServiceFactory factory = WSIFServiceFactory.newInstance();

    // Once you have a factory, you can use it to create a WSIFService object
    // corresponding to the AddressBookService service in the wsdl file.
    // Note: because you only have one service defined in the wsdl file, you
    // do not have to use the namespace and name of the service and can pass
    // null instead. This also applies to the port type, although values have
    // been used below for illustrative purposes.
    WSIFService service = factory.getService(
        wsdlLocation,    // location of the wsdl file
        null,            // service namespace
        null,            // service name
       "http://www.ibm.com/namespace/wsif/samples/ab", // port type namespace
        "AddressBookPT" // port type name
    );

    // The AddressBook.wsdl file contains the definitions for two complexType
    // elements within the schema element. Map these complexTypes
    // to Java classes. These mappings are used by the Apache SOAP provider
    service.mapType(
        new javax.xml.namespace.QName(
            "http://www.ibm.com/namespace/wsif/samples/ab/types",
            "address"),
        Class.forName("com.ibm.www.namespace.wsif.samples.ab.types.WSIFAddress"));
    service.mapType(
        new javax.xml.namespace.QName(
            "http://www.ibm.com/namespace/wsif/samples/ab/types",
            "phone"),
        Class.forName("com.ibm.www.namespace.wsif.samples.ab.types.WSIFPhone"));
        // You now have a WSIFService object. The next step is to create a WSIFPort
        // object for the port you want to use. The getPort(String portName) method
        // allows us to generate a WSIFPort from the port name.
    WSIFPort port = null;

    if (portName != null) {
        port = service.getPort(portName);
    }
    if (port == null) {
        // If no port name was specified, attempt to create a WSIFPort from
        // the available ports for the port type specified on the service
        port = getPortFromAvailablePortNames(service);
    }

    // Once you have a WSIFPort, you can create an operation. Execute
    // the addEntry operation and therefore attempt to create a WSIFOperation
    // corresponding to it. The addEntry operation is overloaded in the wsdl i.e.
// there are two versions of it, each taking different parameters (parts).
```

```
// This overloading requires that you specify the input and output message
// names for the operation in the createOperation method so that the correct
// operation can be resolved.
      // Because the addEntry operation has no output message, you use null for its name.
      WSIFOperation operation =
          port.createOperation("addEntry", "AddEntryWholeNameRequest", null);

      // Create messages to use in the execution of the operation. This should
      // be done by invoking the createXXXXXMessage methods on the WSIFOperation.
      WSIFMessage inputMessage = operation.createInputMessage();
      WSIFMessage outputMessage = operation.createOutputMessage();
      WSIFMessage faultMessage = operation.createFaultMessage();

      // Create a name and address to add to the addressbook
      String nameToAdd="Chris P. Bacon";
      WSIFAddress addressToAdd =
          new WSIFAddress (1,
              "The Waterfront",
              "Some City",
              "NY",
              47907,
              new WSIFPhone (765, "494", "4900"));

      // Add the name and address to the input message
      inputMessage.setObjectPart("name", nameToAdd);
      inputMessage.setObjectPart("address", addressToAdd);

      // Execute the operation, obtaining a flag to indicate its success
      boolean operationSucceeded =
          operation.executeRequestResponseOperation(
              inputMessage,
              outputMessage,
              faultMessage);

      if (operationSucceeded) {
          System.out.println("Successfully added name and address to addressbook\n");
      } else {
          System.out.println("Failed to add name and address to addressbook");
      }

      // Start from fresh
      operation = null;
      inputMessage = null;
      outputMessage = null;
      faultMessage = null;

      // This time you will lookup an address from the addressbook.
      // The getAddressFromName operation is not overloaded in the
      // wsdl and therefore you can specify the operation name
      // without any input or output message names.
      operation = port.createOperation("getAddressFromName");

      // Create the messages
      inputMessage = operation.createInputMessage();
      outputMessage = operation.createOutputMessage();
      faultMessage = operation.createFaultMessage();

      // Set the name to find in the addressbook
      String nameToLookup="Chris P. Bacon";
      inputMessage.setObjectPart("name", nameToLookup);

      // Execute the operation
      operationSucceeded =
          operation.executeRequestResponseOperation(
              inputMessage,
              outputMessage,
              faultMessage);
```

```
        if (operationSucceeded) {
            System.out.println("Successful lookup of name '"+nameToLookup+"' in addressbook");

            // You can get the address that was found by querying the output message
            WSIFAddress addressFound = (WSIFAddress) outputMessage.getObjectPart("address");
            System.out.println("The address found was:");
            System.out.println(addressFound);
        } else {
            System.out.println("Failed to lookup name in addressbook");
        }

    } catch (Exception e) {
        System.out.println("An exception occurred when running the sample:");
        e.printStackTrace();
    }
}
```

The preceding code refers to the following Sample method:

```
    WSIFPort getPortFromAvailablePortNames(WSIFService service)
            throws WSIFException {
        String portChosen = null;

        // Obtain a list of the available port names for the service
        Iterator it = service.getAvailablePortNames();
        {
            System.out.println("Available ports for the service are: ");
            while (it.hasNext()) {
                String nextPort = (String) it.next();
                if (portChosen == null)
                    portChosen = nextPort;
                System.out.println(" - " + nextPort);
            }
        }
        if (portChosen == null) {
            throw new WSIFException("No ports found for the service!");
        }
        System.out.println("Using port " + portChosen + "\n");

        // An alternative way of specifying the port to use on the service
        // is to use the setPreferredPort method. Once a preferred port has
        // been set on the service, a WSIFPort can be obtained through getPort
        // (no arguments). If a preferred port has not been set and more than
        // one port is available for the port type specified in the WSIFService,
        // an exception is thrown.
        service.setPreferredPort(portChosen);
        WSIFPort port = service.getPort();
        return port;
    }
```

The web service uses the following classes:

WSIFAddress:

```
public class WSIFAddress implements Serializable {

    //instance variables
    private int streetNum;
    private java.lang.String streetName;
    private java.lang.String city;
    private java.lang.String state;
    private int zip;
    private WSIFPhone phoneNumber;

    //constructors
    public WSIFAddress () { }
```

```
    public WSIFAddress (int streetNum,
                        java.lang.String streetName,
                        java.lang.String city,
                        java.lang.String state,
                        int zip,
                        WSIFPhone phoneNumber) {
          this.streetNum = streetNum;
          this.streetName = streetName;
          this.city = city;
          this.state = state;
          this.zip = zip;
          this.phoneNumber = phoneNumber;
    }

    public int getStreetNum() {
          return streetNum;
    }

    public  void setStreetNum(int streetNum) {
          this.streetNum = streetNum;
    }

    public java.lang.String getStreetName() {
          return streetName;
    }

    public  void setStreetName(java.lang.String streetName) {
          this.streetName = streetName;
    }

    public java.lang.String getCity() {
          return city;
    }

    public  void setCity(java.lang.String city) {
          this.city = city;
    }

    public java.lang.String getState() {
          return state;
    }

    public  void setState(java.lang.String state) {
          this.state = state;
    }

    public int getZip() {
          return zip;
    }

    public  void setZip(int zip) {
          this.zip = zip;
    }

    public WSIFPhone getPhoneNumber() {
          return phoneNumber;
    }

    public  void setPhoneNumber(WSIFPhone phoneNumber) {
          this.phoneNumber = phoneNumber;
    }
}
```

WSIFPhone:

```
public class WSIFPhone implements Serializable {

    //instance variables
    private int areaCode;
    private java.lang.String exchange;
    private java.lang.String number;

    //constructors
    public WSIFPhone () { }

    public WSIFPhone (int areaCode,
                      java.lang.String exchange,
                      java.lang.String number) {
          this.areaCode = areaCode;
          this.exchange = exchange;
          this.number = number;
    }

    public int getAreaCode() {
          return areaCode;
    }

    public  void setAreaCode(int areaCode) {
          this.areaCode = areaCode;
}

    public java.lang.String getExchange() {
          return exchange;
    }

    public  void setExchange(java.lang.String exchange) {
          this.exchange = exchange;
    }

    public java.lang.String getNumber() {
          return number;
    }

    public  void setNumber(java.lang.String number) {
          this.number = number;
    }
}
```

WSIFAddressBook:

```
public class WSIFAddressBook {
    private Hashtable name2AddressTable = new Hashtable();

    public WSIFAddressBook() {
    }

    public void addEntry(String name, WSIFAddress address)
    {
        name2AddressTable.put(name, address);
    }

    public void addEntry(String firstName, String lastName, WSIFAddress address)
    {
        name2AddressTable.put(firstName+" "+lastName, address);
    }

    public WSIFAddress getAddressFromName(String name)
        throws IllegalArgumentException
    {

        if (name == null)
        {
```

```
            throw new IllegalArgumentException("The name argument must not be " +
                                               "null.");
        }
        return (WSIFAddress)name2AddressTable.get(name);
    }

}
```

The following code is the corresponding WSDL file for the web service:

```
<?xml version="1.0" ?>

```

## Using complex types

WSIF supports user-defined complex types through the mapping of complex types to Java classes. You can specify this mapping manually or automatically.

## About this task

Any calls to the WSIFService mapType and mapPackage methods used for manual mapping override any equivalent mapping information that is produced automatically. This override helps to maintain backwards compatibility, and also accommodates less standard mappings.

To map your user-defined complex types to Java classes, complete either of the following steps:
- Manually map complex types.
- Automatically map complex types.

## Procedure

- Manually map complex types.

  The method to use when you create these mappings manually depends on the provider. For the Java and EJB providers, the mappings are specified in the Web Services Description Language (WSDL) file in the binding element. The following example provides the syntax for specifying the mapping:

```
<binding .... >
    <ejb:binding|java:binding/>
      <format:typeMapping style="Java" encoding="Java"/>?
          <format:typeMap typeName="qname" formatType="nmtoken"/>*
      </format:typeMapping>
 ...
</binding>
```

  In this example:

  – A question mark (“?”) means “optional” and an asterisk (“*”) means “0 or more”.

  – The format:typeMap **typeName** attribute is a qualified name of a complex type or simple type used by one of the operations.

  – The format:typeMap **formatType** attribute is the fully qualified class name for the Java class to which the element specified by **typeName** maps.

  If you use the Apache SOAP provider then you specify the mapping of a complex type to a Java class in the client code through two methods on the org.apache.wsif.WSIFService interface:

```
public void mapType(QName elementType, Class javaType)
```

  and

```
public void mapPackage(String namespaceURI, String packageName)
```

  Use the **mapType** method to specify a mapping between an XML schema element and a Java class. The method takes a QName representing the complex type or simple type, and the corresponding Java class to which it maps.

  Use the **mapPackage** method to specify a more general mapping between a namespace and a Java package. Any custom, complex or simple type whose namespace matches that of the mapping is mapped to a Java class in the corresponding package. The name of the class is derived from the name of the complex type using standard XML to Java naming conventions.

- Automatically map complex types.

  For complex types defined in the WSDL, where a generated bean is used to represent this type in Java, the Web Services Invocation Framework (WSIF) programming model requires that a call is made to the WSIFService.mapType() method. This call tells WSIF the package and class name of the bean representing the XML schema type that is identified with a QName. To make things easier, the WSIFService.mapPackage() method provides a mechanism to specify a wildcard version of this, where any class within a specified package is mapped to the namespace of a QName. This is a mechanism for manually mapping an XML schema type to a Java class and back again (one mapping entry provides a bidirectional mapping).

  There are many ways to convert a QName representing an XML schema type name to a Java package name and class. To enable automatic type mapping, set the WSIF_FEATURE_AUTO_MAP_TYPES feature on the WSIFServiceFactory instance:

```
WSIFServiceFactory factory = WSIFServiceFactory.newInstance();
factory.setFeature(WSIFConstants.WSIF_FEATURE_AUTO_MAP_TYPES, new Boolean(true));
```

WSIF maps types by converting the URI part of the XML schema type QName to a package name, and converting the local part to a class name. WSIF does this mapping by using the WSIFUtils methods getPackageNameFromNamespaceURI and getJavaClassNameFromXMLName.

## Using WSIF to bind a JNDI reference to a web service

You can use the Web Services Invocation Framework (WSIF) to bind a reference to a web service, then look up the reference by using JNDI.

### About this task

You access a web service through information provided in the Web Services Description Language (WSDL) document for the service. If you do not know where to find the WSDL document for the service, but you know that it has been registered in a UDDI registry, then you look it up in the registry. Java programs access Java objects and resources in a similar manner, but using a JNDI interface.

The code fragments in the following steps show how, by using WSIF, you can bind a reference to a web service then look up the reference by using JNDI.

### Procedure

- Specify the argument values for the web service.

  The web service is represented in WSIF by an instance of the org.apache.wsif.naming.WSIFServiceRef class. This simple Referenceable object has the following constructor:

```
public WSIFServiceRef(
        String WSDL,
        String sNS,
        String sName,
        String ptNS,
        String ptName)
{
    [...]
}
```

  In this example
  - *WSDL* is the location of the WSDL file containing the definition of the service.
  - *sNS* is the full namespace for the service definition (you can specify `null` if only one service is defined in the WSDL file).
  - *sName* is the local name for the service definition (you can specify `null` if only one service is defined in the WSDL file).
  - *ptNS* is the full namespace for the port type within the service that you want to use (you can specify `null` if only one port type is available for the service).
  - *ptName* is the local name for the port type (you can specify `null` if only one port type is available for the service).

  For example, if the WSDL file for the web service is available from the web address `http://myServer/WSDL/Example.WSDL` and contains the following service and port type definitions:

```
  <definitions targetNamespace="http://hostname/namespace/example"
               xmlns:abc="http://hostname/namespace/abc"
[...]
    <portType name="ExamplePT">
      <operation name="exampleOp">
        <input name="exampleInput" message="tns:ExampleInputMsg"/>
      </operation>
    </portType>
[...]
    <service name="abc:ExampleService">
```

```
[...]
    </service>
[...]
  </definitions>
```

You can specify the following argument values for the WSIFServiceRef class:
- *WSDL* is `http://myServer/WSDL/Example.WSDL`
- *sNS* is `http://hostname/namespace/abc`
- *sName* is `ExampleService`
- *ptNS* is `http://hostname/namespace/example`
- *ptName* is `ExamplePT`

- Bind the service by using JNDI.

  To bind the service reference in the naming directory by using JNDI, you can use the com.ibm.websphere.naming.JndiHelper class in WebSphere Application Server:

```
[...]
    import com.ibm.websphere.naming.JndiHelper;
    import org.apache.wsif.naming.*;
[...]
    try {
       Context startingContext = new InitialContext();
       WSIFServiceRef ref = new WSIFServiceRef("http://myServer/WSDL/Example.WSDL",
                                               "http://hostname/namespace/abc"
                                               "ExampleService",
                                               "http://hostname/namespace/example",
                                               "ExamplePT");
       JndiHelper.recursiveRebind(startingContext,
            "myContext/mySubContext/myServiceRef", ref);

    }
    catch (NamingException e) {
       // Handle  error.
    }
[...]
```

- Look up the service by using JNDI.

  The following code fragment shows the lookup of a service by using JNDI:

```
[...]
    try {
[...]
       InitialContext ic = new InitialContext();
       WSIFService myService =
        (WSIFService) ic.lookup("myContext/mySubContext/myServiceRef");
[...]
    }
    catch (NamingException e) {
       // Handle error.
    }
[...]
```

## Example: Passing SOAP messages with attachments by using WSIF

Information and example code for using the Web Services Invocation Framework (WSIF) SOAP provider to pass attachments within a MIME multipart/related message in such a way that the SOAP processing rules for a standard SOAP message are not changed. This includes how to write the Web Services Description Language (WSDL) extensions for SOAP attachments, and how to work with types and type mappings.

The W3C SOAP Messages with Attachments document describes a standard way to associate a SOAP message with one or more attachments in their native format (for example GIF or JPEG) by using a multipart MIME structure for transport. It defines specific use of the “Multipart/Related” MIME media type, and rules for the use of URI references to entities bundled within the MIME package. It thereby outlines a

technique for carrying a SOAP 1.1 message within a MIME multipart/related message in such a way that the SOAP processing rules for a standard SOAP message are not changed.

WSIF supports passing attachments in a MIME message using the SOAP provider to link a WSIF service to a SOAP over HTTP service. The attachment is a javax.activation.DataHandler object. The mime:multipartRelated, mime:part and mime:content tags are used to describe the attachment in the WSDL.

- "Example: Writing the WSDL extensions for SOAP attachments"
- "Example: Using WSIF to pass SOAP attachments"
- "SOAP attachments - Working with types and type mappings" on page 1722
- "SOAP attachments - scenarios that are not supported" on page 1722

### Example: Writing the WSDL extensions for SOAP attachments

The following example WSDL illustrates a simple operation that has one attachment called `attch`:

```
<binding name="MyBinding" type="tns:abc" >
  <soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/http"/>
  <operation name="MyOperation">
    <soap:operation soapAction=""/>
    <input>
      <mime:multipartRelated>
        <mime:part>
          <soap:body use="encoded" namespace="http://mynamespace"
            encodingStyle="http://schemas.xmlsoap.org/soap/encoding"/>
        </mime:part>
        <mime:part>
          <mime:content part="attch" type="text/html"/>
        </mime:part>
      </mime:multipartRelated>
    </input>
  </operation>
</binding>
```

In this type of WSDL extension:

- There must be a `part` attribute (in this example `attch`) on the input message for the operation (in this example `MyOperation`). There can be other input parts to `MyOperation` that are not attachments.
- In the binding input there must either be a `<soap:body>` tag or a `<mime:multipartRelated>` tag, but not both.
- For MIME messages, the `<soap:body>` tag is inside a `<mime:part>` tag. There must only be one `<mime:part>` tag that contains a `<soap:body>` tag in the binding input and that must not contain a `<mime:content>` tag as well, because a content type of `text/xml` is assumed for the `<soap:body>` tag.
- There can be multiple attachments in a MIME message, each described by a `<mime:part>` tag.
- Each `<mime:part>` tag that does not contain a `<soap:body>` tag contains a `<mime:content>` tag that describes the attachment itself. The `type` attribute inside the `<mime:content>` tag is not checked or used by the Web Services Invocation Framework (WSIF). It is there to suggest to the application that uses WSIF what the attachment contains. Multiple `<mime:content>` tags inside a single `<mime:part>` tag means that the backend service expects a single attachment with a type specified by one of the `<mime:content>` tags inside that `<mime:part>` tag.
- The `parts="..."` attribute (optional) inside the `<soap:body>` tag is assumed to contain the names of all the MIME parts as well as the names of all the SOAP parts in the message.

### Example: Using WSIF to pass SOAP attachments

The following code fragment can invoke the service described by the example WSDL in "Example: Writing the WSDL extensions for SOAP attachments":

```
import javax.activation.DataHandler;
. . .
DataHandler dh = new DataHandler(new FileDataSource("myimage.jpg"));
WSIFServiceFactory factory = WSIFServiceFactory.newInstance();
```

```
WSIFService service = factory.getService("my.wsdl",null,null,"http://mynamespace","abc");
WSIFOperation op = service.getPort().createOperation("MyOperation");
WSIFMessage in = op.createInputMessage();
in.setObjectPart("attch",dh);
op.executeInputOnlyOperation(in);
```

The associated type mapping in the `DeploymentDescriptor.xml` file depends upon your SOAP server. For example if you use Tomcat with SOAP 2.3, then the `DeploymentDescriptor.xml` file contains the following type mapping:

```
<isd:mappings>
<isd:map encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"
 xmlns:x="http://mynamespace"
 qname="x:datahandler"
 javaType="javax.activation.DataHandler"
 java2XMLClassName="org.apache.soap.encoding.soapenc.MimePartSerializer"
 xml2JavaClassName="org.apache.soap.encoding.soapenc.MimePartSerializer" />
</isd:mappings>
```

In this case, the backend service is invoked with the following signature:

```
public void MyOperation(DataHandler dh);
```

You can also use stubs to pass attachments into the Web Services Invocation Framework (WSIF):

```
DataHandler dh = new DataHandler(new FileDataSource("myimage.jpg"));
WSIFServiceFactory factory = WSIFServiceFactory.newInstance();
WSIFService service = factory.getService("my.wsdl",null,null,"http://mynamespace","abc");
MyInterface stub = (MyInterface)service.getStub(MyInterface.class);
stub.MyOperation(dh);
```

Attachments can also be returned from an operation, but only one attachment can be returned as the return parameter.

### SOAP attachments - Working with types and type mappings

By default, attachments are passed into WSIF as DataHandler objects. If the part on the message that is the DataHandler object maps to a `<mime:part>` tag in the WSDL, then WSIF automatically maps the fully qualified name of the WSDL type to the DataHandler class and sets up that type mapping with the SOAP provider.

In your WSDL, you might have defined a schema for the attachment (for instance as a `binary[]` type). WSIF silently ignores this mapping and treats the attachment as a DataHandler object, unless you explicitly issue a `mapType()` method. WSIF lets the SOAP provider set the MIME content type based on the type of the DataHandler object, instead of the `type` attribute specified for the `<mime:content>` tag in the WSDL.

### SOAP attachments - scenarios that are not supported

The following scenarios are not supported:
- Using DIME.
- Passing in `javax.xml.transform.Source` and `javax.mail.internet.MimeMultipart`.
- Using the mime:mimeXml WSDL tag.
- Nesting a mime:multipartRelated tag inside a mime:part tag.
- Using types that extend `DataHandler`, `Image`, and so on.
- Using types that contain `DataHandler`, `Image`, and soon.
- Using Arrays or Vectors of `DataHandlers`, `Images`, and so on.
- Using multiple in/out or output attachments.

The MIME headers from the incoming message are not preserved for referenced attachments. The outgoing message contains new MIME headers for Content-Type, Content-Id and Content-Transfer-Encoding that are created by WSIF.

# Interacting with the Java EE container in WebSphere Application Server

How, and to what extent, WSIF interacts with the Java EE container that is provided in WebSphere Application Server.

## About this task

You can interact with a container in any of the following ways:

## Procedure

- Use the application server administrative console to define web services to WebSphere Application Server. This task is described in “Using WSIF to bind a JNDI reference to a web service” on page 1719. As part of the definition of a service, the administrator might define a “preferred port”.
- Use the Web Services Invocation Framework (WSIF) to make log and trace calls to the JRAS services in WebSphere Application Server, as described in Tracing and logging WSIF.
- Use WSIF providers to access Java Platform, Enterprise Edition (Java EE) services. For example, use the EJB provider to access the Java Naming and Directory Interface (JNDI) and make calls to remote enterprise beans.
- Use WSIF to wrap the use of container services so that, when WSIF is run in an unmanaged (thin) environment, the operation can succeed.

# Invoking a WSDL-based web service through the WSIF API

The Web Services Invocation Framework (WSIF) provides a Java API for invoking web services, independent of the format of the service, or the transport protocol through which it is invoked.

## Before you begin

WSIF includes an EJB provider for EJB invocation that uses the Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP). However, for EJB(IIOP)-based web service invocation, invoke RMI-IIOP Web services using JAX-RPC instead.

Ensure that your application uses only one thread to call WSIF.

## About this task

The WSIF API supports the invocation of Web Services Description Language (WSDL)-defined web services. WSIF is intended for use in both WSIF clients and web service intermediaries.

The WSIF API is driven by the abstract service description in WSDL; it is completely independent of the binding used. This independence makes the API more natural to work with because it uses WSDL terms to refer to message parts, operations, and other items.

The WSIF API was designed for the WSDL usage model:

1. Select a port that supports the port type that you need.
2. Invoke the operation by providing the necessary abstract input message consisting of the required parts, without worrying about how the message is mapped to a specific binding protocol.

Other web service APIs, for example SOAP APIs, are not designed on WSDL, but for a specific binding protocol with its associated syntax; for example, target URIs and encoding styles.

The main WSIF API interfaces are described in the following procedure. For additional technical details of the WSIF API, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

## Procedure

- Create a message for sending to a port through the WSIFMessage interface.

  In WSDL, a message describes the abstract type of the input or output to an operation. The corresponding WSIF class is WSIFMessage, which represents in memory the input or output of an operation. The WSIFMessage interface separates the representation of the data from the abstract type defined by WSDL.

  A WSIFMessage class is a container for a set of named parts. WSIFMessage classes can be sent between Java Virtual Machines (JVMs).

  1. Choose whether to represent the WSIF message at run time as a Java class or as XML.

     There are two natural ways to represent a WSDL message in a runtime environment:
     – The generated Java class, based on a WSDL to Java mapping such as that provided by a Java API for XML-based remote procedure call (JAX-RPC).
     – The XML representation of the data, for example using SOAP Encoding.

     Each option offers benefits in different scenarios. The Java class is the natural approach when WSIF is used in a standard Java client. However, in other scenarios where WSIF is used in an intermediary, it might be more efficient to keep a WSDL message in the SOAP encoded format. The style used to define messages must be consistent within the message, so all the parts in one message must be consistent. A string - `getRepresentationStyle()` - always returns `null`. This indicates that parts on this WSIFMessage class are represented as Java objects.

  2. Get and set the parts of the WSIF message.

     You add parts to a WSIFMessage class with the setObjectPart or set*Type*Part methods. Each part is named. Part names within a message are unique. If you set a part more than once, the last setting is the one that is used.

     You retrieve parts by name from a WSIFMessage class with the getObjectPart or get*Type*Part methods. If the named part does not exist, the method returns a WSIFException error.

     You can use Iterators to retrieve parts from the message through the getParts() and getPartNames() methods.

     The order in which you set the parts is not important, but the message implementation might be more efficient if the parts are set in the parameter order specified by WSDL.

     WSIFMessage classes are cloneable and serializable. If the parts set are not cloneable, the implementation can try to clone them using serialization. If the parts are not serializable either, then a CloneNotSupportedException exception is thrown if cloning is attempted.

  3. Set the WSIF message name.

     In addition to the containing parts, a WSIFMessage class also has a message name. This is required for operation overloading, which is supported by WSDL and WSIF.

  For more information about the WSIFMessage interface (/wsi/org/apache/wsif/WSIFMessage.html) see the generated API documentation that is supplied with WSIF.

- Find a port factory or service through the WSIFService interface and the WSIFServiceFactory class.

  The WSIFService interface is a port factory that models and supports the WSDL approach in which a service is available on one or more ports. The factory hides the implementation of the port. WSIF supports dynamic ports that are based on a particular protocol and transport and configured using the WSDL at run time. For example, the dynamic SOAP port can invoke any SOAP service based on the WSDL description of that service, so you can hide and modify the set of available ports at run time.

  To find a service from a WSDL document at a web address, or from a code-generated code base, use the WSIFServiceFactory class.

- Invoke an operation through the WSIFPort interface and the WSIFOperation interface.

  A WSIFPort interface handles the details of invoking an operation. The port provides access to the implementation of the service.

A WSDL document can provide many different WSDL bindings, and these bindings can drive multiple ports. The client can choose a port, the service stub can choose a port, or WSIF can choose a default port.

The port offers an interface to retrieve an Operation object. A WSIFOperation interface offers the ability to run the given operation.

If the port is serialized and deserialized at a later time, WSIF ensures that the client provides the correct information to the server to identify the instance. If the server instance is no longer available, the server must decide whether to create a fault or provide a new instance. That behavior can depend on the type of service. For example, for an enterprise bean, the WSIFPort interface stores the EJB Home and uses it to select the bean before each invocation. The client is responsible for serializing or maintaining the port instance if it requires instance support. The client must create a new operation and messages for each invocation.

## WSIFService interface

The WSIFService interface can generate an instance of the WSIFOperation interface to use for a particular invocation of a service operation.

The Web Services Invocation Framework (WSIF) service stores a list of providers that can each generate a WSIF operation for a particular Web Services Description Language (WSDL) binding. This service looks up providers by the provider type. For example, the service knows about one provider that handles SOAP ports, and other providers that handle Java ports that you define. In a managed environment, the container can configure the WSIFService interface.

For more information about the WSIFService interface, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

A WSIFService implementation can choose a preferred port based on a number of criteria. The WSIFService implementation can set the preferred port, or it can be set by calling the setPreferredPort method.

The getPort method returns an instance of the WSIFPort class that is used to invoke a service on the port. Variants of the getPort method are used to define the characteristics of the port to be created:

- the getPort method with no arguments returns the preferred port.
- the getPort method with a string argument returns the port named by the string containing the WSDL identifier for the selected port.

The return value is `null` if the port name is not valid.

If a port is chosen (either by the WSIFService implementation, or by the setPreferredPort method), then the WSIFService implementation validates that the relevant provider exists and is configured. If the provider fails this validation check, the WSIFService interface chooses any other port for which a provider is defined. For example, if the preferred port is SOAP over JMS but the JMS libraries are not available, then WSIF chooses another port. If no preferred port is set, or the preferred port is not available, the WSIF implementation chooses the first available port listed in the WSDL.

The getAvailablePortNames() method returns, as an iteration of strings, the list of WSDL port names filtered by the set of available providers.

The getDefinition() method returns the WSDL definition for the service. If the WSDL definition is not available, this method returns `null`.

## WSIFServiceFactory class

To find a service from a Web Services Description Language (WSDL) document at a web address, or from a code-generated code base, you can use the WSIFServiceFactory class.

**Note:** When you create a WSIFService interface from a WSIFServiceFactory class, you can specify a ClassLoader object to use in locating the WSDL file. You must specify this object when the WSDL file is in a JAR file. In such a case, specify the location of the WSDL file relative to the root of the JAR file, and use forward slashes (/) with the preceding slash removed.

For example:

```
com/myCompany/wsdl/MyWSDLFile.wsdl
```

rather than

```
/com/myCompany/wsdl/MyWSDLFile.wsdl
```

For more information about the WSIFServiceFactory class, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

The WSIFServiceFactory class returns `null` if no service is found with that identifier.

## WSIFPort interface

The port implements a factory method for the WSIFOperation interface.

For detailed information about the WSIFPort interface, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

The createOperation(String) method returns a new instance of a WSIFOperation object. If the operationName value is not valid, or the operation is overloaded, the method throws an exception.

The createOperation(String, String, String) method supports overloaded Web Services Description Language (WSDL) operations. You can overload based on the input parameters, but not on the output parameters.

The client must call the close method when a port is no longer in use. In many cases, where the transport is sessionless, such as HTTP, this has no effect. However, if the port is using a session-based protocol such as MQSeries, Java Message Service (JMS), or External Call Interface (ECI), this supports the port in caching an open connection to the server and then closing it as required. Responsibly-written applications will call the close method if appropriate.

## WSIFOperation interface

You use the WSIFOperation interface to invoke a service, based on a particular binding.

The WSIFOperation interface is the runtime representation of an operation. This interface provides methods to create input, output, and fault messages, and to invoke the operation.

For more information about the WSIFOperation interface, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

**createInputMessage, createOutputMessage and createFaultMessage**
These are factory methods to create the messages required by the invocation methods. All invocation methods require an input message.

**executeRequestResponseOperation**
This method invokes “In Out” operations.

**executeInputOnlyOperation**
This method invokes “In only” operations.

**executeRequestResponseOperation**
If this method is used for invocation, an output and a fault message are instantiated and passed on the call to the method. If the method returns `true`, the output message contains the response message. If the message returns `false`, a fault occurred and is returned in the fault message.

**executeRequestResponseAsync**
This method allows “In Out” operations to be invoked with the reply handled by using an alternative thread. Use of this method is discussed further in “WSIFOperation - Asynchronous interactions reference.”

**setContext and getContext**
Use of these methods is discussed in “WSIFOperation - Context.”

All of the **execute*Nnnn*** methods fail with an exception if there is an error in processing the request in the WSIF provider.

Setting the timeouts for synchronous and asynchronous operations is discussed in “WSIFOperation - Synchronous and asynchronous timeouts reference” on page 1729.

***WSIFOperation - Context:***

Although Web Services Description Language (WSDL) does not define context, a number of uses of the Web Services Invocation Framework (WSIF) require the ability to pass context to the port that is invoking the service.

For example, a SOAP over HTTP port might require an HTTP user name and password. This information is specific to the invocation, but is not a parameter of the service. In general, context is defined as a set of name-value pairs. However, because web services tend to define the types of data by using XML schema types, WSIF represents the name-value pairs of the context by using the same representation that WSIFMessage classes use; that is, a set of named parts, each of which equates to an instance of an XML schema type.

You use the WSIFOperation interface setContext and getContext methods to pass context information to the binding. The port implementation can use this context, for example to update a SOAP header. There is no definition of how a port can use the context.

The parameter of the setContext and getContext methods is a WSIFMessage interface, and this interface has named parts defining the context information. The WSIFConstants class defines constants for the part names that can be set in a context WSIFMessage interface.

The following code fragment shows how to set the user name and password for HTTP basic authentication:

```
// set a basic authentication header
   WSIFMessage headers = new WSIFDefaultMessage();
   headers.setObjectPart( WSIFConstants.CONTEXT_HTTP_USER, "user name" );
   headers.setObjectPart( WSIFConstants.CONTEXT_HTTP_PSWD, "password" );
   operation.setContext( headers );
```

The WSIFOperation interface ignores context parts that it does not support. For example, the previous code is ignored by the WSIF Java provider.

The WSIFConstants class includes the following constants that can be used for context part names:
- CONTEXT_HTTP_USER
- CONTEXT_HTTP_PSWD
- CONTEXT_SOAP_HEADERS

The HTTP header values are expected to be of type String, and the SOAP header value is expected to be of type java.util.List, which should contain entries of type org.w3c.dom.Element.

***WSIFOperation - Asynchronous interactions reference:***

The Web Services Invocation Framework (WSIF) supports asynchronous operation. In this mode of operation, the client puts the request message as part of one transaction, and carries on with the thread of execution. The response message is then handled by a different thread, with a separate transaction.

Asynchronous operation is supported by the WSIF providers for SOAP over JMS and native JMS.

The WSIFPort class uses the supportsAsync method to test whether asynchronous operation is supported.

An asynchronous operation is initiated with the WSIFOperation interface executeRequestResponseAsync method. This method lets a Remote Procedure Call (RPC) method be invoked asynchronously. The method returns before the operation is completed, and the thread of execution continues.

The response to the asynchronous request is processed by the WSIFOperation interface fireAsyncResponse or processAsyncResponse methods.

To initiate the request, there are two forms of the executeRequestResponseAsync method:

- `public WSIFCorrelationId executeRequestResponseAsync (WSIFMessage input, WSIFResponseHandler handler)`
- `public WSIFCorrelationId executeRequestResponseAsync (WSIFMessage input)`

**executeRequestResponseAsync(WSIFMessage input, WSIFResponseHandler handler)**

This method takes an input message and a WSIFResponseHandler handler. The handler is invoked on another thread when the operation completes. When using this method, the client listener calls the fireAsyncResponse method, which then calls the WSIFResponseHandler interface executeAsyncResponse method.

For more information about the WSIFResponseHandler interface, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

**executeRequestResponseAsync(WSIFMessage input)**

This method only takes an input message, and does not use a response handler. The client listener processes the response by calling the WSIFOperation interface processAsyncResponse method. This process updates the WSIFMessage output and fault messages with the result of the request.

WSIF supports correlation between the asynchronous request and response. When the request is sent, the WSIFOperation object is serialized into the WSIFCorrelationService object. The executeRequestResponseAsync methods return a WSIFCorrelationId object that identifies the serialized WSIFOperation object. The client listener can use this to match a response to a particular request.

The correlation service is located with the WSIFCorrelationServiceLocator class getCorrelationService() method in the org.apache.wsif.utils package.

In a managed container a default correlation service is defined in the default Java Naming and Directory Interface (JNDI) namespace by using the name: java:comp/wsif/WSIFCorrelationService. If this correlation service is not available, WSIF uses the WSIFDefaultCorrelationService.

For more information about the WSIFCorrelationService interface, see the generated API documentation that is supplied with WSIF.

This is the correlator ID:

```
public interface WSIFCorrelator extends Serializable {
   public String getCorrelationId();
}
```

The client must implement its own response message listener or message data base so that it can recognize the arrival of response messages. This client implementation manages the correlation of the

response message to the request and call of one of the asynchronous response processing methods. As an example of the requirement for a client listener, the following code fragment shows what can be in the onMessage method of a Java Message Service (JMS) listener:

```
public void onMessage(Message msg) {
     WSIFCorrelationService cs = WSIFCorrelationServiceLocator.getCorrelationService();
           WSIFCorrelationId cid = new JmsCorrelationId( msg.getJMSCorrelationID() );
           WSIFOperation op = cs.get( cid );
           op.fireAsyncResponse( msg );
}
```

***WSIFOperation - Synchronous and asynchronous timeouts reference:***

When you use the Web Services Invocation Framework (WSIF) with the Java Message Service (JMS) you can set timeouts for synchronous and asynchronous operations.

Default values for these timeouts are defined in the wsif.properties file:

```
# maximum number of milliseconds to wait for a response to a synchronous request.
# Default value if not defined is to wait forever.
wsif.syncrequest.timeout=10000

# maximum number of seconds to wait for a response to an async request.
# if not defined or invalid defaults to no timeout
wsif.asyncrequest.timeout=60
```

If you use these default values, a synchronous request (such as a WSIFOperation interface executeRequestResponseOperation method call) times out after ten seconds, and an asynchronous request (such as a WSIFOperation interface executeRequestResponseAsync method call) times out after sixty seconds.

**Note:**

> The code that processes both of these timeout values uses milliseconds as its unit of time. The WSIFProperties class getAsyncTimeout method multiplies the wsif.asyncrequest.timeout value by 1000, to convert the value from seconds to milliseconds.

You can override these default values for a given request by writing a WSDL extension that sets a JMS property on the operation request with the `<jms:property>` and `<jms:propertyValue>` WSDL elements. Set the name of the property to be the name of the timeout from the WSIF properties file.

The following example sets synchronous requests to time out after two minutes (120 seconds):

```
<jms:propertyValue name="wsif.syncrequest.timeout" type="xsd:string" value="120000"/>
```

and the following example disables asynchronous timeouts (a value of zero means wait forever):

```
<jms:propertyValue name="wsif.asyncrequest.timeout" type="xsd:string" value="0"/>
```

When an asynchronous timeout expires, no listener or message data base waiting for the response is notified. The asynchronous timeout is only used to tell the correlation service that the stored WSIFOperation can be deleted. For more information about the correlation service, see “WSIFOperation - Asynchronous interactions reference” on page 1727.

## Running WSIF as a client

You can run the Web Services Invocation Framework (WSIF) in the Application Client for WebSphere Application Server, and in similar clients from other suppliers.

## Procedure

To simplify the process of launching client applications in the Application Client for WebSphere Application Server, use the `launchClient` tool as described in “Running a Java EE client application with launchClient” on page 343.

# Chapter 36. Developing web services - Notification (WS-Notification)

WS-Notification enables web services to use the publish and subscribe messaging pattern.You use publish and subscribe messaging to publish one message to many subscribers. In this pattern a producing application inserts (publishes) a message (event notification) into the messaging system having marked it with a topic that indicates the subject area of the message. Consuming applications that have subscribed to the topic in question, and have appropriate authority, all receive an independent copy of the message that was published by the producing application.

## Developing applications that use WS-Notification

You can code a single application to undertake several WS-Notification tasks. These topics provide sample code for common tasks that your WS-Notification applications can perform.

### Before you begin

Most of these examples use the Java API for XML-based remote procedure call (JAX-RPC) APIs and WebSphere Application Server APIs and SPIs. These JAX-RPC examples can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

If you have an existing Version 6.1 WS-Notification configuration, and you want to use WS-Notification with policy sets, work through the following tasks:

1. Migrating a Version 6.1 WS-Notification configuration from WebSphere Application Server Version 6.1 to Version 7.0 or later.
2. Preparing a migrated Version 6.1 WS-Notification configuration for reliable notification.
3. Configuring WS-Notification for reliable notification.

Your applications can also use WS-Notification to receive event notifications generated by other clients of the service integration bus such as JMS clients. This is described in Topology for WS-Notification as an entry or exit point to the service integration bus and Providing access for WS-Notification applications to an existing bus topic space. For information about developing applications for a mixed clients solution, including cross-streaming from a JMS client, see Interacting with JMS message types.

### About this task

A single application can be coded to undertake several WS-Notification tasks. Use the examples to help you code these tasks into your WS-Notification applications.

For an overview of how applications can use the notification broker, see WS-Notification: How client applications interact at runtime.

WS-Notification applications divide into two broad types: those that expose a Web service endpoint (for example a WS-Notification consumer application that receives notifications of stock valuation changes),

© IBM Corporation 2009

and those that do not expose a web service endpoint (for example applications that generate notifications of stock valuation changes). For broad guidance on the steps you take to develop each of these application types, see the following topics:

- "Writing a WS-Notification application that exposes a web service endpoint."
- "Writing a WS-Notification application that does not expose a web service endpoint" on page 1733.

Rather than receiving all messages on a topic to which you have subscribed, your consuming application can use XML Path (XPath) selectors to filter the messages based upon the contents of each message as described in "Filtering the message content of publications" on page 1734.

The code examples listed in this topic use the following WebSphere Application Server APIs and SPIs:

```
com.ibm.websphere.sib.wsn.AbsoluteOrRelativeTime;
com.ibm.websphere.sib.wsn.CreatePullPoint;
com.ibm.websphere.sib.wsn.CreatePullPointResponse;
com.ibm.websphere.sib.wsn.Filter;
com.ibm.websphere.sib.wsn.GetMessages;
com.ibm.websphere.sib.wsn.GetMessagesResponse;
com.ibm.websphere.sib.wsn.NotificationMessage;
com.ibm.websphere.sib.wsn.TopicExpression;
com.ibm.websphere.webservices.soap.IBMSOAPFactory;
com.ibm.websphere.wsaddressing.EndpointReference;
com.ibm.websphere.wsaddressing.WSAConstants;
com.ibm.wsspi.wsaddressing.EndpointReferenceManager;
```

### Procedure

- For examples of client applications, see the following topics:
  1. "Example: Subscribing a WS-Notification consumer" on page 1735.
  2. "Example: Pausing a WS-Notification subscription" on page 1738.
  3. "Example: Publishing a WS-Notification message" on page 1739.
  4. "Example: Creating a WS-Notification pull point" on page 1741.
  5. "Example: Getting messages from a WS-Notification pull point" on page 1742.
  6. "Example: Registering a WS-Notification publisher" on page 1743.
- For example XML code illustrating message content filtering by using XPath selectors, see "Filtering the message content of publications" on page 1734.
- For an example WSDL document describes a web service that implements the NotificationConsumer portType, see "Example: Creating a Notification consumer web service skeleton" on page 1745.

## Writing a WS-Notification application that exposes a web service endpoint

Write a Java EE application, containing a web service definition, that can be deployed to the application server and act as a NotificationProducer, NotificationConsumer or demand-based publisher.

### Before you begin

This task assumes that you have the following resources:

- An installed and functioning copy of IBM Rational Application Developer, Rational Software Architect or equivalent tooling.
- The WSDL file for the endpoint that is to be exposed.

### About this task

To write a WS-Notification application that exposes a Web service endpoint, follow the method provided by your tooling for creating a web service implementation from a WSDL file. For example in Rational Software Architect there is a wizard in the Tutorials Gallery under "Create and deploy a WS-I compliant web service

and an enterprise bean skeleton from a WSDL document by using the WebSphere Application Server runtime environment". This wizard guides you through the following steps for writing a JAX-RPC application. The steps are very similar for writing a JAX-WS application. For an example of a JAX-WS NotificationConsumer client application that exposes a web service endpoint, see Writing JAX-WS applications for WS-Notification.

### Procedure

1. Create a Dynamic Web Project.
2. Import and validate the WSDL file.
3. Create the web service. Select **File** > **New** > **Other** > **Web services** > **Web service wizard** > **Skeleton EJB web service**.
4. Implement the business methods in the generated EJB class. The methods you choose depend upon the type of endpoint that you are exposing (NotificationProducer, NotificationConsumer or demand based publisher).
5. Export the application.

### What to do next

You are now ready to deploy the application to WebSphere Application Server as described in Installing enterprise application files with the console. In the Select installation options panel, ensure that the **Deploy web services** option is enabled.

## Writing a WS-Notification application that does not expose a web service endpoint

Write a Java EE application that can be run outside of the application server to make web service invocations against an external web service. This application acts as a lightweight publisher, or a pull type consumer by invoking web service operations against another web service such as the NotificationBroker provided by WebSphere Application Server.

### Before you begin

This task assumes that you have the following resources:

- An installed and functioning copy of IBM Rational Application Developer, Rational Software Architect or equivalent tooling.
- Knowledge of where to find the WSDL file for the service that is to be invoked.

### About this task

To write a WS-Notification application that does not expose a web service endpoint, follow the method provided by your tooling for creating a web service implementation from a WSDL file. As an illustration, the following steps describe the method provided by Rational Software Architect for writing a JAX-RPC application. The steps are very similar for writing a JAX-WS application. For examples of JAX-WS publisher and subscriber client applications that do not expose a web service endpoint, see Writing JAX-WS applications for WS-Notification.

### Procedure

1. Get the WSDL files for the service that you want to invoke. If the target service is the notification broker service that was generated by WebSphere Application Server, use the administrative console to publish the WSDL files for the service to a compressed file.
2. Create a Dynamic Web Project with a name of your choice.
3. Choose **File > New > Other > Web services > Web services Client**.
4. Select **Java Proxy**.

5. Enter or select the WSDL you obtained earlier.
6. Choose a Client Type of “Application Client” or “Java” depending upon your requirements.
7. Select your required security configuration.
8. Click **Finish**.
9. Use the generated proxy and stubs to make calls against the remote web service. For detailed coding examples, see “Developing applications that use WS-Notification” on page 1731.

### What to do next

You are now ready to deploy the application for use in the Java EE application client container as described in “Running a Java EE client application with launchClient” on page 343.

## Filtering the message content of publications

Rather than receiving all messages on a topic to which you have subscribed, your consuming application can use XML Path (XPath) selectors to filter the messages based upon the contents of each message. This content-based subscription gives greater flexibility in defining the type of information that you want to receive, your applications can use it to avoid responsibility for their own filtering, and it improves performance by not flowing messages unnecessarily from the server to the application.

### About this task

The WS-Notification publish and subscribe messaging model is topic-based. Each publication is classified as belonging to one of a fixed set of topics. Publishers label each publication with a topic name and consumers subscribe to all publications on a particular topic. For example a stock trading notification system might define a topic for each issue: Publishers post information labeled with the appropriate issue as the topic name, and subscribers subscribe to information regarding some issue.

You can use XPath selectors to filter messages for a given topic, by using a Boolean expression that is evaluated over the XML message content of the message body. For example, a subscriber to a topic-based publish and subscribe system for stock trading might use XPath selectors to specify constraints against three message attributes at the same time:

- issue name
- price
- volume of shares

The resultant Boolean statement might be as follows:

```
(issue="IBM") and (price<120) and (volume>1000)
```

You code your XPath 1.0 message content filters in the subscribing applications, by using XML Path (XPath) language, Version 1.0..

**Note:** If your subscriber applications use message content filtering, and are coded to specify the XPath Version 1.0 SelectorDomain, they can also filter publications from other WS-Notification providers that are of type JMS TextMessage or BytesMessage. For more information about these JMS message types, see Topology for WS-Notification as an entry or exit point to the service integration bus.

To filter the message content of publications by using XPath selectors, complete the following steps.

### Procedure

1. Create a new application that subscribes a WS-Notification consumer.
2. Code an XPath message content filter in the subscribing application. For example code for doing this, see “Example: Subscribing a WS-Notification consumer” on page 1735. For an example of message content filter usage, see the example at the end of this task.

3. Code error handling for cases where the filter is not valid.
4. Invoke the application.

### Example

This example XML code illustrates message content filtering by using XPath selectors. In this example a business, represented by a NotificationConsumer application, wants to be notified of bank transfers of over $1,000,000. The monitoring application subscribes on behalf of the NotificationConsumer specifying a valid XPath Version 1.0 message content filter, in the following WS-Notification subscribe message:

```
<wsnt:Subscribe>
  <wsnt:ConsumerReference>
    wsa:EndpointReference
  </wsnt:ConsumerReference>
  <wsnt:Filter>
    [ <wsnt:TopicExpression Dialect="xsd:anyURI">
        {any} ?
      </wsnt:TopicExpression> |
      <wsnt:ProducerProperties Dialect="xsd:anyURI">
        {any} ?
      </wsnt:ProducerProperties> |
      <wsnt:MessageContent Dialect="xsd:anyURI">
        /bankTransfer[value %gt; 1,000,000]
      </wsnt:MessageContent> |
      {any} *
    ] *
  </wsnt:Filter> ?
  <wsnt:InitialTerminationTime>
    [xsd:dateTime | xsd:duration]
  </wsnt:InitialTerminationTime> ?
  <wsnt:SubscriptionPolicy>
    [ <wsnt:UseRaw/> |
      {any}
    ] *
  </wsnt:SubscriptionPolicy> ?
  {any}*
</wsnt:Subscribe>
```

The WS-Notification service stores the subscription and its filter.

Another WS-Notification application then publishes a notification in which the message body contains the following information:

```
<bankTransfer origin="123456 87654321" target="224466 88664422">
  <originName>IBM Corporation</originName>
  <targetName>Matt Roberts</targetName>
  <date>02/02/2006</date>
  <value currency="USD">100,000,000</value>
</bankTransfer>
```

The WS-Notification service in the application server matches this publication to the earlier subscription and delivers the notification to the consumer specified in the subscription.

## Example: Subscribing a WS-Notification consumer

Use this task to write the code for a JAX-RPC client acting in the publisher registration role, registering a publisher (producer) application with a broker, based on the example code extract provided.

### About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

The article Writing JAX-WS applications for WS-Notification includes an example of a JAX-WS subscriber client application.

**Raw subscriptions:**

In this example, the first optional code block shows you how to create a *raw subscription*. This concept is defined in section 4.2 of the Web Services Base Notification specification.

In the normal case, a wrapped subscription causes the Notify operation of the NotificationConsumer to be driven when matching event notifications become available. If the Subscriber instead creates a raw subscription, then only the application specific content of the event notification (that is, the contents of the NotificationMessage element) are sent to the target consumer endpoint. Note that the web service endpoint specified in the ConsumerReference of the Subscribe request that also specifies **UseRaw** (that is, a raw subscription request) does not have to implement the NotificationConsumer port type because the Notify operation will not be used to deliver event notifications.

This means that the consumer must be able to accept operations for each of the types of application content that will be published on the specified topic. This pattern allows WS-Notification to invoke a group of existing web service applications that are not WS-Notification aware, but that want to receive the same information.

JAX-WS supports action-based dispatch, and JAX-WS raw consumer applications must accept the `http://docs.oasis-open.org/wsn/bw-2/NotificationConsumer/Notify` action URI. For more information, see the troubleshooting tip A JAX-WS application that is a raw consumer of brokered notifications must recognize a notification broker SOAP action.

To write the code for a JAX-RPC client acting in the publisher registration role, registering a publisher (producer) application with a broker, complete the following steps, referring to the example code extract for further information.

## Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
2. Get a stub for the port on which you want to invoke operations.
3. Create the ConsumerReference. This either contains the address of the consumer web service that is being subscribed to, or a reference to a pull point. Specifying a pull point EPR indicates that the consumer is to use pull-based notifications.
4. Create the filter. This provides the name of the topic to which you want to subscribe the consumer.

5. Create a topic expression and add it to the filter. The prefixMappings are mappings between namespace prefixes and their corresponding namespaces for prefixes used in the expression.
6. Create an XPath 1.0 message content filter. For example you could select a subset of the available messages in the topic, based upon salary level. For an example of message content filter usage, see “Filtering the message content of publications” on page 1734.
7. Create the InitialTerminationTime. This is the time when you want the subscription to terminate. For example, you could set a time of 1 year in the future.
8. Create the Policy information.
9. Optional: Construct a policy indicating that the consumer is to receive raw style notifications.
10. Create holders to hold the multiple values returned from the broker:
    - The subscription reference
    - The current time at the broker
    - The termination time for the subscription
    - Any additional elements
11. Invoke the Subscribe operation by calling the associated method on the stub.
12. Get the returned values:
    - An endpoint reference for the subscription that has been created. This is required for subsequent lifetime management of the subscription, for example pausing the subscription.
    - The current time at the broker.
    - The termination time of the subscription.
    - Any other information.

## Example

The following example code describes a subscriber client application that can subscribe a consumer application with a broker:

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Create the ConsumerReference. This contains the address of the consumer web service that is being
// subscribed, or alternatively is a reference to a pull point (see alternative below). Specifying a
// pull point EPR indicates that the consumer is to use pull-based notifications.
EndpointReference consumerEPR =
    EndpointReferenceManager.createEndpointReference(new URI("http://myserver.mycom.com:9080/Consumer"));

/*
// Alternative ConsumerReference for pull-based notifications:

EndpointReference consumerEPR = pullPointEPR;

*/

// Create the Filter. This provides the name of the topic to which you want to subscribe the consumer
Filter filter = new Filter();

// Create a topic expression and add it to the filter. The prefixMappings are mappings between namespace
// prefixes and their corresponding namespaces for prefixes used in the expression
Map prefixMappings = new HashMap();
prefixMappings.put("abc", "uri:example");
TopicExpression exp =
    new TopicExpression(TopicExpression.SIMPLE_TOPIC_EXPRESSION, "abc:ExampleTopic", prefixMappings);
filter.addTopicExpression(exp);

//Create an XPath 1.0 message content filter
//This example selects a subset of the available messages in the topic, based upon salary level
String filterExpression = "/company/department/employee/salary > 10000";
URI xpathURI = new URI(http://www.w3.org/TR/1999/REC-xpath-19991116);
```

```
QueryExpression qexp =
    new QueryExpression(xpathURI, filterExpression);

filter.addMessageContentExpression(qexp);

// Create the InitialTerminationTime. This is the time when you want the subscription to terminate.
// For example, set a time of 1 year in the future.
Calendar cal = Calendar.getInstance();
cal.add(Calendar.YEAR, 1);
AbsoluteOrRelativeTime initialTerminationTime = new AbsoluteOrRelativeTime(cal);

// Create the Policy information
SOAPElement[] policyElements = null;

/*
Optional
--------
The following lines show how to construct a policy indicating that the consumer is to
receive raw style notifications:

    javax.xml.soap.SOAPFactory soapFactory = javax.xml.soap.SOAPFactory.newInstance();
    SOAPElement useRawElement = null;

    if (soapFactory instanceof IBMSOAPFactory) {
        // You can use the value add methods provided by the IBMSOAPFactory API to create the SOAPElement
        // from an XML string.
       String useRawElementXML = "<mno:UseRaw xmlns:mno=\"http://docs.oasis-open.org/wsn/b-2\"/>";
        useRawElement = ((IBMSOAPFactory) soapFactory).createElementFromXMLString(useRawElementXML);
    } else {
        useRawElement = soapFactory.createElement("UseRaw", "mno", "http://docs.oasis-open.org/wsn/b-2");
    }

    policyElements =  new SOAPElement[] { useRawElement };
*/

// Create holders to hold the multiple values returned from the broker:
// The subscription reference
EndpointReferenceTypeHolder subscriptionRefHolder = new EndpointReferenceTypeHolder();

// The current time at the broker
CalendarHolder currentTimeHolder = new CalendarHolder();

// The termination time for the subscription
CalendarHolder terminationTimeHolder = new CalendarHolder();

// Any additional elements
AnyArrayHolder anyOtherElements = new AnyArrayHolder();

// Invoke the Subscribe operation by calling the associated method on the stub
stub.subscribe(consumerEPR,
                       filter,
                       initialTerminationTime,
                       policyElements,
                       anyOtherElements,
                       subscriptionRefHolder,
                       currentTimeHolder,
                       terminationTimeHolder);

// Get the returned values:
// An endpoint reference for the subscription that has been created. It is required for
// subsequent lifetime management of the subscription, for example pausing the subscription
com.ibm.websphere.wsaddressing.EndpointReference subscriptionRef = subscriptionRefHolder.value;

// The current time at the broker
Calendar currentTime = currentTimeHolder.value;

// The termination time of the subscription
Calendar terminationTime = terminationTimeHolder.value;

// Any other information
SOAPElement[] otherElements = anyOtherElements.value;
```

## Example: Pausing a WS-Notification subscription

Use this task to write the code for a JAX-RPC client acting in the subscriber role, pausing a subscription for a consumer application, based on the example code extract provided.

## About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

## Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation. The PauseSubscription operation belongs to the SubscriptionManager service.
2. Get a stub for the port on which you want to invoke operations.
3. Associate the request with the subscription you want to pause. The subscriptionEPR is the EndpointReference returned by the invocation of the Subscribe operation.
4. Create any optional information.
5. Invoke the PauseSubscription operation by calling the associated method on the stub.

## Example

The following example code describes a JAX-RPC client acting in the subscriber role, pausing a subscription for a consumer application:

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
// The PauseSubscription operation belongs to the SubscriptionManager service
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup("java:comp/env/services/SubscriptionManager");

// Get a stub for the port on which you want to invoke operations
SubscriptionManager stub = (SubscriptionManager) service.getPort(SubscriptionManager.class);

// Associate the request with the subscription you want to pause. The subscriptionEPR is the
// EndpointReference returned by the invocation of the Subscribe operation
((Stub) stub)._setProperty(WSAConstants.WSADDRESSING_DESTINATION_EPR, subscriptionEPR);

// Create any optional information
SOAPElement[] optionalInformation =  new SOAPElement[] {};

// Invoke the PauseSubscription operation by calling the associated method on the stub
SOAPElement[] additionalReturnedInformation = stub.pauseSubscription(optionalInformation);
```

# Example: Publishing a WS-Notification message

Use this task to write the code for a publisher client application that can publish a notification message to a broker, based on the example code extract provided.

## About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

The article Writing JAX-WS applications for WS-Notification includes an example of a JAX-WS publisher client application.

To write the code for a publisher client application that can publish a notification message to a broker, complete the following steps, referring to the example code extract for further information.

## Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
2. Get a stub for the port on which you want to invoke operations.
3. Create the message contents for a notification message.
4. Create a notification message from the contents.
5. Add a topic expression to the notification message. The topic expression must indicate to which topic or topics the message corresponds.
6. Create any optional information.
7. Optional: If the broker requires publisher client applications to register, associate the request with a particular publisher registration. The registrationEPR is the ConsumerReference EndpointReference returned by the broker in relation to an invocation of the RegisterPublisher operation.
8. Invoke the Notify operation by calling the associated method on the stub.

## Example

The following example code represents a publisher client application that can publish a notification message to a broker:

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Create the message contents for a notification message
SOAPElement messageContents = null;
javax.xml.soap.SOAPFactory soapFactory = javax.xml.soap.SOAPFactory.newInstance();
if (soapFactory instanceof IBMSOAPFactory) {
    // You can use the value add methods provided by the IBMSOAPFactory API to create the SOAPElement
    // from an XML string.
    String messageContentsXML = "<xyz:MyData xmlns:xyz=\"uri:mynamespace\">Some data</xyz:MyData>";
```

```
    messageContents = ((IBMSOAPFactory) soapFactory).createElementFromXMLString(messageContentsXML);
} else {
    // Build up the SOAPElement using the standard javax.xml.soap APIs
    messageContents = soapFactory.createElement("MyData", "xyz", "uri:mynamespace");
    messageContents.addTextNode("Some data");
}

// Create a notification message from the contents
NotificationMessage message = new NotificationMessage(messageContents);

// Add a topic expression to the notification message indicating to which topic or topics the
// message corresponds
Map prefixMappings = new HashMap();
prefixMappings.put("abc", "uri:example");
TopicExpression exp =
    new TopicExpression(TopicExpression.SIMPLE_TOPIC_EXPRESSION, "abc:ExampleTopic", prefixMappings);
message.setTopic(exp);

// Create any optional information
SOAPElement[] optionalInformation =  new SOAPElement[] {};

/*
Optional
--------
The following line will cause the request to be associated with a particular publisher registration.
You must do this if the broker requires publishers to register. The registrationEPR is the
ConsumerReference EndpointReference returned by the broker in relation to an invocation of the
RegisterPublisher operation.

    ((Stub) stub)._setProperty(WSAConstants.WSADDRESSING_DESTINATION_EPR, consumerReferenceEPR);
*/

// Invoke the Notify operation by calling the associated method on the stub
stub.notify(new NotificationMessage[] { message }, optionalInformation);
```

# Example: Creating a WS-Notification pull point

Use this task to write the code for a JAX-RPC subscriber client. This client creates a pull point for use by consumer applications that use pull style notifications.

## About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

To write the code for a JAX-RPC client acting in the subscriber role, creating a pull point for use by a consumer application that is to use pull style notifications, complete the following steps, referring to the example code extract for further information.

### Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
2. Get a stub for the port on which you want to invoke operations.
3. Create the request information.
4. Invoke the CreatePullPoint operation by calling the associated method on the stub.
5. Retrieve the reference to the pull point from the response.
6. Retrieve any additional information from the response.

### Example

The following example code describes a JAX-RPC client acting in the subscriber role, creating a pull point for use by a consumer application that is to use pull style notifications:

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Create the request information.
SOAPElement[] optionalInformation = null;
CreatePullPoint cpp = new CreatePullPoint(optionalInformation);

// Invoke the CreatePullPoint operation by calling the associated method on the stub
CreatePullPointResponse response = stub.createPullPoint(cpp);

// Retrieve the reference to the pull point from the response
EndpointReference pullPointEPR = response.getPullPoint();

// Retrieve any additional information from the response
SOAPElement[] additionalInformation = response.getElements();
```

## Example: Getting messages from a WS-Notification pull point

Use this task to write the code for a JAX-RPC client acting in the pull style consumer role, requesting messages from a pull point, based on the example code extract provided.

### About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

To write the code for a JAX-RPC client acting in the pull style consumer role, requesting messages from a pull point, complete the following steps, referring to the example code extract for further information.

### Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
2. Get a stub for the port on which you want to invoke operations.
3. Associate the request with a pull point. The pullPointEPR is the EndpointReference returned from invoking the CreatePullPoint operation.
4. Specify the number of messages you want to retrieve.
5. Create any optional information.
6. Create the request information.
7. Invoke the GetMessages operation by calling the associated method on the stub.
8. Get the messages returned from the response.

### Example

The following example code describes a JAX-RPC client acting in the pull style consumer role, requesting messages from a pull point:

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Associate the request with a pull point. The pullPointEPR is the EndpointReference returned
// from invoking the CreatePullPoint operation
((Stub) stub)._setProperty(WSAConstants.WSADDRESSING_DESTINATION_EPR, pullPointEPR);

// Specify the number of messages you want to retrieve
Integer numberOfMessages = new Integer(2);

// Create any optional information
SOAPElement[] optionalInformation =  new SOAPElement[] {};

// Create the request information
GetMessages request = new GetMessages(numberOfMessages, optionalInformation);

// Invoke the GetMessages operation by calling the associated method on the stub
GetMessagesResponse response = stub.getMessages(request);

// Get the messages returned from the response
NotificationMessage[] messages = response.getMessages();
```

## Example: Registering a WS-Notification publisher

Use this task to write the code for a subscriber client application that can subscribe a consumer application with a broker, based on the example code extract provided.

### About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS

- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

To write the code for a subscriber client application that can subscribe a consumer application with a broker, complete the following steps, referring to the example code extract for further information.

## Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
2. Get a stub for the port on which you want to invoke operations.
3. Create a reference for the publisher (producer) being registered. This contains the address of the producer web service.
4. Create a list (array) of topic expressions to describe the topics to which the producer publishes messages.
5. Indicate that you do not want the publisher to use demand based publishing.
6. Set a value for the initial termination time of the registration. For example, you could set a value 1 year in the future.
7. Create holders to hold the multiple values returned from the broker:
   - **PublisherRegistrationReference** defines the endpoint reference for use in lifetime management of the registration.
   - **ConsumerReference** defines the endpoint reference for use in subsequent publishing of messages.
8. Invoke the RegisterPublisher operation by calling the associated method on the stub.
9. Retrieve the PublisherRegistrationReference.
10. Retrieve the ConsumerReference.

## Example

The following example code represents a JAX-RPC client acting in the publisher registration role, registering a publisher (producer) application with a broker.

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Create a reference for the publisher (producer) being registered. This contains the address of the
// producer web service.
EndpointReference publisherEPR =
    EndpointReferenceManager.createEndpointReference(new URI("http://myserver.mysom.com:9080/Producer"));

// Create a list (array) of topic expressions to describe the topics to which the producer publishes
// messages. For this example you add one topic
Map prefixMappings = new HashMap();
prefixMappings.put("abc", "uri:mytopicns");
TopicExpression topic =
    new TopicExpression(TopicExpression.SIMPLE_TOPIC_EXPRESSION, "abc:xyz", prefixMappings);
TopicExpression[] topics = new TopicExpression[] {topic};

// Indicate that you do not want the publisher to use demand based publishing
Boolean demand = Boolean.FALSE;

// Set a value for the initial termination time of the registration. For example, set a value 1 year in
// the future
Calendar initialTerminationTime = Calendar.getInstance();
initialTerminationTime.add(Calendar.YEAR, 1);

// Create holders to hold the multiple values returned from the broker:
```

```
// PublisherRegistrationReference: An endpoint reference for use in lifetime management of
// the registration
EndpointReferenceTypeHolder pubRegMgrEPR = new EndpointReferenceTypeHolder();

// ConsumerReference: An endpoint reference for use in subsequent publishing of messages
EndpointReferenceTypeHolder consEPR = new EndpointReferenceTypeHolder();

// Invoke the RegisterPublisher operation by calling the associated method on the stub
stub.registerPublisher(publisherEPR, topics, demand, initialTerminationTime, null, pubRegMgrEPR, consEPR);

// Retrieve the PublisherRegistrationReference
EndpointReference registrationEPR = pubRegMgrEPR.value;

// Retrieve the ConsumerReference
EndpointReference consumerReferenceEPR = consEPR.value;
```

# Example: Creating a Notification consumer web service skeleton

Use this example when creating a web service that implements the NotificationConsumer portType defined by the Web Services Base Notification specification.

## About this task

This task provides two code examples:

- An example WSDL document that describes a web service that implements the NotificationConsumer portType defined by the Web Services Base Notification specification.
- A basic implementation of the Service Endpoint Interface (SEI) generated from the preceding WSDL document using the WSDL2Java tool.

**Note:** The article Writing JAX-WS applications for WS-Notification also includes an example of a consumer Web service.

## Procedure

If you are creating a Notification consumer web service skeleton, see the following code examples.

## Example

The following example WSDL document describes a web service that implements the NotificationConsumer portType defined by the Web Services Base Notification specification:

```
<?xml version="1.0" encoding="utf-8"?>

<wsdl:definitions xmlns="http://schemas.xmlsoap.org/wsdl/"
    xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:wsn-bw="http://docs.oasis-open.org/wsn/bw-2"
    xmlns:wsdlsoap="http://schemas.xmlsoap.org/wsdl/soap/"
    xmlns:tns="uri:example.wsn/consumer"
    targetNamespace="uri:example.wsn/consumer">

    <wsdl:import namespace="http://docs.oasis-open.org/wsn/bw-2"
                          location="http://docs.oasis-open.org/wsn/bw-2.wsdl" />

    <wsdl:binding name="NotificationConsumerBinding" type="wsn-bw:NotificationConsumer">
        <wsdlsoap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http" />
        <wsdl:operation name="Notify">
            <wsdlsoap:operation soapAction="" />
            <wsdl:input>
                <wsdlsoap:body use="literal" />
            </wsdl:input>
        </wsdl:operation>
    </wsdl:binding>

    <wsdl:service name="NotificationConsumerService">
        <wsdl:port name="NotificationConsumerPort" binding="tns:NotificationConsumerBinding">
            <wsdlsoap:address location="http://myserver.mycom.com:9080/Consumer" />
```

```
        </wsdl:port>
    </wsdl:service>

</wsdl:definitions>
```

The following example shows a basic implementation of the Service Endpoint Interface (SEI) generated from the preceding WSDL document using the WSDL2Java tool:

```
public class ConsumerExample implements NotificationConsumer {

    public void notify(NotificationMessage[] notificationMessage, SOAPElement[] any)
                                                                    throws RemoteException {
        // Process each NotificationMessage
        for (int i=0; i<notificationMessage.length; i++) {
            NotificationMessage message = notificationMessage[i];

            // Get the contents of the message
            SOAPElement messageContent = message.getMessageContents();

            // Get the expression indicating which topic the message is associated with
            TopicExpression topic = message.getTopic();

            // Get a reference to the producer (this value is optional and so might be null)
            EndpointReference producerRef = message.getProducerReference();

            // Get a reference to the subscription (this value is optional and so might be null)
            EndpointReference subscriptionRef = message.getSubscriptionReference();

            // User defined processing ...

        }
    }
}
```

# Chapter 37. Developing web services - Reliable messaging (WS-ReliableMessaging)

To configure a web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent.

## Developing a reliable web service application

Develop a Java API for XML-Based Web Services (JAX-WS) provider or requester application that can compose with a WS-ReliableMessaging-enabled policy set.

### Before you begin

At any stage - that is, before or after you have built your reliable web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

### About this task

You can develop a Java API for XML-Based Web Services (JAX-WS) web service requester application that sends messages reliably, or a web service provider application that requires reliable messaging. Your client application can also take programmatic control of WS-ReliableMessaging sequences.

### Procedure

1. Develop your JAX-WS web service application.

   For a Web service requester application that sends messages reliably:

   a. Get an implementation WSDL document, and select the SOAP over HTTP binding. The WSDL should be WS-I Basic Profile compliant.

   b. Build the JAX-WS application from the WSDL implementation document.

   c. (Optional) Enable transaction support for outbound (requester) one-way message sends. For more information, see “Providing transactional recoverable messaging through WS-ReliableMessaging” on page 1750.

   d. (Optional) Use the waitUntilSequenceCompleted method on the sequenceManager to ensure that reliable messaging state is released after the client finishes messaging, as described in the “Controlling WS-ReliableMessaging sequences programmatically” on page 1748 topic.

   e. (Optional) If you want to use in-order delivery (that is, you want WS-ReliableMessaging to make messages available to your requester application in the order that they were sent), then you must also configure your requester application to poll for the messages in the order in which it should receive them. For more information, see Configuring the WS-ReliableMessaging policy.

   For a web service provider application that requires reliable messaging:

   a. Write or get an interface WSDL document that describes the service interface. The document should be compliant with the WS-I Basic Profile.

   b. Write or get an implementation WSDL document, and select the SOAP over HTTP binding. The WSDL should remain WS-I Basic Profile compliant.

   c. Build the JAX-WS application from the WSDL implementation document.

2. Enable your client application to take programmatic control of WS-ReliableMessaging sequences.

   This helps manage resources on the server, for example by removing sequences after a client application has finished messaging. You can add code to create sequences, send acknowledgement

© Copyright IBM Corp. 2011

requests, close sequences, terminate sequences and wait until sequences are complete. For more information, including example code, see “Controlling WS-ReliableMessaging sequences programmatically.”

### What to do next

You are now ready to configure a policy set instance to enable WS-ReliableMessaging.

## Controlling WS-ReliableMessaging sequences programmatically

Your client application can use the WSRMSequenceManager, part of the WebSphere Application Server SPI for reliable messaging, to gain programmatic control over reliable messaging sequences. This helps manage resources on the server, for example by removing sequences after a client application has finished messaging. You can add code to create sequences, send acknowledgement requests, close sequences, terminate sequences and wait until sequences are complete.

### Before you begin

The WebSphere Application Server SPI for reliable messaging always uses the static policy set configuration that is applied to the client from which the SPI is called. It does not use any alternative policy set that is subsequently configured by WS-Policy to meet the requirements of a WS-Policy intersection.

### About this task

By closing sequences programmatically, you limit the number of open sequences a single client has to support in a single JVM at one time.

For your client application to gain programmatic control over reliable messaging sequences, it needs access to a WSRMSequenceManager instance. Use the following code fragment to achieve this:

```
import com.ibm.wsspi.wsrm.WSRMSequenceManager;
import com.ibm.wsspi.wsrm.WSRMSequenceManagerFactory;

.........

     // Get the factory
     WSRMSequenceManagerFactory factory = WSRMSequenceManagerFactory
         .getInstance();

     // Get the sequence manager instance
     WSRMSequenceManager sequenceManager = factory.createWSRMSequenceManager();
```

All WSRMSequenceManager methods take the following parameters:

- The client instance object. This is either a **Dispatch client** instance, or the **Dynamic proxy client**. For details of the client types, see the JAX-WS client programming model topic.
- The **Port QName** instance for the target endpoint.

To control WS-ReliableMessaging sequences programmatically, add code to your client application as described in the following steps:

### Procedure

- Add code to create a sequence.

  To set the available properties use the following methods:

```
/**
 * Sets the target provider endpoint.
 * A null value will cause a NullPointerException when the WSRMSequenceProperties object is used.
 *
 * @param providerEndPoint The target service endpoint URI
 */
public void setTargetEndpointUri(String providerEndPoint);

/**
 * This is used to indicate that a response flow is required between the provider and requester and the response
 * flow will be established at create sequence time
```

```
 *
 * By calling this method it will indicate that a response flow is required.
 */
public void setUseOfferedSequenceId();

/**
 * Set the Soap version for RM protocol messages.
 * The default value for this property is WSRMSequenceProperties.SOAP_11
 *
 * @param soapVersion
 */
public void setSoapVersion(int soapVersion);

/**
 * If the Sequence Acknowledgement messages are to be sent back asynchronously call this method.
 *
 */
public void useAsyncTransport();
```

To create the reliable messaging sequence use the createNewWSRMSequence method on the WSRMSequenceManager:

```
/**
 * Initiates a new sequence handshake between this client and the target EPR specified in the
 * WSRMSequenceProperties instance.
 *
 * This sequence will only be valid for the client issuing the createNewWSRMSequence call.
 *
 * When returning from this call, there is no guarantee that the sequence has been established.
 *
 * @throws NullPointerException if the sequenceProperties object is null, or the target EPR is null
 *
 * @param clientObject The JAX-WS Dispatch instance, or the Dynamic Proxy client instance.
 * @param sequencePropeties The properties for creating the reliable messaging sequence
 * @throws WSRMNotEnabledException
 * @throws WSRMSequenceAlreadyExistsException
 */
public void createNewWSRMSequence(Object clientObject, QName portQName, WSRMSequenceProperties sequencePropeties)

throws WSRMNotEnabledException,
       WSRMSequenceAlreadyExistsException;
```

- Add code to send an acknowledgment request.

  To send an acknowledgment request for a WS-ReliableMessaging sequence, use the following method on the WSRMSequenceManager:

```
/**
 * Sending an acknowledgement request sends the ACK requested message to the specified target endPointUri.
 * The target will respond with a range of messages that can be acknowledged for the current reliable messaging
 * sequence.
 *
 * @param clientObject The JAX-WS Dispatch instance, or the Dynamic Proxy client instance.
 * @param portQName
 * @param endPointUri The target endpoint uri
 * @throws WSRMNotEnabledException
 * @throws WSRMSequenceUnknownException
 * @throws WSRMSequenceTerminatedException
 * @throws WSRMSequenceClosedException
 */
public void sendAcknowledgementRequest(Object clientObject, QName portQName, String endPointUri)

throws WSRMNotEnabledException,
       WSRMSequenceUnknownException,
       WSRMSequenceTerminatedException,
       WSRMSequenceClosedException;
```

- Add code to close a sequence.

  To close a WS-ReliableMessaging sequence use the following method on the WSRMSequenceManager:

```
/**
 * Closes the web services reliable messaging session from this application to
 * the endpoint url specified.
 *
 * Throws a WSRMSequenceTerminatedException if the session between this application
 * and the target endpoint url is already closed
 *
 * Throws a WSRMSequenceTerminatedException when the session between this application
 * and the target endpoint has already been terminated.
 *
 * Throws WSRMSequenceUnknownException exception when either reliable messaging is not engaged to
 * the specified endpoint url or the sequence has previously been terminated and removed.
 *
 * @param clientObject The JAX-WS Dispatch instance, or the Dynamic Proxy client instance.
 * @param endPointUri The target endpoint url
 *
 * @throws WSRMNotEnabledException
```

```
   * @throws WSRMSequenceUnknownException
   * @throws WSRMSequenceClosedException
   * @throws WSRMSequenceTerminatedException
   */
  public void closeSequence(Object clientObject, QName portQName, String endPointUri)

  throws WSRMNotEnabledException,
         WSRMSequenceUnknownException,
         WSRMSequenceClosedException,
         WSRMSequenceTerminatedException;
```

- Add code to terminate a sequence.

  To terminate a WS-ReliableMessaging sequence use the following method on the WSRMSequenceManager:

```
  /**
   * Terminates web services reliable messaging session from this application to
   * the endpoint url specified.
   *
   * Throws a WSRMSequenceTerminatedException when the session between this application
   * and the target endpoint has already been terminated.
   *
   * Throws WSRMSequenceUnknownException exception when either reliable messaging is not engaged to
   * the specified endpoint url or the sequence has previously been terminated and removed.
   *
   * @param clientObject The JAX-WS Dispatch instance, or the Dynamic Proxy client instance.
   * @param endPointUri The target endpoint url
   * @throws WSRMNotEnabledException
   *
   * @throws WSRMSequenceTerminatedException
   * @throws WSRMSequenceUnknownException
   */
  public void terminateSequence(Object clientObject, QName portQName, String endPointUri) throws WSRMNotEnabledException;
```

- Add code to wait for a sequence to complete.

  To wait for a reliable messaging sequence to complete, you use a method call that ensures that all messages have been sent and acknowledged by the target service. After the sequence is completed, it is terminated and cleaned up.

  There are two ways of using the waitUntilSequenceCompleted method:

  –

```
public boolean waitUntilSequenceCompleted(Object clientObject,
QName portQName, String endPointUri, long waitTime)
```

    This method call waits for the specified **waitTime** for the reliable messaging sequence to complete. If the sequence does not complete in the specified time, the method returns false. If the sequence does complete in time, the method returns true.

  –

```
public boolean waitUntilSequenceCompleted(Object clientObject,
QName portQName, String endPointUri)
```

    This method call does not return until the reliable messaging sequence is completed.

# Providing transactional recoverable messaging through WS-ReliableMessaging

If your WS-ReliableMessaging application runs inside the web container and uses a managed quality of service, you can use WS-ReliableMessaging to provide transactional recoverable messaging.

## About this task

The WS-ReliableMessaging transactional model is as follows:

- On the web service requester side, the transaction is between the application and the local managed store.
- The WS-ReliableMessaging protocol delivers the message to the web service provider side, where a different transaction is used between the second managed store and the application being dispatched.

For the outbound (requestor) case on a one-way message send, if the **enableTransactionalOneWay** property is set to true, then the send is performed under any transactional context currently held by the application thread. (Note that transactions are not supported under an outbound two-way message exchange).

For the inbound (provider) case, if the **inOrderDelivery** property is set to true, then an inbound message is dispatched to the application under a transaction. For an inbound two-way message exchange, the response is also generated under that transaction and is not sent until that transaction has committed.

**Note:**

WS-ReliableMessaging transactions do not use the WS-AtomicTransactions protocol. The relationship between these two protocols is as follows:

- WS-AtomicTransactions and WS-ReliableMessaging are mutually exclusive when WS-ReliableMessaging is being used, with a managed store, to provide transactional recoverable messaging.
- If WS-ReliableMessaging is configured to use an in-memory store, then there are cases where a WS-AtomicTransaction can be flowed between the reliable messaging source and the reliable messaging destination for two-way invocations. In this situation, WS-ReliableMessaging only protects against network failures, not against server failure.

For more information, see WS-AtomicTransactions.

To provide transactional recoverable messaging through WS-ReliableMessaging, work through the steps described in Adding assured delivery to web services through WS-ReliableMessaging and also complete the following additional steps:

### Procedure

- To enable transactional messaging for outbound (requester) one-way message sends, when you develop your JAX-WS web service application set the **enableTransactionalOneWay** property to Boolean.TRUE (or the string true) in the jaxWS request context map.
- To enable transactional messaging for inbound (provider) one-way and two-way message exchanges, when you configure your WS-ReliableMessaging policy either use the administrative console to select the option **Deliver messages in the order that they were sent** or use the wsadmin tool to set the **inOrderDelivery** property to true.

## Configuring endpoints to only support clients that use WS-ReliableMessaging

By default, when a WS-ReliableMessaging enabled policy set is attached to an endpoint, the server supports clients that use reliable messaging and clients that do not use reliable messaging. In this version of the product, you can configure endpoints to only support clients that use reliable messaging.

### About this task

You configure endpoints to only support clients that use reliable messaging by setting a property in either of the following ways:

- Set a property when packaging the application.
- Set a property as a JVM argument for the server.

This setting is reflected by WS-Policy if engaged. For information about how to engage WS-Policy, see Using WS-Policy to exchange policies in a standard format.

### Procedure

- When packaging the application, configure endpoints to only support clients that use reliable messaging by setting the **strictlyEnforceWSRM** property in the META-INF/MANIFEST.MF of a WAR file or EJB module.

- Using a JVM argument for the server, configure endpoints to only support clients that use reliable messaging by defining the Java virtual machine custom property **com.ibm.ws.websvcs.rm.strictlyEnforceWSRM** on the server. For more information, see Configuring the JVM.

# Chapter 38. Developing web services - RESTful services

You can use Java API for RESTful Web Services (JAX-RS) to develop services that follow Representational State Transfer (REST) principles. RESTful services are based on manipulating resources. Resources can contain static or dynamically updated data. By identifying the resources in your application, you can make the service more useful and easier to develop.

## Planning JAX-RS web applications

## Planning to use JAX-RS to enable RESTful services

By using the Java API for RESTful Web Services (JAX-RS) API, application developers can quickly develop RESTful applications. When planning to use JAX-RS to enable RESTful services, consider how to best implement the capabilities and characteristics of a RESTful application with JAX-RS.

### Before you begin

Read the overview of JAX-RS information to learn about REST services and the advantages of using JAX-RS to build RESTful services.

### About this task

JAX-RS is a programming model that provides a mechanism for developing services that follow Representational State Transfer (REST) principles. Using JAX-RS, development of RESTful services is simplified.

JAX-RS is a Java API for developing REST applications quickly. While JAX-RS provides a faster way for developing web applications than servlets, the primary goal of JAX-RS is to build RESTful services. JAX-RS 1.0 defines a server-side component API to build REST applications. IBM JAX-RS provides an implementation of the JAX-RS (JSR 311) specification.

By using JAX-RS technology, REST applications are simpler to develop, simpler to consume, and simpler to scale when compared to other types of distributed systems. Many popular and widely used Internet services have successfully provided RESTful APIs to their applications. Third parties have used various REST APIs to build their own businesses and applications.

Due to the simple consumption of RESTful services, you can write clients in many languages on different platforms. Most languages require no third-party libraries as long as there is a method to use an HTTP connection. Because of the pervasiveness of web browsers, the most prevalent clients are typically web browsers. For example, many Web 2.0 properties use a JavaScript framework such as Dojo toolkit for developing a client in a browser in conjunction with a RESTful server-side application that provides the data for the client.

### Procedure

1. Review existing business and middleware applications in your environment to determine which services you want to implement as REST services.
2. Define the resources in your RESTful applications.
3. Determine the URL patterns, operations, and media type formats to use for each resource.
   a. Define the URI patterns for resources in RESTful applications.
   b. Define the client capabilities for RESTful applications using HTTP methods .
   c. Define the HTTP headers and response codes for RESTful applications using HTTP methods.

© Copyright IBM Corp. 2011

## Results

You have a design plan for using JAX-RS to implementing REST services.

# Defining the resources in RESTful applications

You can use Java API for RESTful Web Services (JAX-RS) to develop services that follow Representational State Transfer (REST) principles. RESTful services are based on manipulating resources. Resources can contain static or dynamically updated data. By identifying the resources in your application, you can make the service more useful and easier to develop.

## Before you begin

After you have identified the application that you want to expose as a RESTFUL service, you must first define the resources for your RESTful application. When defining the resources for your application, consider the type of data do you want to expose. Perhaps you already have a relational database that contains information that you want to expose to users using REST technology. Do you already have a set of Java classes defined for accessing that data?

For example, consider the case of an application defined to support a book store. This application currently has a database with several tables that define the various items in the collection of books and the inventory of each book. In this example, there are a number of ways to represent the data in the database in a RESTful application. One approach is to consider each table as an individual resource, so that each of the verbs in the RESTful request maps to the actions that the database supports on that table such as select, insert, update, delete. This example is a simple approach to creating a RESTful application. This approach using the book store example is also used in the documentation that describes defining URL patterns for resources, resource methods, HTTP headers and response codes, media types, and parameters for request representations to resources

In support of this database for the book store application, there might already be existing code that is responsible for accessing the database and retrieving the data from each table. Even though the rows in each of the tables logically represents each resource, the accessor classes are used to define the resources. The implementing JAX-RS applications documentation provides more details on how these classes are incorporated into your JAX-RS application.

Alternately, you might have more static content that does not reside in a database that you want to distribute as resources. Whether it is a collection of documents in various formats or a resource-based facade for other remote systems, using JAX-RS, you can distribute content from multiple sources.

## About this task

Resources are the basic building block of a RESTful service. Examples of a resource from an online book store application include a book, an order from a store, and a collection of users.

Resources are addressable by URLs and HTTP methods can perform operations on resources. Resources can have multiple representations using different formats such as XML and JSON. You can use HTTP headers and parameters to pass additional information that is relevant to the request and response.

With JAX-RS, you can annotate existing or new Plain Old Java objects (POJO) with JAX-RS specific annotations. JAX-RS annotated resource classes and the annotated methods are invoked depending on the URI patterns. You can use the annotated resource classes after these resource classes are added to the list of resources returned by the overridden methods in the JAX-RS application class.

## Procedure

1. Identify the types of resources in the application.
2. (optional) Identify existing Java classes that you can use as resource classes.

3. Create new Java classes for resources that do not have an existing Java class.

### Results

You have defined the content that you want to expose as a collection of resources in your application.

### What to do next

Based on the resources that you have defined, read about defining URL patterns for resources, resource methods, HTTP headers and response codes, media types, and parameters for request representations to resources to learn more about additional steps you can take to define the resources for your JAX-RS application.

## Defining the URI patterns for resources in RESTful applications

Representational State Transfer (REST) services are based on manipulating resources. Resources for RESTful services are addressable, and URLs are the primary way of achieving addressability in REST.

### Before you begin

Identify the resources in the application that you want to expose as a RESTful service.

### About this task

URLs are used to specify the location of a resource. Interaction between the server and client is based on issuing HTTP operations to URLs. Defining URL patterns is important because URLs often have a long lifetime so that clients can directly address a resource long after the resource is initially discovered.

URLs are typically used when you enter addresses to web browsers, such as `http://www.ibm.com/` or `http://www.example.com/bookstore/books/ISBN123`. Although URLs are not required to be understandable by users, RESTful services that provide logical URLs in understandable patterns enable client application developers to work efficiently.

RESTful clients use URLs to manipulate resources. Each resource must have its own unique URL. Some URL patterns have a collection path with a unique identifier appended. For example, you can use `http://www.example.com/bookstore/books` as the collection resource URL, `http://www.example.com/bookstore/books/ISBN123` as a unique book resource URL, and you can use `http://www.example.com/bookstore/books/ISBN123/authors` to retrieve a collection resource describing `ISBN123` authors.

The application developer must carefully consider the granularity of URLs because it can affect usage of the application and performance. For example, you can include the author information of a book as part of the book resource or you can define the author information as a unique resource with its own URL that is referenced in the book resource. Depending on the reuse of resources, it might be more efficient to define a separate resource for the author information that is referenced in a hyperlink of the book resource for cases when the author writes a different book.

After an initial URL is given to a client, subsequent related requests are discoverable by parsing the current resource. In the book example, a GET request to `http://www.example.com/bookstore/books/` retrieves a list of book URLs that can include `http://www.example.com/bookstore/books/ISBN123`.

Because systems rely on resources being available, URLs typically have longevity. Because HTTP has built-in status codes for redirection, such as the 301 moved permanently code and the 307 temporarily redirected code, users and clients with caches often reuse previously discovered URLs first. You can additionally consider including a version identifier in the URL pattern, such as `http://www.example.com/bookstore/v2/books/ISBN123`. Like the planning involved to define an interface using Java code, be sure to carefully choose your URL patterns because of expected longevity.

In Java API for RESTful Web Services (JAX-RS), you must add @Path annotations to the Java class files or the Java methods to define the relative URL of the resource. You can use JAX-RS subresource locators and subresource methods to define resources. Use parameters, such as the path parameter or matrix parameter, in the URL to identify the resource.

The value in the @Path annotation defines the relative part of the full URL to your resource. The base URL is derived from the domain, port, application module context root, and any URL pattern mappings in the web.xml file of the application module. For example, if the domain is `www.example.com`, the port is `9060`, the module context root is `example`, the servlet URL pattern is `store/*`, and the value of the @Path annotation is `/bookstore/books`. The full URL is: `http://www.example.com:9060/example/store/bookstore/books`.

## Procedure

1. Identify the types of resources in the application. Suppose that you have two types of resources, a BooksCollection and an individual Book object which have the following class definitions:

```
public class BooksCollection {
    public BooksCollection() {
        /* no argument constructor */
    }

}

public class Book {
    public Book(String ISBN) {
        /* This constructor has an argument that will be annotated with a JAX-RS annotation.
         See the JAX-RS specification for information on valid constructors. */
    }
}
```

   As defined in the JAX-RS specification, by default, resource instances are created per request. For the JAX-RS runtime environment to create a resource instance, you must have either a constructor with no argument or a constructor with only JAX-RS annotated parameters present.

2. Add a @javax.ws.rs.Path annotation to each resource class. For each @javax.ws.rs.Path annotation, set the value as the part of the URL after the base URL of the application.

```
/*
 * BooksCollection.java
 * This Java class represents the books collection URL at /bookstore/books.
 */
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {

}
```

   After completing the application, you can use the resource by visiting `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books`. For this URL, specify the context root value as the part of the URL after the context module. Specify the servlet path as any URL patterns in the web.xml file, if it exists.

3. (optional) Determine if a resource needs to use part of the URL as a parameter. If a resource needs to use part of the URL as a parameter, such as an identifier, you can use the @javax.ws.rs.Path annotation with a regular expression. You can then add a @javax.ws.rs.PathParam annotation in either the resource constructor or the resource method.

```
/*
 * Book.java represents individual books.
  */
@javax.ws.rs.Path("/bookstore/books/{bookID}")
public class Book {
   public Book(@javax.ws.rs.PathParam("bookID") String ISBN) {

   }
}
```

   When an HTTP request is made to `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books/ISBN_number`, a Book instance is created with *ISBN_number* passed in to the ISBN parameter of the constructor.

For more information about other possible parameters, read about defining parameters for requests to resources in RESTful applications.

4. Create the javax.ws.rs.core.Application subclass to define to the JAX-RS runtime environment which classes are part of the JAX-RS application. The resource classes are returned in the getClasses() method; for example:

```
public class BookApplication extends javax.ws.rs.core.Application {
    public Set<Class<?>> getClasses() {
        Set<Class<?>> classes = new HashSet<Class<?>>();
        classes.add(BooksCollection.class);
        classes.add(Book.class);
        return classes;
    }
}
```

By defining the javax.ws.rs.core.Application subclass, classes returned from its methods are registered to the JAX-RS runtime environment. When configuring the web.xml file, you must specify the javax.ws.rs.core.Application subclass as a parameter to the servlet or filter. For more information, read about configuring the web.xml file for JAX-RS applications.

### Results

You have created a URL to identify your resources for your RESTful service. By considering issues with URL patterns early in the application design, the RESTful service increases its usability and value over an extended time.

### What to do next

The resource at the defined URL exists. However, the resource does not yet have any methods to handle HTTP method actions such as GET, POST, PUT, or DELETE. See the defining resource methods for RESTful applications to learn more about defining capabilities of resources using supported HTTP methods.

## Defining resource methods for RESTful applications

Individual resources can define their capabilities using supported HTTP methods. In Representational State Transfer (REST) services, the supported methods are GET, PUT, DELETE, and POST. All operations are typically conducted by using one of the predefined HTTP methods with a resource.

### Before you begin

Understand the predefined HTTP methods and their known attributes. Some HTTP methods are meant to be safe, meaning that issuing the request does not change the resource, or idempotent, meaning that multiple invocations of the operation do not change the result. While HTTP methods are defined to have certain attributes, the service implementation follows the definitions. See the HTTP method definitions information to learn more about the common set of methods for HTTP.

### About this task

Clients use HTTP methods to perform certain operations. Unlike other distributed systems where unique interfaces are defined by each system, RESTful systems based on HTTP mainly rely on predefined methods. The four most common methods are GET, PUT, DELETE, and POST. Resources are not required to permit all HTTP methods for all clients.

The HTTP GET method retrieves a resource representation. It is safe and idempotent. Repeated GET requests do not change any resources.

The HTTP PUT method is often used to update resources or to create a new entity at a known URL. When a resource must be updated or created, an HTTP PUT method is issued at the resource URL with the new resource data as the request entity, also known as the message body. The HTTP PUT method is

idempotent so multiple identical PUT requests with the same entity to the same URL yields the same result as if only one PUT request was issued. This method assumes that no other relevant requests were made.

The HTTP DELETE method removes a resource at a given URL. It is also idempotent.

The HTTP POST method is often used when creating a resource in a collection when the final resource URL is not known. For instance, an administrator issues a POST request to a `/users` collection resource that creates a user with a unique ID such as `1234567890`. The unique ID is then used as part of the URL path to describe the new user resource, such as `/users/1234567790`. It is not safe and is not idempotent. In this case, the multiple POST requests to the `/users` collection can continue creating a new unique ID and adding this new ID to the users collection even if the user has the same information.

Because most RESTful services use well-known HTTP methods that provide expected results, you can more easily create clients. RESTful service developers can take advantage of the expected behaviors of HTTP methods. Resource methods can also use parameters, such as path parameters, query parameters, or matrix parameters to identify the resource. Read about defining the use of parameters for request representations to resources to learn more.

(optional) If you have a sub-resource method and a sub-resource locator method that have an `@Path` annotation with the same value in the same resource class, the sub-resource locator is not considered when determining the method to invoke by default. This is in compliance with the JAX-RS specification.

Use the `wink.searchPolicyContinuedSearch` property with a value of `true` to modify this behavior. This results in sub-resource locators being used if no sub-resource methods match the request.

To enable the property, include a properties file in the `WEB-INF` directory of the module that has the `wink.searchPolicyContinuedSearch` property and value specified. In the `web.xml` file of the application module, include an `init-param` element with the `propertiesLocation` value for the `param-name` element. The `param-value` element specifies the location of the properties file, for example, `WEB-INF/my_wink.properties`.

The following example illustrates the `web.xml` file:

```
<servlet>
    ...
    ...
    <init-param>
        <param-name>propertiesLocation</param-name>
        <param-value>/WEB-INF/my_wink.properties</param-value>
    </init-param>
</servlet>
```

The following example illustrates the `WEB-INF/my_wink.properties` properties file:

```
wink.searchPolicyContinuedSearch=true
```

## Procedure

1. Identify the types of resources in the application.

   For each resource class, identify an existing method or create a method that you want to invoke for each supported HTTP method. Methods that respond to HTTP requests are also known as resource methods. For each resource method in the resource class, annotate the Java method with a single JAX-RS HTTP method annotation such as @javax.ws.rs.GET, @javax.ws.rs.POST, @javax.ws.rs.DELETE or @javax.ws.rs.PUT. For example, if an HTTP GET method is supported by the BooksCollection class, then you can create and annotate a method like the following snippet:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBooksCollection() {
        String str = /* Construct a String representation of the resource. */
        return str;
    }
}
```

When issuing an HTTP GET request to `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books` URL using a web browser or another HTTP client, the previous getBooksCollection() method is invoked.

2. Ensure that the resource supports the required HTTP methods.

   Each resource typically has multiple resource methods; for example:

```
@javax.ws.rs.Path("/bookstore/books/{bookID}")
public class Book {
    /* This is a database key. */
    private String ISBN;

    public Book(@javax.ws.rs.PathParam("bookID") String ISBN) {
        this.ISBN = ISBN;
    }

    @javax.ws.rs.GET
    public String retrieveSpecificBookInformation() {
        /* This code retrieves a book resource based on the ISBN key. */
    }

    @javax.ws.rs.PUT
    public String updateBookInformation(String updatedBookInfo) {
        /* This code updates the book resource based on ISBN key and the entity (message body) sent
         in the request that is stored in updatedBookInfo. */
    }

    @javax.ws.rs.DELETE
    public void removeBook() {
        /* This code deletes a book resource based on ISBN key. */
    }
}
```

   When issuing an HTTP GET request to the `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books/<isbn_number>` URL using a web browser or another HTTP client, the retrieveSpecificBookInformation() method is invoked. Sending an HTTP PUT request to the same URL invokes the updateBookInformation method and any content in the request message body is passed as the value of the `updatedBookInfo` object. Finally, sending an HTTP DELETE request to the same URL invokes the removeBook() method.

   **Note:** According to the JAX-RS specification, you must not put multiple HTTP method annotations, such as @javax.ws.rs.POST or @javax.ws.rs.PUT on the same resource method Because HTTP methods have uniquely defined semantics, do not use a resource method for multiple HTTP methods.

### Results

You have defined valid operations for the resources.

## Defining the HTTP headers and response codes for RESTful applications

HTTP headers and status codes are useful to help intermediary and client programs understand information about requests and responses for applications. HTTP headers contain metadata information. HTTP status codes provide status information about the response.

### Before you begin

See the HTTP 1.1 specification to become familiar with HTTP headers and HTTP status codes.

### About this task

HTTP headers contain metadata information such as security authentication information, the user agent that is used, and cache control metadata. Standard HTTP headers are defined in the HTTP specification; however, you can use custom HTTP headers, if necessary.

You can read HTTP headers from the request and set the headers in the response. There are a set of common request and response headers, but there are also unique request and unique response headers. JAX-RS provides the HttpHeaders injectable interface and the @HeaderParam parameter annotation for reading HTTP headers. If a javax.ws.rs.core.Response object is returned from a resource method, you can set HTTP headers on the response. Also, you can set HTTP headers when an entity is written using the MessageBodyWriter interface.

You can set HTTP response status codes to help client programs understand the response. While responses can contain an error code in XML or other format, client programs can quickly and more easily understand an HTTP response status code. The HTTP specification defines several status codes that are typically understood by clients.

### Procedure

- To read a specific request header, add a @javax.ws.rs.HeaderParam annotated parameter.

```
@javax.ws.rs.Path("/bookstore/books/{bookID}")
public class Book {
    @javax.ws.rs.GET
    public String retrieveSpecificBookInformation(@javax.ws.rs.HeaderParam("User-Agent") String theUserAgent) {
        /* The book ID was sent in a HTTP request header with the name "bookID". */
    }
}
```

- To read any request header, use the @javax.ws.rs.core.Context javax.ws.rs.core.HttpHeaders injected object.

```
@javax.ws.rs.Path("/bookstore/books/{bookID}")
public class Book {
    @javax.ws.rs.GET
    public String retrieveSpecificBookInformation(@javax.ws.rs.core.Context HttpHeaders requestHeaders) {
        /* Call methods on "requestHeaders" to get any request header sent by the client. */
        List<String> bookIdValues = requestHeaders.getRequestHeader("User-Agent");
    }
}
```

- To set a response status code or header, return a javax.ws.rs.core.Response object and build the response with the appropriate status code and headers.

```
@javax.ws.rs.Path("/bookstore/books/{bookID}") public class Book {
    @javax.ws.rs.GET public javax.ws.rs.core.Response retrieveSpecificBookInformation() {
        return Response.status(200).header("responseHeaderName", "responseHeaderValue").header("anotherResponseHeaderName", "foo").build();
    }
}
```

### Results

You have used HTTP headers to read request headers and set response status codes and headers for JAX-RS web applications.

## Defining media types for resources in RESTful applications

Resources are represented by multiple formats. XML, JavaScript Object Notation (JSON), Atom, binary formats such as PNG, JPEG, GIF, plain text, and proprietary formats are used to represent resources. Representational State Transfer (REST) provides the flexibility to represent a single resource in multiple formats.

### Before you begin

Define the resources in the JAX-RS web application.

### About this task

Resources have representations. A resource representation is the content in the HTTP message that is sent to, or returned from the resource using the URI. Each representation that a resource supports has a corresponding media type. For example, if a resource is going to return content formatted as XML, you can use `application/xml` as the associated media type in the HTTP message.

Depending on the requirements of your application, resources can return representations in a preferred single format or in multiple formats. For example, resources that are accessed using JavaScript clients might prefer JSON representations because JSON is easy to consume.

JAX-RS provides @Consumes and @Produces annotations to declare the media types that are acceptable for a resource method to read and write.

JAX-RS also maps Java types to and from resource representations using entity providers. A `MessageBodyReader` entity provider reads a request entity and deserializes the request entity into a Java type. A `MessageBodyWriter` entity provider serializes from a Java type into a response entity.

*Table 237. Standard entity providers and basic Java types. This table includes the standard entity providers and basic Java types that are included in the JAX-RS runtime environment, along with the corresponding supported content types.*

| Java type | MessageBodyReader | MessageBodyWriter | Supported Content types |
|---|---|---|---|
| byte[] | X | X | */* |
| java.io.InputStream | X | X | */* |
| java.io.Reader | X | X | */* |
| java.lang.String | X | X | */* |
| java.io.File | X | X | */* |
| javax.activation.DataSource | X | X | */* |
| javax.xml.transform.Source | X | X | text/xml, application/xml, application/*+xml |
| javax.ws.rs.core.MultivaluedMap | X | X | application/x-www-form-urlencoded |
| JAXB types | X | X | text/xml, application/xml, application/*+xml |
| javax.ws.rs.core.StreamingOutput | | X | */* |

If a `String` value is used as the request entity parameter, the `MessageBodyReader` entity provider deserializes the request body into a new `String`. If a JAXB type is used as the return type on a resource method, the MessageBodyWriter serializes the Java Architecture for XML Binding (JAXB) object into a response body.

If you need a custom mapping from a Java type to a specific representation, see the information for using an application-defined entity provider.

If your client can handle multiple formats and you want the server to determine the best resource representation to return, read about using content negotiation in JAX-RS applications to serve multiple content types.

The specifications for XML, JSON, and Atom provide details regarding the formats of resource representations for applications. See the specifications to learn more about the formats of resource representations.

## Procedure

1. Determine the resource representation format such as XML, JSON, or ATOM to use for either the request or the response.
2. Add the @Consumes and @Produces annotations appropriately to the resource method.
3. If the resource needs to read the content of the request, add a request entity parameter to the resource method. The request entity parameter is a single Java parameter on the method that does not have an annotation.

4. If the resource method returns content in the response, return a Java object that is writable by a JAX-RS entity provider. This Java object is mapped to the response entity in the HTTP response. The returned object must be a JAX-RS supported Java type or wrapped in a javax.ws.rs.core.Response or javax.ws.rs.core.GenericEntity type.

## Results

You have mapped the request entities to the resource method entity parameter and any response objects that are returned are mapped to the response entity for the resource representation.

## Example

The following example illustrates defining XML as the resource representation for a RESTful bookstore application.

1. Identify the resource methods that you want to read the request entity or return a response entity.

   In the retrieveSpecificBookInformation method example that follows, there is no request entity that is read. However, there is a response object that is returned. This object wraps a JAXB object that contains the entity information. Adding the @Produces annotation on the resource method with a media type of `application/xml` indicates that the resource method always returns an XML representation with a media type of `application/xml`.

   Clients that have an Accept HTTP request header value compatible with the `application/xml` media type invoke the method correctly.

   Clients that do not have an Accept HTTP header value compatible with the `application/xml` media type automatically receive a `406 Not Acceptable` response status which indicates that the server cannot produce an acceptable response.

   The following example identifies the resource methods that read the request entity or return a response entity:

```
/*
 * Book.java
 * This class represents individual books. The @Produces annotation specifies a media type of application/xml.
 */
@Path("/bookstore/books/{bookID}")
public class Book {
  @GET
  @Produces("application/xml")
  public javax.ws.rs.core.Response retrieveSpecificBookInformation(@PathParam("bookID") String theBookID,
   @Context javax.ws.rs.core.HttpHeaders headers) {
   /* ... */
   return
    Response.ok(/* JAXB object to represent response body entity */).expires(/* Expires response header value*/).header("CustomHeaderName", "CustomHeaderValue").build();
   }
   @PUT
   public String updateBookInformation(@PathParam("bookID") String theBookID, String theRequestEntity,
    @javax.ws.rs.HeaderParam("Content-Length") String contentLengthHeader) { /* ... */ }

   @DELETE
   public void removeBook(@PathParam("bookID") String theBookID) { /* ... */ }
}
```

2. Identify the resource methods that need to consume the request information.

   In the following snippet, the PUT method on the book resource accepts the request entity content if a media type of `text/plain` is sent, as defined in the @Consumes annotation. This method returns content with a `text/plain` representation as specified in the @Produces annotations.

   If a client does not send a message with a Content-Type value of `text/plain`, then the PUT resource method is not invoked. If `Content-Type: application/xml` is sent in the HTTP request headers, the `updateBookInformation` Java method is not be called.

   The DELETE method neither reads a request entity nor returns a response entity; therefore, it does not require either an @Consumes or an @Produces annotation.

   The following example identifies the resource methods that consume the request information:

```
/*
 * Book.java
 * This class represents represent individual books with custom headers.
 */
@Path("/bookstore/books/{bookID}")
public class Book {
  @GET
  @Produces("application/xml")
  public javax.ws.rs.core.Response retrieveSpecificBookInformation(@PathParam("bookID") String theBookID, @Context javax.ws.rs.core.HttpHeaders headers) {
```

```
    /* ... */
    return Response.ok(/* JAXB object to represent response body entity */).expires(/* Expires response header value).header("CustomHeaderName", "CustomHeaderValue").build();
  }
  @PUT
  @Consumes("text/plain")
  @Produces("text/plain")
  public String updateBookInformation(@PathParam("bookID") String theBookID, String theRequestEntity, @javax.ws.rs.HeaderParam("Content-Length") String contentLengthHeader) {
    /* ... */
    String responseEntity = /* a plain text representation */;
    return responseEntity;
  }

  @DELETE
  public void removeBook(@PathParam("bookID") String theBookID) { /* ... */ }
}
```

## What to do next

See the JAX-RS specification for a list of all the standard media formats that are supported for representations.

Advanced users might consider defining custom mappings of Java types to representations or using content negotiation for clients to negotiate preferred resource representations. To learn more about these options, see the using custom defined entity formats information or the serving multiple content types with content negotiation information.

# Defining parameters for request representations to resources in RESTful applications

Parameters are used to pass and add additional information to a request. You can use parameters as part of the URL or in the headers. Path parameters, matrix parameters, query parameters, header parameters, and cookie parameters are useful for passing in additional information to a request.

## About this task

Multiple parameters types exist. Java API for RESTful Web Services (JAX-RS) enables easy access to all the types of parameters using annotated injected parameters.

You can use any basic Java primitive type including java.lang.String as parameters, as well as Java types with a constructor that uses a single String or a valueOf(String) static method. Additionally, you can use `List`, `SortedSet`, and `Set` interfaces where the generic type is one of the previously mentioned types, such as a Set when a parameter can have multiple values. If you need to parse requests, then use String as the parameter type to enable you to complete basic inspection and customization of error path responses.

JAX-RS provides the following annotations to use on resource method parameters to specify that the resource method can be invoked with correct parameter values.

**javax.ws.rs.PathParam annotation**

Path parameters are part of the URL. For example, the URL can include `/collection/{item}`, where `{item}` is a path parameter that identifies the item in the collection. Because path parameters are part of the URL, they are essential in identifying the request.

If parts of the URL are parameters, you can use a @javax.ws.rs.PathParam annotated parameter; for example:

```
@javax.ws.rs.Path("/bookstore/books/{bookId}")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getSpecificBookInfo(@javax.ws.rs.PathParam("bookId") String theBookId) {
        /* theBookId would contain the next path segment after /bookstore/books/  */
    }
}
```

In this example, requests to `/bookstore/books/12345` assigns the value of `12345` to the `theBookId` variable.

**javax.ws.rs.MatrixParam annotation**

Matrix parameters are part of the URL. For example, if the URL includes the path segment, `/collection;itemID=itemIDValue`, the matrix parameter name is `itemID` and `itemIDValue` is the value.

You can read matrix parameters with a @javax.ws.rs.MatrixParam annotated parameter; for example:

```
@javax.ws.rs.Path("/bookstore/books")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBookCollectionInfo(@javax.ws.rs.MatrixParam("page") int page, @javax.ws.rs.MatrixParam("filter") String filter) {
        /* This statement uses the page and filter parameters. */
    }
}
```

In this example, requests to`/bookstore/books;page=25;filter=test` invoke the `getBookCollectionInfo` parameter so that the value for the `page` variable is set to `25` and the value for `filter` variable is set to `test`.

### javax.ws.rs.QueryParam annotation

Query parameters are appended to the URL after a "?" with name-value pairs. For instance, if the URL is `http://example.com/collection?itemID=itemIDValue`, the query parameter name is `itemID` and `itemIDValue` is the value. Query parameters are often used when filtering or paging through HTTP GET requests.

You can read query parameters with a @javax.ws.rs.QueryParam annotated parameter; for example:

```
@javax.ws.rs.Path("/bookstore/books")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBookCollectionInfo(@javax.ws.rs.QueryParam("page") int page, @javax.ws.rs.QueryParam("filter") String filter) {
        /* This statement uses the page and filter parameters. */
    }
}
```

In this example, requests to`/bookstore/books;page=25;filter=test` invoke the `getBookCollectionInfo` parameter so that the value for the `page` variable is set to `25` and the value for `filter` variable is set to `test`.

### javax.ws.rs.HeaderParam annotation

Header parameters are HTTP headers. While there are pre-defined HTTP headers, you can also use custom headers. Headers often contain control metadata information for the client, intermediary, or server.

If a HTTP request header must be read, use the @javax.ws.rs.HeaderParam annotation; for example:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBookCollectionInfo(@javax.ws.rs.HeaderParam("Range") String rangeValue) {
        /* The rangeValue variable contains the value of the HTTP request header "Range" */
    }
}
```

In this example, requests to `/bookstore/books/` with a `Range` HTTP request header value of `bytes=0-499` invokes the method with `bytes=0-499` as the value for the `rangeValue` variable.

### javax.ws.rs.CookieParam annotation

Cookie parameters are special HTTP headers. While cookies are associated with storing session identification or stateful data that is not accepted as RESTful, cookies can contain stateless information.

If an HTTP cookie is sent, such as `mycustomid=customvalue123`, you can retrieve the value of the `mycustomid` variable using the following example:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.GET
```

```
    public String getBookCollectionInfo(@javax.ws.rs.CookieParam("mycustomid") String mycustomid) {
        /* The cookie value is passed to the mycustomid variable. */
    }
}
```

### javax.ws.rs.FormParam annotation

Form parameters are used when submitting a HTML form from a browser with a media type of `application/x-www-form-urlencoded`. The form parameters and values are encoded in the request message body in the form like the following: `firstParameter=firstValue &secondParameter=secondValue`. The javax.ws.rs.FormParam annotation enables easy access to individual form parameter values.

If a form is submitted and the entity value is `firstName=Bob&lastName=Smith`, you can retrieve the values of the form parameters using the following example:

```
@javax.ws.rs.Path("/customer")
public class Custommer {
    @javax.ws.rs.POST
    public String postCustomerInfo(@javax.ws.rs.FormParam("firstName") String firstName, @javax.ws.rs.FormParam("lastName") String lastName) {
        /* firstName would be "Bob" and secondName would be "Smith" */
    }
}
```

**Note:** You can either use a single unannotated parameter to represent the message body or use multiple FormParam annotated parameters, but not both. Because the FormParam requires the request message body to be read and the message body is represented as a byte stream, the message body cannot be read again. The following code is not valid:

```
@javax.ws.rs.Path("/bookstore/books")
public class BooksCollection {
    @javax.ws.rs.POST
    public String postSpecificBookInfo(@javax.ws.rs.FormParam("bookId") String theBookId, String theRequestEntity) {
        /* This code is invalid.  Can only use FormParam or a request entity parameter like "String theRequestEntity" and not both */
    }
}
```

Choose one of the following ways to define variables to read parameters.

## Procedure

- Add a parameter to the resource method by using an appropriate JAX-RS parameter annotation on the method to identify the type of parameter. You can read multiple types of parameters from a request; for example:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBookCollectionInfo(@javax.ws.rs.QueryParam("page") int page, @javax.ws.rs.QueryParam("filter") String filter) {
        /* This statement uses the page and filter parameters. */
    }
}
```

  Issuing an HTTP GET request using a web browser or other HTTP client, such as `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books?page=10&filter=FilterValue`, invokes the getBookCollectionInfo() method with the page set to 10 and filter set to `FilterValue`.

- Add the parameter annotation on the fields, JavaBeans properties, and constructor arguments; for example:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.QueryParam("page") int page;

    String filter;

    @javax.ws.rs.QueryParam("filter")
    public void setFilter(String filter) {
        this.filter = filter;
    }

    @javax.ws.rs.GET
    public String getBookCollectionInfo() {
        /* This statement uses the page and filter parameters. */
    }
}
```

Issuing an HTTP GET request using a web browser or other HTTP client, such as `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books?page=10&filter=FilterValue`, also invokes the getBookCollectionInfo() method with the page set to 10 and filter set to `FilterValue`.

### Results

Your resource methods are defined so that they can be invoked with appropriate parameter values.

### Example

## Defining exception mappers for resource exceptions and errors

Java API for RESTful Web Services (JAX-RS) applications can produce exceptions and errors. The default behavior is to use the exception handling functionality of application container such as JavaServer Pages (JSP) error pages. However, you can customize the error handling and send specific responses back when an exception or error occurs.

### About this task

JAX-RS resource methods, like any Java method, can throw checked and unchecked exceptions. By default, an unchecked runtime exception or error occurs in the container again. A checked exception is wrapped in a `ServletException` for resources running in the web container. Therefore, a developer can use error handling facilities such as JSP error pages to handle exceptions thrown from a JAX-RS application.

JAX-RS introduced the exception, `javax.ws.rs.WebApplicationException`. A developer can specify a specific error class name or `javax.ws.rs.core.Response` object when creating a `WebApplicationException`. When the `WebApplicationException` is thrown, the information included in the exception by way of a status class name or Response object is used to serialize a response.

If you cannot throw the exception, `WebApplicationException`, in your code and you cannot use the error handling facilities in the web container, but you want to use a custom error response, then you can create a customized JAX-RS `javax.ws.rs.ext.ExceptionMapper` class to map exceptions to HTTP error responses.

The following procedure illustrates how to write a custom `ExceptionMapper` class.

### Procedure

1. Create a class that implements the `javax.ws.rs.ext.ExceptionMapper` class and annotate the class with the `javax.ws.rs.ext.Provider` annotation. This step assumes that your JAX-RS resource can throw the exception, `MyCustomException`, in its methods. The following example illustrates a simple `ExceptionMapper` class:

```
import javax.ws.rs.core.Response;
import javax.ws.rs.ext.ExceptionMapper;
import javax.ws.rs.ext.Provider;

@Provider
public class CustomExceptionMapper implements ExceptionMapper<MyCustomException> {

    public Response toResponse(MyCustomException exception) {
        return null;
    }

}
```

2. In the `toResponse(MyCustomException)` method, return a `Response` object that contains the customized error response. The following example illustrates a customized `ExceptionMapper.toResponse(MyCustomException)` method:

```
@Provider
public class CustomExceptionMapper implements ExceptionMapper<MyCustomException> {

    public Response toResponse(MyCustomException exception) {
        return Response.status(500).entity("Unfortunately, the application cannot
```

```
            process your request at this time.").type("text/plain").build();
    }

}
```

You can have additional code where you log an error, inspect the exception thrown, or use more complex logic.

3. Package the compiled custom `ExceptionMapper` class with your web application project. If you rely on the annotation scanning capabilities to find all of your JAX-RS classes in your web application, no additional steps are required. However, if you return all of the relevant JAX-RS resource classes and providers in a JAX-RS application subclass method, then you must also add the custom `ExceptionMapper` class to the returned set. The following example illustrates a preexisting `javax.ws.rs.core.Application` subclass:

```
import java.util.HashSet;
import java.util.Set;

import javax.ws.rs.core.Application;

public class MyApplication extends Application {

    @Override
    public Set<Class<?>> getClasses() {
        Set<Class<?>> classes = new HashSet<Class<?>>();
        classes.add(CustomExceptionMapper.class);
        /* add your additional JAX-RS classes here */
        return classes;
    }
}
```

When exceptions occur in your JAX-RS resource methods, you can customize the HTTP error response so that a user cannot see a stack trace or potentially confidential data. Use an `ExceptionMapper` or the exception handling functionality in the web container to give more helpful responses if the application is not behaving correctly.

### Results

You have written a custom `ExceptionMapper` to handle exceptions in your JAX-RS web application.

---

# Developing JAX-RS web applications

## Getting started with IBM JAX-RS

JAX-RS is a collection of interfaces and Java annotations that simplifies development of server-side REST applications. By using JAX-RS technology, Representational State Transfer (REST) applications are easier to develop and easier to consume when compared to other types of distributed systems.

### About this task

JAX-RS is a Java API for developing REST applications quickly. While JAX-RS provides a faster way of developing web applications than servlets, the primary goal of JAX-RS is to build RESTful services. JAX-RS 1.0 defines a server-side component API to build REST applications. The IBM implementation of JAX-RS provides an implementation of the JAX-RS (JSR 311) specification.

Use this Getting Started guide to help you quickly develop and deploy a simple JAX-RS web application.

This procedure illustrates developing a simple Hello World service that is packaged inside a web application archive (WAR) module.

### Procedure

1. Create a Java class. This class is used to represent a type of resource.

```
package com.ibm.jaxrs.sample;

public class HelloWorldResource {

}
```

2. Annotate the Java class with a `javax.ws.rs.Path` annotation. The value of the annotation is the relative part of the URL after the application context. The application context is fully defined during deployment. In JAX-RS terminology, this class is known as a root resource.

```
package com.ibm.jaxrs.sample;

@javax.ws.rs.Path("/helloworld")
public class HelloWorldResource {

}
```

3. Create a Java method that returns a `Hello World!` response. It is intended for the method to be invoked when an HTTP request is received.

```
package com.ibm.jaxrs.sample;

@javax.ws.rs.Path("/helloworld")
public class HelloWorldResource {

    public String sayHelloWorld() {
        return "Hello World!";
    }
}
```

4. Add a `javax.ws.rs.GET` annotation to the Java method.

   Now, whenever an HTTP GET request is received by the application to the `/helloworld` path, the `sayHelloWorld` Java method is invoked. The response message body will contain `Hello World!` as its content.

```
package com.ibm.jaxrs.sample;

@javax.ws.rs.Path("/helloworld")
public class HelloWorldResource {

    @javax.ws.rs.GET
    public String sayHelloWorld() {
        return "Hello World!";
    }
}
```

   The resource implementation is now complete.

5. You must create the JAX-RS `javax.ws.rs.core.Application` configuration subclass. This subclass needs to return the set of Java classes that is relevant to the JAX-RS runtime environment.

```
package com.ibm.jaxrs.sample;

public class HelloWorldAppConfig extends javax.ws.rs.core.Application {
    public Set<Class<?>> getClasses() {
        Set<Class<?>> classes = new HashSet<Class<?>>();
        classes.add(com.ibm.jaxrs.sample.HelloWorldResource.class);
        return classes;
    }
}
```

6. Create the `web.xml` web module configuration file.

   The file tells the web container that the web module contains the IBM JAX-RS REST servlet. You must initialize the IBM JAX-RS Rest servlet with the application configuration class.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_9" version="2.4" xmlns=http://java.sun.com/xml/ns/j2ee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
         xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd">
    <servlet>
        <servlet-name>HelloWorldApp</servlet-name>
        <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
        <init-param>
            <param-name>javax.ws.rs.Application</param-name>
            <param-value>com.ibm.jaxrs.sample.HelloWorldAppConfig</param-value>
        </init-param>
        <load-on-startup>1</load-on-startup>
    </servlet>
    <servlet-mapping>
        <servlet-name>HelloWorldApp</servlet-name>
        <url-pattern>/rest/*</url-pattern>
    </servlet-mapping>
</web-app>
```

See the servlet mapping that is specified in the previous example. The pattern is used to help determine the final URL of the RESTful service.

7. Add the `j2ee.jar` file to the classpath.

   Get the `j2ee.jar` file from the `app_server_root/dev/JavaEE` directory and add the JAR file to the classpath. Compile the classes.

8. Assemble the web application.

   By using the jar command-line tool that is included with the JDK, run the following command:

```
jar cvf helloworld-jaxrs.war *
```

   This command creates a WAR file.

9. Deploy the application onto the application server.

   When deploying the application, you might be prompted to provide a value for the context root of the module. The context root is used to define the application context.

   When using the IBM JAX-RS servlet, the following URL defines the application context:

```
http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/servlet_mapping_pattern
```

   Root resource URLs that are specified by the `@javax.ws.rs.Path` values are relative to the application context root. Therefore, if the context root is defined as `myapplication` during deployment, the URL pattern is defined in the `web.xml` file as `/rest/*`, and the Java root resource class has a `@javax.ws.rs.Path` value of `/helloworld`. An example of the final URL is:

```
http://localhost:9080/myapplication/rest/helloworld
```

   Now, you can send a client request to the final URL by using a web browser or any other HTTP client.

### Results

You have developed and deployed a JAX-RS web application on the application server.

## Setting up a development environment for JAX-RS applications

The application server provides command-line tools to develop web services clients and implementations that are based on the Java API for RESTful Web Services (JAX-RS) specification. You must set up your development environment before you start developing web services.

### Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information about installing the application server, read about installing your application server environment.

To develop JAX-RS applications, the JAX-RS libraries must be added to the class path definition. See the information for your assembly tools to understand how to include libraries on the class path for the JAX-RS application.

### About this task

Set up a web services development environment by completing the following actions.

### Procedure

1. Set up the environment.

   Windows Run the setupCmdLine.bat command from the */profile_root/<application_server>/bin* directory.

   Linux AIX HP-UX Solaris Operating systems such as AIX or Linux ***source*** the script to the parent shell to inherit the exported variables by running the following command from the **.** */profile_root/<application_server>/bin* directory:

**. ./setupCmdLine.sh** (Notice the space between the periods.)

You can set **WAS_USER_SCRIPT** to *profile_root*\<*application_server*>\bin\setupCmdLine.bat, which has the same effect as running the setupCmdLine command.

2. Configure the path. You can add the WebSphere and Java `bin` directories to your path by typing:

Windows

```
set PATH=%WAS_PATH%;%PATH%
```

AIX HP-UX Solaris Linux

```
export PATH=$WAS_PATH:$PATH
```

### Results

You have set up an environment so that you can develop RESTful web services.

### What to do next

Develop your JAX-RS application and configure the `web.xml` file for the JAX-RS servlet.

## Assembly tools

WebSphere Application Server supports *assembly tools* that you can use to develop, assemble, and deploy Java Platform, Enterprise Edition (Java EE) modules.

The IBM Rational Application Developer for WebSphere Software product and the IBM Assembly and Deploy Tools for WebSphere Administration product are supported assembly tools. Although this information center refers to the products as the *assembly tools*, you can use the products to do more than assemble modules.

The Rational Application Developer product provides an integrated development environment to design, develop, analyze, test, profile, and deploy web, service-oriented architecture (SOA), Java, and Java EE applications. It contains tools for software developers, including many simple wizards and visual editors, that support the Java EE programming model.

The Rational Application Developer product provides Service Component Architecture (SCA) Development Tools that you can use to assemble SOA components based on open SCA specifications. Use the tools to do the following:

- Develop SCA service components implemented with annotated Java code.
- Wire components together graphically to form new composite services.
- Associate protocol bindings and quality of service intents to SCA components.
- Package SCA assets and deploy them to a WebSphere Application Server server in a business-level application.

A subset of the capability in the Rational Application Developer product is available in Assembly and Deploy Tools for WebSphere Administration, which is available with WebSphere Application Server. With these tools, you can assemble and deploy applications to a WebSphere Application Server server .

For documentation on the tools, see "Rational Application Developer documentation." Topics on application assembly in this information center supplement that documentation.

The assembly tools are available in the WebSphere Application Server disc package with two licenses. The license for IBM Assembly and Deploy Tools for WebSphere Administration does not expire. The license for IBM Rational Application Developer for WebSphere Software is available on a Trial basis and is only available for a limited time.

The Trial download for Rational Application Developer is available at `http://www.ibm.com/developerworks/downloads/r/rad/`.

**Important:** The assembly tools run on Windows and Linux Intel platforms. Users of WebSphere Application Server on all platforms must assemble their modules using an assembly tool installed on Windows or Linux Intel platforms. To install an assembly tool, follow instructions available with the tool.

# Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

## Default product locations (distributed)

The following file paths are default locations. You can install the product and other components or create profiles in any directory where you have write access. Multiple installations of WebSphere Application Server - Express products or components require multiple locations. Default values for installation actions by root and nonroot users are given. If no nonroot values are specified, then the default directory values are applicable to both root and nonroot users.

*app_client_root*

*Table 238. Default installation root directories for the Application Client for IBM WebSphere Application Server.*

*This table shows the default installation root directories for the Application Client for IBM WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppClient` (Java EE Application client only)<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\Program Files\IBM\WebSphere\AppClient` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\IBM\WebSphere\AppClient` |

*app_server_root*

*Table 239. Default installation directories for WebSphere Application Server.*

*This table shows the default installation directories for WebSphere Application Server - Express.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppServer`<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppServer`<br>Windows `C:\Program Files\IBM\WebSphere\AppServer` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppServer`<br>Windows *user_home*`\IBM\WebSphere\AppServer` |

*component_root*
: The component installation root directory is any installation root directory described in this topic. Some programs are for use across multiple components—in particular, the Web Server Plug-ins, the Application Client, and the IBM HTTP Server. All of these components are part of the product package.

*gskit_root*
: IBM Global Security Kit (GSKit) can now be installed by any user. GSKit is installed locally inside

the installing product's directory structure and is no longer installed in a global location on the target system. The following list shows the default installation root directory for Version 8 of the GSKit, where *product_root* is the root directory of the product that is installing GSKit, for example IBM HTTP Server or the web server plug-in.

AIX HP-UX Linux Solaris

*product_root*/gsk8

Windows

*product_root*\gsk8

*profile_root*

*Table 240. Default profile directories.*

*This table shows the default directories for a profile named profile_name on each distributed operating system.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/AppServer/profiles/*profile_name*<br>HP-UX Linux Solaris /opt/IBM/WebSphere/AppServer/profiles/*profile_name*<br>Windows C:\Program Files\IBM\WebSphere\AppServer\profiles*profile_name* |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/AppServer/profiles<br>Windows *user_home*\IBM\WebSphere\AppServer\profiles |

*plugins_root*

*Table 241. Default installation root directories for the Web Server Plug-ins.*

*This table shows the default installation root directories for the Web Server Plug-ins for WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/Plugins<br>HP-UX Linux Solaris /opt/IBM/WebSphere/Plugins<br>Windows C:\Program Files\IBM\WebSphere\Plugins |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/Plugins<br>Windows C:\IBM\WebSphere\Plugins |

*wct_root*

*Table 242. Default installation root directories for the WebSphere Customization Toolbox.*

*This table shows the default installation root directories for the WebSphere Customization Toolbox.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/Toolbox<br>HP-UX Linux Solaris /opt/IBM/WebSphere/Toolbox<br>Windows C:\Program Files\IBM\WebSphere\Toolbox |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/Toolbox<br>Windows C:\IBM\WebSphere\Toolbox |

*web_server_root*

*Table 243. Default installation root directories for the IBM HTTP Server.*

*This table shows the default installation root directories for the IBM HTTP Server.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/HTTPServer<br>HP-UX Linux Solaris /opt/IBM/HTTPServer<br>Windows C:\Program Files\IBM\HTTPServer |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/HTTPServer<br>Windows C:\IBM\HTTPServer |

# Configuring the web.xml file for JAX-RS servlets

The web.xml file contains information about the structure and external dependencies of web components in the module and describes how the components are used at run time. To enable the web container to run Java API for RESTful Web Services (JAX-RS) applications, you can configure the web.xml file to point directly to the IBM JAX-RS servlet. When using servlets, you can define a servlet path in the web.xml file that is appended to the base URL.

## About this task

You can configure the web.xml file for your web application to enable the JAX-RS application code. You can specify an IBM specific JAX-RS servlet to use to run your JAX-RS code. The web.xml file provides configuration and deployment information for the web components that comprise a web application. Read about configuring the web.xml file for JAX-RS to learn more about this deployment descriptor file.

When using servlets, any servlet path that is defined in the web.xml is appended to the base URL. For example, if a root resource has a @javax.ws.rs.Path value of myresource and a servlet path of myservletpath, the final URL of the resource is http://*<your_hostname>*:*<your Web_container_port>*/*<context_root_of_Web_application>*//*myservletpath*/*myresource*.

## Procedure

1. Open the WEB-INF/web.xml file.
2. Add the following servlet definition to the WEB-INF/web.xml file. In the following servlet, you must replace the *unique_servlet_name* with your unique servlet name. Also, replace the *Java_class_name* variable with the full Java package and class name of the javax.ws.rs.core.Application subclass.

```
<servlet>
     <servlet-name>unique_servlet_name</servlet-name>
     <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
     <init-param>
         <param-name>javax.ws.rs.Application</param-name>
         <param-value>Java_class_name </param-value>
     </init-param>
     <load-on-startup>1</load-on-startup>
</servlet>
```

3. (optional) If there are multiple JAX-RS application subclasses needed in the same web application, you must include an additional servlet initialization parameter, requestProcessorAttribute, in the servlet definition that you add to the WEB-INF/web.xml file. In the following servlet, you must replace the *unique_servlet_name* with your unique servlet name, the *Java_class_name* variable with the full Java package and class name of the javax.ws.rs.core.Application subclass, and the *unique_identifier* variable with a unique identifier.

```
<servlet>
     <servlet-name>unique_servlet_name_a</servlet-name>
     <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
     <init-param>
         <param-name>javax.ws.rs.Application</param-name>
```

```
        <param-value>Java_class_name_a </param-value>
    </init-param>
    <init-param>
        <param-name>requestProcessorAttribute</param-name>
        <param-value>unique_identifier_a</param-value>
    </init-param>
    <load-on-startup>1</load-on-startup>
</servlet>
<servlet>
    <servlet-name>unique_servlet_name_b</servlet-name>
    <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
    <init-param>
        <param-name>javax.ws.rs.Application</param-name>
        <param-value>Java_class_name_b</param-value>
    </init-param>
    <init-param>
        <param-name>requestProcessorAttribute</param-name>
        <param-value>unique_identifier_b </param-value>
    </init-param>
    <load-on-startup>1</load-on-startup>
</servlet>
```

4. Add servlet mappings in the `WEB-INF/web.xml` file for each servlet definition. The servlet path is appended to the context root of the web application.

```
<servlet-mapping>
    <servlet-name>servlet_name</servlet-name>
    <url-pattern>servlet_pattern_path</url-pattern>
</servlet-mapping>
```

   For example, if the *servlet_pattern_path* is `/restapi/*`, all valid requests start at the following URL:

```
http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/restapi/
```

## Results

After editing the `WEB-INF/web.xml` file, the web application is configured for the JAX-RS application.

## Example

The following example illustrates a `WEB-INF/web.xml` file that configures a servlet path for a JAX-RS application. The servlet path that is defined in the `web.xml` file is appended to the base URL.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_9" version="2.4"
xmlns=http://java.sun.com/xml/ns/j2ee
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd">

<servlet>
    <servlet-name>RestApplication1</servlet-name>
    <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
    <init-param>
        <param-name>javax.ws.rs.Application</param-name>
        <param-value>com.ibm.rest.sample.app1.MyApplication</param-value>
    </init-param>
    <init-param>
        <param-name>requestProcessorAttribute</param-name>
        <param-value>restApplication1ProcessorID</param-value>
    </init-param>
    <load-on-startup>1</load-on-startup>
</servlet>

<servlet>
    <servlet-name>OtherRestApplicationServlet</servlet-name>
    <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
    <init-param>
        <param-name>javax.ws.rs.Application</param-name>
        <param-value>com.ibm.rest.other.sample.OtherApplication </param-value>
    </init-param>
    <init-param>
       <param-name>requestProcessorAttribute</param-name>
        <param-value>otherRestApplicationID </param-value>
    </init-param>
   <load-on-startup>1</load-on-startup>
</servlet>

<servlet-mapping>
    <servlet-name> RestApplication1</servlet-name>
    <url-pattern>/rest/api/*</url-pattern>
</servlet-mapping>

<servlet-mapping>
```

```
    <servlet-name>OtherRestApplicationServlet /servlet-name>
    <url-pattern>/other/*</url-pattern>
</servlet-mapping>
</web-app>
```

### What to do next

Assemble the web application.

## Configuring the web.xml file for JAX-RS filters

The web.xml file contains information about the structure and external dependencies of web components in the module and describes how the components are used at run time. To enable the web container to run Java API for RESTful Web Services (JAX-RS) applications, you can configure the web.xml file to define filters that indicate the possible URLs on which the filter can be invoked.

### About this task

You can configure the web.xml file for your web application to enable the JAX-RS application code. You can specify an IBM specific JAX-RS filter to use to run your JAX-RS code. The web.xml file provides configuration and deployment information for the web components that comprise a web application. Read about configuring the web.xml file for JAX-RS to learn more about this deployment descriptor file.

When using servlets, any servlet path defined in the web.xml is appended to the base URL. Filters do not append a path to the resource base URL. Instead, filter URL mappings indicate the possible URLs on which the filter can be invoked. For instance, if a root resource has a @javax.ws.rs.Path value of `myresource`, the final URL of the resource is `http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource`. The URL mapping pattern for the filter must match `myresource` for the root resource to be served correctly. For this example, you can use `/*` or `/myresource` for the URL pattern. When there are multiple resources in the application, the URL pattern for the filter must match all of the resources. The `/*` pattern is a common value for the filter.

If the incoming request URL does not match any JAX-RS resources in the JAX-RS application, the request is passed to the rest of the filter chain. Depending on the application, you might want to use the filter behavior so that requests are served by the JAX-RS application, or if there is no JAX-RS resource available, the request can proceed to an underlying web container artifact, such as a JavaServer Pages (JSP). If the web container has no matching artifact, then the web container is responsible for the error response.

### Procedure

1. Open the WEB-INF/web.xml file.
2. Define your filter in the WEB-INF/web.xml file. Add the following filter definition to the WEB-INF/web.xml file. Replace the *unique_filter_name* with your unique filter name. Also replace the *Java_class_name* variable with the full Java package and class name of the JAX-RS application Java subclass.

```
<filter>
        <filter-name>unique_filter_name</filter-name>
        <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
        <init-param>
                <param-name>javax.ws.rs.Application</param-name>
                <param-value>Java_class_name</param-value>
        </init-param>
 </filter>
```

3. (optional) If there are multiple JAX-RS application subclasses needed in the same web application, you must include an additional filter initialization parameter, `requestProcessorAttribute`, in the filter definition that you add to the WEB-INF/web.xml file. In the following filter, replace the *unique_filter_name* with your unique filter name; replace the *Java_class_name* variable with the full Java package and the class name of the JAX-RS application Java subclass; replace the *unique_identifier* variable with a unique identifier.

```
<filter>
   <filter-name>unique_filter_name_a</filter-name>
   <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
   <init-param>
       <param-name>javax.ws.rs.Application</param-name>
       <param-value>Java_class_name_a</param-value>
   </init-param>

   <init-param>
       <param-name>requestProcessorAttribute</param-name>
       <param-value>unique_identifier_a</param-value>
   </init-param>
</filter>

<filter>
   <filter-name>unique_filter_name_b</filter-name>
   <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
   <init-param>
       <param-name>javax.ws.rs.Application</param-name>
       <param-value>Java_class_name_b</param-value>
   </init-param>

   <init-param>
       <param-name>requestProcessorAttribute</param-name>
       <param-value>unique_identifier_b</param-value>
   </init-param>
</filter
```

4. Add filter mappings in the WEB-INF/web.xml file for each filter definition.

   The URL pattern specified in the filter mapping defines to the container the valid URL patterns for invoking the `IBMRestFilter` filter. If an incoming request URL is compatible with the URL pattern, the `IBMRestFilter` is invoked. If the request URL does not match, the filter is not invoked. The request URLs always start at the context root for the filter. See the following example filter mappings:

```
<filter-mapping>
    <filter-name>filter_name</filter-name>
    <url-pattern>/*</url-pattern>
</filter-mapping>
```

   For example, suppose you have the following two resources:

```
@javax.ws.rs.Path("myresource")
public class MyResource {

}
```

```
@javax.ws.rs.Path("myresource2")
public class MyResource2 {

}
```

   You can reach the resources using the following URL:

```
http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource
```

```
http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource2
```

   If you apply the following filter mapping:

```
<filter-mapping>
        <filter-name>filter_name</filter-name>
        <url-pattern>/myresource</url-pattern>
</filter-mapping>
```

   you can use MyResource root resource by visiting the following URL:

```
http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource
```

   This URL invokes the `IBMRestFilter` filter and the URL can find the resource. Because the `/myresource` path matches with the URL pattern in the filter-mapping, the `IBMRestFilter` does get invoked and there is a root resource that has a matching @Path value.

   However, suppose you visit the following URL:

```
http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource2
```

   the `IBMRestFilter` filter is not invoked because the URL pattern `/myresource` does not match `/myresource2`.

## Results

After editing the WEB-INF/web.xml file to apply filters, the web application is configured for the JAX-RS application.

## Example

The following example illustrates a WEB-INF/web.xml file that is configured to apply filters to a JAX-RS application. This example defines the `RestApplication1` filter. If an incoming request URL matches a resource in the RestApplication1 filter, the response is generated from RestApplication1 filter. If the incoming request URL does not match a resource in the RestApplication1 filter but matches a resource in OtherRestApplicationFilter, then the response is generated from the OtherRestApplicationFilter filter. If the incoming URL does not match either filter, then the request can be served from another web container artifact, such as a JSP.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_9" version="2.4"
xmlns=http://java.sun.com/xml/ns/j2ee
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd">

     <filter>
        <filter-name>RestApplication1</filter-name>
        <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
        <init-param>
            <param-name>javax.ws.rs.Application</param-name>
            <param-value>com.ibm.rest.sample.app1.MyApplication</param-value>
        </init-param>
        <init-param>
            <param-name>requestProcessorAttribute</param-name>
            <param-value>restApplication1ProcessorID</param-value>
        </init-param>
    </filter>
     <filter>
        <filter-name>OtherRestApplicationServlet</filter-name>
        <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
        <init-param>
            <param-name>javax.ws.rs.Application</param-name>
            <param-value>com.ibm.rest.other.sample.OtherApplication</param-value>
        </init-param>
        <init-param>
            <param-name>requestProcessorAttribute</param-name>
            <param-value>otherRestApplicationID </param-value>
        </init-param>
    </filter>

    <filter-mapping>
        <filter-name>RestApplication1</filter-name>
        <url-pattern>/*</url-pattern>
    </filter-mapping>

    <filter-mapping>
        <filter-name>OtherRestApplicationServlet</filter-name>
        <url-pattern>/*</url-pattern>
    </filter-mapping>
</web-app>
```

## What to do next

Assemble the web application.

# Configuring JAX-RS web applications

## Configuring JAX-RS applications using JAX-RS 1.1 methods

You can configure Java API for RESTful Web Services (JAX-RS) applications in multiple ways depending on your needs. To take advantage of the Java Platform, Enterprise Edition (Java EE) 6 functionality, you can use the annotation scanning capabilities. By using annotation scanning, you can omit a JAX-RS javax.ws.rs.core.Application subclass or have a minimally defined javax.ws.rs.core.Application subclass.

## About this task

The JAX-RS 1.1 specification supports several new ways to configure a JAX-RS application. You can use the built-in annotation scanning to help automatically configure the application. You can optionally add javax.ws.rs.core.Application subclasses to your application and then add the URL patterns required using either the javax.ws.rs.ApplicationPath annotation or a web.xml servlet definition. When using the IBM JAX-RS implementation, you do not have to specify the servlet class implementation because it is automatically added to the configuration of the web module by the time the JAX-RS application is started.

When using a web.xml file, you must use a Java Servlet 3.0 web.xml file.

## Procedure

- Configure the JAX-RS application with only one JAX-RS default application in the web.xml file. Use this method if you only need one JAX-RS application and all resource classes are located after a single URL pattern. You can also specify security constraints with this method, if needed.
  1. Add all of your JAX-RS resource and provider classes to the WEB-INF/classes or WEB-INF/lib directory for your web application. You do not need to add a javax.ws.rs.core.Application subclass to your web application.
  2. In your web.xml file, add a servlet definition with javax.ws.rs.core.Application as the servlet name. You do not need to add a servlet-class. You must add a servlet URL pattern to the web.xml file. The application server runtime environment adds the specific IBM JAX-RS implementation to the configuration of the web module by the time the JAX-RS application is started; for example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns="http://java.sun.com/xml/ns/j2ee" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee
http://java.sun.com/xml/ns/j2ee/web-app_3_0.xsd"
 version="3.0">
 <servlet>
  <servlet-name>javax.ws.rs.core.Application</servlet-name>
 </servlet>
 <servlet-mapping>
  <servlet-name>javax.ws.rs.core.Application</servlet-name>
  <url-pattern>/rest/*</url-pattern>
 </servlet-mapping>
</web-app>
```

     The JAX-RS resources are now available at a URL such as:

```
http://{hostname}:{port}/{context_root_of_Web_ module}/{value_of_Web.xml_URL_pattern}/{value_of_@javax.ws.rs.Path}
```

- Configure the JAX-RS application using the javax.ws.rs.core.Application subclass and the web.xml file. Use this method if you need multiple JAX-RS applications or require only specific resources in certain JAX-RS applications with specific URL patterns. You can also specify security constraints with this method, if needed.
  1. Create a javax.ws.rs.core.Application subclass. In your javax.ws.rs.core.Application subclass getClasses() or getSingletons() methods, return the relevant JAX-RS resources and providers. If you return empty sets in both the getClasses() and getSingletons() methods, all the JAX-RS resource and provider classes that are found in the application are added to the JAX-RS application subclass; for example:

```
package com.example;

public class MyApplication extends javax.ws.rs.core.Application {

}
```

     This example uses the default implementations of javax.ws.rs.core.Application subclass getClasses() and getSingletons() methods that return empty sets. Therefore, all relevant JAX-RS classes are assumed to be returned by the javax.ws.rs.core.Application subclass.
  2. Add the javax.ws.rs.core.Application subclass to your web application.
  3. Add a partial servlet definition in the web.xml file. The servlet name is the full name of the javax.ws.rs.core.Application subclass. Do not define the servlet-class. You must add a servlet

URL pattern to the web.xml file. The application server runtime environment adds the specific IBM JAX-RS implementation to the configuration of the web module by the time the JAX-RS application is started; for example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns="http://java.sun.com/xml/ns/j2ee" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee
http://java.sun.com/xml/ns/j2ee/web-app_3_0.xsd"
 version="3.0">
 <servlet>
  <servlet-name>com.example.MyApplication</servlet-name>
 </servlet>
 <servlet-mapping>
  <servlet-name>com.example.MyApplication</servlet-name>
  <url-pattern>/rest/*</url-pattern>
 </servlet-mapping>
</web-app>
```

The JAX-RS resources are now available at a URL such as:

http://{*hostname*}:{*port*}/{context_root_of_Web_ module}/{*value_of_Web.xml_URL_pattern_for_Application_subclass*}/{*value_of_@javax.ws.rs.Path*}

- Configure the JAX-RS application without a web.xml file. Use this method if you do not want to use a web.xml file. When you use this method, you cannot specify security constraints. To specify security constraints, you must use a web.xml file.
  1. Create a javax.ws.rs.core.Application subclass. In your javax.ws.rs.core.Application subclass getClasses() or getSingletons() methods, return the relevant JAX-RS resources and providers. If you return empty sets in both the getClasses() and getSingletons() methods, all the JAX-RS resource and provider classes that are found in the application are added to the JAX-RS application subclass; for example:

```
package com.example;

public class MyApplication extends javax.ws.rs.core.Application {

}
```

This example uses the default implementations of javax.ws.rs.core.Application subclass getClasses() and getSingletons() methods that return empty sets. Therefore, all relevant JAX-RS classes are assumed to be returned by the javax.ws.rs.core.Application subclass.

  2. Add a javax.ws.rs.ApplicationPath annotation to the javax.ws.rs.core.Application subclass. The ApplicationPath annotation is supported with the JAX-RS 1.1 specification. The value of the ApplicationPath annotation is used as the servlet URL pattern which is equivalent to the servlet URL pattern in the web.xml file; for example:

```
package com.example;

@javax.ws.rs.ApplicationPath("rest")
public class MyApplication extends javax.ws.rs.core.Application {

}
```

  3. Add the javax.ws.rs.core.Application subclass to your web application. When the application is started, the resources are available at the following URL:

http://{*hostname*}:{*port*}/{context_root_of_Web_ module}/{*value_of_@javax.ws.rs.ApplicationPath*}}/{*value_of_@javax.ws.rs.Path*}

### Results

You have configured your JAX-RS application using JAX-RS 1.1 supported methods by taking advantage of annotation scanning to help automatically configure the application.

## Configuring the web.xml file for JAX-RS servlets

The `web.xml` file contains information about the structure and external dependencies of web components in the module and describes how the components are used at run time. To enable the web container to run

Java API for RESTful Web Services (JAX-RS) applications, you can configure the web.xml file to point directly to the IBM JAX-RS servlet. When using servlets, you can define a servlet path in the web.xml file that is appended to the base URL.

## About this task

You can configure the web.xml file for your web application to enable the JAX-RS application code. You can specify an IBM specific JAX-RS servlet to use to run your JAX-RS code. The web.xml file provides configuration and deployment information for the web components that comprise a web application. Read about configuring the web.xml file for JAX-RS to learn more about this deployment descriptor file.

When using servlets, any servlet path that is defined in the web.xml is appended to the base URL. For example, if a root resource has a @javax.ws.rs.Path value of myresource and a servlet path of myservletpath, the final URL of the resource is http://*<your_hostname>*:*<your Web_container_port>*/*<context_root_of_Web_application>*//*myservletpath/myresource*.

## Procedure

1. Open the WEB-INF/web.xml file.
2. Add the following servlet definition to the WEB-INF/web.xml file. In the following servlet, you must replace the *unique_servlet_name* with your unique servlet name. Also, replace the *Java_class_name* variable with the full Java package and class name of the javax.ws.rs.core.Application subclass.

```
<servlet>
     <servlet-name>unique_servlet_name</servlet-name>
     <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
     <init-param>
         <param-name>javax.ws.rs.Application</param-name>
         <param-value>Java_class_name </param-value>
     </init-param>
     <load-on-startup>1</load-on-startup>
</servlet>
```

3. (optional) If there are multiple JAX-RS application subclasses needed in the same web application, you must include an additional servlet initialization parameter, requestProcessorAttribute, in the servlet definition that you add to the WEB-INF/web.xml file. In the following servlet, you must replace the *unique_servlet_name* with your unique servlet name, the *Java_class_name* variable with the full Java package and class name of the javax.ws.rs.core.Application subclass, and the *unique_identifier* variable with a unique identifier.

```
<servlet>
     <servlet-name>unique_servlet_name_a</servlet-name>
     <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
     <init-param>
         <param-name>javax.ws.rs.Application</param-name>
         <param-value>Java_class_name_a </param-value>
     </init-param>
     <init-param>
         <param-name>requestProcessorAttribute</param-name>
         <param-value>unique_identifier_a</param-value>
     </init-param>
     <load-on-startup>1</load-on-startup>
</servlet>
<servlet>
     <servlet-name>unique_servlet_name_b</servlet-name>
     <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
     <init-param>
         <param-name>javax.ws.rs.Application</param-name>
         <param-value>Java_class_name_b</param-value>
     </init-param>
     <init-param>
         <param-name>requestProcessorAttribute</param-name>
         <param-value>unique_identifier_b </param-value>
     </init-param>
     <load-on-startup>1</load-on-startup>
</servlet>
```

4. Add servlet mappings in the WEB-INF/web.xml file for each servlet definition. The servlet path is appended to the context root of the web application.

```
<servlet-mapping>
     <servlet-name>servlet_name</servlet-name>
     <url-pattern>servlet_pattern_path</url-pattern>
</servlet-mapping>
```

For example, if the *servlet_pattern_path* is /restapi/*, all valid requests start at the following URL:

http://<*your_hostname*>:<*your Web_container_port*>/<*context_root_of_Web_application*>/restapi/

### Results

After editing the WEB-INF/web.xml file, the web application is configured for the JAX-RS application.

### Example

The following example illustrates a WEB-INF/web.xml file that configures a servlet path for a JAX-RS application. The servlet path that is defined in the web.xml file is appended to the base URL.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_9" version="2.4"
xmlns=http://java.sun.com/xml/ns/j2ee
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd">

<servlet>
     <servlet-name>RestApplication1</servlet-name>
     <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
     <init-param>
         <param-name>javax.ws.rs.Application</param-name>
         <param-value>com.ibm.rest.sample.app1.MyApplication</param-value>
     </init-param>
     <init-param>
         <param-name>requestProcessorAttribute</param-name>
         <param-value>restApplication1ProcessorID</param-value>
     </init-param>
     <load-on-startup>1</load-on-startup>
</servlet>

<servlet>
     <servlet-name>OtherRestApplicationServlet</servlet-name>
     <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
     <init-param>
         <param-name>javax.ws.rs.Application</param-name>
         <param-value>com.ibm.rest.other.sample.OtherApplication </param-value>
     </init-param>
     <init-param>
        <param-name>requestProcessorAttribute</param-name>
         <param-value>otherRestApplicationID </param-value>
     </init-param>
    <load-on-startup>1</load-on-startup>
</servlet>

<servlet-mapping>
     <servlet-name> RestApplication1</servlet-name>
     <url-pattern>/rest/api/*</url-pattern>
</servlet-mapping>

<servlet-mapping>
     <servlet-name>OtherRestApplicationServlet /servlet-name>
     <url-pattern>/other/*</url-pattern>
</servlet-mapping>
</web-app>
```

### What to do next

Assemble the web application.

## Configuring the web.xml file for JAX-RS filters

The web.xml file contains information about the structure and external dependencies of web components in the module and describes how the components are used at run time. To enable the web container to run Java API for RESTful Web Services (JAX-RS) applications, you can configure the web.xml file to define filters that indicate the possible URLs on which the filter can be invoked.

### About this task

You can configure the web.xml file for your web application to enable the JAX-RS application code. You can specify an IBM specific JAX-RS filter to use to run your JAX-RS code. The web.xml file provides configuration and deployment information for the web components that comprise a web application. Read about configuring the web.xml file for JAX-RS to learn more about this deployment descriptor file.

When using servlets, any servlet path defined in the web.xml is appended to the base URL. Filters do not append a path to the resource base URL. Instead, filter URL mappings indicate the possible URLs on which the filter can be invoked. For instance, if a root resource has a @javax.ws.rs.Path value of `myresource`, the final URL of the resource is `http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource`. The URL mapping pattern for the filter must match `myresource` for the root resource to be served correctly. For this example, you can use `/*` or `/myresource` for the URL pattern. When there are multiple resources in the application, the URL pattern for the filter must match all of the resources. The `/*` pattern is a common value for the filter.

If the incoming request URL does not match any JAX-RS resources in the JAX-RS application, the request is passed to the rest of the filter chain. Depending on the application, you might want to use the filter behavior so that requests are served by the JAX-RS application, or if there is no JAX-RS resource available, the request can proceed to an underlying web container artifact, such as a JavaServer Pages (JSP). If the web container has no matching artifact, then the web container is responsible for the error response.

## Procedure

1. Open the WEB-INF/web.xml file.
2. Define your filter in the WEB-INF/web.xml file. Add the following filter definition to the WEB-INF/web.xml file. Replace the *unique_filter_name* with your unique filter name. Also replace the *Java_class_name* variable with the full Java package and class name of the JAX-RS application Java subclass.

```
<filter>
        <filter-name>unique_filter_name</filter-name>
        <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
        <init-param>
                <param-name>javax.ws.rs.Application</param-name>
                <param-value>Java_class_name</param-value>
        </init-param>
 </filter>
```

3. (optional) If there are multiple JAX-RS application subclasses needed in the same web application, you must include an additional filter initialization parameter, `requestProcessorAttribute`, in the filter definition that you add to the WEB-INF/web.xml file. In the following filter, replace the *unique_filter_name* with your unique filter name; replace the *Java_class_name* variable with the full Java package and the class name of the JAX-RS application Java subclass; replace the *unique_identifier* variable with a unique identifier.

```
<filter>
   <filter-name>unique_filter_name_a</filter-name>
   <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
   <init-param>
       <param-name>javax.ws.rs.Application</param-name>
       <param-value>Java_class_name_a</param-value>
   </init-param>

   <init-param>
       <param-name>requestProcessorAttribute</param-name>
       <param-value>unique_identifier_a</param-value>
   </init-param>
</filter>

<filter>
   <filter-name>unique_filter_name_b</filter-name>
   <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
   <init-param>
       <param-name>javax.ws.rs.Application</param-name>
       <param-value>Java_class_name_b</param-value>
   </init-param>

   <init-param>
       <param-name>requestProcessorAttribute</param-name>
       <param-value>unique_identifier_b</param-value>
   </init-param>
</filter
```

4. Add filter mappings in the WEB-INF/web.xml file for each filter definition.

   The URL pattern specified in the filter mapping defines to the container the valid URL patterns for invoking the `IBMRestFilter` filter. If an incoming request URL is compatible with the URL pattern, the

`IBMRestFilter` is invoked. If the request URL does not match, the filter is not invoked. The request URLs always start at the context root for the filter. See the following example filter mappings:

```
<filter-mapping>
    <filter-name>filter_name</filter-name>
    <url-pattern>/*</url-pattern>
</filter-mapping>
```

For example, suppose you have the following two resources:

```
@javax.ws.rs.Path("myresource")
public class MyResource {

}
```

```
@javax.ws.rs.Path("myresource2")
public class MyResource2 {

}
```

You can reach the resources using the following URL:

`http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource`

`http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource2`

If you apply the following filter mapping:

```
<filter-mapping>
        <filter-name>filter_name</filter-name>
        <url-pattern>/myresource</url-pattern>
</filter-mapping>
```

you can use MyResource root resource by visiting the following URL:

`http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource`

This URL invokes the `IBMRestFilter` filter and the URL can find the resource. Because the `/myresource` path matches with the URL pattern in the filter-mapping, the `IBMRestFilter` does get invoked and there is a root resource that has a matching @Path value.

However, suppose you visit the following URL:

`http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource2`

the `IBMRestFilter` filter is not invoked because the URL pattern `/myresource` does not match `/myresource2`.

## Results

After editing the WEB-INF/web.xml file to apply filters, the web application is configured for the JAX-RS application.

## Example

The following example illustrates a WEB-INF/web.xml file that is configured to apply filters to a JAX-RS application. This example defines the `RestApplication1` filter. If an incoming request URL matches a resource in the RestApplication1 filter, the response is generated from RestApplication1 filter. If the incoming request URL does not match a resource in the RestApplication1 filter but matches a resource in OtherRestApplicationFilter, then the response is generated from the OtherRestApplicationFilter filter. If the incoming URL does not match either filter, then the request can be served from another web container artifact, such as a JSP.

```
<?xml version="1.0" encoding="UTF-8"?>

    </filter-mapping>

    <filter-mapping>
        <filter-name>OtherRestApplicationServlet</filter-name>
        <url-pattern>/*</url-pattern>
    </filter-mapping>
</web-app>
```

### What to do next

Assemble the web application.

## Implementing clients using the Apache Wink REST client

You can use the Apache Wink REST client to send requests and process responses from RESTful services. You can use the client API in Java programs to communicate with web services.

### About this task

By default, the Apache Wink client uses the java.net.HttpURLConnection class from the Java runtime environment for issuing requests and processing responses. The Apache Wink client can also use Apache HttpClient 4.0 as the underlying client transport.

You can also use JAX-RS entity providers to help serialize request entities or deserialize response entities. The standard JAX-RS providers used in the JAX-RS server-side services are provided with the client.

You can configure the Apache Wink REST client programmatically or by setting Java Virtual Machine (JVM) properties.

To implement an Apache Wink REST client, you must first create an org.apache.wink.client.ClientConfig object that is then used to construct an org.apache.wink.client.RestClient. You can change the configuration settings for the RestClient object programmatically, or you can use JVM properties to modify the default ClientConfig object values.

To configure the configuration settings for the RestClient object programmatically, invoke the public methods of the ClientConfig object.

**Note:** After a ClientConfig object is used to construct a RestClient object, the ClientConfig object can no longer be modified. Attempting to do so results in an org.apache.wink.client.ClientConfigException error message.

Alternatively, you can configure the configuration settings for the RestClient object using JVM properties to modify the default ClientConfig object values. Use the following JVM properties to modify the default ClientConfig object values:

**wink.client.readTimeout**

This property specifies how long the RestClient object waits (in milliseconds) for a response to requests before timing out. A value of zero (0) means that the client waits for an unlimited amount of time and will not timeout.

The default value is 60,000 milliseconds.

**wink.client.connectTimeout**

This property specifies how long the RestClient object waits (in milliseconds) before timing out when attempting to connect to the target resource. A value of zero (0) means that the client waits for an unlimited amount of time and will not timeout.

The default value is 60,000 milliseconds.

You can programmatically alter any values for the RestClient object that you specify using JVM properties. The programmatic values take precedence over any JVM property values.

## Procedure

1. Create an org.apache.wink.client.ClientConfig object.

   The following code snippet illustrates how to create an org.apache.wink.client.ClientConfig object:

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();
```

   .

   If you use an Apache HTTP client as the underlying transport, create and use an org.apache.wink.client.ApacheHttpClientConfig object instead. You must also include the Apache HTTP client libraries in the classpath. The following code snippet illustrates how to create an org.apache.wink.client.ApacheHttpClientConfig object:

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ApacheHttpClientConfig();
```

2. (optional) Modify the default ClientConfig object values that you want to use for the RestClient object.
   - You can optionally modify the default configuration settings for the RestClient object programmatically. To specify the configuration settings for the RestClient object programmatically, invoke the public methods of the ClientConfig object; for example:

```
clientConfig.connectTimeout(30000);
clientConfig.readTimeout(30000);
```

   - If you are using the Thin Client for JAX-RS in a stand-alone unmanaged client runtime environment, you can optionally modify the configuration settings for the RestClient object using JVM properties. Set the custom JVM properties on the JVM under which the thin client is running.
   - If you are not using the Thin Client for JAX-RS as a stand-alone client runtime environment, but you are using the RestClient object in an application that is intended for installation on the application server, you can optionally modify the configuration settings for the RestClient object using JVM properties. Set the custom JVM properties using the administrative console for your REST client code that is running within an application that is installed on the application server. See the Java virtual machine custom properties information for details on using the administrative console to set these custom JVM properties.
3. (optional) If you use a custom entity provider, add the entity provider using the client configuration.

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();

javax.ws.rs.core.Application app = new javax.ws.rs.core.Application() {
       public Set<Class<?>> getClasses() {
           Set<Class<?>> classes = new HashSet<Class<?>>();
           classes.add(MyCustomEntityProvider.class);
           return classes;
       }
};
clientConfig.applications(app);
```

4. Create a org.apache.wink.client.RestClient object with the client configuration.

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();

javax.ws.rs.core.Application app = new javax.ws.rs.core.Application() {
       public Set<Class<?>> getClasses() {
           Set<Class<?>> classes = new HashSet<Class<?>>();
```

```
            classes.add(MyCustomEntityProvider.class);
            return classes;
        }
};
clientConfig.applications(app);

org.apache.wink.client.RestClient client = new org.apache.wink.client.RestClient(clientConfig);
```

5. Create a org.apache.wink.client.Resource object with a URI from the REST client.

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();

javax.ws.rs.core.Application app = new javax.ws.rs.core.Application() {
       public Set<Class<?>> getClasses() {
            Set<Class<?>> classes = new HashSet<Class<?>>();
            classes.add(MyCustomEntityProvider.class);
            return classes;
        }
};
clientConfig.applications(app);

org.apache.wink.client.RestClient client = new org.apache.wink.client.RestClient(clientConfig);

org.apache.wink.client.Resource resource = client.resource("http://www.example.com/rest/api/book/123");
```

6. You can add request headers to the pending request by calling methods on the Resource object.

   You can call a Java method such as post() with the request content as a parameter to send the request. In the following example, an HTTP POST request is made with a Content-Type header value of `text/plain` and an Accept header value of `*/*`.

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();

javax.ws.rs.core.Application app = new javax.ws.rs.core.Application() {
       public Set<Class<?>> getClasses() {
            Set<Class<?>> classes = new HashSet<Class<?>>();
            classes.add(MyCustomEntityProvider.class);
            return classes;
        }
};
clientConfig.applications(app);

org.apache.wink.client.RestClient client = new org.apache.wink.client.RestClient(clientConfig);

org.apache.wink.client.Resource resource = client.resource("http://www.example.com/rest/api/book/123");

ClientResponse response = resource.contentType("text/plain").accept("*/*").post("The request body as a string");
```

   Instead of calling `resource.post("The request body as a string")` with a String object, you can use any other object that has a class with a valid javax.ws.rs.ext.MessageBodyWriter object such as a JAXB annotated class, a byte[], or a custom class that has a custom entity provider.

7. Process the response by using the status code, response headers, or the response message body.

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();

javax.ws.rs.core.Application app = new javax.ws.rs.core.Application() {
       public Set<Class<?>> getClasses() {
            Set<Class<?>> classes = new HashSet<Class<?>>();
            classes.add(MyCustomEntityProvider.class);
            return classes;
        }
};
clientConfig.applications(app);

org.apache.wink.client.RestClient client = new org.apache.wink.client.RestClient(clientConfig);

org.apache.wink.client.Resource resource = client.resource("http://www.example.com/rest/api/book/123");

ClientResponse response = resource.contentType("text/plain").accept("*/*").post("The request body as a string");

System.out.println("The response code is: " + response.getStatusCode());
System.out.println("The response message body is: " + response.getEntity(String.class));
```

   Instead of calling the `response.getEntity(String.class)` object with String.class file, you can use any other class that has a valid javax.ws.rs.ext.MessageBodyReader object, such as a JAXB annotated class, a byte[], or a custom class that has a custom entity provider.

8. (optional) Configure the client to transmit basic authentication security tokens. To configure basic authentication for your client, you can choose to manage the appropriate HTTP headers yourself, or more simply, you can use the provided BasicAuthSecurityHandler handler class. The BasicAuthSecurityHandler class simplifies the enablement of basic authentication in the Wink client

application. To learn more about using the security client handler to perform basic HTTP authentication, see the securing JAX-RS applications within the web container information.

### Results

You have implemented a JAX-RS client using the Apache Wink REST client that can issue requests to a JAX-RS application.

## Implementing a client using the unmanaged RESTful web services JAX-RS client

WebSphere Application Server provides a thin Java Platform, Standard Edition 6 (Java SE 6) RESTful web services client runtime to enable application developers to quickly and easily create JAX-RS client applications. The Thin Client for JAX-RS with WebSphere Application Server is a stand-alone Java SE 6 client environment that enables running unmanaged JAX-RS RESTful web services client applications in a non-WebSphere environment to invoke JAX-RS RESTful web services that are hosted by the application server.

### Before you begin

**Note:** You can use the Thin Client for JAX-RS with WebSphere Application Server as a stand-alone client run time in a pure Java SE environment. The Thin Client for JAX-RS running within WebSphere Application Server or WebSphere Application Client environments is not supported. In this version of the application server, other Thin Client run times provided with the application server can also reside in the CLASSPATH and coexist with the Thin Client for JAX-RS.

Before you set up a JAX-RS unmanaged client execution environment, obtain the Thin Client for JAX-RS Java archive (JAR) file. To obtain the Thin Client for JAX-RS, install WebSphere Application Server Version 8.0 or the Application Client for WebSphere Application Server Version 8.0. The Thin Client for JAX-RS JAR file, `com.ibm.jaxrs.thinclient_8.0.0.jar`, is located in the *app_server_root*`\runtimes` directory.

Copy the Thin Client for JAX-RS `com.ibm.jaxrs.thinclient_8.0.0.jar` file to other machines to create a lightweight client environment that enables communications with the product. Copies of the Thin Client for JAX-RS are subject to the same terms and conditions of the license agreement for the WebSphere product where you obtained the Thin Client for JAX-RS. Refer to the license agreements for correct usage and other limitations.

The Thin Client for JAX-RS works with IBM Software Development Kits (SDKs) Version 6.0 and higher. The Thin Client for JAX-RS is also supported on non-IBM software development kits that are V6.0 and higher.

### About this task

Set up a Thin Client for JAX-RS environment by completing the following steps.

### Procedure

1. Configure the path. Enter the following command to add the Java `bin` directories to your path:

   Windows

```
set PATH=<your_JDK_bin_directory>;%PATH%
```

   AIX HP-UX Solaris Linux

```
export PATH=<your_JDK_bin_directory>:$PATH
```

2. Configure the class path. Add the Thin Client for JAX-RS JAR file to the classpath definition; for example:

   Windows

```
set CLASSPATH=.;<your_jax-rs_thin_client_install_directory>\com.ibm.jaxrs.thinclient_8.0.0.jar;
<your_application_jars>;%CLASSPATH%
```

AIX HP-UX Solaris Linux

```
export CLASSPATH=.:<your_JAX-RS_thin_client_install_directory>/com.ibm.jaxrs.thinclient_8.0.0.jar:
<your_application_jars>;$CLASSPATH
```

3. Enter the following command to run your client application:

Windows

```
%JAVA_HOME%/bin/java <your_client_application>
```

AIX HP-UX Solaris Linux

```
$JAVA_HOME/bin/java <your_client_application>
```

### Results

You have set up an unmanaged JAX-RS client runtime environment to invoke RESTful web services that are hosted on a WebSphere Application Server.

## Migrating a Feature Pack for Web 2.0 JAX-RS application to WebSphere Version 8

When packaging an application for the Feature Pack for Web 2.0, you must manually make the Java API for RESTful Web Services (JAX-RS) run time available on the application `CLASSPATH`. A common way of doing this is placing the JAX-RS runtime Java archive (JAR) files in the `WEB-INF/lib` directory of the web archive (WAR) module. In Version 8, the JAX-RS runtime environment is native to the application server. It is no longer necessary to manually add the path of the runtime libraries on the `CLASSPATH`. Migrating Web 2.0 applications to the native runtime environment simplifies packaging and deployment, and allows for future updates to take advantage of Java Platform, Enterprise Edition (Java EE) integration features.

### Before you begin

Identify Feature Pack for Web 2.0 JAX-RS applications to migrate to the native Version 8 JAX-RS runtime environment. Identify where the JAX-RS runtime JAR files have been made available to the application `CLASSPATH`. Two common methods are the `WEB-INF/lib` directory of the WAR module or by way of a shared library.

### About this task

In WebSphere Version 8, the JAX-RS run time runs natively within the application server process. Unlike deploying JAX-RS applications with the Web 2.0 Feature Pack installed on WebSphere Version 7 or earlier, it is no longer necessary to package the JAX-RS runtime JAR files as an external library for the application.

To migrate Web 2.0 applications to the Version 8 runtime environment, simply remove the external JAX-RS runtime libraries. For example, if the runtime JAR files were placed in the `WEB-INF/lib` directory of the WAR module, delete them from that directory before redeploying the application. No other changes are necessary. All other application configurations, such as `web.xml` configuration, are still valid in WebSphere Version 8.

Once the external JAX-RS runtime library is removed, the native runtime environment runs the JAX-RS application. There are advantages to this over Web 2.0 deployment. Application packaging and deployment are simplified since it is no longer necessary to add external libraries on the application `CLASSPATH`. Additionally, new Java EE integration features can be taken advantage of in future updates to the application. Examples are Enterprise JavaBeans (EJB) in a WAR and Java Contexts and Dependency Injection (JCDI) support.

### Procedure

1. Remove external JAX-RS runtime libraries from the Feature Pack for Web 2.0 application.
2. Redeploy the application.

### Results

You have migrated a Web 2.0 Feature Pack JAX-RS application to the native WebSphere Version 8 JAX-RS runtime environment.

## Disabling the JAX-RS runtime environment

There are cases where you must disable the Java API for RESTful Web Services (JAX-RS) runtime environment. When disabling the JAX-RS runtime environment, JAX-RS features are not available, including base JAX-RS runtime capabilities, Enterprise JavaBeans (EJB) runtime integration, Java Contexts and Dependency Injection (JCDI) runtime integration, and Servlet 3.0 web container integration.

### About this task

By disabling the JAX-RS runtime environment, any JAX-RS related processing of the application, including processing of classes with scanned JAX-RS annotations, EJB metadata, and JCDI bean enablement, is no longer performed. The JAX-RS runtime environment is not used to process requests and responses to and from the web container.

**Note:** Disabling the JAX-RS runtime environment does not disable Servlet 3.0 based annotation scanning for JAX-RS annotations such as `javax.ws.rs.Path`. To disable annotation scanning, set the `metadata-complete` attribute. If annotation scanning is disabled, it is disabled for all other components outside of JAX-RS.

The explicit plug points to the IBM JAX-RS runtime environment are the `com.ibm.websphere.jaxrs.server.IBMRestServlet` servlet class and the `com.ibm.websphere.jaxrs.server.IBMRestFilter` filter class. If you specify these classes as your servlet-class or servlet-filter in the web module's `web.xml` file, the IBM JAX-RS runtime environment is used to process requests to that servlet.

To disable the JAX-RS runtime environment from doing so, replace those classes with any other servlet or filter class that can handle expected requests to the servlet, or remove the servlet entirely from the `web.xml` file.

**Note:** Replacing the `IBMRestServlet` class with another might modify existing behavior in the application. Removing the servlet entirely results in requests not being processed.

Even if not explicitly using the `com.ibm.websphere.jaxrs.server.IBMRestServlet` or `com.ibm.websphere.jaxrs.server.IBMRestFilter` classes, the JAX-RS integration runtime environment may still process the application. For example, if the `web.xml` file of a web module is Servlet 3.0 based, and appropriate conditions are met according to the JSR-311 specification, the JAX-RS integration runtime environment processes scanned classes with JAX-RS annotations and may inject a servlet that can handle requests to the JAX-RS resources in the application.

To disable this functionality, and other functionality such as EJB and JCDI integration, set the `com.ibm.websphere.jaxrs.server.DisableIBMJAXRSEngine` custom Java virtual machine (JVM) property on the application server with a value of `true`.

### Procedure

1. Remove references to `IBMRestServlet` and `IBMRestFilter` from the `web.xml` file. The following example illustrates a sample `web.xml` file from an application that uses the IBM JAX-RS runtime environment:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns="http://java.sun.com/xml/ns/j2ee" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee http://java.sun.com/xml/ns/j2ee/web-app_3_0.xsd"
    version="3.0">
    <servlet>
        <servlet-name>MyRestApplication1</servlet-name>
        <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
        <init-param>
            <param-name>javax.ws.rs.Application</param-name>
            <param-value>com.ibm.websphere.jaxrs.example.Application1</param-value>
        </init-param>
        <init-param>
            <param-name>requestProcessorAttribute</param-name>
            <param-value>MyRestApplication1RequestProcessorAttribute</param-value>
        </init-param>
        <load-on-startup>1</load-on-startup>
    </servlet>
    <servlet>
        <servlet-name>MyNonJAXRSApplication</servlet-name>
        <servlet-class>com.ibm.websphere.example.NonJAXRSServlet</servlet-class>
        <load-on-startup>1</load-on-startup>
    </servlet>
    <filter>
        <filter-name>MyRestApplication2</filter-name>
        <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
        <init-param>
            <param-name>javax.ws.rs.Application</param-name>
            <param-value>com.ibm.websphere.jaxrs.example.Application2</param-value>
        </init-param>
        <init-param>
            <param-name>requestProcessorAttribute</param-name>
            <param-value>MyRestApplication2RequestProcessorAttribute</param-value>
        </init-param>
    </filter>
    <servlet-mapping>
        <servlet-name>MyRestApplication1</servlet-name>
        <url-pattern>/jaxrsapp1/*</url-pattern>
    </servlet-mapping>
    <servlet-mapping>
        <servlet-name>MyNonJAXRSApplication</servlet-name>
        <url-pattern>/nonjaxrsapp/*</url-pattern>
    </servlet-mapping>
    <filter-mapping>
        <filter-name>MyRestApplication2</servlet-name>
        <url-pattern>/jaxrsapp2/*</url-pattern>
    </filter-mapping>
<web-app>
```

The following example illustrates how the `web.xml` file looks after removing the references to the `IBMRestServlet` and `IBMRestFilter` classes:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns="http://java.sun.com/xml/ns/j2ee" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee http://java.sun.com/xml/ns/j2ee/web-app_3_0.xsd"
    version="3.0">
    <servlet>
        <servlet-name>MyNonJAXRSApplication</servlet-name>
        <servlet-class>com.ibm.websphere.example.NonJAXRSServlet</servlet-class>
        <load-on-startup>1</load-on-startup>
    </servlet>
    <servlet-mapping>
        <servlet-name>MyNonJAXRSApplication</servlet-name>
        <url-pattern>/nonjaxrsapp/*</url-pattern>
    </servlet-mapping>
</web-app>
```

2. Set the `com.ibm.websphere.jaxrs.server.DisableIBMJAXRSEngine` custom JVM property on the application server with a value of `true`.
3. Restart the application server for the custom JVM property to take effect.

## Results

You have disabled the JAX-RS runtime environment from processing your application.

## Assembling JAX-RS web applications

After you develop the Java class files for your Java API for RESTful Web Services (JAX-RS) web application and edit the web.xml file to enable the JAX-RS servlet, you must assemble the application.

### Before you begin

Identify the assembly tool to use to assemble your application. The web application is assembled into a web application archive (WAR) package. You can assemble the WAR package into an enterprise archive (EAR) package if required.

Before assembling the web application, ensure that you have customized the web.xml file to enable the JAX-RS servlet or filter configuration. To learn more, see the information about configuring the web.xml file for the JAX-RS application.

### About this task

You must add the JAX-RS libraries to the web application in the WEB-INF/lib directory before you assemble the web application.

By packaging your JAX-RS application classes into the WEB-INF/classes directory of your WAR package and editing the web.xml file, you can use the built-in JAX-RS runtime environment.

### Procedure

Create the WAR package using assembly tools.

1. Package your compiled JAX-RS Java classes into the `WEB-INF/classes` directory of your WAR package.
2. Package the web.xml file for your web application in the `WEB-INF/` directory into the WAR package.

### Results

A WAR package is created that contains the web application. If needed, you can add the WAR package to an EAR package. The application server can deploy either the WAR or EAR packages.

### What to do next

Deploy the web application.

## Deploying JAX-RS web applications

After you assemble your Java API for RESTful Web Services (JAX-RS) web application, you can deploy the web application archive (WAR) package or the enterprise archive (EAR) package onto the application server.

### Before you begin

To deploy a JAX-RS web application, you need a WAR package or EAR package that is configured and enabled for RESTful services.

### About this task

Every web application must have a context root for the web application to deploy successfully. A context root for each Web module is defined in the application deployment descriptor during application assembly or during application deployment. The context root is combined with the defined servlet mapping from the

WAR file to compose the full URL that users type to access the servlet. The context root for each deployed web application must be unique on the server. The context root can also be empty. For instance, if a Web application used a context root of `sample/application/`, the web application request URL begins with `http://<hostname>:<port>/sample/application/`.

The URL pattern of a servlet is appended to the context root of the Web application. For example, if the context root is `sample/application/` and the servlet URL mapping is `rest/api/*`, the base URI for the JAX-RS web application is `http://<hostname>:<port>/sample/application/rest/api`.

## Procedure

Deploy the JAX-RS web application WAR package or EAR package onto the application server. Read about installing enterprise application files to learn more about deploying web applications.

## Results

The JAX-RS web application is deployed and ready for your business use.

Deployment of a Java API for RESTful Web Services (JAX-RS) web application is successful if you can access the application by typing a Uniform Resource Locator (URL) in a browser or if you can access the application by following a link. If you cannot access your application, follow these steps to eliminate some common errors that can occur during deployment.

**Note:**

Use the following tips to resolve common errors during deployment of JAX-RS web applications.

**An HTTP 404 Not Found error message is sent back to the client in the server response.**

To resolve this problem, take the following actions:

- Verify that the root resource classes are annotated with a @javax.ws.rs.Path annotation and that value in the annotation is correct. Root resource classes without a @Path annotation are not registered with the JAX-RS runtime. To learn more, see the defining the URI patterns for resources in RESTful applications information.
- Verify that the root resource class is added to the set of classes returned from the getClasses() method for the subclasses of the javax.ws.rs.core.Application class. Classes not registered in the subclasses of the javax.ws.rs.core.Application class are not recognized by the JAX-RS runtime environment. To learn more, see the defining the URI patterns for resources in RESTful applications information.
- Verify that the web.xml configuration is correct with the expected URL patterns. For additional details, see the configuring the web.xml file for JAX-RS servlets and filters information.
- Verify that the URL that is being used is correct and includes the context root. If you are using a servlet, the servlet URL pattern is a part of the final URL. Using a filter might be more suitable in your web application. For additional details, see the configuring the web.xml file for JAX-RS servlets and filters information.

**An HTTP 406 Not Acceptable error message is automatically being sent back to the client in the server response.**

To resolve this problem, take the following actions:

- Verify that the Accept HTTP request header in the incoming request is correct. To learn more, see the Implementing content negotiation based on HTTP headers information.
- Verify that the @javax.ws.rs.Produces value on the resource method or resource class is compatible with the incoming Accept HTTP request header. To learn more, see the defining media types for resources in RESTful applications.

**An HTTP 415 Unsupported Media Type error message is automatically being sent back to the client in the server response.**

To resolve this problem, take the following actions:

- Verify that that the Content-Type HTTP request header in the incoming request is correct and is being sent. To learn more, see the defining media types for resources in RESTful applications.
- Verify that the @javax.ws.rs.Consumes value on the resource method or resource class is compatible with the incoming Content-Type HTTP request header.

**An HTTP 204 No Content response status is automatically being sent back to the client in the server response.**

To resolve this problem, take the following action:

- If the object returned from a resource method is a null value, then a 204 No Content status response code is sent back from the server runtime automatically.

For information about known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem.

# Chapter 39. Developing web services - Security (WS-Security)

The Web Services Security specification defines core facilities for protecting the integrity and confidentiality of a message, and provides mechanisms for associating security-related claims with a message.

## Developing applications that use Web Services Security

The Web Services Security specification provides a flexible framework for building secure web services to implement message content integrity and confidentiality. The Web Services Security service programming model supports this flexible framework by providing extension points to integrate new token formats, and methods to obtains keys needed for message protection. The application server programming model provides Web Services Security programming application programming interfaces (WSS API) for securing SOAP messages.

## Configuring HTTP basic authentication for JAX-RPC web services programmatically

You can configure HTTP basic authentication for Java API for XML-based RPC (JAX-RPC) web services by programmatically modifying HTTP properties.

### Before you begin

This task is one of three ways that you can configure HTTP basic authentication. You can also configure HTTP basic authentication with an assembly tool or with the administrative console.

If you programmatically configure HTTP basic authentication, the properties are configured in the Stub or Call instance. If you choose to configure HTTP basic authentication with the administrative console or an assembly tool, the Web Services Security binding information is modified. The values that are set programmatically take precedence over the values defined in the binding.

### About this task

The HTTP basic authentication that is discussed in this topic is orthogonal to WS-Security and is distinct from basic authentication that WS-Security supports. WS-Security supports basic authentication token, not HTTP basic authentication.

Configure HTTP basic authentication programmatically with the following steps.

### Procedure

Set the properties in the Stub or Call instance for a Web service or a web service client. You can set properties with the following constant names:

```
javax.xml.rpc.Call.USERNAME_PROPERTY
javax.xml.rpc.Call.PASSWORD_PROPERTY
javax.xml.rpc.Stub.USERNAME_PROPERTY
javax.xml.rpc.Stub.PASSWORD_PROPERTY
```

### Example

The following code enables you to configure basic authentication programmatically:

```
Properties prop = new Properties();
InitialContext ctx = new InitialContext(prop);
Service service = (Service)ctx.lookup("java:comp/env/service/StockQuoteService");
QName portQname = new QName("http://httpchannel.test.wsfvt.ws.ibm.com", "StockQuoteHttp");
StockQuote sq = (StockQuote)service.getPort(portQname, StockQuote.class);
((javax.xml.rpc.Stub) sq)._setProperty(javax.xml.rpc.Stub.USERNAME_PROPERTY, "myUser");
((javax.xml.rpc.Stub) sq)._setProperty(javax.xml.rpc.Stub.PASSWORD_PROPERTY, "myPwd");
```

# Developing message-level security for JAX-WS web services

JAX-WS applications can be secured with Web Services Security in one of two ways. The application can be secured using policy sets, or through the use of the Web Services Security API (WSS API). The WSS API can only be used to secure a JAX-WS client application. The Web Services Security service programming interface (WSS SPI) provides additional programming interfaces for securing web services.

## Web Services Security API programming model

The application server programming model provides Web Services Security programming application programming interfaces (WSS API) for securing SOAP messages.

The API programming model is an interface-based programming model that is based on Web Services Security Version 1.1 standards, but the design also includes support for Web Services Security Version 1.0 for securing SOAP messages. The WSS API programming model implementation is a simplified version, which is based on an early draft proposal of JSR-183, which is the JSR for defining Java API binding for Web Services Security. By design, because the application code is programmed to the interface, any application code that is programmed with the open source implementation should be able to run on the WebSphere Application Server with minimal changes or no changes at all.

The configuration model for web services has also been redesigned from a deployment descriptor model to a policy set model. Web Services Security can be enabled by either using a policy set that is configured by using the administrative console, or by using the WSS API for configuration. The functions provided by the policy set configurations are the same as the functions supported by the WSS API for the Web Services Security run time. However, the security policy that is defined using policy sets has a higher priority over the WSS API. When the WSS API and the policy set are both used in the application, the default behavior is for the security policy from the policy set to be enforced and the WSS API to be ignored. To use the WSS API in the application, you must make sure that there is no policy set attached to the application or to the application resources, or make sure there is no security policy in the attached policy set.

You can still use your existing JAX-RPC applications with Web Services Security; however, those applications cannot take advantage of the Web Services Security Version 1.1 functions, such as configuring the security policy using a policy set, OM filter performance improvements, WSS API, Web Services Secure Conversation (WS-SecureConversation), Kerberos token and the associated SHA-1 key for message protection and identity propagation, and Web Services Trust (WS-Trust) features.

In order to take advantage of the Web Services Security Version 1.1 functions, you must rewrite an existing JAX-RPC application as a JAX-WS application, manually re-configure the security constraints to a policy set, and perform code migration of the DOM-based SPIs to the OM-based SPIs.

For example, when using the JAX-WS programming model, the improved design of the pluggable token framework allows the same security implementation to be used for both the API and policy sets. The framework uses the JAAS Login Module and JAAS Callback Handler for token creation and token validation.

The following diagrams illustrate differences between the programming models.

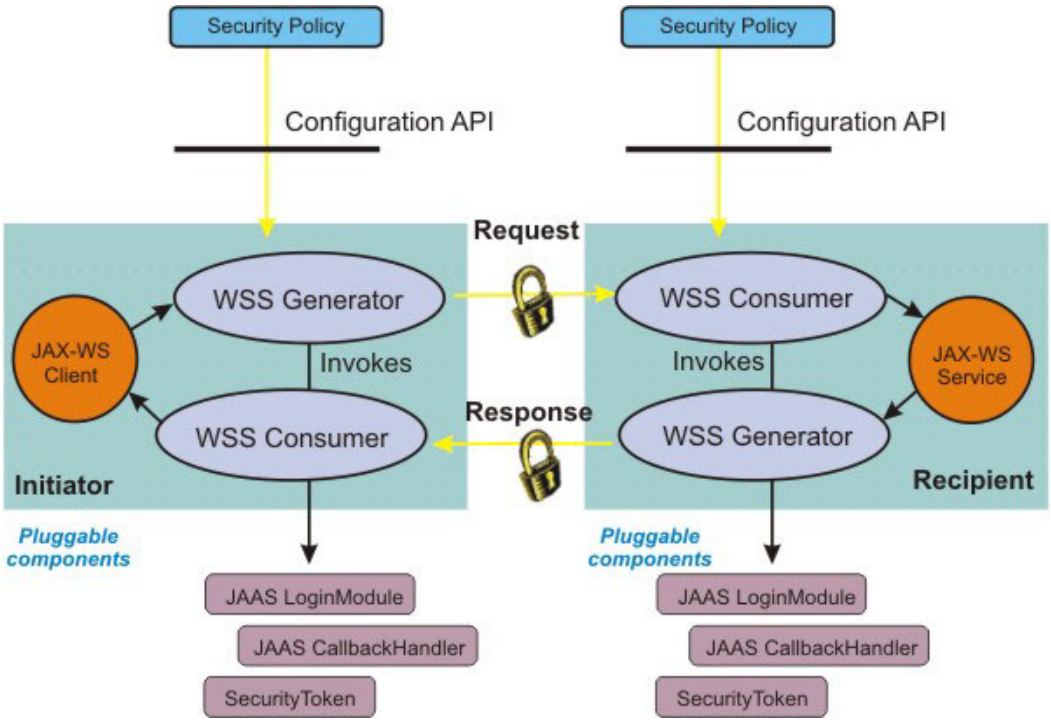

*Figure 5. Pluggable token architecture using the JAX-WS programming model*

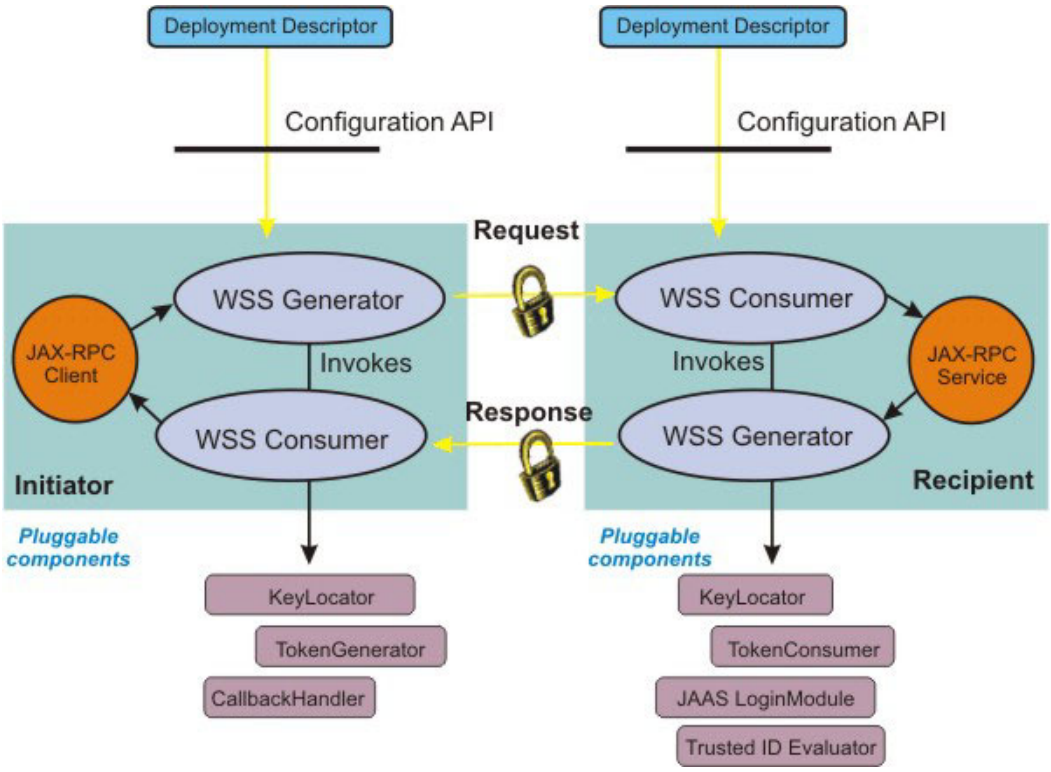

*Figure 6. Pluggable token architecture using the JAX-RPC programming model*

## What is supported when using the WSS APIs

The WSS API can only be used on the client. You can use the Java SE 6 client, the J2EE Application client, or a server client (a service provider acting as client) using the API to secure SOAP message with message-level security.

You should have Web Services Security (WSS) knowledge to use the WSS APIs. Before using the WSS API, keep in mind that the WSS API:

- Are Java-based interfaces.
- Are implemented by using a factory model (WSSFactory).
- Supports the WS-Security Version 1.0 and 1.1 standards, which include the Username and X.509 token profiles, Versions 1.0 and 1.1.
- Are very XML centric.
- Include an object-oriented design which simplifies the APIs.
- Are task oriented and allow common usage scenarios, such as: signing the body and encrypting the SOAP message body content.
- Are flexible and extensible, and they let you to extend the token type support.
- Are based on the provider framework and allow the use of different data models to be used, such as: AXIOM or DOM.
- Provides application programmer with better control and flexibility in applying WSS in their applications.

The default values for the WSS API are predefined and are part of the Web Services Security run time. Default values are provided for:

- The duration of the timestamp
- The signing algorithm, canonicalization algorithm, digest method, transform algorithm, security token reference method and signed parts such as the SOAP body, Web Services Addressing headers and the time stamp.
- The key encryption algorithm, data encryption algorithm, security token reference method, and encrypted parts such as the SOAP body content.

The signature validation has similar default values as the signature (signing information). Similarly, decryption has similar default values as encryption.

## What is not supported when using the WSS APIs

The WSS API provided with the application server does not support the following function:

- The application programming model is JAX-WS, meaning JAX-RPC (JSR-109) applications are not supported.
- The WSS API is available in the synchronous message exchange of the JAX-WS client application. However, the WSS API are not supported for the asynchronous client.
- WSS API support is available only for the requester and not for the provider.
- The identity assertion semantic programming model is not supported in the WSS API because identity assertion is not part of the Web Services Security Version 1.0 standard. However, you can use the WSS API to add Identity Assertion semantic in the token processing.

## WS-Trust and WS-SecureConversation scenarios

There are several ways to secure the WS-Trust SOAP messages:

- Using the bootstrap policy defined in the policy set.
- Using the WSS API, which supports WS-SecureConversation.

- Enabling dynamic policy for the provider so that the client can retrieve the provider-side policy at run time.

An application would use the WSS API to acquire a security context token for programmatic API-based secure conversation. The WebSphere Application Server trust service provides an application the ability to request a security token for access to a service. The scope and focus of the trust service is only for a WebSphere Application Server Security Context Token (SCT) for WS-SecureConversation.

The WS-SecureConversation and WS-Trust scenarios focus on the inter-operability functions, such as the configuration and runtime interaction of various components. You would use the WSS API to secure the bootstrap RST and RSTR to acquire the security context token from the trust service. After acquiring the security context token, a Derived Key Token is created by using the WSS API. Then the Derived Key Token can be used for signature and encryption.

There are two conditions when using the WSS API to secure the SOAP message with Web Services Security:

- Generation of the secure SOAP message, which is in the request generator application code.
- Consuming of the secured SOAP message, which is in the response consumer application code.

In both cases, a Java exception class com.ibm.websphere.wssecurity.wssapi.WSSException is provided if an error is encountered.

### Web services client security context

When the JAX-WS client invokes web services, the current security context that is constructed by the security handler is stored in the RequestContext object. By default, the security context in the JAX-WS web services client runtime environment is reconstructed for the next web services request invocation. You can preserve the security context for subsequent web services invocations. An example of this is a scenario where the security policy requires the client to send a username security token with the user name and password. When the client sends the first request to invoke the service, you are prompted to enter the required user name and password. The user name and password is saved in a Username SecurityToken token in a Subject in the security context. To avoid being prompted to enter the same user name and password again in subsequent request invocations, you can preserve the security context. There are two methods to preserve the security context: 1) configure the client run time to automatically preserve the client security context for subsequent request invocations; or 2) preserve the security context manually.

To configure the JAX-WS client run time environment to automatically preserve the security context, set the Java system property `com.ibm.websphere.wssecurity.context.management` to true. When this system property is true, the JAX-WS client run time copies the security context constructed by the security handler to the RequestContext automatically, and the context is used for subsequent request invocations.

To manually preserve the security context, use the following sample code:

```
// First request
Service svc = Service.create(...);
svc.addPort(...);
Dispatch<String> dispatch = svc.createDispatch(...);
Map<String, Object> requestContext = dispatch.getRequestContext();
String response = dispatch.invoke(body.toString());

Object securityContext = requestContext.get(com.ibm.wsspi.websvcs.Constants.WEBSPHERE_SECURITY_CONTEXT);

// Subsequent request

Dispatch<String> dispatch = svc.createDispatch(...);
Map<String, Object> requestContext = dispatch.getRequestContext();
Object securityContext = requestContext.put(com.ibm.wsspi.websvcs.Constants.WEBSPHERE_SECURITY_CONTEXT, securityContext);
```

## Service Programming Interfaces (SPI)

The Web Services Security service programming interface (WSS SPI) provides programming interfaces for securing Web Services Security.

The Web Services Security specification provides a flexible framework for building secure web services to implement message content integrity and confidentiality. The specification does not define specific token formats, but instead associates separate profile documents that define various security token formats and semantics for using those tokens. The Web Services Security service programming model supports the flexible framework by providing extension points to integrate with new token formats, and with methods to obtains keys needed for message protection. Web Services Security uses this programming model to implement support for the standard X.509 token profile, the Username token profile, and the Kerberos token profiles. The programming model is also used to implement support for the LTPA security token, and for new security token types.

The Web Service Security run time token generation and token consuming Service Programming Interfaces (SPI) have been redesigned so that the same security token interface and JAAS Login Module implementation can be used for both the WSS API and the SPI. The WSS SPI for the service provider extends the security token types and provides keys and deriving keys for signing, signature verification, encryption and decryption.

The Web Services Security service programming model provides mechanisms to process custom security tokens, to use custom token in signing and encryption, and to retrieve encryption and signing keys. The Web Services Security service programming interfaces for the JAX-RPC run time, and for the JAX-WS run time, are similar, but not identical.

### JAX-RPC run time

The plug-in programming interfaces for the JAX-RPC run time consist of the TokenGenerator, KeyLocator, and JAAS CallbackHandler for outbound message processing, and the TokenConsumer, KeyLocator, and JAAS LoginModule for inbound message processing.

**Token Generator, KeyLocator, and Callback Handler**

The TokenGenerator class is responsible for formatting the security token to the XML element. This class calls the CallbackHandler class that is specified in the TokenGeneratorConfig object, which obtains the security token input data, and then stores the resulting security token in the Subject object private credentials.

**Token Consumer, KeyLocator and JAAS LoginModule**

The KeyLocator class is responsible for obtaining the required key for signing and encrypting SOAP message elements from a key store that is specified by the KeyStoreConfig and the KeyLocatorConfig configuration. The TokenConsumer class extracts the token data from the XML security token representation, and stores it in the JAAS Subject using a JAAS LoginModule. The specified KeyLocator class is invoked to find the required key for verifying the digital signature and decrypting the SOAP message elements.

### JAX-WS run time

The plug-in programming interfaces for the JAX-WS run time are based on the JAAS programming model for both inbound and outbound SOAP message processing. The JAAS LoginModule and CallbackHandler are responsible for processing the security tokens in SOAP messages. The Login Module and Callback Handler both retrieve and generate tokens, and store the SecurityToken objects in the run time. They replace the functionality of the TokenGenerator, TokenConsumer, and KeyLocator interfaces.

Due to the differences in the programming models, any WebSphere Application Server or custom SPI implementation from the Web Services Security Version 6.1 run time is not supported to run on the Web Services Security run time with the Version 6.1 Feature Pack for Web Services, or the Version 7.0 and later Web Services Security runtime. However, the Web Services Security Version 6.1 run time is

supported simultaneously with the Version 6.1 Feature Pack for Web Services, meaning the Version 6.1 SPI implementations are still supported through the original run time. Before using the new Web Services Security run time, a code migration is required to reprogram the Version 6.1 DOM-based SPIs to the AXIOM-based SPIs in the Feature Pack for Web Services, before the SPI can be used.

## Developing SAML applications

Use the SAML library application programming interface (API), the SAMLTokenFactory, to configure token parameters, create a SAML token, and bind the created token to a service request. The SAML trust client API provides helper functions that send WS-Trust SOAP requests to the specified external Security Token Service (STS).

### About this task

The SAMLTokenFactory API creates SAML tokens through various method signatures. The API also instantiates runtime configuration objects related to the SAML token requester, as well as the recipient.

The WS-Trust Client API for SAML includes the WSSTrustClient class, the WSSTrustClientValidateResult class, and other configuration utility classes.

The following topics provide more information about developing SAML applications using the APIs.

***WS-Trust client API:***

The WS-Trust client application programming interface (API) includes the WSSTrustClient class, the WSSTrustClientValidateResult class, and other configuration utility classes. The WSSTrustClient class provides helper functions that send WS-Trust SOAP requests to the specified external Security Token Service (STS) so that the STS can issue or validate one or more SAML assertions and other types of security tokens.

**Overview**

WebSphere Application Server Version 7.0.0.7 and later includes WS-Trust client function, implemented through the WSSTrustClient class, that sends WS-Trust SOAP requests to a specified external Security Token Service (STS). Using the trust requests, the STS can issue one or more SAML assertions or other types of security tokens. The WSSTrustClient class supports the OASIS WS-Trust Version 1.3 specification, and also the WS-Trust Version 1.2 specification. In addition, the SOAP Version 1.1 and SOAP Version 1.2 specifications are supported by the function.

The sample code which follows demonstrates how a web services client uses the WSSTrustClient API to request a SAML bearer token. In the explanatory text which precedes the code sample, the term **SAML token** is used interchangeably with the term **SAML assertion**.

**The WSSTrustClient class**

You can copy the sample code into an assembly tool application, such as Rational Application Developer, and start using the code after completing the configuration steps. Use the WSSTrustClient class, together with other SAML APIs, to build useful SAML functions. Refer to the SAML API Javadoc for more information.

The WSSTrustClient class is an abstract class and has two concrete implementations: a WS-Trust Version 1.3 implementation and a WS-Trust v1.2 implementation. On line 50 of the code sample, the SAMLWSTrustClientExample web services client code invokes the WSSTrustClient.getInstance(ProviderConfig) method to retrieve the WS-Trust v1.3 implementation. The getInstance() method takes a single ProviderConfig object, which specifies configuration data that are relevant to the SAML token issuer. A ProviderConfig object is also instantiated in the sample code on line 32. The client code sends WS-Trust Version 1.3 request messages to a target STS endpoint. In the

sample, the endpoint is https://MyCompany/Trust/13/UsernameMixed. To use the sample code, replace this example STS endpoint with the specific STS endpoint you plan to use.

**Note:** Starting with WebSphere Application Server Release 8, you can use the `com.ibm.websphere.wssecurity.wssapi.token.SAMLToken` class in Web Services Security (WSS) application programming interface (API). When there is no concern of confusion we use the term `SAMLToken` instead of using its complete package name. You can use WSS API to request SAMLToken processing from an external Security Token Service (STS), to propagate SAMLTokens in SOAP request messages, and to use a symmetric or asymmetric key identified by SAMLTokens to protect SOAP messages.

The WSS API SAML support complements the `com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory` and `com.ibm.websphere.wssecurity.wssapi.trust.WSSTrustClient` interfaces. SAMLTokens that are generated using the `com.ibm.websphere.wssecurity.wssapi.WSSFactory newSecurityToken()` method can be processed by the `SAMLTokenFactory` and `WSSTrustClient` programming interfaces. Conversely, SAMLTokens that are generated by `SAMLTokenFactory` or returned by `WSSTrustClient` can be used in WSS API. Deciding which API to use in your application depends on your specific needs. WSS API SAML support is self contained in the sense that it provides functionality equivalent to that of the `SAMLTokenFactory` and `WSSTrustClient` interfaces as far as web services client applications are concerned. The `SAMLTokenFactory` interface has additional functions to validate SAMLTokens and to create the JAAS Subject that represents authenticated SAMLTokens. This validation is useful for the Web services provider side. When you develop applications to consume SAMLTokens, the `SAMLTokenFactory` programming interface is more suitable for you.

### Example: Web services client code that uses the WSSTrustClient class

```
1.  package sample;
2.
3.   import com.ibm.websphere.wssecurity.wssapi.WSSException;
4.   import com.ibm.websphere.wssecurity.wssapi.token.SecurityToken;
5.   import com.ibm.websphere.wssecurity.wssapi.trust.WSSTrustClient;
6.   import com.ibm.websphere.wssecurity.wssapi.token.SAMLToken;
7.   import com.ibm.websphere.wssecurity.wssapi.XMLStructure;
8.
9.
10.  import com.ibm.wsspi.wssecurity.core.token.config.RequesterConfiguration;
11.  import com.ibm.wsspi.wssecurity.core.token.config.WSSConstants.Namespace;
12.  import com.ibm.wsspi.wssecurity.core.token.config.WSSConstants.TokenType;
13.  import com.ibm.wsspi.wssecurity.core.token.config.WSSConstants.WST13;
14.  import com.ibm.wsspi.wssecurity.trust.config.ProviderConfig;
15.  import com.ibm.wsspi.wssecurity.trust.config.RequesterConfig;
16.  import com.ibm.wsspi.wssecurity.wssapi.OMStructure;
17.
18.  import org.apache.axiom.om.OMElement;
19.  import org.apache.axis2.util.XMLPrettyPrinter;
20.
21.  import java.util.List;
22.  import java.io.ByteArrayOutputStream;
23.  import java.io.InputStream;
24.  import java.io.BufferedReader;
25.  import java.io.InputStreamReader;
26.  import java.io.IOException;
27.
28.  public class WSSTrustClientExample {
29.
30.    public static void main(String[] args) {
31.          try {
32.          ProviderConfig providerConfig = WSSTrustClient.newProviderConfig(Namespace.WST13, https://MyCompany.com/Trust/13/UsernameMixed );
33.
34.          showProviderConfigDefaultValue(providerConfig);
35.
36.          providerConfig.setPolicySetName("Username WSHTTPS default");
37.          providerConfig.setBindingName("SamlTCSample");
38.          providerConfig.setBindingScope("domain");
39.
40.
41.          RequesterConfig requesterConfig = WSSTrustClient.newRequesterConfig(Namespace.WST13);
42.
43.          showRequestConfigDefaultValue(requesterConfig);
44.
45.          requesterConfig.put(RequesterConfiguration.RSTT.APPLIESTO_ADDRESS, "https://user.MyCompany:9443/WSSampleSei/EchoService12");
46.          requesterConfig.put(RequesterConfiguration.RSTT.TOKENTYPE, TokenType.SAML11);
47.          requesterConfig.put(RequesterConfiguration.RSTT.KEYTYPE, WST13.KEYTYPE_BEARER);
48.          requesterConfig.setSOAPNamespace(Namespace.SOAP12);
49.
50.          WSSTrustClient client = WSSTrustClient.getInstance(providerConfig);
51.          List<SecurityToken> securityTokens = client.issue(providerConfig, requesterConfig);
52.
53.          // Process SAML token
54.          if (securityTokens != null && !securityTokens.isEmpty()) {
55.            System.out.println("Number of tokens returned = " + securityTokens.size());
56.            SecurityToken token = securityTokens.get(0);
```

```
57.           if (token instanceof SAMLToken) {
58.             showSAMLToken((SAMLToken)token);
59.           } else {
60.             System.out.println("Returned token is not an SAMLToken");
61.           }
62.         } else {
63.           System.out.println("No securityToken obtained.");
64.         }
65.
66.     } catch (SoapSecurityException ex) {
67.       System.out.println("Caught exception: " + ex.getMessage());
68.       ex.printStackTrace();
69.     }
70.   }
71.
72.   private static void showProviderConfigDefaultValue(ProviderConfig providerConfig) {
73.     System.out.println("providerConfig.getApplicationName() = " + providerConfig.getApplicationName());
74.     System.out.println("providerConfig.getBindingName() = " + providerConfig.getBindingName());
75.     System.out.println("ProviderConfig.getBindingScope() = " + providerConfig.getBindingScope());
76.     System.out.println("providerConfig.getIssuerURI() = " + providerConfig.getIssuerURI());
77.
78.     System.out.println("providerConfig.getPolicySetName() = " + providerConfig.getPolicySetName());
79.     System.out.println("ProviderConfig.getPortName() = " + providerConfig.getPortName());
80.     System.out.println("providerConfig.getProvider() = " + providerConfig.getProvider());
81.     System.out.println("ProviderConfig.getServiceName() = " + providerConfig.getServiceName());
82.     System.out.println("providerConfig.getWSTrustNamespace() = " + providerConfig.getWSTrustNamespace());
83.     System.out.println("ProviderConfig.toString() = " + providerConfig.toString());
84.   }
85.
86.   private static void showRequestConfigDefaultValue(RequesterConfig requesterConfig) {
87.     System.out.println("requesterConfig.getRSTTProperties() = " + requesterConfig.getRSTTProperties());
88.     System.out.println("requesterConfig.getSecondaryParameters() = " + requesterConfig.getSecondaryParameters());
89.     System.out.println("requesterConfig.getSOAPNamespace() = " + requesterConfig.getSOAPNamespace());
90.     System.out.println("requesterConfig.getWSAddressingNamespace() = " + requesterConfig.getWSAddressingNamespace());
91.
92.     System.out.println("requesterConfig.getMessageID() = " + requesterConfig.getMessageID());
93.     System.out.println("requesterConfig.toString() = " + requesterConfig.toString());
94.   }
95.
96.   private static void showSAMLToken(SAMLToken samlToken){
97.     System.out.println("samlToken.getAssertionQName() = " + samlToken.getAssertionQName());
98.     System.out.println("samlToken.getAudienceRestriction() = " + samlToken.getAudienceRestriction());
99.     System.out.println("samlToken.getAuthenticationMethod() = " + samlToken.getAuthenticationMethod());
100.    System.out.println("samlToken.getConfirmationMethod() = " + samlToken.getConfirmationMethod());
101.    System.out.println("samlToken.getId() = " + samlToken.getId());
102.    System.out.println("samlToken.getKeyIdentifier() = " + samlToken.getKeyIdentifier());

### WSSTrustClient class support for policy sets and bindings

The WS-Trust client function supports both application-specific bindings and general bindings for use with the trust client policy set and binding documents. In addition, general bindings and default bindings are supported if the application is running in the application server environment. General bindings are supported in the thin client environment, but default bindings are not.

Managing the policy set and bindings for the WS-Trust client API is similar to managing a policy set and bindings for a web services client. However, differences exist that are unique to the WS-Trust client. One difference is that the WS-Trust client does not use policy set attachments. Instead, the policy set name and binding name are specified in a ProviderConfig object, as shown in line 36 and line 37 of the sample code.

When the WS-Trust client looks for bindings, the way the client manages the search scope differs from the web services client. If you do not specify the wstrustClientBindingScope property for the trust client binding, the system first searches the application for an application-specific binding with the binding name that you specified. If a binding is found, it is used for the trust client request. If no application-specific binding is found, the system searches the available general bindings for a binding with the name that you specified. If a general binding is found, it is used for the trust client request. If no bindings with the specific name are found, then default bindings are used in a server environment. Default bindings are only used in a server environment. If the binding scope is specified, only that scope is used for the binding search.

Line 38 of the sample code, `providerConfig.setBindingScope("domain")`, indicates that the example uses general bindings. You can also set the binding scope to `application` to indicate that the sample code uses application-specific bindings. The example uses the general binding named **SamlTCSample**. Both application-specific and general bindings are supported in the application server and the thin client environment. For more information about configuring the SamlTCSample bindings when the application is installed on the application server, read about configuring policy sets and bindings to communicate with STS.

The showProviderConfigDefaultValue(providerConfig) code on line 34 of the sample code shows the default settings. The sample code includes a utility method that prints out the contents of providerConfig.

Line 51 of the sample code, List<SecurityToken> securityTokens = client.issue(providerConfig, requesterConfig), sends an issue WS-Trust request. The second parameter on this line specifies the RequesterConfig object, and this parameter determines the content of the issue request. The code on line 41, RequesterConfig requesterConfig = WSSTrustClient.newRequesterConfig(Namespace.WST13), instantiates a RequesterConfig object that is used to construct the trust request using the WS-Trust Version 1.3 namespace. A utility function is shown on line 43: showRequestConfigDefaultValue(requesterConfig). This function displays the default settings for the RequesterConfig object. The code between lines 45 and 48 initializes the RequesterConfig to request a Version 1.1 SAML bearer token. This token is used to access the service endpoint using the SOAP 1.2 namespace. In the example, the service endpoint is https://user.MyCompany.com:9443/WSSampleSei/EchoService12.

### JVM arguments support

Before executing the sample code, you must set up several Java Virtual Machine (JVM) arguments. The sample code implements the Username WSHTTPS default policy set, which has two requirements: 1) a Username token is sent to the STS; and 2) messages are protected using Secure Sockets Layer (SSL). To set up the environment to meet these requirements, first configure the `ssl.client.props` file to define a truststore. For step-by-step instructions, read about running an unmanaged web services JAX-WS client.

To meet the second requirement regarding SSL message protection, obtain a copy of the STS SSL X.509 certificate and inset it into the truststore. To do this, follow the steps in the topic, Using the retrieveSigners command in SSL, to enable server-to-server trust. Alternately, you can accept the STS certificate when you send the first trust request to the STS if the `com.ibm.ssl.enableSignerExchangePrompt` property in the `profile_home/properties/ssl.client.props` file is set to `true`. For more information about this option, read about changing the signer auto-exchange prompt at the client.

In addition, you must specify the client JAAS configuration file so that the client runtime environment can locate the Username token LoginModule JAAS login configuration. Specify the parameter using this code: `-Djava.security.auth.login.config="%WAS_HOME%\properties\wsjaas_client.conf`. You must also include the thin client jar, for example com.ibm.jaxws.thinclient_8.0.0.jar, in the classpath. For more information, read about running an unmanaged web services JAX-WS client application.

### Sample code execution

A prerequisite to executing the sample code is to set up an external STS endpoint to issue a SAML 1.1 bearer token for the specified web services as defined by the `RequesterConfiguration.RSTT.APPLIESTO_ADDRESS` property.

Executing the sample code generates a WS-Trust issue request message, as shown in the example:

```
177.  <?xml version="1.0" encoding="UTF-8"?><soapenv:Envelope xmlns:soapenv="http://www.w3.org/2003/05/soap-envelope">
178.      <soapenv:Header>
179.          <wsa:To xmlns:wsa="http://www.w3.org/2005/08/addressing">https://user.MyCompany.com/Trust/13/UsernameMixed</wsa:To>
180.          <wsa:MessageID xmlns:wsa="http://www.w3.org/2005/08/addressing">urn:uuid:4951B6775950CAC92A1252458259166</wsa:MessageID>
181.          <wsa:Action xmlns:wsa="http://www.w3.org/2005/08/addressing">http://docs.oasis-open.org/ws-sx/ws-trust/200512/RST/Issue</wsa:Action>
182.      </soapenv:Header>
183.      <soapenv:Body>
184.          <wst:RequestSecurityToken xmlns:wst="http://docs.oasis-open.org/ws-sx/ws-trust/200512">
185.              <wst:TokenType>http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV1.1</wst:TokenType>
186.              <wst:RequestType>http://docs.oasis-open.org/ws-sx/ws-trust/200512/Issue</wst:RequestType>
187.              <wst:KeyType>http://docs.oasis-open.org/ws-sx/ws-trust/200512/Bearer</wst:KeyType>
188.              <wsp:AppliesTo xmlns:wsp="http://schemas.xmlsoap.org/ws/2004/09/policy">
189.                  <wsa:EndpointReference xmlns:wsa="http://www.w3.org/2005/08/addressing">
190.                      <wsa:Address>https://user.MyCompany.com:9443/WSSampleSei/EchoService12</wsa:Address>
191.                  </wsa:EndpointReference>
192.              </wsp:AppliesTo>
193.          </wst:RequestSecurityToken>
194.      </soapenv:Body>
195.  </soapenv:Envelope>
```

To view the WS-Trust request message, you must enable a client-side trace. Set the following JVM properties:

- `-DtraceSettingsFile=MyTraceSettings.properties`
- `-Djava.util.logging.manager=com.ibm.ws.bootstrap.WsLogManager`
- `-Djava.util.logging.configureByServer=true`

For more information about these properties, read about enabling trace on client and stand-alone applications. In addition to setting the JVM properties, you must also specify the trace setting, `com.ibm.ws.wssecurity.*=all=enabled`, in the `MyTraceSettings.properties` file. Look for `Trust Client outgoing request:` in the trace log file.

### SAML token return

The code on line 51 of the sample code, `List<SecurityToken> securityTokens = client.issue(providerConfig, requesterConfig)`, returns a SAML token if the WS-Trust issue request is processed successfully. The code between lines 54 and 64 processes the returned SAML token. The utility

function shown on line 58, `showSAMLToken((SAMLToken)token)`, displays the content of the received SAML token. The `showSAMLToken()` routine shows the SAML token as an XML document. An example of this XML document is provided in line 196 to line 233 of the sample code.

```

### *SAML token library APIs:*

The SAML token library application programming interfaces (APIs) provide methods you can use to create, validate, parse, and extract SAML tokens.

#### Overview

The library implementation for SAML Version 1.1 and SAML Version 2.0 provides three types of subject confirmation: holder-of-key (HoK), bearer, and sender-vouches. You can use the SAML token library APIs to create, validate, and extract the attributes of a SAML HoK or bearer token. SAML token propagation from web services SOAP messages is also discussed. Sample code is provided to demonstrate the use of the APIs.

WebSphere Application Server with SAML provides default policy sets to support the bearer and HoK subject confirmation.

These sections discuss creating a SAML token using the SAML token library APIs:

1. “Configuration of token creation parameters” on page 1807
2. “SAML token factory instance creation” on page 1808
3. “SAML token creation” on page 1808
4. “Sample code” on page 1809

The SAMLTokenFactory API is the primary SAML token library programming interface. SAMLTokenFactory supports creating, parsing, and validating both SAML 1.1 and SAML 2.0 tokens. Using the SAMLTokenFactory API, you can create ProviderConfid, RequesterConfig, and ConsumerConfig configuration objects to define the required SAML token characteristics. Read the API documentation for more details.

You can perform additional operations on a SAML token after it is created, including:

- “SAML token validation” on page 1808

- “SAML token identity mapped to a subject” on page 1808
- “Parse assertion elements” on page 1809
- “SAML token attributes extraction” on page 1809

**Note:** Starting with WebSphere Application Server Release 8, you can use the `com.ibm.websphere.wssecurity.wssapi.token.SAMLToken` class in Web Services Security (WSS) application programming interface (API). When there is no concern of confusion we use the term `SAMLToken` instead of using its complete package name. You can use WSS API to request SAMLToken processing from an external Security Token Service (STS), to propagate SAMLTokens in SOAP request messages, and to use a symmetric or asymmetric key identified by SAMLTokens to protect SOAP messages.

The WSS API SAML support complements the `com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory` and `com.ibm.websphere.wssecurity.wssapi.trust.WSSTrustClient` interfaces. SAMLTokens that are generated using the `com.ibm.websphere.wssecurity.wssapi.WSSFactory newSecurityToken()` method can be processed by the `SAMLTokenFactory` and `WSSTrustClient` programming interfaces. Conversely, SAMLTokens that are generated by `SAMLTokenFactory` or returned by `WSSTrustClient` can be used in WSS API. Deciding which API to use in your application depends on your specific needs. WSS API SAML support is self contained in the sense that it provides functionality equivalent to that of the `SAMLTokenFactory` and `WSSTrustClient` interfaces as far as web services client applications are concerned. The `SAMLTokenFactory` interface has additional functions to validate SAMLTokens and to create the JAAS Subject that represents authenticated SAMLTokens. This validation is useful for the Web services provider side. When you develop applications to consume SAMLTokens, the `SAMLTokenFactory` programming interface is more suitable for you.

**Configuration of token creation parameters**

When you configure the token creation parameters, the configuration information relates to either the requesting entity, the issuing entity, or the receiving entity. In this example, configuration information is defined for the requesting and the issuing entities. For each type of supported subject confirmation, the SAML token library provides pre-configured attributes for the requesting entity. These attributes are used during the creation of the self-issued SAML token by the WebSphere runtime environment. A self-issued SAML token is one that is generated locally, instead of one that is requested from a Security Token Service (STS). If you need to customize the attributes for a default parameter, use the RequesterConfig parameter. For more information, read about the RequesterConfig parameter in the SAMLTokenFactory API topic.

First, set up the requestor configuration information:

```
// Setup the requester's configuration information (parameters needed
// to create the token specified as configuration properties).
// in this case we are using the configuration information to create a
// SAML token that contains a symmetric holder of key subject
// confirmation.
RequesterConfig requesterData =
     samlFactory.newSymmetricHolderOfKeyTokenGenerateConfig();
```

Next, set the recipient public key alias and optionally, the authentication method:

```
// Set recipient's public key alias
// (in this example we use SOAPRecipient), so the provider can encrypt secret
// key for the receiving end.
requesterData.setKeyAliasForAppliesTo("SOAPRecipient");

// Set the authentication method that took place. This is an optional
// parameter.
reqData.setAuthenticationMethod("Password");
```

Then set the issuer configuration attributes:

```
// Set issuer information by instantiating a default ProviderConfig.
// See javadocs for the SAMLTokenFactory class on the details of the
// default values and how to modify them.
ProviderConfig samlIssuerCfg =
  samlFactory.newDefaultProviderConfig("WebSphereSelfIssuer");
```

### SAML token factory instance creation

Use the SAMLTokenFactory class, specifying the SAML token type, either Version 1.1 or Version 2.0. Set additional parameters for creating the SAML token.

Use the SAMLTokenFactory class with the SAML token type:

```
// Instantiate a token factory based on the version level of the token
// to use. In this example we use the SAML v1.1 token factory.
SAMLTokenFactory samlFactory =
SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11);
```

Set additional parameters in the CredentialConfig object using the caller subject or the runAsSubject:

```
// Retrieve the caller subject or the runAsSubject (depending on your
// scenario) then use the Subject to get a CredentialConfig object
// using the SAML token library.
// This invocation requires the
// wssapi.SAMLTokenFactory.newCredentialConfig" Java Security
// permission.
CredentialConfig cred = samlFactory.newCredentialConfig(runAsSubject);
```

### SAML token creation

Create the SAML token using the token factory:

```
// Now create the SAML token. This invocation requires the
// "wssapi.SAMLTokenFactory.newSAMLToken" Java Security permission.
SecurityToken samlToken =
                samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

### SAML token validation

An entity that receives a SAML token, such as a business service, can use the SAML token library API to validate the token before using it. For example, the service needs to validate the token before extracting the SAML attributes from the requester. An existing SAML assertion document can be validated using the configuration data from the consumer.

The following API code validates the token:

```
ConsumerConfig consumerConfig = samlFactory.newConsumerConfig();
 XMLStructure xml =
 try {
    SAMLToken token = samlFactory.newSAMLToken( consumerConfig, XMLStructure xml );
    // token successfully validated
 } catch(WSSException e){
  // token failed validation
 }
```

### SAML token identity mapped to a subject

A SAML token can be used to create a subject. The name identifier in the SAML token is mapped to a user in the user registry to obtain the principal name for the subject.

```
Subject subject;
SAMLToken aSAMLToken = ...;
  try {
        subject = samlFactory.newSubject(aSAMLToken);
  } catch(WSSException e) {
  }
```

### Parse assertion elements

The recipient of a SAML token can parse and extract assertion elements from the SAML token using the SAMLToken APIs, which are included in the SAML token library API. For example, the token creation time can be extracted using this code:

```
Date dateCreated = samlToken.getSamlCreated();
```

Extract the name of the token issuer and the confirmation method as follows:

```
String confirmationMethpo = samlToken.getConfirmationMethod();
String issuerName = samlToken.getSAMLIssuerName();
```

If the extracted subject confirmation method is returned as holder-of-key confirmation, then you can use the following API to retrieve the bytes for the key material:

```
byte[] hokBytes = samlToken.getHolderOfKeyBytes();
```

For more information about all the SAML APIs, read the API documentation for the SAMLToken interface.

### SAML token attributes extraction

Extract SAML attributes from the initiating entity (service requester) using the SAMLToken API, as shown in the following code snippets.

```
// Get all attributes
List<SAMLAttribute> allAttributes =
             ((SAMLToken) samlToken).getSAMLAttributes();

// Iterate over the attribute and process accordingly
Iterator<SAMLAttribute> iter = allAttributes.iterator();
while (iter.hasNext())
{
    SAMLAttribute anAttribute = iter.next();

    // Handle attributes
    String attributeName = anAttribute.getName();
    String[] attributeValues = anAttribute.getStringAttributeValue();

}
```

### Sample code

The sample code demonstrates how to use the SAML token library APIs to accomplish some of the operations previously described. A JVM property that points to the location of the SAML properties file is a prerequisite for running this code. The SAML properties file, `SAMLIssuerConfig.properties`, must contain configuration attributes related to the issuer (provider) of the SAML token.

The default location of the SAMLIssuerConfig.properties file for the cell level is: *app_server_root*/profiles/*$PROFILE*/config/cells/*$CELLNAME*/sts.

For the server level, the default location is: *app_server_root*/profiles/*$PROFILE*/config/cells/*$CELLNAME*/nodes/*$NODENAME*/servers/*$SERVERNAME*.

  }
 }
}
```

### Sample code output

```
default holder of key confirmation key type is: http://docs.oasis-open.org/ws-sx/ws-trust/200512/SymmetricKey
authentication method for requester is: Password
confirmation method for requester is: holder-of-key
key alias for requester is: null
key alias for recipient as set in requester config is SOAPRecipient
holder of key confirmation key type is: http://docs.oasis-open.org/ws-sx/ws-trust/200512/SymmetricKey
time to live from the default provider config: 3600000
keyStore path from default provider config: C:/saml/samlsample/saml-provider.jceks
keyStore type from default provider config: jceks
key alias from default provider config: samlissuer
token's creation Date is: Mon Sep 14 15:49:00 CDT 2009
token's expiration Date is: Mon Sep 14 16:49:00 CDT 2009
token's subject confirmation method is: urn:oasis:names:tc:SAML:1.0:cm:holder-of-key
attribute name = EmployeeInfo  attribute value = [GreenRoofing, JohnDoe, 19XY981245]
```

### *Creating a SAML bearer token using the API:*

Use the SAML library API to create a SAML bearer token.

### About this task

This library allows you to create a SAML bearer token. You can use the SAML library API to create required SAML configuration objects, then use those configuration objects to generate a bearer SAML token.

### Procedure

1. Create a SAMLTokenFactory instance using the SAML token version as a parameter.
   a. Use the following line of code to import the method:

```
import com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory;
```

   b. Use one of these lines of code to create the instance, depending on the token version.
      - Add the following line of code to create a SAMLTokenFactory instance for a version 1.1 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11);
```

      - Add the following line of code to create a SAMLTokenFactory instance for a version 2.0 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token20);
```

2. After you create the instance, the SAMLTokenFactory is used to create a RequesterConfig instance, which determines how the token will be generated, according the authentication requirements of the requester. Use this line of code to create the RequesterConfig instance for the bearer token:

```
RequesterConfig reqData = samlFactory.newBearerTokenGenerateConfig();
```

   The default RequestConfig instance is sufficient to generate a simple bearer token, but additional assertions can be included in the SAML token by customizing the RequesterConfig instance. For example, to include password authentication information in the token, use setAuthenticationMethod:

```
reqData.setAuthenticationMethod("password");
```

   To disable signing in a SAML assertion, use the setAssertionSignatureRequired method, for example:

```
reqData.setAssertionSignatureRequired(false);
```

   For more information, read about the SAML bearer assertion.
3. Use the SAMLTokenFactory to create a ProviderConfig instance, which describes the token issuer. The ProviderConfig instance specifies the SAML issuer name, as well as keystore and truststore information, which identifies the key for SAML encryption and signing. The ProviderConfig instance is created using property values from a property file. The property file specifies the default value of the ProviderConfig object. In a Java client environment, this property file is defined by a JVM system property, com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath.

   In the WebSphere Application Server runtime environment, the property file name is SAMLIssuerConfig.properties. The file can be located either under the server level configuration directory, or the cell level directory, in that order of precedence. An example of the server level path follows:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/nodes/$NODENAME/servers/$SERVERNAME/SAMLIssuerConfig.properties
```

   An example of the cell level path follows:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/sts/SAMLIssuerConfig.properties
```

   The JVM system property, com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath, is ignored if the property is defined in server runtime environment. For a detailed description of all the properties, read about configuration of a SAML token during token creation.

   Use the following line of code to create a default ProviderConfig instance:

```
ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("any issuer name");
```

The issuer name is optional. If the issuer name is specified, the Issuer name appears in the SAML assertion. If the issuer name is not specified, a default issuer name property from the SAMLIssuerConfig.properties is used as the issuer name.

4. Optional: When creating a new SAML token, the SAMLTokenFactory uses either a JAAS subject or a CredentialConfig instance to populate the new SAML token. To use a JAAS subject to populate the token, use the com.ibm.websphere.security.auth.WSSubject getCallerSubject() API or the getRunAsSubject() API to obtain a JAAS subject that represents the requesting client, or the identity of the execution thread.

   When you use the JAAS subject to create a new SAML token, the SAMLTokenFactory searches for a SAMLToken object in the subject PrivateCredentials list. If a SAMLToken object exists, the NameId or NameIdentifier are copied to the new SAML token. The SAMLTokenFactory also copies the SAML attributes and AuthenticationMethod from the existing SAML token to the new SAML token. The new SAML token includes a new issuer name, new signing certificate, confirmation method, new KeyInfo for the holder-of-key confirmation method, and new NotBefore and NotOnAfter conditions. These token settings are determined by the configuration parameters in the ProviderConfig and RequesterConfig objects.

   If there is no SAMLToken object in the subject, only the WSPrincipal principal name is copied from the subject to the new SAML token. No other attributes in the subject are copied into the new SAML token. Similarly, the issuer name, signing certificate, confirmation method, KeyInfo for the holder-of-key, and NotBefore and NotOnOrAfter conditions are determined by configuration parameters in ProviderConfig and RequesterConfig objects.

   Alternately, you can use the RunAsSubject method on the execution thread to create the SAML token. When using this method, do not pass the JAAS subject or the CredentialConfig object to the SAMLTokenFactory to create the SAML token. Instead, the content of the existing SAML token is copied to the new SAML token, as described previously.

   Another method of creating a SAML token is to use a CredentialConfig object to populate the SAML NameId and Attributes programmatically. Use this method in the following circumstances:

   - Custom SAML attributes must be included in the new SAML token.
   - The SAML token is created manually instead of using the SAMLTokenFactory to populate the SAML token from a JAAS subject automatically.
   - There is no existing SAML token in the subject.
   - There is no JAAS subject available.

   To create a CredentialConfig object without using the JAAS subject, use this line of code:

```
CredentialConfig cred = samlFactory.newCredentialConfig ();
```

   There is no initial value provided for this CredentialConfig object, so you must use setter methods to populate the CredentialConfig object.

   To populate the SAML NameIdentifier or NameID, use the following line of code:

```
cred.setRequesterNameID("any name");
```

   The value of the *any name* variable is used as the principal name in the SAML token. The name appears in the assertion as the NameIdentifier in a SAML Version 1.1 token, or NameId in the SAML Version 2.0 token. For example, if the value of *any name* is `Alice`, the following assertion is generated in a SAML Version 1.1 token:

```
<saml:NameIdentifier>Alice</saml:NameIdentifier>
```

   The following assertion is generated in a SAML Version 2.0 token:

```
<saml2:NameID>Alice</saml2:NameID>
```

   To include SAML attributes in the <AttributeStatement> portion of an assertion, use this code:

```
SAMLAttribute samlAttribute = new SAMLAttribute("email" /* Name*/, new String[] {"joe@websphere"}
/*Attribute Values*/, null, "IBM WebSphere namespace" /* namespace*/, "email" /* format*/, "joe" /*friendly name */);
ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
```

```
al.add(samlAttribute)
sattribute = new SAMLAttribute("Membership", new String[] {"Super users", "Gold membership"}, null, null /* format*/, null, null );
al.add(samlAttribute );
cred.setSAMLAttributes(al);
```

This sample code generates the following <Attribute> assertions:

```
<saml:Attribute AttributeName="email" NameFormat="email" AttributeNamespace="IBM WebSphere namespace">
<saml:AttributeValue>joe@websphere</saml:AttributeValue>
</saml:Attribute>
<saml:Attribute AttributeName="Membership">
<saml:AttributeValue>Super users</saml:AttributeValue><saml:AttributeValue>Gold membership</saml:AttributeValue>
</saml:Attribute>
```

5. Generate a SAML bearer token using this line of code:

```
SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

This method requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken.

Complete code samples using lines of code from the previous steps are included in the Example section.

### Example

Use this sample code to create a SAML version 1.1 bearer token from the subject:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11)

RequesterConfig reqData = samlFactory.newBearerTokenGenerateConfig();

ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("WebSphere Server");

Subject subject =  com.ibm.websphere.security.auth.WSSubject.getRunAsSubject();

SAMLToken samlToken = samlFactory.newSAMLToken(subject, reqData, samlIssuerCfg);
```

Use this sample code to create a SAML version 1.1 bearer token without using the subject:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11);

RequesterConfig reqData = samlFactory.newBearerTokenGenerateConfig();
reqData.setAuthenticationMethod("Password"); //Authentication method for Assertion

ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig(Self issuer);

CredentialConfig cred = samlFactory.newCredentialConfig ();
cred.setRequesterNameID("Alice");   // SAML NameIdentifier
//SAML attributes:
SAMLAttribute attribute = new SAMLAttribute
   ("email" /* Name*/, new String[] {"joe@websphere"}
   /*Attribute Values in String*/,null
   /*Attribute Values in XML */, "WebSphere" /* Namespace*/, "email" /* format*/, "joe" /*Friendly_name */);
ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
al.add(attribute);
attribute = new SAMLAttribute("Membership", new String[] {"Super users", "My team"}, null, null, null, null  );
al.add(attribute);
cred.setSAMLAttributes(al);

SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

### *Creating a SAML holder-of-key token using the API:*

The SAML holder-of-key token extends the security token public interface in WebSphere Application Server, and can be used as a protection token. WebSphere Application Server Version 7.0.0.7 and later provides a SAML library API for SAML holder-of-key token creation.

### About this task

SAML token creation requires three parameters:

- com.ibm.wsspi.wssecurity.saml.config.RequesterConfig
- com.ibm.wsspi.wssecurity.saml.config.ProviderConfig
- com.ibm.wsspi.wssecurity.saml.config.CredentialConfig

Follow the steps to create an instance for each of the parameters and then create a SAML holder-of-key token. As an alternative to CredentialConfig, you can also use javax.security.auth.Subject. For more information, read the API documentation.

**Procedure**

1. Create a com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory instance using the SAML token version as a parameter. The supported SAMLToken versions are http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV1.1 and http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV2.0. The SAMLTokenFactory instance is a singleton and therefore is thread-safe. Use one of these lines of code to create the instance, depending on the token version.
   - Use the following line of code to create a com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory instance for a version 1.1 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11);
```

   - Use the following line of code to create a com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory instance for a version 2.0 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token20);
```

2. The SAMLTokenFactory instance is used to create a RequesterConfig instance, which determines how the token is generated, according the authentication requirements of the requester. Use one of these lines of code to create the RequesterConfig instance, depending on whether you want the token to use a secret key (symmetric key) or a public key:
   - Use the following line of code to create a default RequesterConfig for the SAML holder-of-key token using a secret key (symmetric key), which is included in the SubjectConfirmation:

```
RequesterConfig reqData = samlFactory. newSymmetricHolderOfKeyTokenGenerateConfig ();
```

     You must also set the key alias for the target service so the provider can encrypt the secret key for the service:

```
reqData.setKeyAliasForAppliesTo("Soap Recipient");
```

   - Use the following line of code to create a default RequesterConfig for the SAML holder-of-key token using a public key, which is included in the SubjectConfirmation:

```
RequesterConfig reqData = samlFactory. newAsymmetricHolderOfKeyTokenGenerateConfig ();
```

     You must also set the key alias for the requester so the provider can extract the public key from the requester, and include the key in the SubjectConfirmation:

```
reqData.setKeyAliasForRequester("SOAP Initiator");
```

   The default RequestConfig instance is sufficient to generate a simple holder-of-key token, but additional assertions can be included in the SAML token by customizing the RequesterConfig instance. For example, to include password authentication information in the token, use setAuthenticationMethod:

```
reqData.setAuthenticationMethod("password");
```

3. Use the SAMLTokenFactory to create a ProviderConfig instance, which describes the token issuer. The ProviderConfig instance specifies the SAML issuer name, as well as keystore and truststore information, which identifies the key for SAML encryption and signing. The ProviderConfig instance is created using property values from a property file. The property file specifies the default value of the ProviderConfig object. In a Java client environment, this property file is defined by a JVM system property, com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath.

   In the WebSphere Application Server runtime environment, the property file name is SAMLIssuerConfig.properties. The file can be located either under the server level configuration directory, or the cell level directory, in that order of precedence. An example of the server level path follows:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/nodes/$NODENAME/servers/$SERVERNAME/SAMLIssuerConfig.properties
```

An example of the cell level path follows:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/sts/SAMLIssuerConfig.properties
```

The JVM system property, com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath, is ignored if the property is defined in server runtime environment. For a detailed description of all the properties, read about configuration of a SAML token during token creation.

Use the following line of code to create a default ProviderConfig instance:

```
ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("any issuer name");
```

The issuer name is optional. If the issuer name is specified, the Issuer name appears in the SAML assertion. If the issuer name is not specified, a default issuer name property from the SAMLIssuerConfig.properties is used as the issuer name.

4. Optional: When creating a new SAML token, the SAMLTokenFactory uses either a JAAS subject or a CredentialConfig instance to populate the new SAML token. To use a JAAS subject to populate the token, use the com.ibm.websphere.security.auth.WSSubject getCallerSubject() API or the getRunAsSubject() API to obtain a JAAS subject that represents the requesting client, or the identity of the execution thread.

   When you use the JAAS subject to create a new SAML token, the SAMLTokenFactory searches for a SAMLToken object in the subject PrivateCredentials list. If a SAMLToken object exists, the NameId or NameIdentifier are copied to the new SAML token. The SAMLTokenFactory also copies the SAML attributes and AuthenticationMethod from the existing SAML token to the new SAML token. The new SAML token includes a new issuer name, new signing certificate, confirmation method, new KeyInfo for the holder-of-key confirmation method, and new NotBefore and NotOnAfter conditions. These token settings are determined by the configuration parameters in the ProviderConfig and RequesterConfig objects.

   If there is no SAMLToken object in the subject, only the WSPrincipal principal name is copied from the subject to the new SAML token. No other attributes in the subject are copied into the new SAML token. Similarly, the issuer name, signing certificate, confirmation method, KeyInfo for the holder-of-key, and NotBefore and NotOnOrAfter conditions are determined by configuration parameters in ProviderConfig and RequesterConfig objects.

   Alternately, you can use the RunAsSubject method on the execution thread to create the SAML token. When using this method, do not pass the JAAS subject or the CredentialConfig object to the SAMLTokenFactory to create the SAML token. Instead, the content of the existing SAML token is copied to the new SAML token, as described previously.

   Another method of creating a SAML token is to use a CredentialConfig object to populate the SAML NameId and Attributes programmatically. Use this method in the following circumstances:

   - Custom SAML attributes must be included in the new SAML token.
   - The SAML token is created manually instead of using the SAMLTokenFactory to populate the SAML token from a JAAS subject automatically.
   - There is no existing SAML token in the subject.
   - There is no JAAS subject available.

   To create a CredentialConfig object without using the JAAS subject, use this line of code:

```
CredentialConfig cred = samlFactory.newCredentialConfig ();
```

   There is no initial value provided for this CredentialConfig object, so you must use setter methods to populate the CredentialConfig object.

   To populate the SAML NameIdentifier or NameID, use the following line of code:

```
cred.setRequesterNameID("any name");
```

   The value of the *any name* variable is used as the principal name in the SAML token. The name appears in the assertion as the NameIdentifier in a SAML Version 1.1 token, or NameId in the SAML Version 2.0 token. For example, if the value of *any name* is `Alice`, the following assertion is generated in a SAML Version 1.1 token:

```
<saml:NameIdentifier>Alice</saml:NameIdentifier>
```

The following assertion is generated in a SAML Version 2.0 token:

```
<saml2:NameID>Alice</saml2:NameID>
```

To include SAML attributes in the <AttributeStatement> portion of an assertion, use this code:

```
SAMLAttribute samlAttribute = new SAMLAttribute("email" /* Name*/, new String[] {"joe@websphere"}
/*Attribute Values*/, null, "IBM WebSphere namespace" /* namespace*/, "email" /* format*/, "joe" /*friendly name */);
ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
al.add(samlAttribute)
sattribute = new SAMLAttribute("Membership", new String[] {"Super users", "Gold membership"}, null, null /* format*/, null, null );
al.add(samlAttribute );
cred.setSAMLAttributes(al);
```

This sample code generates the following <Attribute> assertions:

```
<saml:Attribute AttributeName="email" NameFormat="email" AttributeNamespace="IBM WebSphere namespace">
<saml:AttributeValue>joe@websphere</saml:AttributeValue>
</saml:Attribute>
<saml:Attribute AttributeName="Membership">
<saml:AttributeValue>Super users</saml:AttributeValue><saml:AttributeValue>Gold membership</saml:AttributeValue>
</saml:Attribute>
```

5. Generate a SAML holder-of-key token using this line of code:

```
SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

This method requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken. Complete code samples using lines of code from the previous steps are included in the Example section.

### Example

Use this sample code to create a SAML version 1.1 holder-of-key token using a secret key (symmetric key) from the subject.

```
import com.ibm.wsspi.wssecurity.saml.config.RequesterConfig;
import com.ibm.wsspi.wssecurity.saml.config.ProviderConfig;
import com.ibm.wsspi.wssecurity.saml.config.CredentialConfoig ;
import com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory

SAMLTokenFactory samlFactory =  SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11);

RequesterConfig reqData  =  samlFactory.newSymmetricHolderOfKeyTokenGenerateConfig();

//Map "AppliesTo" to key alias, so library knows how to encrypt the Symmetric Key
reqData.setKeyAliasForAppliesTo("SOAPRecipient");

ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig(IsserUri);

Subject subject =  com.ibm.websphere.security.auth.WSSubject.getRunAsSubject();

SAMLToken samlToken = samlFactory.newSAMLToken(subject, reqData, samlIssuerCfg);
```

Use this sample code to create a SAML version 2.0 holder-of-key token using a public key from the subject:

```
//User expression on how SAML should be created, default provided
RequesterConfig reqData =  samlFactory.newAsymmetricHolderOfKeyTokenGenerateConfig();

//Choose a public key to be included in SAML
reqData.setKeyAliasForRequester("SOAPInitiator");

//Get issuer key store so can sign or encrypt assertion, issuer name
ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("any_issuer");

//Get JAAS Subject so the factory can populate principal and attributes to SAML
Subject subject =  com.ibm.websphere.security.auth.WSSubject.getRunAsSubject();

SAMLToken samlToken = samlFactory.newSAMLToken(subject, reqData, samlIssuerCfg);
```

Use this sample code to create a SAML version 2.0 holder-of-key token using a secret key (symmetric key):

```
SAMLTokenFactory samlFactory =  SAMLTokenFactory.getInstance (SAMLTokenFactory.WssSamlV20Token11);

RequesterConfig reqData = samlFactory. newSymmetricHolderOfKeyTokenGenerateConfig ();
//Map "AppliesTo" to key alias so library knows how to encrypt the Symmetric Key
reqData.setKeyAliasForAppliesTo("SOAPRecipient");

ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig(null);

CredentialConfig cred = samlFactory.newCredentialConfig ();
cred.setRequesterNameID("any_name");

SAMLToken samlToken =  samlFactory.newSAMLToken(subject, reqData, samlIssuerCfg);
```

### *Creating a SAML sender-vouches token using the API:*

Use the SAML library API to create a SAML sender-vouches token, which includes the sender-vouches confirmation method. The sender-vouches confirmation method is used when a server needs to propagate the client identity or behavior of the client.

#### About this task

When SAML function is installed on a WebSphere server, a SAML library API is provided. Use the library to create a SAML sender-vouches token. You can use the SAML library API to create required SAML configuration objects. Then, use those configuration objects to generate a SAML sender-vouches token.

#### Procedure

1. Create a SAMLTokenFactory instance using the SAML token version as a parameter.
   a. Use the following line of code to import the method:

```
import com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory;
```

   b. Use one of these lines of code to create the instance, depending on the token version.
      - Add the following line of code to create a SAMLTokenFactory instance for a version 1.1 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11);
```

      - Add the following line of code to create a SAMLTokenFactory instance for a version 2.0 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token20);
```

2. After you create the instance, the SAMLTokenFactory is used to create a RequesterConfig instance, which determines how the token will be generated, according the authentication requirements of the requester. Use this line of code to create the RequesterConfig instance for the sender-vouches token:

```
RequesterConfig reqData = samlFactory.newSenderVouchesTokenGenerateConfig();
```

   The default RequestConfig instance is sufficient to generate a simple sender-vouches token, but additional assertions can be included in the SAML token by customizing the RequesterConfig instance. For example, to include password authentication information in the token, use the method, setAuthenticationMethod:

```
reqData.setAuthenticationMethod("password");
```

   The trust validation for a sender-vouches assertion is the responsibility of the sender, not the issuer, so the Enveloped-Signature element is not required in the assertion. To remove the Enveloped-Signature element from the SAML assertion, use the setAssertionSignatureRequired method; for example:

```
reqData.setAssertionSignatureRequired(false);
```

3. Use the SAMLTokenFactory API to create a ProviderConfig instance, which describes the token issuer. The ProviderConfig instance specifies the SAML issuer name, as well as keystore and truststore information, which identifies the key for SAML encryption and signing. The ProviderConfig instance is created using property values from a property file. The property file specifies the default value of the ProviderConfig object. In a Java client environment, this property file is defined by a JVM system property, com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath.

In the WebSphere Application Server runtime environment, the property file name is SAMLIssuerConfig.properties. The file can be located either under the server level configuration directory, or the cell level directory, in that order of precedence. See the following example of the server-level path:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/nodes/$NODENAME/servers/$SERVERNAME/SAMLIssuerConfig.properties
```

See the following example of the cell-level path:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/sts/SAMLIssuerConfig.properties
```

The JVM system property, com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath, is ignored if the property is defined in server runtime environment. For a detailed description of all the properties, read about configuration of a SAML token during token creation.

Use the following line of code to create a default ProviderConfig instance:

```
ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("any issuer name");
```

The issuer name is optional. If the issuer name is specified, the Issuer name appears in the SAML assertion. If the issuer name is not specified, a default issuer name property from the SAMLIssuerConfig.properties is used as the issuer name.

4. Optional: When creating a new SAML token, the SAMLTokenFactory uses either a Java Authentication and Authorization Service (JAAS) subject or a CredentialConfig instance to populate the new SAML token. To use a JAAS subject to populate the token, use the com.ibm.websphere.security.auth.WSSubject getCallerSubject() API or the getRunAsSubject() API to obtain a JAAS subject that represents the requesting client, or the identity of the execution thread.
   - When you use the JAAS subject to create a new SAML token, the SAMLTokenFactory API searches for a SAMLToken object in the subject PrivateCredentials list. If a SAMLToken object exists, the NameId or NameIdentifier objects are copied to the new SAML token. The SAMLTokenFactory also copies the SAML attributes and AuthenticationMethod method from the existing SAML token to the new SAML token. The new SAML token includes a new issuer name, new signing certificate, confirmation method, new KeyInfo for the holder-of-key confirmation method, and new NotBefore and NotOnAfter conditions. These token settings are determined by the configuration parameters in the ProviderConfig and RequesterConfig objects.

     If there is no SAMLToken object in the subject, only the WSPrincipal principal name is copied from the subject to the new SAML token. No other attributes in the subject are copied into the new SAML token. Similarly, the issuer name, signing certificate, confirmation method, KeyInfo for the holder-of-key, and NotBefore and NotOnOrAfter conditions are determined by configuration parameters in ProviderConfig and RequesterConfig objects.

     Alternately, you can use the RunAsSubject method on the execution thread to create the SAML token. When using this method, do not pass the JAAS subject or the CredentialConfig object to the SAMLTokenFactory to create the SAML token. Instead, the content of the existing SAML token is copied to the new SAML token, as described previously.
   - Another method of creating a SAML token is to use a CredentialConfig object to populate the SAML NameId and Attributes programmatically. Use this method in the following circumstances:
     – Custom SAML attributes must be included in the new SAML token.
     – The SAML token is created manually instead of using the SAMLTokenFactory to populate the SAML token from a JAAS subject automatically.
     – There is no existing SAML token in the subject.
     – There is no JAAS subject available.

   a. To create a CredentialConfig object without using the JAAS subject, use this line of code:

```
CredentialConfig cred = samlFactory.newCredentialConfig ();
```

      There is no initial value provided for this CredentialConfig object, so you must use setter methods to populate the CredentialConfig object.

   b. To populate the SAML NameIdentifier or NameID, use the following line of code:

```
cred.setRequesterNameID("any name");
```

The value of the parameter passed to the setRequesterNameID() method is used as the principal name in the SAML token. The name appears in the assertion as the NameIdentifier in a SAML Version 1.1 token, or NameId in the SAML Version 2.0 token. For example, if the value of the parameter passed to the setRequesterNameID() method is `Alice`, the following assertion is generated in a SAML Version 1.1 token:

```
<saml:NameIdentifier>Alice</saml:NameIdentifier>
```

The following assertion is generated in a SAML Version 2.0 token:

```
<saml2:NameID>Alice</saml2:NameID>
```

c. To include SAML attributes in the <AttributeStatement> portion of an assertion, use this code:

```
SAMLAttribute samlAttribute = new SAMLAttribute("email" /* Name*/, new String[] {"joe@websphere"}
/*Attribute Values*/, null, "IBM WebSphere namespace" /* namespace*/, "email" /* format*/, "joe" /*friendly name */);
ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
al.add(samlAttribute)
sattribute = new SAMLAttribute("Membership", new String[] {"Super users", "Gold membership"}, null, null /* format*/, null, null );
al.add(samlAttribute );
cred.setSAMLAttributes(al);
```

This sample code generates the following <Attribute> assertions:

```
<saml:Attribute AttributeName="email" NameFormat="email" AttributeNamespace="IBM WebSphere namespace">
<saml:AttributeValue>joe@websphere</saml:AttributeValue>
</saml:Attribute>
<saml:Attribute AttributeName="Membership">
<saml:AttributeValue>Super users</saml:AttributeValue><saml:AttributeValue>Gold membership</saml:AttributeValue>
</saml:Attribute>
```

5. Generate a SAML sender-vouches token using this line of code:

```
SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

This method requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken.

Complete code samples using lines of code from the previous steps are included in the Example section.

### Example

Use this sample code to create a SAML version 1.1 sender-vouches token from the subject:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11)

RequesterConfig reqData = samlFactory.newSenderVouchesTokenGenerateConfig();

ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("WebSphere Server");

Subject subject =  com.ibm.websphere.security.auth.WSSubject.getRunAsSubject();

SAMLToken samlToken = samlFactory.newSAMLToken(subject, reqData, samlIssuerCfg);
```

Use this sample code to create a SAML version 1.1 sender-vouches token without using the subject:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11);

RequesterConfig reqData = samlFactory.newSenderVouchesTokenGenerateConfig();
reqData.setAuthenticationMethod("Password"); //Authentication method for Assertion

ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig(Self issuer);

CredentialConfig cred = samlFactory.newCredentialConfig ();
cred.setRequesterNameID("Alice");   // SAML NameIdentifier
//SAML attributes:
SAMLAttribute attribute = new SAMLAttribute
   ("email" /* Name*/, new String[] {"joe@websphere"}
   /*Attribute Values in String*/,null
   /*Attribute Values in XML */, "WebSphere" /* Namespace*/, "email" /* format*/, "joe" /*Friendly_name */);
ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
al.add(attribute);
attribute = new SAMLAttribute("Membership", new String[] {"Super users", "My team"}, null, null, null, null  );
al.add(attribute);
cred.setSAMLAttributes(al);

SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

### *Propagation of SAML tokens using the API:*

The SAML propagation function is useful for applications that interact across multiple servers. The propagation feature communicates token information from the originating server downstream to other servers.

You can propagate SAML tokens using administrative commands, or programmatically using the SAML application programming interface (API). Propagation through administrative commands is discussed in the topics Propagating SAML tokens and SAML token propagation methods.

Programmatic propagation of SAML tokens is achieved through a combination of explicit programming and use of the Web Services Security runtime environment. For example, you can extract the SAMLToken from the org.apache.axis2.jaxws.BindingProvider object. The token is then used for outbound calls. In this example, since WebSphere security is not required, programmatically propagating the SAML token allows you to exploit SAML security at the application level. Furthermore, the SAML token can be communicated downstream using any protocol.

Use the following sample code to extract the SAMLToken on the client side after the first request is completed.

Create a Dispatch object and invoke the request:

```
javax.xml.ws.Dispatch dispatch = ...;
dispatch.invoke();
```

Obtain a response context and extract the SAMLToken:

```
Map<String, Object> responseContext = dispatch.getResponseContext();
   SAMLToken samlToken =
       (SAMLToken ) responseContext.get(com.ibm.wsspi.wssecurity.saml.config.SamlConstants.
    SAMLTOKEN_OUT_MESSAGECONTEXT);
```

The following sample code shows how to reuse a SAMLToken for subsequent web services requests.

The web services client program creates a dispatch instance to invoke a service:

```
javax.xml.ws.Dispatch dispatch = ...;
```

The web services client then uses this code to pass a SAMLToken to the Web Services Security handler:

```
Map<String, Object> requestContext = dispatch.getRequestContext();
     requestContext.put(com.ibm.wsspi.wssecurity.saml.config.SamlConstants.
     SAMLTOKEN_IN_MESSAGECONTEXT, samlToken);
```

The web services provider (receiver) can use the following code to extract a SAMLToken from an incoming web services request.

Extract a SAMLToken from the requestContext:

```
Subject subject = (Subject) context.get(com.ibm.wsspi.wssecurity.core.Constants.WSSECURITY_TOKEN_WSSSUBJECT);
 SAMLToken samlToken = null;
     try
     {
      samlToken = (SAMLToken) AccessController.doPrivileged(
        new java.security.PrivilegedExceptionAction() {
         public Object run() throws
             java.lang.Exception
         {
          final java.util.Iterator authIterator =
                subject.getPrivateCredentials(SAMLToken.class)
                .iterator();
          if ( authIterator.hasNext() ) {
           final SAMLToken token = (SAMLToken)
                  authIterator.next();

           return token;
          }
          return null;
         }
        });
 } catch (Exception ex) {
  // Error handling
```

Extract the SAML attributes:

```
List<SAMLAttribute> allAttributes;
allAttributes = ((SAMLToken) samlToken).getSAMLAttributes();
```

The web services client runtime environment can cache the SAML token. On subsequent client requests within the application, the security runtime environment retrieves the SAML token from the cache for use with the target.

***Web services client token cache for SAML:***

When a SAML token is initially requested, the web services runtime environment automatically caches the SAMLToken. As a result of this automatic client token caching function, subsequent web services requests can use the SAMLToken from the previous request.

The web services client token cache for SAML enables web services clients to reuse SAML tokens when accessing business services. Reusing valid SAML tokens reduces traffic to the Security Token Service (STS) and also reduces the performance impact of sending WS-Trust request messages. There are several requirements for a token to be considered valid and therefore available for caching and reuse.

In order for a SAML token to be reused, the expiration time of the token must be equivalent to, or greater than, the current time. A cache cushion is added to the current time when comparing the token expiration time with the current time so that the token does not expire immediately after it is sent.

In addition, a token is valid only if it is sent again to the same business service. The SAML function in WebSphere Application Server does not verify the AudienceRestriction condition for the SAML token. Therefore, a practical way to ensure that the SAML token is reused for the right audience is to reuse the token only for the same web service that originally used the token. If an assertion contains the OneTimeUse assertion, the SAML token is not cached.

To take advantage of the SAMLToken cache, the application and SAMLToken must meet the following requirements:

- The SAMLToken must have a relatively long expiration time, with at least 5 minutes remaining in the token lifetime after the first request is completed. The WS-Security runtime environment validates the cached SAMLToken expiration time against a predefined cache cushion. The cached token is valid only if the remaining token lifetime is greater than the cushion value. The default cushion value is 5 minutes. This value can be configured using the custom property, cacheCushion. To override the default cache cushion, edit the CallbackHandler custom property for the SAMLToken generator. Add the cacheCushion property and set the cache cushion value in milliseconds. If the cached SAMLToken lifetime is within the cache cushion limit, a new SAMLToken is requested. For example, you can change the cache cushion to 3 minutes or 180000 milliseconds.

| Custom property name | Value |
|---|---|
| cacheCushion | 180000 |

- The SAML token cannot contain the OneTimeUse assertion.
- If the SAML token is encrypted, make sure that the STS communicates the token expiration time outside the encrypted token, and that the SAML token does not include the OneTimeUse assertion.

When you do not want to reuse the same SAMLToken for subsequent requests, you can disable the client side SAMLToken cache with the cacheToken custom property. To disable the client side SAMLToken cache, modify the custom property in the CallbackHandler for the SAMLToken generator. Add the cacheToken property and set the value to `false`.

| Custom property name | Value |
|---|---|
| cacheToken | false |

## Securing web services applications using the WSS APIs at the message level

Standards and profiles address how to provide protection for messages that are exchanged in a web service environment. Web Services Security is a message-level standard that is based on securing SOAP messages through XML digital signature, confidentiality through XML encryption, and credential propagation through security tokens.

### Before you begin

To secure web services, you must consider a broad set of security requirements, including authentication, authorization, privacy, trust, integrity, confidentiality, secure communications channels, delegation, and auditing across a spectrum of application and business topologies. One of the key requirements for the security model in today's business environment is the ability to interoperate between formerly incompatible security technologies in heterogeneous environments. The complete Web Services Security protocol stack and technology roadmap is described in the web services roadmap.

### About this task

The Organization for the Advancement of Structured Information Standards (OASIS) Web Services Security: SOAP Message Security Version 1.1 specification is the basic messaging transport for all web services. SOAP 1.2 adds extensions to the existing SOAP 1.1 extensions so that you can build secure web services. Attachments can be added to SOAP messages by using Message Transmission Optimization Mechanism (MTOM) and XML-binary Optimized Packaging (XOP) instead of the SOAP with Attachments (SWA) profile.

The OASIS Web Services Security (WS-Security) Version 1.1 specification is the building block that is used in conjunction with other web service and application-specific protocols to accommodate a wide variety of security models. Web Services Security for WebSphere Application Server is based on specific standards that are included in the OASIS Web Services Security Version 1.1 specification and profiles.

The Version 1.1 specification defines additional facilities for protecting the integrity and confidentiality of a message. The Version 1.1 specification also provides the mechanisms for associating security-related claims with the message. The Web Services Security Version 1.1 standards that are supported by WebSphere Application Server include the signature confirmation, encrypted header elements, the Username Token Profile and the X.509 Token Profile. The Username Token Profile and the X.509 Token Profile have been updated as Version 1.1 profiles. For the X.509 Certificate Token Profile, one new type of security token reference is the Thumbprint reference, which is specified in the binding.

XML Schema, Part 1 and Part 2 are specifications that explain how schemas are organized in XML documents. The two WS-Security Version 1.0 schemas have been updated to the Version 1.1 specifications plus a new Version 1.1 schema has been added. Note that the Version 1.1 schema does not replace the Version 1.0 schema but instead builds upon it by defining an additional set of capabilities within a Version 1.1 namespace.

You can use the following methods to configure Web Services Security and to define policy types to secure the SOAP messages:

- **Use the administrative console to configure policy sets.**

  This method uses the bootstrap policy that is defined in the policy set. You can use policy sets, or assertions about how services are defined, to simplify your security configuration for web services. You can use the administrative console to create, modify, and delete custom policy sets. A set of default policy sets are available.

  For example, you can define the bootstrap policy in the policy set to secure the Web Services Trust (WS-Trust) SOAP messages.

You can also use the administrative console to perform policy set management tasks and to secure web services using encryption, signing information, and security tokens.

The following steps high-level steps describe how to configure WebSphere Application Server to use WS-Security and to secure the SOAP messages using the administrative console. The generator and consumer tasks that are discussed in the following steps use WS-Security Versions 1.0 and 1.1.

- Create and configure the application policy sets or the system policy sets for trust service.
- Define the policy types to be used to secure the SOAP messages when creating and configuring the policy sets.
- Configure the policy set binding. Select either the symmetric or asymmetric binding assertion to describe the token type and the algorithm to be used for message protection.
- Assemble your Web Services Security-enabled application by using an assembly tool.

- **Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client)**

  WebSphere Application Server uses a new API programming model. In addition to the existing JAX-RPC programming model, a new programming model, Java API for XML Web Services (JAX-WS), has been added. The JAX-WS programming standard aligns with the document-centric messaging model and replaces the remote procedure call programming model defined by the Java API for XML-based RPC (JAX-RPC) specification.

  For example, an application could create system policy sets and then use the WebSphere Application Server WSS API to acquire the security context token for programmatic API-based Web Services Secure Conversation (WS-SecureConversation).

  You can also use the administrative console to perform the encryption, signing, and token configuration tasks that the WSS APIs perform to secure web services.

  The following high-level steps describe how to configure WebSphere Application Server to use WS-Security and to secure the SOAP messages using the WSS APIs. The generator and consumer tasks that are discussed in the following steps use WS-Security Versions 1.0 and 1.1.

  - Use the WSSSignature API to configure the signing information for the request generator (client side) binding.

    Different message parts can be specified in the message protection for a request on the generator side. The default required parts are BODY, ADDRESSING_HEADERS and TIMESTAMP.

    The WSSSignature API also specifies the different algorithm methods to be used with the signature for message protection. The default signature method is RSA_SHA1. The default canonicalization method is EXC_C14N.
  - Use the WSSSignPart API if you want to change the digest method and the transform method.

    The default signed parts are WSSSignature.BODY, WSSSignature.ADDRESSING_HEADERS and WSSSignature.TIMESTAMP.

    The WSSSignPart API also specifies the different algorithm methods to be used if you added or changed the signed parts. The default digest method is SHA1. The default transform method is TRANSFORM_EXC_C14N. For example, use the WSSSignPart API if you want to generate the signature for the SOAP message using the SHA256 digest method instead of the default value of SHA1.
  - Use the WSSEncryption API to configure the encryption information on the request generator side.

    The encryption information on the generator side is used for encrypting an outgoing SOAP message for the request generator (client side) bindings. The default targets of encryption are BODY_CONTENT and SIGNATURE.

    The WSSEncryption API also specifies the different algorithm methods to be used to protect message confidentiality. The default data encryption method is AES128. The default key encryption method is KW_RSA_OAEP.
  - Use the WSSEncryptPart API if you want to set the transform method only.

    For example, if you want to change the data encryption method from the default value of AES128 to TRIPLE_DES.

No algorithm methods are required for encrypted parts.

– Use the WSS API to configure the token on the generator side.

  The requirements for the security token depend on the token type. The JAAS Login Module and the JAAS CallbackHandler are responsible for creating the security token on the generator side. Different stand-alone tokens can be sent in request and response. The default token is the X509Token. The other token that can be used for signing is the DerivedKeyToken, which is used only with Web Services Secure Conversation (WS-SecureConversation).

– Use the WSSVerification API to verify the signature for the response consumer (client side) binding.

  Different message parts can be specified in the message protection for a response on the consumer side. The required targets for verification are BODY, ADDRESSING_HEADERS and TIMESTAMP.

  The WSSVerification API also specifies the different algorithm methods to be used for verifying the signature and for message protection. The default signature method is RSA_SHA1. The default canonicalization method is EXC_C14N.

– Use the WSSVerifyPart API to change the digest method and the transform method. The required verify parts are WSSVerification.BODY, WSSVerification.ADDRESSING_HEADERS and WSSVerification.TIMESTAMP.

  The WSSVerifyPart API also specifies the different algorithm methods to be used if you added or changed the verification parts. The default digest method is SHA1. The default transform method is TRANSFORM_EXC_C14N.

– Use the WSSDecryption API to configure the decryption information for the response consumer (client side) binding.

  The decryption information on the consumer side is used for decrypting an incoming SOAP message. The targets of decryption are BODY_CONTENT and SIGNATURE. The default key encryption method is KW_RSA_OAEP.

  No algorithm methods are required for decryption.

– Use the WSSDecryptPart API if you want to set the transform method only.

  For example, if you want to change the data encryption method from the default value of AES128 to TRIPLE_DES.

  No algorithm methods are required for decrypted parts.

– Use the WSS API to configure the token on the consumer side.

  The requirements for the security token depend on the token type. The JAAS Login Module and the JAAS CallbackHandler are responsible for validating (authenticating) the security token on the consumer side. Different stand-alone tokens can be sent in request or response.

  The WSS API adds the information for the candidate token that is used for decryption. The default token is X509Token.

- **Use the wsadmin administrative scripting tool to configure policy sets.**

  This method allows you to create, manage, and delete policy sets from the command-line or to create scripts to automate your tasks. You can use the wsadmin tool and the PolicySetManagement command group to manage default policy sets, create custom policy sets, configure policies, and manage attachments and bindings. For more information, use the policy set scripting topics in the information center.

To secure web services with WebSphere Application Server, you must configure the generator and the consumer security constraints. You must specify several different configurations. Although there is no specific sequence to specify these different configurations, some configurations reference other configurations. For example, decryption configurations reference encryption configurations.

## Results

After completing these high-level steps for WebSphere Application Server, you have secured web services by configuring policy sets and by using the WSS API to configure encryption and decryption, the signature

and signature verification information, and the consumer and generator tokens.

***Securing messages at the request generator using WSS APIs:***

You can secure SOAP messages by configuring signing information, encryption, and generator tokens to protect message integrity, confidentiality, and authenticity, respectively. This request (client-side) generator configuration defines the Web Services Security requirements for the outgoing SOAP message request.

**Before you begin**

To secure web services with WebSphere Application Server, you must configure the generator and the consumer security constraints. Therefore, in addition to securing messages at the request generator level, you must also secure messages at the response consumer level.

**About this task**

The request (client-side) generator configuration requirements involve generating a SOAP message request that uses a digital signature, incorporates encryption, and attaches security tokens.

To secure web service applications, you must specify several different configurations. Although there is no specific sequence to specify these different configurations, some configurations reference other configurations. For example, decryption configurations reference encryption configurations.

You can use the following interfaces to configure Web Services Security and to define policy types to secure the SOAP messages:

- Use the administrative console to configure policy sets.
- Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client)

The following high-level steps use the WSS APIs:

**Procedure**

- Configure generator signing to protect message integrity.
- Configure encryption to protect message confidentiality.
- Attach generator tokens to protect message authenticity.
- Propagate self-issued SAML bearer tokens using WSS APIs.
- Propagate self-issued SAML sender-vouches tokens with message protection using WSS APIs.
- Propagate self-issued SAML sender-vouches tokens with transport protection using WSS APIs.
- “Sending self-issued SAML holder-of-key tokens with symmetric key using WSS APIs” on page 1929.
- “Sending self-issued SAML holder-of-key tokens with asymmetric key using WSS APIs” on page 1931.

**Results**

After completing these procedures, you have secured messages at the request generator level.

**What to do next**

Next, if not already configured, secure messages with signature verification, decryption, and consumer tokens at the response consumer (client-side) level.

*Configuring encryption to protect message confidentiality using the WSS APIs:*

You can configure encryption information for the client-side request generator (sender) bindings. Encryption information is used to specify how the generators (senders) encrypt outgoing SOAP messages. To configure encryption, specify which message parts to encrypt and specify which algorithm methods and security tokens are to be used for encryption.

### Before you begin

Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone understanding the message flowing across the Internet. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the correct target. Prior to configuring encryption, familiarize yourself with XML encryption.

### About this task

For encryption, you must specify the following:

- Which parts of the message are to be encrypted.
- Which encryption algorithms to specify.

To configure encryption and encrypted parts on the client side, use the WSSEncryption and WSSEncryptPart APIs, or configure policy sets using the administrative console.

WebSphere Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

WebSphere Application Server uses encryption information for the default generator to encrypt parts of the SOAP message. The WSSEncryption API configures the following required parts as encrypted parts.

*Table 244. Required encrypted parts. Use encrypted parts to increase the confidentiality of SOAP messages.*

| Encryption parts | Description |
|---|---|
| Keywords | Keywords are used to add the encrypted parts to the SOAP message. |
| XPath expression | An XPath expression is used to add the encrypted parts to the SOAP message. |
| WSSEncryptPart object | This object adds the encrypted parts to the SOAP message. |
| WSSSignature object | This object adds the signature component as an encrypted part. |
| Header | This part adds the header in the SOAP header, specified by QName, as an encryption part. |
| Security token object | This object adds the security token as an encryption part. |

Web Services Security API (WSS API) supports symmetric encryption, by using a shared key, only when Web Services Secure Conversation (WS-SecureConversation) is used.

The WSS APIs allow the use of either keywords or an XPath expression to specify the parts of the message that are to be encrypted. WebSphere Application Server supports the use of the following keywords:

*Table 245. Supported encryption keywords. Use keywords to specify encrypted parts.*

| Keyword | References |
|---|---|
| BODY_CONTENT | The keyword for the contents of the SOAP message body as an encryption target. |
| SIGNATURE | The keyword for the signature component as an encryption target. |

If configuring using the WSS APIs, the WSSEncryption and WSSEncryptPart APIs complete these high-level steps:

### Procedure

1. Use the WSSEncryption API to configure encryption. The WSSEncryption API performs these tasks by default:

a. Generates the callback handler.
b. Generates the generator security token object.
c. Adds the security token reference type.
d. Adds the signature component.
e. Adds the WSSEncryptPart object.
f. Adds the parts to be encrypted. Adds the default parts as targets of encryption by using keywords and XPath expressions.
g. Adds the header in the SOAP message, specified by QName.
h. Sets the default data encryption method.
i. Specifies whether the key is to be encrypted using a Boolean value.
j. Sets the default key encryption method.
k. Selects a part reference.
l. Sets the MTOM optimization Boolean value.

2. Use the WSSEncryptPart API to configure encrypted parts or add a transform method. The WSSEncryptPart API performs these tasks by default:
   a. Sets the encrypted parts specified by using keywords or an XPath expression.
   b. Sets the encrypted parts specified by an XPath expression.
   c. Sets the signature component object, WSSSignature.
   d. Sets the header in the SOAP message, specified by QName.
   e. Sets the generator security token.
   f. Adds the transform method, if needed.
3. Change from the default values for algorithm or message parts, as needed. For example: you could change one or more of the following items:
   - Change the data encryption algorithm from the default value of AES 128.
   - Change the key encryption algorithm from the default value of KW_RSA_OAEP.
   - Specify to not encrypt the key (false).
   - Change the security token type from default of X.509 token.
   - Change the security token reference type from the default value of SecurityToken.REF_STR.
   - Only use BODY_CONTENT as an encryption part and not use SIGNATURE also.
   - Turn MTOM optimization on (true).

### Results

The encryption information is configured for the generator binding.

### Example

The following is an example of the WSSEncryption API:

```
WSSFactory factory = WSSFactory.getInstance();
WSSGenerationContext gencont = factory.newWSSGenerationContext();

X509GenerateCallbackHandler callbackhandler = generateCallbackHandler();
SecurityToken token = factory.newSecurityToken(X509Token.class, callbackHandler);
WSSEncryption enc = factory.newWSSEncryption(token);

gencont.add(enc);
```

### What to do next

You must configure similar decryption information for the client-side response consumer (receiver) bindings, if you have not already configured the information.

Next, review the WSSEncryption API process.

*Encrypting the SOAP message using the WSSEncryption API:*

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure the client for request encryption on the generator side, use the WSSEncryption API to encrypt the SOAP message. The WSSEncryption API specifies which request SOAP message parts to encrypt when configuring the client.

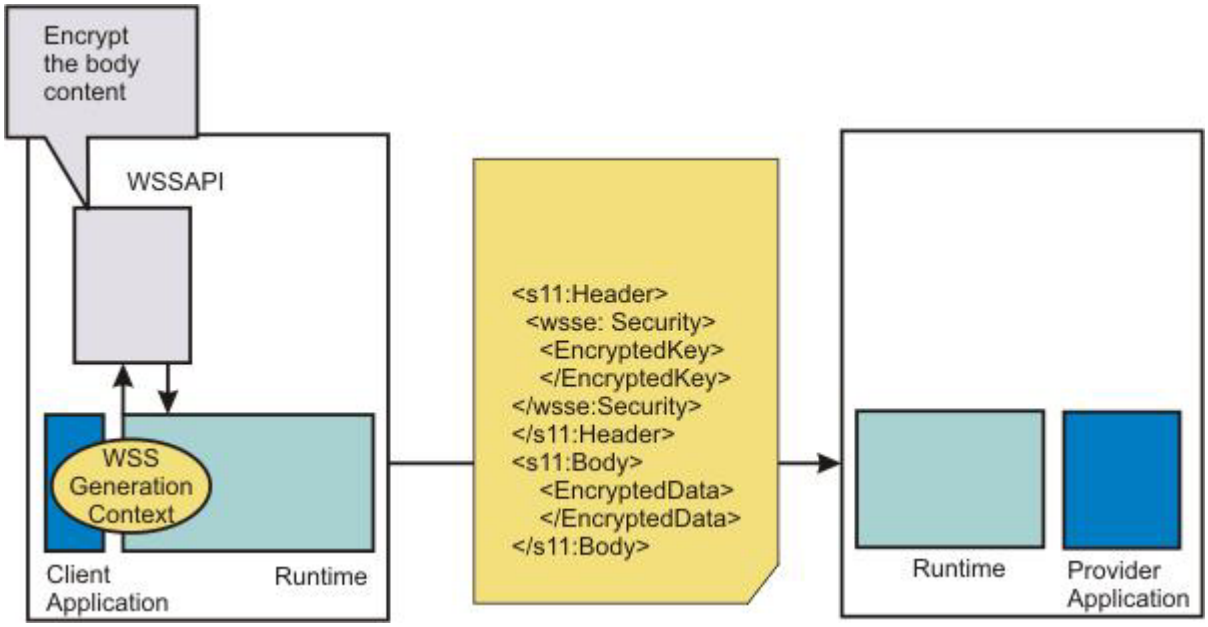
**Before you begin**

You can use the WSS API or use policy sets on the administrative console to enable encryption and add generator security tokens in the SOAP message. To secure SOAP messages, use the WSS APIs to complete the following encryption tasks, as needed:

- Configure encryption and choose the encryption methods using the WSSEncryption API.
- Configure the encrypted parts, as needed, using the WSSEncryptPart API.

**About this task**

The encryption information on the generator side is used for encrypting an outgoing SOAP message for the request generator (client side) bindings. The client generator configuration must match the configuration for the provider consumer.



Confidentiality settings require that confidentiality constraints be applied to generated messages. These constraints include specifying which message parts within the generated message must be encrypted, and which message parts to attach encrypted Nonce and timestamp elements to.

The following encryption parts can be configured:

*Table 246. Encryption parts. Use the encryption parts to enable encryption in messages.*

| Encryption parts | Description |
|---|---|
| part | Adds the WSSEncryptPart object as a target of the encryption part. |

*Table 246. Encryption parts (continued). Use the encryption parts to enable encryption in messages.*

| Encryption parts | Description |
|---|---|
| keyword | Adds the encryption parts using keywords. WebSphere Application Server supports the following keywords:<br>• BODY_CONTENT<br>• SIGNATURE |
| xpath | Adds the encryption part using an XPath expression. |
| signature | Adds the WSSignature component as a target of the encrypted part. |
| header | Adds the SOAP header, specified by QName, as a target of the encrypted part. |
| securityToken | Adds the SecurityToken object as a target of the encrypted part. |

For encryption, certain default behaviors occur. The simplest way to use the WSSEncryption API is to use the default behavior (see the example code).

WSSEncryption provides defaults for the key encryption algorithm, the data encryption algorithm, the security token reference method, and the encryption parts such as the SOAP body content and the signature. The encryption default behaviors include:

*Table 247. Encryption decisions. Use encryption default behavior to secure the message body content and signature.*

| Encryption decisions | Default behavior |
|---|---|
| Which SOAP message parts to encrypt using keywords | Sets the encryption parts that you can add using keywords. The default encryption parts are the BODY_CONTENT and SIGNATURE. WebSphere Application Server supports using these keywords:<br>• WSSEncryption.BODY_CONTENT<br>• WSSEncryption.SIGNATURE |
| Which data encryption method to choose (algorithm) | Sets the data encryption method. Both data and key encryption methods can be specified. The default data encryption algorithm method is AES 128. WebSphere Application Server supports these data encryption methods:<br>• WSSEncryption.AES128: http://www.w3.org/2001/04/xmlenc#aes128-cbc<br>• WSSEncryption.AES192: http://www.w3.org/2001/04/xmlenc#aes192-cbc<br>• WSSEncryption.AES256: http://www.w3.org/2001/04/xmlenc#aes256-cbc<br>• WSSEncryption.TRIPLE_DES: http://www.w3.org.2001/04/xmlenc#tripledes-cbc |
| Whether to encrypt the key (isEncrypt) | Specifies whether to encrypt the key. The values are `true` or `false`. The default value is to encrypt the key (`true`). |
| Which key encryption method to choose (algorithm) | Sets the key encryption method. Both data and key encryption methods can be specified. The default key encryption algorithm method is key wrap RSA OAEP. WebSphere Application Server supports these key encryption methods:<br>• WSSEncryption.KW_AES128: http://www.w3.org/2001/04/xmlenc#kw-aes128<br>• WSSEncryption.KW_AES192: http://www.w3.org/2001/04/xmlenc#kw-aes192<br>• WSSEncryption.KW_AES256: http://www.w3.org/2001/04/xmlenc#kw-aes256<br>• WSSEncryption.KW_RSA_OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p<br>• WSSEncryption.KW_RSA15: http://www.w3.org/2001/04/xmlenc#rsa-1_5<br>• WSSEncryption.KW_TRIPLE_DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes |
| Which security token to specify (securityToken) | Sets the SecurityToken. The default security token type is the X509Token. WebSphere Application Server provides the following pre-configured consumer token types:<br>• Derived key token<br>• X.509 tokens |
| Which token reference to use (refType) | Sets the type of the security token reference. The default token reference is SecurityToken.REF_KEYID. WebSphere Application Server supports the following token reference types:<br>• SecurityToken.REF_KEYID<br>• SecurityToken.REF_STR<br>• SecurityToken.REF_EMBEDDED<br>• SecurityToken.REF_THUMBPRINT |
| Whether to use MTOM (mtomOptimize) | Sets Message Transmission Optimization Mechanism (MTOM) optimization for the encrypted part. |

## Procedure

1. To encrypt the SOAP message using the WSSEncryption API, first ensure that the application server is installed.

2. The WSS API process for encryption performs these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance
   b. Creates the WSSGenerationContext instance from the WSSFactory instance.
   c. Creates the SecurityToken from WSSFactory used for encryption.
   d. Creates WSSEncryption from the WSSFactory instance using the SecurityToken. The default behavior of WSSEncryption is to encrypt the body content and the signature.
   e. Adds a new part to be encrypted in WSSEncryption if the existing part is not appropriate. After addEncryptPart(), addEncryptHeader(), or addEncryptPartByXPath() is called, the default part is cleared.
   f. Calls the encryptKey(false) if the key is not to be encrypted.
   g. Sets the data encryption method if the default method is not appropriate.
   h. Sets the key encryption method if the default method is not appropriate.
   i. Sets the token reference if the default token reference is not appropriate.
   j. Adds WSSEncryption to WSSConsumingContext.
   k. Calls WSSGenerationContext.process() with the SOAPMessageContext.

### Results

If there is an error condition during encryption, a WSSException is provided. If successful, the API calls the WSSGenerationContext.process(), the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

### Example

The following example provides sample code using methods that are defined in WSSEncryption:

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance (step: a)
WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSGenerationContext instance (step: b)
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate the callback handler
X509GenerateCallbackHandler callbackHandler = new
         X509GenerateCallbackHandler(
     "",
     "enc-sender.jceks",
     "jceks",
     "storepass".toCharArray(),
     "bob",
     null,
     "CN=Bob, O=IBM, C=US",
     null);

// Generate the security token used for encryption (step: c)
SecurityToken token = factory.newSecurityToken(X509Token.class , callbackHandler);

// Generate WSSEncryption instance (step: d)
WSSEncryption enc = factory.newWSSEncryption(token);

// Set the part to be encrypted (step: e)
// DEFAULT: WSSEncryption.BODY_CONTENT and WSSEncryption.SIGNATURE

// Set the part specified by the keyword (step: e)
   enc.addEncryptPart(WSSEncryption.BODY_CONTENT);

// Set the part in the SOAP Header specified by QName (step: e)
   enc.addEncryptHeader(new QName("http://www.w3.org/2005/08/addressing",
                                  "MessageID"));

// Set the part specified by WSSSignature (step: e)
   SecurityToken sigToken = getSecurityToken();
      WSSSignature sig = factory.newWSSSignature(sigToken);
   enc.addEncryptPart(sig);

// Set the part specified by SecurityToken (step: e)
   UNTGenerateCallbackHandler untCallbackHandler =
          new UNTGenerateCallbackHandler("Chris", "sirhC");
```

```
      SecurityToken unt = factory.newSecurityToken(UsernameToken.class,
                                                   untCallbackHandler);
   enc.addEncryptPart(unt, false);

// sSt the part specified by XPath expression (step: e)
   StringBuffer sb = new StringBuffer();
      sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
         and local-name()='Envelope']");
      sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
         and local-name()='Body']");
      sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
         and local-name()='Ping']");
      sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
         and local-name()='Text']");
   enc.addEncryptPartByXPath(sb.toString());

// Set whether the key is encrypted (step: f)
// DEFAULT: true
   enc.encryptKey(true);

// Set the data encryption method (step: g)
// DEFAULT: WSSEncryption.AES128
   enc.setEncryptionMethod(WSSEncryption.TRIPLE_DES);

// Set the key encryption method (step: h)
// DEFAULT: WSSEncryption.KW_RSA_OAEP
   enc.setEncryptionMethod(WSSEncryption.KW_RSA15);

// Set the token reference (step: i)
// DEFAULT: SecurityToken.REF_KEYID
  enc.setTokenReference(SecurityToken.REF_STR);

// Add the WSSEncryption to the WSSGenerationContext (step: j)
  gencont.add(enc);

// Process the WS-Security header (step: k)
gencont.process(msgcontext);
```

**Note:** The X509GenerationCallbackHandler does not need the key password because the public key is used for encryption. You do not need a password to obtain the public key from the Java keystore.

### What to do next

If you have not previously specified which encryption methods to choose, use the WSS API or configure the policy sets using the administrative console to choose the data and key encryption algorithm methods.

*Choosing encryption methods for generator bindings:*

To configure the client for request encryption for the generator binding, you must specify which encryption methods to use when the client encrypts the SOAP messages.

### Before you begin

Prior to completing these steps, read the XML encryption information to become familiar with encrypting and decrypting SOAP messages.

To specify which algorithm methods are to be used when the client encrypts the SOAP messages, complete the following tasks:

- Use the WSSEncryption API to configure the data encryption algorithm and the key encryption algorithm methods.
- Use the WSSEncryptPart API to configure a transform algorithm method, if needed. The default is no transform algorithm.

### About this task

Some of the encryption-related definitions are based on the XML-Encryption specification. The following information defines some data encryption-related terms:

**Data encryption method algorithm**

Data encryption algorithms specify the algorithm uniform resource identifier (URI) of the data encryption method. This algorithm encrypts and decrypts data in fixed size, multiple octet blocks.

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files.

For the AES256-cbc and the AES192-cbc algorithms, you must download the unrestricted Java™ Cryptography Extension (JCE) policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

**Key encryption method algorithm**

Key encryption algorithms specify the algorithm uniform resource identifier (URI) of the method to encrypt the key that is used to encrypt data. The algorithm represents public key encryption algorithms that are specified for encrypting and decrypting keys.

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property.

The property name is: com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod. The property value is one of the following URIs of the digest method:

- http://www.w3.org/2001/04/xmlenc#sha256
- http://www.w3.org/2001/04/xmlenc#sha512

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

**Important:** You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.

For the KW-AES256 and the KW-AES192 key encryption algorithms, you must download the unrestricted JCE policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

**Important:** Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

*Table 248. Encryption usage types. The encryption usage types describe encryptions methods.*

| Usage types | Description |
|---|---|
| Data encryption | Specifies the algorithm URI that is used for both encrypting and decrypting data. Encrypts and decrypts data in fixed size, multiple octet blocks. |
| Key encryption | Specifies the algorithm URI that is used for encrypting and decrypting the encryption key. |

**Data encryption**

WebSphere Application Server supports the following pre-configured data encryption algorithms:

*Table 249. Data encryption algorithms. These pre-configuring encryption algorithms are supported by WebSphere Application Server.*

| Data encryption name | Algorithm URI |
|---|---|
| WSSEncryption.AES128 (the default value) | A URI of data encryption algorithm, AES 128: http://www.w3.org/2001/04/xmlenc#aes128-cbc |
| WSSEncryption.AES192 | A URI of data encryption algorithm, AES 192: http://www.w3.org/2001/04/xmlenc#aes192-cbc |
| WSSEncryption.AES256 | A URI of data encryption algorithm, AES 256: http://www.w3.org/2001/04/xmlenc#aes256-cbc |
| WSSEncryption.TRIPLE_DES | A URI of data encryption algorithm, 3DES: http://www.w3.org.2001/04/xmlenc#tripledes-cbc |

### Key encryption

WebSphere Application Server supports the following pre-configured key encryption algorithms:

*Table 250. Key encryption algorithms. These pre-configured encryption algorithms are supported by WebSphere Application Server.*

| Key encryption name | Algorithm URI |
|---|---|
| WSSEncryption.KW_AES128 | A URI of key encryption algorithm, key wrap AES 128: http://www.w3.org/2001/04/xmlenc#kw-aes128 |
| WSSEncryption.KW_AES192 | A URI of key encryption algorithm, key wrap AES 192: http://www.w3.org/2001/04/xmlenc#kw-aes192<br>**Restriction:** Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP). |
| WSSEncryption.KW_AES256 | A URI of key encryption algorithm, key wrap AES 256: http://www.w3.org/2001/04/xmlenc#kw-aes256 |
| WSSEncryption.KW_RSA_OAEP (the default value) | A URI of key encryption algorithm, key wrap RSA OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p |
| WSSEncryption.KW_RSA15 | A URI of key encryption algorithm, key wrap RSA 1.5: http://www.w3.org/2001/04/xmlenc#rsa-1_5 |
| WSSEncryption.KW_TRIPLE_DES | http://www.w3.org/2001/04/xmlenc#kw-tripledes |

To configure the encryption and encrypted part algorithm methods, use the WSSEncryption API, or configure policy sets using the administrative console.

**Note:** Policy sets do not support symmetric key encryption. If you are using the WSS API for symmetric key encryption, you will not be able to interoperate with web services endpoints that use policy sets.

The WSS API process completes the following high-level steps to specify which encryption methods to use when configuring the client for request encryption:

### Procedure

1. Using the WSSEncryption API, adds the required data encryption algorithm. The data encryption algorithm is used for encrypting or decrypting parts of a SOAP message. Data encryption algorithms specify the algorithm uniform resource identifier (URI) of the data encryption method.

   The client generator configuration must match the configuration for the provider consumer.

   The default data encryption algorithm is AES 128. The data encryption name is AES128, and the URI of the data encryption algorithm, is http://www.w3.org/2001/04/xmlenc#aes128-cbc. WebSphere Application Server supports the following pre-configured data encryption algorithms:

   - AES 128: http://www.w3.org/2001/04/xmlenc#aes128-cbc

     The AES 128 algorithm is the default data algorithm method.
   - AES 192: http://www.w3.org/2001/04/xmlenc#aes192-cbc

     Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

     To use this AES 192-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

- AES 256: http://www.w3.org/2001/04/xmlenc#aes256-cbc

  To use this AES 256-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
- TRIPLEDES: http://www.w3.org/2001/04/xmlenc#tripledes-cbc

2. As needed, changes the WSSEncryption API method to specify another data encryption algorithm. For example, you might add the following code to change from the default AES 128 algorithm to the Triple DES algorithm:

```
// Default data encryption algorithm: AES128
WSSEncryption enc = factory.newWSSEncryption(x509t);
   enc.setEncryptionMethod(EncryptionMethod.TRIPLEDES_CBC);
gencont.add(enc);
```

3. Using the WSSEncryption API, adds the required key encryption algorithm. The key encryption algorithm is used for encrypting the key that is used for encrypting the message parts within the SOAP message. If the encryption key, which is the key that is used for encrypting the message parts, is not encrypted, then the decryption API selects `false` to match the encryption key.

   The client generator configuration must match the configuration for the provider consumer.

   The default key encryption algorithm value is key wrap RSA OAP. The key encryption name is KW_RSA_OAEP, and the URI of the key encryption algorithm is http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p. WebSphere Application Server supports the following pre-configured key encryption algorithms:

   - KW AES128: http://www.w3.org/2001/04/xmlenc#kw-aes128
   - KW AES192: http://www.w3.org/2001/04/xmlenc#kw-aes192

     To use this key wrap AES 192 algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

     Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).KW AES 256: http://www.w3.org/2001/04/xmlenc#kw-aes256

     To use this key wrap AES 256-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
   - KW RSA OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p.

     The KW RSA OAEP algorithm is the default key algorithm method.

     When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms does not include this algorithm. This algorithm appears in the list of supported key transport algorithms when running with SDK Version 1.5. See more information at http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p
   - KW RSA15: http://www.w3.org/2001/04/xmlenc#rsa-1_5
   - KW TRIPLE DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes

   **Note:** For Web Services Secure Conversation, the WSSEncryption API might specify addition key-related information, such as the:
   - algorithmName
   - keyLength

### Results

If there is an error condition, a WSSException is provided. If successful, the API calls the WSSGenerationContext.process(), the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

### Example

The following example provides sample WSS API code using WSSEncryption.setEncryptionMethod() and WSSEncryption.setKeyEncryptionMethod().

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance
   WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSGenerationContext instance
   WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate callback handler
   X509GenerateCallbackHandler callbackHandler = new
       X509GenerateCallbackHandler(
                                   "",
                                   "enc-sender.jceks",
                                   "jceks",
                                   "storepass".toCharArray(),
                                   "bob",
                                   null,
                                   "CN=Bob, O=IBM, C=US",
                                   null);

// Generate the security token used for encryption
   SecurityToken token = factory.newSecurityToken(X509Token.class , callbackHandler);

// Generate WSSEncryption instance
   WSSEncryption enc = factory.newWSSEncryption(token);

// Set the data encryption method
// DEFAULT: WSSEncryption.AES128
      enc.setEncryptionMethod(WSSEncryption.TRIPLE_DES);

// Set the key encryption method
// DEFAULT: WSSEncryption.KW_RSA_OAEP
      enc.setEncryptionMethod(WSSEncryption.KW_RSA15);

// Add the WSSEncryption to the WSSGenerationContext
   gencont.add(enc);

// Generate the WS-Security header
gencont.process(msgcontext);
```

### What to do next

Next, if you want to add a transform algorithm, review the WSSEncryptPart API process task.

*Encryption methods:*

For request generator binding settings, the encryption methods include specifying the data and key encryption algorithms to use to encrypt the SOAP message. The WSS API for encryption (WSSEncryption) specifies the algorithm name and the matching algorithm uniform resource identifier (URI) for the data and key encryption methods. If the data and key encryption algorithms are specified, only elements that are encrypted with those algorithms are accepted.

### Data encryption algorithms

The data encryption algorithm is used to encrypt parts of the SOAP message, including the body and the signature. Data encryption algorithms specify the algorithm uniform resource identifier (URI) for each type of data encryption algorithms.

The following pre-configured data encryption algorithms are supported:

*Table 251. Data encryption algorithms. The algorithms are used to encrypt SOAP messages.*

| Data encryption algorithm name | Algorithm URI |
|---|---|
| WSSEncryption.AES128 (the default value) | A URI of data encryption algorithm, AES 128: http://www.w3.org/2001/04/xmlenc#aes128-cbc |
| WSSEncryption.AES192 | A URI of data encryption algorithm, AES 192: http://www.w3.org/2001/04/xmlenc#aes192-cbc |

*Table 251. Data encryption algorithms (continued). The algorithms are used to encrypt SOAP messages.*

| Data encryption algorithm name | Algorithm URI |
|---|---|
| WSSEncryption.AES256 | A URI of data encryption algorithm, AES 256: http://www.w3.org/2001/04/xmlenc#aes256-cbc |
| WSSEncryption.TRIPLE_DES | A URI of data encryption algorithm, TRIPLE DES: http://www.w3.org/2001/04/xmlenc#tripledes-cbc |

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files.

**Important:** Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

For the AES256-cbc and the AES192-CBC algorithms, you must download the unrestricted Java™ Cryptography Extension (JCE) policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

The data encryption algorithm configured for encryption for the generator side must match the data encryption algorithm that is configured for decryption for the consumer side.

### Key encryption algorithms

This algorithm is used to encrypt and decrypt keys. This key information is used to specify the configuration that is needed to generate the key for digital signature and encryption. The signing information and encryption information configurations can share the key information. The key information on the consumer side is used for specifying the information about the key that is used for validating the digital signature in the received message or for decrypting the encrypted parts of the message. The request generator is configured for the client.

**Note:** Policy sets do not support symmetric key encryption. If you are using the WSS API for symmetric key encryption, you will not be able to interoperate with web services endpoints using the policy sets.

Key encryption algorithms specify the algorithm uniform resource identifier (URI) of the key encryption method. The following pre-configured key encryption algorithms are supported:

*Table 252. Supported pre-configured key encryption algorithms. The algorithms are used to encrypt and decrypt keys.*

| WSS API | URI |
|---|---|
| WSSEncryption.KW_AES128 | A URI of key encryption algorithm, key wrap AES 128: http://www.w3.org/2001/04/xmlenc#kw-aes128 |
| WSSEncryption.KW_AES192 | A URI of key encryption algorithm, key wrap AES 192: http://www.w3.org/2001/04/xmlenc#kw-aes192<br>**Restriction:** Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP). |
| WSSEncryption.KW_AES256 | A URI of key encryption algorithm, key wrap AES 256: http://www.w3.org/2001/04/xmlenc#kw-aes256 |
| WSSEncryption.KW_RSA_OAEP (the default value) | A URI of key encryption algorithm, key wrap RSA OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p |
| WSSEncryption.KW_RSA15 | A URI of key encryption algorithm, key wrap RSA 1.5: http://www.w3.org/2001/04/xmlenc#rsa-1_5 |
| WSSEncryption.KW_TRIPLE_DES | A URI of key encryption algorithm, key wrap TRIPLE DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes |

For Secure Conversation, additional key-related information must be specified, such as:

- algorithmName
- keyLength

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. The property name is: `com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod`. The property value is one of the following URIs of the digest method:

- http://www.w3.org/2001/04/xmlenc#sha256
- http://www.w3.org/2001/04/xmlenc#sha512

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

**Important:** You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.

For the KW-AES256 and the KW-AES192 key encryption algorithms, you must download the unrestricted JCE policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

The key encryption algorithm for the generator must match the key decryption algorithm that is configured for the consumer.

This example provides sample code for encryption to use the Triple DES for the data encryption method and to use RSA1.5 for the key encryption method:

```
// get the message context
Object msgcontext = getMessageContext();

// generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

// generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// generate callback handler
X509GenerateCallbackHandler callbackHandler = new X509GenerateCallbackHandler(
  "",
  "enc-sender.jceks",
  "jceks",
  "storepass".toCharArray(),
  "bob",
  null,
  "CN=Bob, O=IBM, C=US",
  null);

// generate the security token used to the encryption
SecurityToken token = factory.newSecurityToken(X509Token.class,
     callbackHandler);

// generate WSSEncryption instance to encrypt the SOAP body content
WSSEncryption enc = factory.newWSSEncryption(token);
enc.addEncryptPart(WSSEncryption.BODY_CONTENT);

// set the data encryption method
// DEFAULT: WSSEncryption.AES128
enc.setEncryptionMethod(WSSEncryption.TRIPLE_DES);

// set the key encryption method
// DEFAULT: WSSEncryption.KW_RSA_OAEP
enc.setEncryptionMethod(WSSEncryption.KW_RSA15);

// add the WSSEncryption to the WSSGenerationContext
gencont.add(enc);

// generate the WS-Security header
gencont.process(msgcontext);
```

*Adding encrypted parts using the WSSEncryptPart API:*

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure encrypted parts for the request generator (client side) bindings, use the WSSEncryptPart API to define and add to the listing of elements in the encrypted part. WSSEncryptPart is an interface that is part of the com.ibm.websphere.wssecurity.wssapi.encryption package.

**Before you begin**

You can use the WSS APIs or configure policy sets using the administrative console to enable the encrypted parts. To secure SOAP messages, use the WSS APIs to complete the following encryption tasks, as needed:

- Configure encryption and choose the encryption methods using the WSSEncryption API.
- Configure the encrypted parts using the WSSEncryptpart API, as needed.

**About this task**

Confidentiality settings require that confidentiality constraints be applied to generated messages. These constraints include specifying which message parts within the generated message must be encrypted, and which message parts to attach encrypted elements to. The encryption information on the generator side is used for encrypting an outgoing SOAP message. The request generator is configured for the client.

The WSSEncryptPart API specifies information related to encrypted parts and sets the encrypted parts that have been added for message confidentiality protection. Use the WSSEncryptPart to set the transform method and to specify the part to which the transform method is to be applied. Sets the transform method only if using SOAP with Attachments. The WSSEncryptPart is usually not needed except, in some case for tasks such as setting the transform method.

The encrypted parts and related information displayed in the following table are used to protect the confidentiality of messages.

*Table 253. Encrypted parts. Use encrypted parts to secure messages.*

| Encrypted parts | Description |
|---|---|
| part | Adds the WSSEncryptPart object as a target of the encryption part. |
| keyword | Adds the encrypted parts using keywords. The default encryption parts that you can add using keywords are the BODY_CONTENT and SIGNATURE. WebSphere Application Server supports using these keywords:<br>• BODY_CONTENT<br>• SIGNATURE |
| xpath | Adds the encrypted part by using an XPath expression. |
| signature | Adds the WSSSignature component as a target of the encrypted part.<br><br>WSSSignature is applicable only if the SOAP message contains a signature element. |
| header | Adds the SOAP header, specified by QName, as a target of the encrypted part. |
| securityToken | Adds the SecurityToken object as a target of the encrypted part. |

For encrypted parts, certain default behaviors occur. The simplest way to use the WSSEncryptPart API is to use the default behavior. The WSSEncryptPart API provides defaults for specifying the transform algorithm, setting objects as targets, specifying the encrypted parts, such as: the SOAP body content and the signature.

The encryption default behaviors include:

*Table 254. Encrypted part decisions. Several encrypted message parts are set by default.*

| Encrypted part decisions | Default behavior |
|---|---|
| Which SOAP message parts to encrypt using keywords | Specifies which keywords to use for the encrypted parts. WebSphere Application Server sets the following SOAP message parts by default for encryption:<br>• WSSEncryption.BODY_CONTENT<br>• WSSEncryption.SIGNATURE |
| Which transform method to add | WebSphere Application Server does not specify any transform method by default. Specify a transform method only if using SOAP with Attachments. |

**Procedure**

1. To encrypt the SOAP message parts using the WSSEncryptPart API, first ensure that the application server is installed.
2. The WSS API process using WSSEncryptPart follows these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSGenerationContext instance from the WSSFactory instance.
   c. Creates the SecurityToken from WSSFactory to configure the encryption.
   d. Creates WSSEncryption from the WSSFactory instance using SecurityToken.
   e. Creates WSSEncryptPart from WSSFactory.
   f. Adds the parts to be encrypted and to be applied with the transform in WSSEncryptPart. WebSphere Application Server sets these encrypted parts by default for WSSEncryptPart: the BODY_CONTENT and SIGNATURE. After you add other encrypted parts, the default values are no longer valid. For example, if you call addEncryptPart(securityToken, false), only the security token is encrypted, and not the signature and body content. So if you want to encrypt the security token, the signature, and the body content, you must call addEncryptPart(securityToken, false), addEncryptPart(WSSEncryption.SIGNATURE), and addEncryptPart(WSSEncrypyion.BODY_CONTENT).
   g. Sets the transform method.
   h. Adds WSSEncryptPart to WSSEncryption.
   i. Adds WSSEncryption to WSSGenerationContext.
   j. Calls WSSGenerationContext.process() with the SOAPMessageContext.

**Results**

If there is an error condition during encryption of the message parts, a WSSException is provided. If successful, the API calls the WSSGenerationContext.process(), the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

**What to do next**

After enabling encrypted parts for the request generator (client side) binding, you must specify the same parts to be decrypted for the response consumer (client side) bindings. Next, to configure decryption and decrypted parts, use the WSS APIs or configure policy sets using the administrative console.

*Configuring generator signing information to protect message integrity using the WSS APIs:*

You can configure the signing information to protect message integrity for the request (client side) generator binding. Signing information includes the signature and the signed parts. To keep the integrity of the message, digital signatures are typically applied.

**Before you begin**

In addition to using a digital signature and configuring the signing information, the following tasks should also be performed:

- Verify the signing information.
- Incorporate encryption.
- Attach security tokens.

**About this task**

Integrity refers to digital signature while confidentiality refers to encryption. Integrity is provided by applying a digital signature to a SOAP message. To configure the signing information to protect message integrity, you must first digitally sign and then verify the signature for the SOAP messages. Integrity decreases the risk of data modification when you transmit data across a network.

Also, message integrity is provided by digitally signing the body, time stamp, and WS-Addressing headers using the signature algorithm methods. The WSS APIs specify which algorithm is to be used to sign the certificate. The signature algorithms specify the Uniform Resource Identifiers (URI) of the signature method. WebSphere Application Server supports several pre-configured request signing algorithm methods.

You can use the following interfaces to configure Web Services Security and to protect SOAP message integrity:

- Use the administrative console to configure policy sets for the signing information.
- Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client).

Perform the following signing tasks, using the WSS APIs, to configure the signing information and to protect message integrity for the generator binding.

**Procedure**

- Configure the signing information using the WSSSignature API. Configure the signing information for the generator binding using the WSSSignature API. Signing information is used to sign parts of a message including the SOAP body, the time stamp, and the WS-Addressing headers. Both signing and encryption can be applied to the same message parts, such as the SOAP body.
- Add or change signed parts using the WSSSignPart API.
- Configure the client for request signing methods using the WSSSignature or WSSSignPart APIs. To configure the client for request signing, choose the signing methods. The request signing methods include the signature, the canonicalization, the digest, and the transform methods. Use the WSSSignature API to configure the signature and canonicalization methods. Use the WSSSignPart API to configure the digest and transform methods.

**Results**

The WSS APIs also specify the security token for the generator (client) binding and set the type of token reference to protect message authenticity. By completing the steps in these tasks, you have configured generator signing to protect the integrity of the SOAP message.

**What to do next**

Next, verify the consumer signing information by using the WSS APIs or by configuring policy sets using the administrative console.

*Configuring signing information using the WSS APIs:*

You can configure the signing information for the client-side request generator (sender) bindings. Signing information is used to sign and validate parts of a message including the SOAP body, the timestamp information, and the Username token. To configure the client for request signing, specify which message parts to digitally sign when configuring the client.

**Before you begin**

WebSphere Application Server uses XML digital signature with existing algorithms such as RSA, HMAC, and SHA1. XML signature defines many methods for describing key information and enables the definition of a new method. Prior to completing these steps, familiarize yourself with XML digital signature for signing and verifying digital signatures for digital content.

**About this task**

By including XML signature in SOAP messages, the following issues are realized: message integrity and authentication. *Integrity* refers to digital signature whereas confidentiality refers to encryption. Integrity decreases the risk of data modification while the data is transmitted across the Internet. WebSphere Application Server uses the signing information for the default generator to sign parts of the message, such as the body, time stamp, and Username token.

For the signing information, you must specify the following:

- Which parts of the message are to be signed.
- The key information that is referenced by the key information for the signing keys.
- The signing algorithms.

WebSphere Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

The WSSSignature API configures the following parts as signature parts:

*Table 255. Pre-configured signature parts. Use the signing information to validate parts of a message.*

| | |
|---|---|
| Security token object | This object authenticates the client. If this option is specified, then the message is signed. You can digitally sign the message using a security token if a login configuration authentication method is selected. |
| WSSTimestamp object | This object adds a time stamp to a message. The time stamp determines if the message is valid based on the time that the message is sent and then received. |
| WSSSignature Part object | This object adds the signature parts to a message. |
| SOAP header and the QName as a target | This signature part adds the header, specified by QName, as a verification part. |

The WSS APIs allow the use of keywords or an XPath expression to specify which parts of the message are to be signed. WebSphere Application Server supports the use of the following keywords:

*Table 256. Supported signature keywords. Key information is used to specify which parts of a message are signed.*

| Keyword | References |
|---|---|
| ADDRESSING_HEADERS | The Web Services Addressing (WS-Addressing) headers. |
| BODY | The SOAP message body. The body is the user data portion of the message. |
| TIMESTAMP | The creation and expiration timestamp information. |

The Web Services Security API (WSS API) are used to configure the signing information for the request generator (client side) section of the bindings file. To configure the signing information on the client side, use the WSS APIs or configure policy sets for signing using the administrative console.

If configuring using the WSS APIs, the WSSSignature and WSSSignPart APIs complete the following steps to specify which message parts to digitally sign when configuring the client for request generator signing:

**Procedure**

1. The WSSSignature API adds the required parts of the SOAP message to digitally sign. Either a keyword or an XPath expression can be used to specify the required encryption parts.
2. The WSSSignature API sets the signature method algorithm. The default signature method is RSA_SHA1. WebSphere Application Server supports the following pre-configured algorithms:
   - RSA SHA1: http://www.w3.org/2000/09/xmldsig#rsa-sha1
   - HMAC SHA1http://www.w3.org/2000/09/xmldsig#hmac-sha1

   WebSphere Application Server does not support the following algorithm for DSA-SHA1: http://www.w3.org/2000/09/xmldsig#dsa-sha1. You cannot use the DSA-SHA1 algorithm if you want to be compliant with the Basic Security Profile (BSP).

   Any ds:SignatureMethod/@Algorithm element in a signature is based on a symmetric key and must have a value of RSA-SHA1 or HMAC-SHA1.

   The algorithm that is specified for the request generator configuration must match the algorithm that is specified for the request consumer configuration.
3. The WSSSignature API sets the canonicalization method. The default signature method is EXC_C14N. WebSphere Application Server supports the following pre-configured algorithms:
   - The URI of the exclusive canonicalization algorithm, EXC_C14N: http://www.w3.org/2001/10/xml-exc-c14n#.
   - The URI of the inclusive canonicalization algorithm, C14N: http://www.w3.org/2001/10/xml-c14n#.

   The canonicalization algorithm that you specify for the generator must match the algorithm for the consumer.
4. The WSSSignature API adds a security token. The API adds information about the security token that is to be used for the signature, such as:
   - The class for security token.
   - The callback handler
   - The name of the JAAS login configuration.
5. The WSSSignature API sets the type of security token and sets the type of token reference. WebSphere Application Server supports the following pre-configured token references:
   - SecurityToken.REF_STR

     Represents the security token reference as a token reference type.
   - SecurityToken.REF_KEYID

     Represents the key identifier reference as a token reference type.
   - SecurityToken.REF_EMBEDDED

     Represents the embedded reference as a token reference type.
   - SecurityToken.REF_THUMBPRINT

     Represents the thumbprint reference as a token reference type.
6. If SecurityToken.REF_KEYID is set as the type of token reference, the WSSSignature API sets the key information signature type and configures the key information that is referenced by the key information references. WebSphere Application Server supports the following:
   - Specifying that the KeyInfo element is not signed.
   - Specifying that the entire <KeyInfo> element is signed.
   - Specifying that the child elements <Keyinfochildelements> of the <KeyInfo> element are signed.

   If you do not specify one of the previous signature types, WebSphere Application Server specifies that the entire <KeyInfo> element is signed, by default.

   If you select Keyinfo or Keyinfochildelements and you select http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform as the transform algorithm in a subsequent step, WebSphere Application Server also signs the referenced token.

   The key information signature type for the generator must match the signature type for the consumer.

7. The WSSSignature API specifies whether to require signature confirmation. The OASIS Web Services Security (WS-Security) Version 1.1 specification defines the use of signature confirmation. If you are using WS-Security Version 1.0, this function is not available.

   The signature confirmation value is stored in order to validate the signature confirmation with it after the receiving message is returned. This method is called if the response message is expected to attach the signature confirmation into the SOAP message.

8. The WSSSignPart API specifies the part reference. The part reference specifies which parts of the message to digitally sign.

   The part reference refers to the message part that is digitally signed. The part attribute refers to the name of the <Integrity> element when the <PartReference> element is specified for the signature. You can specify multiple <PartReference> elements within the <SigningInfo> element. The <PartReference> element has two child elements when it is specified for the signature verification: <DigestTransform> and <Transform>.

9. The WSSSignPart API specifies the digest method algorithm. The digest method algorithm specified within the <DigestMethod> element is used in the <SigningInfo> element.

   WebSphere Application Server supports the following pre-configured digest algorithms:

   - http://www.w3.org/2000/09/xmldsig#sha1
   - http://www.w3.org/2001/04/xmlenc#sha256
   - http://www.w3.org/2001/04/xmlenc#sha512

10. The WSSSignPart API specifies the transform algorithm. The transform algorithm is that is specified within the <Transform> element and specifies the transform algorithm for the signature. WebSphere Application Server supports the following pre-configured transform algorithms:

    - http://www.w3.org/2001/10/xml-exc-c14n#
    - http://www.w3.org/TR/1999/REC-xpath-19991116

      Do not use this transform algorithm if you want to be compliant with the Basic Security Profile (BSP). Instead use http://www.w3.org/2002/06/xmldsig-filter2 to ensure compliance.
    - http://www.w3.org/2002/06/xmldsig-filter2
    - http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
    - http://www.w3.org/2002/07/decrypt#XML
    - http://www.w3.org/2000/09/xmldsig#enveloped-signature

    The transform algorithm that you select for the generator must match the transform algorithm that you select for the consumer.

    **Important:** If both of the following conditions are true, WebSphere Application Server signs the referenced token:

    - You previously selected the Keyinfo or the Keyinfochildelements option
    - You select http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform as the transform algorithm.

11. If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when running the client, you might need to configure the actor. Configure policy sets using the administrative console to configure the same actor strings for the web service on the server, which processes the request and sends the response back.

    The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The actor might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The

downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

### Results

After the WSSSignature and WSSSignPart APIs complete these steps, the signing information is configured for the generator sections of the bindings files.

### Example

The following example shows WSS API sample code to configure the signature, to generate the callback handler, and to specify the X.509 token type as the security token:

```
WSSFactory factory = WSSFactory.getInstance();
// Instantiate a generation context
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate the callback handler and specify the X.509 token
   X509GenerateCallbackHandler callbackhandler = generateCallbackHandler();
   SecurityToken token = factory.newSecurityToken(X509Token.class,
                                                  callbackHandler);

// Set the signature information
WSSSignature sig = factory.newWSSSignature(token);
// Add the header using QName
   sig.addSignHeader(new QName("http://www.w3.org/2005/08/addressing", "To"));
   sig.addSignHeader(new QName("http://www.w3.org/2005/08/addressing", "MessageID"));
   sig.addSignHeader(new QName("http://www.w3.org/2005/08/addressing", "Action"));
// Apply the signature
   gencont.add(sig);

// Secure the message
gencont.process(msgctx);
```

### What to do next

You must configure similar signature information for the client-side request consumer (receiver) bindings by completing the following verification tasks:

- Verify the signature
- Choose the signature algorithm methods.
- Change or add signed parts, as needed.

If signature verification is already configured, configure the encryption and decryption information, or configure the consumer and generator tokens.

*Configuring signing information using the WSSSignature API:*

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure the signing information for the generator binding sections for the client-side request, use the WSSSignature API. The WSSSignature API is part of the com.ibm.websphere.wssecurity.wssapi.signature package.

### Before you begin

Either you can use the WSS API or you can configure the policy sets by using the administrative console to enable the signing information. To secure SOAP messages, you must complete the following signing tasks:

- Configure the signing information.
- Choose the signing methods.
- Add or change signed parts, as needed.

### About this task

WebSphere Application Server uses the signing information for the default generator to sign parts of the message, and uses XML digital signature with existing algorithms such as RSA-SHA1 and HMAC-SHA1.

XML signature defines many methods for describing key information and enables the definition of a new method. XML canonicalization (C14N) is often needed when you use XML signature. Information can be represented in various ways within serialized XML documents. The C14N process is used to canonicalize XML information. Select an appropriate C14N algorithm because the information that is canonicalized depends on this algorithm.

The signing information specifies the integrity constraints that are applied to generated messages. The constraints include specifying which message parts within the generated message must be digitally signed, and the message parts to attach digitally signed Nonce and timestamp elements to. The following signature and related signature part information are configured:

*Table 257. Signature parts information. Use the signature parts to secure messages.*

| signature parts | Description |
|---|---|
| keyword | Adds a signature part using keywords. Use the following keywords for the signature parts:<br>• ADDRESSING_HEADERS<br>• BODY<br>• TIMESTAMP<br>The WS-Addressing headers are not encrypted but can be signed. |
| xpath | Adds a signature part by using an XPath expression. |
| part | Adds a WSSSignPart object as a target of the signature part. |
| timestamp | Adds a WSSTimestamp object as a target of the signature part. When specified, the timestamp information also specifies when the message is generated and when it expires. |
| header | Adds the header, specified by QName, as a target of the signature part. |
| securityToken | Adds a SecurityToken object as a target of the signature part. |

For signing information, certain default behaviors occur. The simplest way to use the WSSSignature API is to use the default behavior (see the example code). The default values are defined by the WSS API for the signing method, the canonicalization method, the security token references, and the signature parts.

*Table 258. Signature default behaviors. Several signature behaviors are configured by default.*

| Signature decisions | Default behavior |
|---|---|
| Which keywords to use | Sets the keywords. WebSphere Application Server supports the following keywords by default:<br>• ADDRESSING_HEADERS<br>• BODY<br>• TIMESTAMP |
| Which signature method to use | Sets the signature algorithm. The default signature method is RSA SHA1. WebSphere Application Server supports the following pre-configured signature methods:<br>• WSSSignature.RSA_SHA1: http://www.w3.org/2000/09/xmldsig#rsa-sha1<br>• WSSSignature.HMAC_SHA1: http://www.w3.org/2000/09/xmldsig#hmac-sha1<br>The DSA-SHA1 digital signature method (http://www.w3.org/2000/09/xmldsig#dsa-sha1) is not supported. |
| Which canonicalization method to use | Sets the canonicalization algorithm. The default canonicalization method is EXC C14N. WebSphere Application Server supports the following pre-configured canonicalization methods:<br>• WSSSignature.EXC_C14N; http://www.w3.org/2001/10/xml-exc-c14n#<br>• WSSSignature.C14N: http://www.w3.org/2001/10/xml-c14n# |
| Whether signature confirmation is required | Sets whether to require signature confirmation. The default value is **false**. Signature confirmation is defined in the OASIS Web Services Security Version 1.1 specification. If required, the value of your signature confirmation is stored in order to use it to validate the signature confirmation after receiving back the message that generated the signature confirmation in the response message. This method is for the requestor side. |

*Table 258. Signature default behaviors (continued). Several signature behaviors are configured by default.*

| Signature decisions | Default behavior |
|---|---|
| Which security token to use | Sets the SecurityToken. The token type specifies which type of token to use for signing and validating messages. The X.509 token is the default token type.<br><br>WebSphere Application Server provides the following pre-configured consumer token types:<br>• Derived Key Token<br>• X509 tokens<br><br>You can also create custom token types, as needed. |
| Which token reference to set | Sets the refType. SecurityToken.REF_STR is the default value for the type of token reference. WebSphere Application Server supports these pre-configured token references types:<br>• SecurityToken.REF_STR<br>• SecurityToken.REF_KEYID<br>• SecurityToken.REF_EMBEDDED<br>• SecurityToken.REF_THUMBPRINT |

If WSSSignature.requireSignatureConfirmation() is called, then the WSSSignature API expects that the response message will include the signature confirmation.

### Procedure

1. To configure the signing information in a SOAP message by using the WSS API, first ensure that the application server is installed.
2. Use the WSSSignature API to sign the message parts and specify the algorithms in a SOAP message. The WSS API process for signature follows these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSGenerationContext instance from the WSSFactory instance. WSSGenerationContext must be called in a JAX-WS client application.
   c. Creates the SecurityToken from WSSFactory to configure the key for signing.
   d. Creates WSSSignature from the WSSFactory instance using the SecurityToken. The default behavior of WSSSignature is to sign these signature parts: BODY, ADDRESSING_HEADERS, and TIMESTAMP.
   e. Adds the part to be signed, if the default part is not appropriate. If the digest method or transform method is changed, creates WSSSignPart and add it to WSSSignature.
   f. Creates WSSSignaturePart to WSSSignature. Calls the requiredSignatureConfirmation() method, if the signature confirmation is to be applied.
   g. Sets the canonicalization method, if the default is not appropriate.
   h. Sets the signature method, if the default is not appropriate.
   i. Sets the token reference, if the default is not appropriate.
   j. Adds WSSSignature to WSSGenerationContext.
   k. Calls WSSGenerationContext.process() with the SOAPMessageContext.

### Results

You have completed the steps to configure the signature for the generator section of the bindings. If there is an error condition when signing the message parts, a WSSException is provided. If successful, the WSSGenerationContext.process() is called, and Web Services Security is applied to the SOAP message.

### Example

The following example provides sample code that uses methods that are defined in the WSSignature API.

```
// Get the message context
   Object msgcontext = getMessageContext();
```

```
// Generate the com.ibm.websphere.wssecurity.wssapi.WSSFactory instance  (step: a)
   WSSFactory factory = com.ibm.websphere.wssecurity.wssapi.WSSFactory.getInstance();

// Generate the WSSGenerationContext instance  (step: b)
   WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate the callback handler
   X509GenerateCallbackHandler callbackHandler = new
       X509GenerateCallbackHandler(
       "",
       "dsig-sender.ks",
       "jks",
       "client".toCharArray(),
       "soaprequester",
       "client".toCharArray(),
       "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP", null);

// Generate the security token to be used for the signature  (step: c)
   SecurityToken token = factory.newSecurityToken(X509Token.class,
        callbackHandler);

// Generate the WSSSignature instance (step: d)
   WSSSignature sig = factory.newWSSSignature(token);

// Set the part to be signed  (step: e)
// DEFAULT: WSSSignature.BODY, WSSSignature.ADDRESSING_HEADERS,
//          and WSSSignature.TIMESTAMP.

// Set the part in the SOAP Header specified by QName  (step: e)
      sig.addSignHeader(new
                        QName("http://www.w3.org/2005/08/addressing",
                        "MessageID"));

// Set the part specified by the keyword  (step: e)
      sig.addSignPart(WSSSignature.BODY);

// Set the part specified by SecurityToken  (step: e)
   UNTGenerateCallbackHandler untCallbackHandler = new
      UNTGenerateCallbackHandler("Chris", "sirhC");
      SecurityToken unt = factory.newSecurityToken(UsernameToken.class,
         untCallbackHandler);
      sig.addSignPart(unt);

// Set the part specified by WSSSignPart  (step: e)
   WSSSignPart sigPart = factory.newWSSSignPart();
      sigPart.setSignPart(WSSSignature.TIMESTAMP);
      sigPart.setDigestMethod(WSSSignPart.SHA256);
      sig.addSignPart(sigPart);

// Set the part specified by WSSTimestamp  (step: e)
   WSSTimestamp timestamp = factory.newWSSTimestamp();
      sig.addSignPart(timestamp);

// Set the part specified by XPath expression  (step: e)
   StringBuffer sb = new StringBuffer();
      sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
         and local-name()='Envelope']");
      sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
         and local-name()='Body']");
      sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
         and local-name()='Ping']");
      sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
         and local-name()='Text']");
      sig.addSignPartByXPath(sb.toString());

// Set to apply the signature confirmation  (step: f)
      sig.requireSignatureConfirmation();

// Set the canonicalization method  (step: g)
// DEFAULT: WSSSignature.EXC_C14N
      sig.setCanonicalizationMethod(WSSSignature.C14N);

// Set the signature method  (step: h)
// DEFAULT: WSSSignature.RSA_SHA1
      sig.setSignatureMethod(WSSSignature.HMAC_SHA1);

// Set the token reference  (step: i)
// DEFAULT: SecurityToken.REF_STR
      sig.setTokenReference(SecurityToken.REF_KEYID);

// Add the WSSSignature to WSSGenerationContext  (step: j)
   gencont.add(sig);

// Generate the WS-Security header  (step: k)
gencont.process(msgctx);
```

**Note:** The X509GenerationCallbackHandler needs the key password because the private key is used for signing.

### What to do next

Next, chose the algorithm methods if you want a method that is different from the default values. If the algorithm methods do not need to be changed, next use the WSSVerification API to verify the signature and specify the algorithm methods in the consumer section of the binding. Note that the WSSVerification API is only supported on the response consumer (client side).

*Adding signed parts using the WSSSignPart API:*

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure parts to be signed for the request generator (client side) bindings, use the WSSSignPart API to protect the integrity of messages and to configure the digest and transform algorithm methods. The WSSSignPart API is part of the com.ibm.websphere.wssecurity.wssapi.signature package.

### Before you begin

Either you can use the WSS API or you can configure the policy sets by using the administrative console to configure the signing information. To secure SOAP messages using the signing information, you must complete one of the following tasks:

- Configure the signature information
- Configure signed parts, as needed.

### About this task

WebSphere Application Server uses the signing information for the default generator to sign parts of the message, and uses XML digital signature with existing digest and transform algorithms (for example, SHA1 or TRANSFORM_EXC_C14N).

The signing information specifies the integrity constraints that are applied to generated messages. The signed parts are used to protect the integrity of messages. You can specify the signed parts to add for message integrity protection.

The following table shows the required signed parts when the digital signature security constraint (integrity) is defined:

*Table 259. Signed parts information. Use the signed parts to secure messages.*

| Signed parts | Description |
|---|---|
| keyword | Adds signed parts using keywords. WebSphere Application Server supports the following keywords for signed parts:<br>• BODY<br>• ADDRESSING_HEADERS<br>• TIMESTAMP<br>The WS-Addressing headers are not encrypted but can be signed. |
| xpath | Adds the required signed parts by using an XPath expression. |
| header | Adds the header, specified by QName, as a signed part. |
| timestamp | Adds a WSSTimestamp object as a signed part. If specified, the timestamp information specifies when the message is generated and when it expires. |

Different message parts can be specified in the message protection for request on the generator side. WSSSignPart allows for adding a transform algorithm, setting a digest method, setting objects as targets, specifying whether an element, and the signed parts, such as: the SOAP body, the WS-Addressing header, and timestamp information.

For signing information, certain default behaviors occur. The simplest way to use the WSSSignPart API is to use the default behavior (see the example code). The signed parts default behaviors include:

*Table 260. Default behavior of signed parts. Several signed part characteristics are configured by default.*

| Signature decisions | Default behavior |
|---|---|
| Which SOAP message parts to sign | WebSphere Application Server supports the following SOAP message parts to be signed and used for message protection:<br>• WSSSignature.BODY<br>• WSSSignature.ADDRESSING_HEADERS<br>• WSSSignature.TIMESTAMP |
| Which digest method to use | Sets the digest algorithm method. The digest method algorithm that is specified within the <DigestMethod> element is used in the <SigningInfo> element.<br><br>WebSphere Application Server supports the following pre-configured digest methods:<br>• WSSSignPart.SHA1 (the default value): http://www.w3.org/2000/09/xmldsig#sha1<br>• WSSSignPart.SHA256: http://www.w3.org/2001/04/xmlenc#sha256<br>• WSSSignPart.SHA512: http://www.w3.org/2001/04/xmlenc#sha512 |
| Which transform algorithms to use | Adds the transform method. The transform algorithm is specified within the <Transform> element and specifies the transform algorithm for the signature.<br><br>WebSphere Application Server supports the following pre-configured transform algorithms:<br>• WSSSignPart.TRANSFORM_EXC_C14N (the default value): http://www.w3.org/2001/10/xml-exc-c14n#<br>• WSSSignPart.TRANSFORM_XPATH2_FILTER: http://www.w3.org/2002/06/xmldsig-filter2<br>Use this transform method to ensure compliance with the Basic Security Profile (BSP).<br>• WSSSignPart.TRANSFORM_STRT10: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform<br>• WSSSignPart.TRANSFORM_ENVELOPED_SIGNATURE: http://www.w3.org/2000/09/xmldsig#enveloped-signature |

### Procedure

1. To enable Web Services Security by using the WSS API (WSSSignPart), first ensure that the application server is installed.
2. Use the WSSSignPart API to sign the message parts and specify the algorithms in a SOAP message. The WSS API process for signed parts follows these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSGenerationContext instance from the WSSFactory instance.
   c. Creates the SecurityToken from WSSFactory to configure the key for signing.
   d. Creates WSSSignature from the WSSFactory instance using the SecurityToken.
   e. Creates WSSSignPart from the WSSFactory instance.
   f. Sets the part to be signed and the digest method or transform method specified by step g or step h if the default is not appropriate.
   g. Sets the digest method if the default is not appropriate.
   h. Sets the transform method if the default is not appropriate.
   i. Adds WSSSignPart to WSSSignature. After any WSSSignPart is set to WSSSignature, the default parts to be signed, which are specified in WSSSignature, are ignored.
   j. Adds WSSSignature to WSSGenerationContext.
   k. Calls WSSGenerationContext.process() with the SOAPMessageContext.

### Results

You have completed the steps to configure the signed parts for the generator section of the bindings files. If there is an error condition, a WSSException is provided. If successful, the WSSGenerationContext.process() is called, and Web Services Security is applied to the SOAP message.

### Example

The following example provides sample code that uses all of methods that are defined in the WSSSignPart API:

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance  (step: a)
   WSSFactory factory = WSSFactory.getInstance();

// Generate WSSGenerationContext instance  (step: b)
   WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate callback handler
   X509GenerateCallbackHandler callbackHandler = new
      X509GenerateCallbackHandler
      "",
      "dsig-sender.ks",
      "jks",
      "client".toCharArray(),
      "soaprequester",
      "client".toCharArray(),
      "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP", null);

// Generate the security token used to the signature  (step: c)
   SecurityToken token = factory.newSecurityToken(X509Token.class, callbackHandler);

// Generate WSSSignature instance (step: d)
   WSSSignature sig = factory.newWSSSignature(token);

// Set the part specified by WSSSignPart  (step: e)
   WSSSignPart sigPart = factory.newWSSSignPart();

// Set the part specified by WSSSignPart  (step: f)
   sigPart.setSignPart(WSSSignature.BODY);

// Set the digest method specified by WSSSignPart  (step: g)
   sigPart.setDigestMethod(WSSSignPart.SHA256);

// Set the transform method specified by WSSSignPart  (step: h)
   sigPart.setTransformMethod(WSSSignPart.TRANSFORM_STRT10);

// Add the part specified by WSSSignPart  (step: i)
   sig.addSignPart(sigPart);

// Add the WSSSignature to the WSSGenerationContext  (step: j)
   gencont.add(sig);

// Generate the WS-Security header  (step: k)
gencont.process(msgcontext);
```

**Note:** The X509GenerationCallbackHandler needs the key password because the private key is used for signing.

### What to do next

Use the WSSVerifyPart API or configure policy sets using the administrative console to verify the signed parts on the consumer side.

*Configuring request signing methods for the client:*

Use the WSSSignature and WSSSignPart APIs to choose the signing methods. The request signing methods include the signature, canonicalization, digest, and transform methods.

### Before you begin

First, you must have specified which parts of the message sent by the client must be digitally signed using the WSS APIs or configuring policy sets using the administrative console.

### About this task

The following table describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following website http://www.w3.org/TR/xmldsig-core.

*Table 261. Signing methods. Use the signing methods to secure messages.*

| Name of method | Description |
|---|---|
| Canonicalization algorithm | Canonicalizes the <SignedInfo> element before the information is digested as part of the signature operation. |
| Signature algorithm | Calculates the signature value of the canonicalized <SignedInfo> element. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration. |
| Transform method | Transforms the parts to be signed before the information is digested as part of the signature operation. |
| Digest method | Calculates the digest value of the transformed parts. The algorithm selected for the client request sender configuration must match the algorithms selected in the server request receiver configuration. |

You can use the WSS APIs or configure policy sets using the administrative console to configure the signing algorithm methods. If using the WSS APIs, use the WSSSignature and WSSSignPart APIs to specify which message parts to digitally sign when configuring the client for request signing.

The WSSSignature and WSSSignPart APIs complete the following steps to configure the signature and signed part algorithm methods:

**Procedure**

1. For the generator binding, the WSSSignature API specifies the signature method. WebSphere Application Server supports the following pre-configured signature methods:
   - WSSSignature.RSA_SHA1 (the default value): http://www.w3.org/2000/09/xmldsig#rsa-sha1
   - WSSSignature.HMAC_SHA1: http://www.w3.org/2000/09/xmldsig#hmac-sha1

   For the WSS APIs, WebSphere Application Server does not support the DSA-SHA1 digital signature method, http://www.w3.org/2000/09/xmldsig#dsa-sha1.
2. For the generator binding, the WSSSignature API specifies the canonicalization method. WebSphere Application Server supports the following pre-configured canonicalization algorithms:
   - WSSSignature.EXC_C14N (the default value): The exclusive canonicalization algorithm, http://www.w3.org/2001/10/xml-exc-c14n#
   - WSSSignature.C14N: The inclusive canonicalization algorithm, http://www.w3.org/2001/10/xml-c14n#
3. For the generator binding, the WSSSignPart API specifies the digest method. WebSphere Application Server supports the following pre-configured digest methods:
   - WSSSignPart.SHA1 (the default value): http://www.w3.org/2000/09/xmldsig#sha1
   - WSSSignPart.SHA256: http://www.w3.org/2001/04/xmlenc#sha256
   - WSSSignPart.SHA512: http://www.w3.org/2001/04/xmlenc#sha512
4. For the generator binding, the WSSSignPart API specifies the transform method. WebSphere Application Server supports the following pre-configured transform algorithms:
   - WSSSignPart.TRANSFORM_EXC_C14N (the default value): http://www.w3.org/2001/10/xml-exc-c14n#
   - WSSSignPart.TRANSFORM_XPATH2_FILTER: http://www.w3.org/2002/06/xmldsig-filter2
   - WSSSignPart.TRANSFORM_STRT10: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
   - WSSSignPart.TRANSFORM_ENVELOPED_SIGNATURE: http://www.w3.org/2000/09/xmldsig#enveloped-signature

   For the WSS APIs, WebSphere Application Server does not support the following transform algorithms:
   - http://www.w3.org/TR/1999/REC-xpath-19991116
   - http://www.w3.org/2002/07/decrypt#XML

### Results

Using the WSS APIs, you have specified which algorithm methods are used to digitally sign a message when the client sends a message to a server.

### Example

The following example is sample code for specifying the signature information, HMAC_SHA1 as signature method, C14N as a canonicalizaion method, SHA256 as a digest method, and EXC_C14N and TRANSFORM_STRT10 as the transform methods:

```
//get the message context
Object msgcontext = getMessageContext();

//generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

//generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

//generate callback handler
X509GenerateCallbackHandler callbackHandler = new X509GenerateCallbackHandler(
  "",
  "dsig-sender.ks",
  "jks",
  "client".toCharArray(),
  "soaprequester",
  "client".toCharArray(),
  "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP",
  null);

//generate the security token used to the signature
SecurityToken token = factory.newSecurityToken(X509Token.class, callbackHandler);

//generate WSSSignature instance
WSSSignature sig = factory.newWSSSignature(token);

//set the canonicalization method
// DEFAULT: WSSSignature.EXC_C14N
sig.setCanonicalizationMethod(WSSSignature.C14N);

//set the signature method
// DEFAULT: WSSSignature.RSA_SHA1
sig.setSignatureMethod(WSSSignature.HMAC_SHA1);

//set the part specified by WSSSignPart
WSSSignPart sigPart = factory.newWSSSignPart();

//set the digest method
 // DEFAULT: WSSSignPart.SHA1
sigPart.setDigestMethod(WSSSignPart.SHA256);

//add the transform method
// DEFAULT: WSSSignPart.TRANSFORM_EXC_C14N
sigPart.addTransformMethod(WSSSignPart.TRANSFORM_EXC_C14N);
sigPart.addTransformMethod(WSSSignPart.TRANSFORM_STRT10);

 // add the WSSSignPart to the WSSSignature
 sig.addSignPart(sigPart);

//add the WSSSignature to the WSSGenerationContext
gencont.add(sig);

//generate the WS-Security header
gencont.process(msgcontext);
```

### What to do next

After you configure the client to digitally sign the message and to choose the algorithm methods, you must configure the server to verify the digital signature for request signing and to choose the algorithm methods.

Configure policy sets using the administrative console to configure the signature verification information and methods on the server.

*Digital signing methods using the WSSSignature API:*

You can configure the signing information for the generator binding using the WSS API. To configure the client for request signing, choose the digital signing methods. The algorithm methods include the signing and canonicalization methods.

You must configure generator signing information to protect message integrity by digitally signing SOAP messages. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network.

After you have specified which message parts to digitally sign, you must specify which method is used to digitally sign the message.

### Methods

Methods that are used for the signing information include the:

**Signature method**
Sets the signature algorithm method.

**Canonicalization method**
Sets the canonicalization algorithm method.

### Signature algorithms

The signature algorithms specify the algorithm that is used to sign the certificate. The signature algorithms specify the Uniform Resource Identifiers (URI) of the signature method. WebSphere Application Server supports the following pre-configured algorithms:

*Table 262. Signature algorithms. The algorithms include the signing methods.*

| Algorithm | Description |
|---|---|
| WSSSignature.HMAC_SHA1 | A URI of the signature algorithm, HMAC: http://www.w3.org/2000/09/xmldsig#hmac-sha1 |
| WSSSignature.RSA_SHA1 (the default value) | A URI of the signature algorithm, RSA: http://www.w3.org/2000/09/xmldsig#rsa-sha1 |

For the WSS APIs, WebSphere Application Server does not support the DSA-SHA1 algorithm, http://www.w3.org/2000/09/xmldsig#dsa-sha1

The signing algorithm that is specified for the request generator configuration must match the algorithm that is specified for the request consumer configuration.

### Canonicalization algorithms

The canonicalization algorithms specify the Uniform Resource Identifiers (URI) of the canonicalization method. WebSphere Application Server supports the following pre-configured algorithms:

*Table 263. Signature canonicalization algorithms. The algorithms include the canonicalization methods.*

| Algorithm | Description |
|---|---|
| WSSSignature.EXC_C14N (the default value) | A URI of the exclusive canonicalization algorithm EXC_C14N: http://www.w3.org/2001/10/xml-exc-c14n# |
| WSSSignature.C14N | A URI of the inclusive canonicalization algorithm, C14N: http://www.w3.org/2001/10/xml-c14n# |

The canonicalization algorithm that is specified for the request generator configuration must match the algorithm that is specified for the request consumer configuration.

The following example provides sample WSS API code that specifies the HMAC_SHA1 as a signature method and C14n as a canonicalization method:

```
//generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

//generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

//generate callback handler
X509GenerateCallbackHandler callbackHandler = new
     X509GenerateCallbackHandler(
  "",
  "dsig-sender.ks",
  "jks",
  "client".toCharArray(),
  "soaprequester",
  "client".toCharArray(),
  "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP",
  null);

//generate the security token used to the signature
SecurityToken token = factory.newSecurityToken(X509Token.class,
     callbackHandler);

//generate WSSSignature instance
WSSSignature sig = factory.newWSSSignature(token);

//set the canonicalization method
// DEFAULT: WSSSignature.EXC_C14N
sig.setCanonicalizationMethod(WSSSignature.C14N);

//set the signature method
// DEFAULT: WSSSignature.RSA_SHA1
sig.setSignatureMethod(WSSSignature.HMAC_SHA1);

//add the WSSSignature to the WSSGenerationContext
gencont.add(sig);

//generate the WS-Security header
gencont.process(msgcontext);
```

*Signed parts methods using the WSSSignPart API:*

You can configure the signed parts information for the generator binding using the WSS API. The algorithms include the digest and transform methods.

You can protect message integrity by configuring signed parts and key information. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network.

### Methods

Methods that are used for the signed parts include the:

**Digest method**
Sets the digest algorithm method.

**Transform algorithm**
Sets the transform algorithm method.

### Digest algorithms

The digest method algorithm specified within the element is used in the element. WebSphere Application Server supports the following pre-configured algorithms:

*Table 264. Signed parts digest methods. The methods are used for the signed parts.*

| Digest method | Description |
|---|---|
| WSSSignPart.SHA1 (the default value) | A URI of the digest algorithm, SHA1: http://www.w3.org/2000/09/xmldsig#sha1 |
| WSSSignPart.SHA256 | A URI of the digest algorithm, SHA256: http://www.w3.org/2001/04/xmlenc#sha256 |
| WSSSignPart.SHA512 | A URI of the digest algorithm, SHA256: http://www.w3.org/2001/04/xmlenc#sha512 |

### Transform algorithms

The transform method algorithm specified within the element is used in the element. WebSphere Application Server supports the following pre-configured algorithms:

*Table 265. Signed parts transform methods. The methods are used for the signed parts.*

| Digest method | Description |
|---|---|
| WSSSignPart.TRANSFORM_ENVELOPED_SIGNATURE | A URI of the transform algorithm, enveloped signature: http://www.w3.org/2000/09/xmldsig#enveloped-signature |
| WSSSignPart.TRANSFORM_STRT10 | A URI of the transform algorithm, STR-Transform: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform |
| WSSSignPart.TRANSFORM_EXC_C14N (the default value) | A URI of the transform algorithm, Exc-C14N: http://www.w3.org/2001/10/xml-exc-c14n# |
| WSSSignPart.TRANSFORM_XPATH2_FILTER | A URI of the transform algorithm, XPath2 filter: http://www.w3.org/2002/06/xmldsig-filter2 |

The transform algorithm is specified within the <Transform> element and specifies the transform algorithm for the signed part.

For the WSS APIs, WebSphere Application Server does not support the following transform algorithms:

- http://www.w3.org/TR/1999/REC-xpath-19991116
- http://www.w3.org/2002/07/decrypt#XML

The following example provides sample WSS API code for specifying the signature and signed parts, setting the signing key and adding the STR-Transform transform algorithm as signed parts:

```
//get the message context
Object msgcontext = getMessageContext();

//generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

//generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

//generate callback handler
X509GenerateCallbackHandler callbackHandler = new
      X509GenerateCallbackHandler(
  "",
  "dsig-sender.ks",
  "jks",
  "client".toCharArray(),
  "soaprequester",
  "client".toCharArray(),
  "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP",
  null);

//generate the security token used to the signature
SecurityToken token = factory.newSecurityToken(X509Token.class,
     callbackHandler);

//generate WSSSignature instance
WSSSignature sig = factory.newWSSSignature(token);

//set the part specified by WSSSignPart
WSSSignPart sigPart = factory.newWSSSignPart();

//set the part specified by WSSSignPart
sigPart.setSignPart(WSSSignature.BODY);

//set the digest method specified by WSSSignPart
sigPart.setDigestMethod(WSSSignPart.SHA256);

//set the transform method specified by WSSSignPart
sigPart.addTransform(WSSSignPart.TRANSFORM_STRT10);

//set the part specified by WSSSignPart
sig.addSignPart(sigPart);

//add the WSSSignature to the WSSGenerationContext
gencont.add(sig);

//generate the WS-Security header
gencont.process(msgcontext);
```

*Attaching the generator token using WSS APIs to protect message authenticity:*

When you specify the token generator, the information is used on the generator side to generate the security token.

**Before you begin**

The token processing and pluggable token architecture in the Web Services Security run time reuses the same security token interface and Java Authentication and Authorization Service (JAAS) Login Module from the Web Services Security APIs (WSS API). The same implementation of token creation and validation can be used in both the WSS API and the WSS SPI in the Web Services Security run time.

**Restriction:** The `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` interface is not used with JAX-WS web services. If you are using JAX-RPC web services, this interface is still valid.

Note that the key name (KeyName) element is not supported in the application server because there is no KeyName policy assertion defined in the current OASIS Web Services Security draft specification.

**About this task**

The JAAS callback handler (CallbackHandler) and the JAAS login module (LoginModule) are responsible for creating the security token on the generator side and validating (authenticating) the security token on the consumer side.

For example, on the generator side, the Username token is created by the JAAS LoginModule and using the JAAS CallbackHandler to pass the authentication data. The JAAS LoginModule creates the Username SecurityToken object and passes it to the Web Services Security run time.

Then, on the consumer side, the Username Token XML format is passed to the JAAS LoginModule for validation or authentication and the JAAS CallbackHandler is used to pass authentication data from the Web Services Security run time to the LoginModule. After the token is authenticated, a Username SecurityToken object is created and passed it to the Web Services Security run time.

**Note:** WebSphere Application Server does not support a stackable login module with the WebSphere Application Server default login module implementation, meaning adding the login module before or after the WebSphere Application Server login module implementation. If you want to stack the login module implementations, you must develop the required login modules because there is no default implementation.

The com.ibm.websphere.wssecurity.wssapi.token package provided by WebSphere Application Server includes support for these classes:

- Security token (SecurityTokenImpl)
- Binary security token (BinarySecurityTokenImpl)

In addition, WebSphere Application Server provides the following pre-configured sub-interfaces for security tokens:

- Derived key token
- Security context token (SCT)
- Username token
- LTPA token propagation
- LTPA token
- X509PKCS7 token
- X509PKIPath token

- X509v3 token
- Kerberos v5 token

The Username token, the X.509 tokens, and the LTPA tokens are used by default for message authenticity. The derived key token and the X.509 tokens are used by default for signing and encryption.

The WSS API and WSS SPI are only supported on the client. To specify the security token type on the generator side, you can also configure policy sets using the administrative console. You can also use the WSS APIs or policy sets for matching consumer security tokens.

The default Login Module and Callback implementations are designed to be used as a pair, meaning both a generator and a consumer part. To use the default implementations, select the appropriate generator and consumer security token in a pair. For example, select `system.wss.generate.x509` in the token generator and `system.wss.consume.x509` in the token consumer when the X.509 token is required.

To configure the generator-side security token, use the appropriate pre-configured token generator interface from the WSS APIs to complete the following token configuration process steps:

**Procedure**

1. Generate the wssFactory instance.
2. Generate the wssGenerationContext instance.

   The WSSGenerationContext interface stores the components for generating Web Services Security (WS-Security), such as the signing and encryption information, the security token, and the time stamp. When the generate() method is called, all of these components are generated.
3. Create the generator-side components, such as the WSSSignature and the WSSEncryption objects.
4. Specify a JAAS configuration by specifying the name of the JAAS login configuration. The Java Authentication and Authorization Service (JAAS) configuration specifies the name of the JAAS configuration. The JAAS configuration specifies how the token logs in on the consumer side. Do not remove the predefined system or application login configurations. However, within these configurations, you can add module class names and specify the order in which WebSphere Application Server loads each module.
5. Specifiy a token generator class name. The token generator class name specifies the required information to generate the SecurityToken. The Username token, the X.509 tokens, and the LTPA tokens are used by default for message authenticity.
6. Specifiy the settings for the callback handler by specifying a callback handler class name and also specifies the callback handler keys. This class name is the name of the callback handler implementation class that is used for the plug-in to the security token framework.

   The callback handler implementation obtains the required security token and passes it to the token generator. The token generator inserts the security token in the Web Services Security header within the SOAP message. Also, the token generator is a plug-in point for the pluggable security token framework. Service providers can provide their own implementation, but the implementation must use the WSSGenerationContext interface.

   WebSphere Application Server provides the following default callback handler implementations for the generator side:

   **com.ibm.websphere.wssecurity.callbackhandler.PropertyCallback**
   This class is a callback for handling the name-value pair in elements in the Web Services Security (WS-Security) configuration XMI files.

   **com.ibm.websphere.wssecurity.callbackhandler.UNTGUIPromptCallbackHandler**
   This class is a callback handler for the Username token with the GUI prompt on the generator side. This instance is used to set the WSSGenerationContext object to generate a Username token.

**com.ibm.websphere.wssecurity.callbackhandler.UNTGenerateCallbackHandler**
This class is a callback handler for the Username token on the generator side. This instance is used to set into WSSGenerationContext object to attach a Username token. Use this implementation for a Java Platform, Enterprise Edition (Java EE) application client only.

**com.ibm.websphere.wssecurity.callbackhandler.X509GenerateCallbackHandler**
This class is a callback handler that is used to generate the X.509 certificate that is inserted in the Web Services Security header within the SOAP message as a binary security token on the generator side. This instance is used to generate the WSSSignature and WSSEncryption objects, set the objects into the WSSGenerationContext object to generate the X.509 binary security tokens. A keystore and a key definition are required for this callback handler. If you use this implementation, a key store password, path, and type must be provided on the generator side.

**com.ibm.websphere.wssecurity.callbackhandler.LTPAGenerateCallbackHandler**
This class is a callback handler for the Lightweight Third Party Authentication (LTPA) tokens on the generator side. This instance is used to generate WSSSignature object and WSSEncryption object to generate a LTPA token.

This callback handler is used to validate the LTPA security token inserted in the Web Services Security header within the SOAP message as a binary security token. However, if the user name and password are specified, WebSphere Application Server authenticates the user name and password to obtain the LTPA security token rather than obtaining it from the Run As Subject. Use this callback handler only when the web service is acting as a client on the application server. It is recommended that you do not use this callback handler on a Java EE application client. If you use this implementation, a basic authentication user ID and password must have been provided on the generator side.

**com.ibm.websphere.wssecurity.callbackhandler.KRBTokenConsumeCallbackHandler**
This class is a callback handler for the Kerberos v5 token on the generator side. This instance is used to set the WSSGenerationContext object to generate the Kerberos v5 AP-REQ as a binary security token. The instance is also used to generate the WSSSignature and WSSEncryption objects to use the Kerberos session key or derived key in the SOAP message signature and encryption.

7. If a X.509 token is specified, additional token information is also specified.

*Table 266. Information for X.509 token. Use the X.509 token for signing and encryption.*

| | |
|---|---|
| storeRef | The reference name of the keystore. |
| storePath | The keystore file path from which the keystore is loaded, if needed. It is recommended that you use the `${USER_INSTALL_ROOT}` in the path name as this variable expands to the WebSphere Application Server path on your machine. This path is required when you use the X.509 tokens callback handler implementations. |
| storePassword | The password that is used to check the integrity of the keystore, or the keystore password that is used to unlock the keystore and to access the keystore file. The keystore and its configuration are used for some of the default callback handler implementations that are provided by WebSphere Application Server. |
| storeType | The keystore type of keystore that is used for the key locator. This selection indicates the format that is used by the keystore file. The following values are available for selection:<br>**JKS** Use this option if the keystore uses the Java Keystore (JKS) format.<br>**JCEKS** Use this option if the Java Cryptography Extension is configured in the software development kit (SDK). The default IBM JCE is configured in WebSphere Application Server. This option provides stronger protection for stored private keys by using Triple DES encryption.<br>**JCERACFKS** Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).<br>**PKCS11KS (PKCS11)** Use this format if your keystore uses the PKCS#11 file format. Keystores using this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.<br>**PKCS12KS (PKCS12)** Use this option if your keystore uses the PKCS#12 file format. |
| alias | The key alias name. The key alias is used by the key locator to find the key within the keystore file. |

*Table 266. Information for X.509 token (continued). Use the X.509 token for signing and encryption.*

| | |
|---|---|
| keyPassword | The key password that is used for recovering the key. This password is needed to access the key object within the keystore file. |
| keyName | The name of the key. For digital signatures, the key name is used by the request generator or response consumer signing information to determine which key is used to digitally sign the message. For encryption, the key name is used to determine the key used for encryption. The key name must be a fully qualified, distinguished name (DN). For example, `CN=Bob,O=IBM,C=US`. |
| certStores | A list of certificate stores. A collection certificate store includes a list of untrusted, intermediary certificates and certificate revocation lists (CRLs). This step configures a collection certificate store and certificate revocation lists for the generator bindings. |
| identityAssertion | Specifies whether identity assertion is used. Selects this item if identity assertion is defined. This option indicates that only the identity of the initial sender is required and inserted into the Web Services Security header within the SOAP message. For an X.509 token generator, the application server sends the original signer certification only. |
| requestorCertificate | Specifies whether the certificate of the requestor is used. |

The following can be specified for a X.509 token:

a. Without any keystore.

b. With a trust anchor. A trust anchor specifies a list of keystore configurations that contain trusted root certificates. These configurations are used to validate the certificate path of incoming X.509-formatted security tokens. For example, when you select the trust anchor or the certificate store of a trusted certificate, you must configure the trust anchor and the certificate store before setting the certificate path.

c. With a keystore that is used for the key locator.

First, you must have created the keystore file, by using a key tool utility, for example. The keystore is used to retrieve the X.509 certificate. This entry specifies the password that is used to access the keystore file. Keystore objects within trust anchors contain trusted root certificates that are used by the CertPath API to validate the trustworthiness of a certificate chain.

d. With keystore that is used for the key locator and the trust anchor.

e. With a map that includes key-value pairs. For example, you might specify the value type name and the value type Uniform Resource Identifier (URI). The value type specifies the namespace URI of the value type for the generated token, and represents the token type of this class:

**ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3**

Specifies an X.509 certificate token.

**ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1**

Specifies X.509 certificates in a public key infrastructure (PKI) path. This callback handler is used to create X.509 certificates encoded with the PkiPath format. The certificate is inserted in the Web Services Security header within the SOAP message as a binary security token. A keystore is required for this callback handler. A CRL is not supported by the callback handler; therefore, the collection certificate store is not required or used. If you use this implementation, you must provide a key store password, path, and type on this panel.

**ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7**

Specifies a list of X.509 certificates and certificate revocation lists in a PKCS#7 format. This callback handler is used to create X.509 certificates encoded with the PKCS#7 format. The certificate is inserted in the Web Services Security header in the SOAP message as a binary security token. A keystore is required for this callback handler. You can specify a certificate revocation list (CRL) in the collection certificate store. The CRL is encoded with the X.509 certificate in the PKCS#7 format. If you use this implementation, you must provide a key store password, path, and type.

For some tokens, WebSphere Application Server provides a predefined local name for the value type. When you specify the following local name, you do not need to specify a value type URI:

**ValueType: http://www.ibm.com/websphere/appserver/tokentype/5.0.2**
For an LTPA token, you can use `LTPA` for the value type local name. This local name causes `http://www.ibm.com/websphere/appserver/tokentype/5.0.2` to be specified for the value type Uniform Resource Identifier (URI).

**ValueType: http://www.ibm.com/websphere/appserver/tokentype/5.0.2**
For LTPA token propagation, you can use `LTPA_PROPAGATION` for the value type local name. This local name causes `http://www.ibm.com/websphere/appserver/tokentype` to be specified for the value type Uniform Resource Identifier (URI).

8. If the Username token is specified as the token generator class name, the following token information can be specified:
   a. Whether to use IdentityAssertion option. This option is selected if identity assertion is defined. This option indicates that only the identity of the initial sender is required and inserted into the Web Services Security header within the SOAP message. For example, WebSphere Application Server sends only the user name of the original caller for a Username token generator.
   b. Whether to use RunAsSubject identity option. This option is used if an identity assertion is defined and you want to use the Run As identity instead of the initial caller identity for identity assertion in a downstream call. This option is valid only if you have configured the Username token as the token generator.
   c. Whether to use sendRealm.
   d. Whether to specify the nonce.

      This option indicates whether a Nonce is included for the token generator. Nonce is a unique, cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of Username tokens. Nonce is valid only when the generated token type is a Username token, and it is available only for the request generator binding.
   e. Specifies the keyword of the time stamp. This option indicates whether to verify a time stamp in the Username token. The time stamp is valid only when the incorporated token type is a Username token.
   f. Specifies a map that includes key-value pairs. For example, you might specify the value type name and the value type Uniform Resource Identifier (URI). The value type specifies the namespace URI of the value type for the generated token, and represents the token type of this class:

      **URI value type: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken**
      Specifies a Username token.
9. If the Kerberos v5 token is specified as the token generator class name, the following token information can be specified:

| Token Information | Description | Default Value |
|---|---|---|
| name | Kerberos client principal name | |
| password | Kerberos client password | |
| realm | Kerberos realm associated with the Kerberos client | Default realm name in Kerberos configuration file.<br><br>Specify null to use the default value. |
| targetService | Kerberos service name associated with the target web services. | |
| targetHost | Kerberos realm name associated with the Kerberos service name. | |
| tokenValueType | Kerberos token value type in QName defined by Oasis Kerberos Token Profile v1.1 specification. | http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ |

| Token Information | Description | Default Value |
| --- | --- | --- |
| targetRealm | Kerberos realm name associated with the Kerberos service name. | Default realm name in the Kerberos configuration file |
| prompt | A boolean value to enable the login prompt. | false |
| supportTokenRequireSHA1 | A boolean value to require a SHA1 key that is used in subsequent request messages when the Kerberos token is used as a supporting token. | false<br><br>SHA1 key is consumed only if the supporting Kerberos token is protected. If set to true, the SHA1 key is always consumed. |
| alwaysAPREQ | A boolean value to indicate that the client should always send the Kerberos AP_REQ token in the request messages. | false<br><br>The SHA1 key is used instead in the subsequent messages. If set to true, the Kerberos AP_REQ token is always used. |
| requireDKT | A boolean value to require a derived key for message protection. | false |
| clabel | The client label for the derived key. | WS-SecureConversation<br><br>Specify null to use the default value. |
| slabel | The service label for the derived key. | WS-SecureConversation<br><br>Specify null to use the default value. |
| keylen | The length of the derived key. | 16<br><br>Specify zero to use the default value |
| noncelen | The length of the nonce. | 16<br><br>Specify zero to use the default value |
| encComponent | An instance of WSSEncryption. | Set encComponent and sigComponent to null to initialize this first for either the encryption or signature component. Then, use the initialized component only in the callback handler constructor for the second component. |
| sigComponent | An instance of WSSSignature. | Set encComponent and sigComponent to null to initialize this first for either the encryption or signature component. Then, use the initialized component only in the callback handler constructor for the second component. |

Additional token value types are defined in the OASIS Kerberos Token Profile v1.1 specification. Specify the token value type as the local name. It is not necessary to specify the value type URI for the Kerberos v5 token.

- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ4120

- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ4120

10. If Secure Conversation is used for message protection, the following information must be specified:

| Information | Description |
|---|---|
| bootstrapWSSGenerationContext | The bootstrap configuration used to secure the RequestSecurityToken (RST) token. |
| bootstrapWSSConmingContext | The bootstrap configuration used for consuming a secured RequestSecurityTokenResponse (RSTR). |
| ENDPOINT_URL | The service end point URL. |
| EncryptionAlgorithm | This determines the key size. |
| cLabel | The client label used when creating the derived key. |
| sLabel | The server label used when creating the derived key. |

11. Set the components into the wssGenerationContext object.
12. Invoke the wssGenerationContext.process() method.

**Results**

Using the Web Services Security API (WSS API) process, you can configured the token generator.

**What to do next**

Next, you must specify a similar token consumer configuration.

*Configuring generator security tokens using the WSS API:*

You can secure the SOAP messages, without using policy sets, by using the Web Services Security APIs. To configure the token on the generator side, use the Web Services Security APIs (WSS API). The generator security tokens are part of the `com.ibm.websphere.wssecurity.wssapi.token` interface package.

**Before you begin**

The pluggable token framework in WebSphere Application Server has been redesigned so that the same framework from the WSS API can be reused. The same implementation of creating and validating security token can be used both for the Web Services Security runtime and for the WSS API application code. The redesigned framework also simplifies the SPI programming model and will make it easier to add security token types.

You can use the WSS API or you can configure the tokens by using the administrative console. To configure tokens, you must complete the following token tasks:

- Configure the generator tokens.
- Configure the consumer tokens.

**About this task**

The JAAS CallbackHandler and JAAS LoginModule are responsible for creating the security token on the generator side.

On the generator side, the token is created by using the JAAS LoginModule and by using JAAS CallbackHandler to pass authentication data. Then, the JAAS LoginModule creates the securityToken object, such as the UsernameToken, and passes it to the Web Services Security run time.

On the consumer side, the XML format is passed to the JAAS LoginModule for validation or authentication. then the JAAS CallbackHandler is used to pass authentication data from the Web Services Security runtime to the LoginModule. After the token is authenticated, a security token object is created, and the token is passed it to the Web Services Security runtime.

When using the WSS API for generator token creation, certain default behaviors occur. The simplest way to use the WSS API is to use the default behavior (see the example code). The WSS API provide default values for the token type, the token value, and the JAAS confirmation name. The default token behaviors include:

*Table 267. Token decisions and default behaviors. Several token characteristics are configured by default.*

| Generator token decisions | Default behavior |
|---|---|
| Which token type to use | The token type specifies which type of token to use for message integrity, message confidentiality, or message authenticity.<br><br>WebSphere Application Server provides the following pre-configured generator token types for message integrity and message confidentiality:<br>• Derived key token<br>• X509 tokens<br>You can also create custom token types, as needed.<br><br>WebSphere Application Server also provides the following pre-configured generator token types for the message authenticity:<br>• Username token<br>• LTPA tokens<br>• X509 tokens<br><br>You can also create custom token types, as needed. |
| What JAAS login configuration name to specify | The JAAS login configuration name specifies which JAAS login configuration name to use. |
| Which configuration type to use | The JAAS login module specifies the configuration type. Only the pre-configured generator configuration types can be used for generator token types. |

The SecurityToken class (com.ibm.websphere.wssecurity.wssapi.token.SecurityToken) is the generic token class and represents the security token that has methods to get the identity, the XML format, and the cryptographic keys. Using the SecurityToken class, you can apply both the signature and encryption to the SOAP message. However, to apply both, you must have two SecurityToken objects, one for the signature and one for encryption, respectively.

The following tokens types are subclasses of the generic security token class:

*Table 268. Subclasses of the SecurityToken. Use the subclasses to represent the security token.*

| Token type | JAAS login configuration name |
|---|---|
| Username token | system.wss.generate.unt |
| Security context token | system.wss.generate.sct |
| Derived key token | system.wss.generate.dkt |

The following tokens types are subclasses of the binary security token class:

*Table 269. Subclasses of the BinarySecurityToken. Use the subclasses to represent the binary security token.*

| Token type | JAAS login configuration name |
|---|---|
| LTPA token | system.wss.generate.ltpa |
| LTPA propagation token | system.wss.generate.ltpaProp |
| X.509 token | system.wss.generate.x509 |
| X.509 PKI Path token | system.wss.generate.pkiPath |
| X.509 PKCS7 token | system.wss.generate.pkcs7 |

**Notes:**

- For each JAAS login token generator configuration name, there is a respective token consumer configuration name. For example, for the Username token, the respective token consumer configuration name is system.wss.consume.unt.
- The LTPA and LTPA propagation tokens are only available to a requester that is running as a server-based client. The LTPA and LTPA propagation tokens are not supported for the Java SE 6 or Java EE application client.

**Procedure**

1. To configure the securityToken package, `com.ibm.websphere.wssecurity.wssapi.token`, first ensure that the application server is installed.
2. Use the Web Services Security token generator process to configure the tokens. For each token type, the process is similar to the following process that demonstrates the UsernameToken token generator process:
   a. Use WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Create the WSSGenerationContext instance from the WSSFactory instance.
   c. Create a JAAS CallbackHandler. The authentication data, such as the user name and password are specified as part of the CallbackHandler. For example, the following code specifies Chris as the user name and sirhC as the password: UNTGenerationCallbackHandler("Chris", "sirhC");
   d. Call any JAAS CallbackHandler parameters and review the token class information for which parameters are required or optional. For example, for the UsernameToken, the following parameters can be configured also:

      **Nonce**
      Indicates whether a nonce is included in the user name token for the token generator. Nonce is a unique, cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of user name tokens. The nonce value is valid only when the generated token type is a UsernameToken and only when it applies to the request generator binding.

      **Created timestamp**
      Indicates whether to insert a time stamp into the UsernameToken. The timestamp value is valid only when the generated token type is a UsernameToken and only when it applies to the request generator binding.

   e. Create the SecurityToken from WSSFactory.

      By default, the UsernameToken API specifies the ValueType as: "http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken"

      By default, the UsernameToken API provides the QName of this class and specifies the NamespaceURI as http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd and also specifies the LocalPart as UsernameToken.
   f. Optional: Specify the JAAS login module configuration name. On the generator side, the configuration type is always `generate` (for example, `system.wss.generate.unt`).
   g. Add the SecurityToken to the WSSGenerationContext.
   h. Call WSSGenerationContext.process() and generate the WS-Security header.

**Results**

If there is an error condition, a WSSException is provided. If successful, the WSSGenerationContext process() is called, and the security token for the generator binding is attached.

### Example

The following example code shows how to use WSS APIs to create a Username security token, attach the Username token to the SOAP message, and configure the Username token in the generator binding.

```
// import the packages
import javax.xml.ws.BindingProvider;
import com.ibm.websphere.wssecurity.wssapi.*;
import com.ibm.websphere.wssecurity.callbackhandler.*;
...
   // obtain the binding provider
   BindingProvider bp = ... ;

   // get the request context
   Map<String, Object> reqContext = bp.getRequestContext();

   // generate WSSFactory instance
   WSSFactory factory = WSSFactory.getInstance();

   // generate WSSGenerationContext instance
   WSSGenerationContext gencont = factory.newWSSGenerationContext();

   // generate callback handler
   UNTGenerateCallbackHandler untCallbackHandler =
   new UNTGenerateCallbackHandler("Chris", "sirhC");

   // generate the username token
   SecurityToken unt = factory.newSecurityToken(UsernameToken.class, untCallbackHandler);

   // add the SecurityToken to the WSSGenerationContext
   gencont.add(unt);

   // generate the WS-Security header
   gencont.process(reqContext);
```

The following example code shows how to modify the preceding Username token sample to create an LTPAv2 token from the runAs identity on the current thread. The two lines of code that instantiate the callback handler and create the security token are replaced with the following two lines of code:

```
// generate callback handler
LTPAGenerateCallbackHandler ltpaCallbackHandler = new LTPAGenerateCallbackHandler(null, null);

// generate the LTPAv2 token
SecurityToken ltpa = wssfactory.newSecurityToken(LTPAv2Token.class, ltpaCallbackHandler);
```

The instantiation of the LTPAGenerateCallbackHandler object with (null, null) indicates that the LTPA token should be generated from the current runAs identity. If the callback handler is instantiated with basicAuth information, ("userName", "password"), a new LTPA token is created using the specified basicAuth information.

The following example shows how to use secure conversation with the WSS APIs to configure the generator tokens, as well as the consumer tokens. In this example, the SecurityContextToken token is created using the WS-SecureConversation draft namespace: `http://schemas.xmlsoap.org/ws/2005/02/sc/sct`. To use the WS-SecureConversation version 1.3 namespace, `http://docs.oasis-open.org/ws-sx/ws-secureconversation/200512/sct`, specify SecurityContextToken13.class instead of SecurityContextToken.class.

```
// import the packages
import javax.xml.ws.BindingProvider;
import com.ibm.websphere.wssecurity.wssapi.*;
import com.ibm.websphere.wssecurity.callbackhandler.*;
...
   // obtain the binding provider
   BindingProvider bp = ... ;

   // get the request context
   Map<String, Object> reqContext = bp.getRequestContext();

   // generate WSSFactory instance
   WSSFactory wssFactory = WSSFactory.getInstance();

   WSSGenerationContext bootstrapGenCon = wssFactory.newWSSGenerationContext();

   // Create a Timestamp
   ...
   // Add Timestamp
   ...

   // Sign the SOAP Body, WS-Addressing headers, and Timestamp
```

```
X509GenerateCallbackHandler btspReqSigCbHandler = new X509GenerateCallbackHandler(...);
SecurityToken btspReqSigToken = wssFactory.newSecurityToken(X509Token.class,
                                                            btspReqSigCbHandler);
WSSSignature bootstrapReqSig = wssFactory.newWSSSignature(btspReqSigToken);
bootstrapReqSig.setCanonicalizationMethod(WSSSignature.EXC_C14N);

// Add Sign Parts
...
bootstrapGenCon.add(bootstrapReqSig);

// Encrypt the SOAP Body and the Signature
X509GenerateCallbackHandler btspReqEncCbHandler = new X509GenerateCallbackHandler(...);
SecurityToken btspReqEncToken = wssFactory.newSecurityToken(X509Token.class,
                                                            btspReqEncCbHandler);
WSSEncryption bootstrapReqEnc = wssFactory.newWSSEncryption(btspReqEncToken);
bootstrapReqEnc.setEncryptionMethod(WSSEncryption.AES128);
bootstrapReqEnc.setKeyEncryptionMethod(WSSEncryption.KW_RSA15);

// Add Encryption parts
...
bootstrapGenCon.add(bootstrapReqEnc);
WSSConsumingContext bootstrapConCon = wssFactory.newWSSConsumingContext();
X509ConsumeCallbackHandler btspRspVfyCbHandler = new X509ConsumeCallbackHandler(....);
WSSVerification bootstrapRspVfy = wssFactory.newWSSVerification(X509Token.class,
                                                                btspRspVfyCbHandler);
bootstrapRspVfy.addAllowedCanonicalizationMethod(WSSVerification.EXC_C14N);

// Add Verify parts
...
bootstrapConCon.add(bootstrapRspVfy);
X509ConsumeCallbackHandler btspRspDecCbHandler = new X509ConsumeCallbackHandler(...);
WSSDecryption bootstrapRspDec = wssFactory.newWSSDecryption(X509Token.class,
                                                            btspRspDecCbHandler);
bootstrapRspDec.addAllowedEncryptionMethod(WSSDecryption.AES128);
bootstrapRspDec.addAllowedKeyEncryptionMethod(WSSDecryption.KW_RSA15);

// Add Decryption parts
...
bootstrapConCon.add(bootstrapRspDec);
SCTGenerateCallbackHandler sctgch = new SCTGenerateCallbackHandler(bootstrapGenCon,
                                                                   bootstrapConCon,
                                                                   ENDPOINT_URL,
                                                                   WSSEncryption.AES128);
SecurityToken[] scts = wssFactory.newSecurityTokens(new Class[]{SecurityContextToken.class},
                                                    sctgch);
SecurityContextToken sct = (SecurityContextToken)scts[0];

// Use the SCT to generate DKTs for Secure Conversation
// Signature algorithm and client and service labels
DerivedKeyToken dktSig = sct.getDerivedKeyToken(WSSSignature.HMAC_SHA1,
                                                "WS-SecureConversation",
                                                "WS-SecureConversation");

// Encryption algorithm and client and service labels
DerivedKeyToken dktEnc = sct.getDerivedKeyToken(WSSEncryption.AES128,
                                                "WS-SecureConversation",
                                                "WS-SecureConversation");

// Create the application generation context for the request message
WSSGenerationContext applicationGenCon = wssFactory.newWSSGenerationContext();

// Create and add Timestamp
...

// Add the derived key token and Sign the SOAP Body and WS-Addressing headers
WSSSignature appReqSig = wssFactory.newWSSSignature(dktSig);
appReqSig.setSignatureMethod(WSSSignature.HMAC_SHA1);
appReqSig.setCanonicalizationMethod(WSSSignature.EXC_C14N);
...
applicationGenCon.add(appReqSig);

// Add the derived key token and Encrypt the SOAP Body and the Signature
WSSEncryption appReqEnc = wssFactory.newWSSEncryption(dktEnc);
appReqEnc.setEncryptionMethod(WSSEncryption.AES128);
appReqEnc.setTokenReference(SecurityToken.REF_STR);
appReqEnc.encryptKey(false);
...
applicationGenCon.add(appReqEnc);

// Create the application consuming context for the response message
WSSConsumingContext applicationConCon = wssFactory.newWSSConsumingContext();

//client and service labels and decryption algorithm
SCTConsumeCallbackHandler sctCbHandler = new SCTConsumeCallbackHandler("WS-SecureConversation",
                                                                       "WS-SecureConversation",
                                                                       WSSDecryption.AES128);

// Derive the token from SCT and use it to Decrypt the SOAP Body and the Signature
WSSDecryption appRspDec = wssFactory.newWSSDecryption(SecurityContextToken.class,
                                                      sctCbHandler);
```

```
appRspDec.addAllowedEncryptionMethod(WSSDecryption.AES128);
appRspDec.encryptKey(false);
...
applicationConCon.add(appRspDec);

// Derive the token from SCT and use it to Verify the
// signature on the SOAP Body, WS-Addressing headers, and Timestamp
WSSVerification appRspVfy = wssFactory.newWSSVerification(SecurityContextToken.class,
                                                          sctCbHandler);
...
applicationConCon.add(appRspVfy);
...
applicationGenCon.process(reqContext);
applicationConCon.process(reqContext);
```

**What to do next**

For each token type, configure the token using the WSS APIs or using the administrative console. Next, specify the similar consumer tokens if you have not done so.

If both the generator and consumer tokens are configured, continue securing SOAP messages either by signing the SOAP message or by encrypting the message, as needed. You can use either the WSS APIs or the administrative console to secure the SOAP messages.

*Securing messages at the request generator using WSS APIs:*

You can secure SOAP messages by configuring signing information, encryption, and generator tokens to protect message integrity, confidentiality, and authenticity, respectively. This request (client-side) generator configuration defines the Web Services Security requirements for the outgoing SOAP message request.

**Before you begin**

To secure web services with WebSphere Application Server, you must configure the generator and the consumer security constraints. Therefore, in addition to securing messages at the request generator level, you must also secure messages at the response consumer level.

**About this task**

The request (client-side) generator configuration requirements involve generating a SOAP message request that uses a digital signature, incorporates encryption, and attaches security tokens.

To secure web service applications, you must specify several different configurations. Although there is no specific sequence to specify these different configurations, some configurations reference other configurations. For example, decryption configurations reference encryption configurations.

You can use the following interfaces to configure Web Services Security and to define policy types to secure the SOAP messages:

- Use the administrative console to configure policy sets.
- Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client)

The following high-level steps use the WSS APIs:

**Procedure**

- Configure generator signing to protect message integrity.
- Configure encryption to protect message confidentiality.
- Attach generator tokens to protect message authenticity.
- Propagate self-issued SAML bearer tokens using WSS APIs.
- Propagate self-issued SAML sender-vouches tokens with message protection using WSS APIs.

- Propagate self-issued SAML sender-vouches tokens with transport protection using WSS APIs.
- “Sending self-issued SAML holder-of-key tokens with symmetric key using WSS APIs” on page 1929.
- “Sending self-issued SAML holder-of-key tokens with asymmetric key using WSS APIs” on page 1931.

**Results**

After completing these procedures, you have secured messages at the request generator level.

**What to do next**

Next, if not already configured, secure messages with signature verification, decryption, and consumer tokens at the response consumer (client-side) level.

*Configuring encryption to protect message confidentiality using the WSS APIs:*

You can configure encryption information for the client-side request generator (sender) bindings. Encryption information is used to specify how the generators (senders) encrypt outgoing SOAP messages. To configure encryption, specify which message parts to encrypt and specify which algorithm methods and security tokens are to be used for encryption.

**Before you begin**

Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone understanding the message flowing across the Internet. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the correct target. Prior to configuring encryption, familiarize yourself with XML encryption.

**About this task**

For encryption, you must specify the following:
- Which parts of the message are to be encrypted.
- Which encryption algorithms to specify.

To configure encryption and encrypted parts on the client side, use the WSSEncryption and WSSEncryptPart APIs, or configure policy sets using the administrative console.

WebSphere Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

WebSphere Application Server uses encryption information for the default generator to encrypt parts of the SOAP message. The WSSEncryption API configures the following required parts as encrypted parts.

*Table 270. Required encrypted parts. Use encrypted parts to increase the confidentiality of SOAP messages.*

| Encryption parts | Description |
|---|---|
| Keywords | Keywords are used to add the encrypted parts to the SOAP message. |
| XPath expression | An XPath expression is used to add the encrypted parts to the SOAP message. |
| WSSEncryptPart object | This object adds the encrypted parts to the SOAP message. |
| WSSSignature object | This object adds the signature component as an encrypted part. |
| Header | This part adds the header in the SOAP header, specified by QName, as an encryption part. |
| Security token object | This object adds the security token as an encryption part. |

Web Services Security API (WSS API) supports symmetric encryption, by using a shared key, only when Web Services Secure Conversation (WS-SecureConversation) is used.

The WSS APIs allow the use of either keywords or an XPath expression to specify the parts of the message that are to be encrypted. WebSphere Application Server supports the use of the following keywords:

*Table 271. Supported encryption keywords. Use keywords to specify encrypted parts.*

| Keyword | References |
|---|---|
| BODY_CONTENT | The keyword for the contents of the SOAP message body as an encryption target. |
| SIGNATURE | The keyword for the signature component as an encryption target. |

If configuring using the WSS APIs, the WSSEncryption and WSSEncryptPart APIs complete these high-level steps:

**Procedure**

1. Use the WSSEncryption API to configure encryption. The WSSEncryption API performs these tasks by default:
   a. Generates the callback handler.
   b. Generates the generator security token object.
   c. Adds the security token reference type.
   d. Adds the signature component.
   e. Adds the WSSEncryptPart object.
   f. Adds the parts to be encrypted. Adds the default parts as targets of encryption by using keywords and XPath expressions.
   g. Adds the header in the SOAP message, specified by QName.
   h. Sets the default data encryption method.
   i. Specifies whether the key is to be encrypted using a Boolean value.
   j. Sets the default key encryption method.
   k. Selects a part reference.
   l. Sets the MTOM optimization Boolean value.
2. Use the WSSEncryptPart API to configure encrypted parts or add a transform method. The WSSEncryptPart API performs these tasks by default:
   a. Sets the encrypted parts specified by using keywords or an XPath expression.
   b. Sets the encrypted parts specified by an XPath expression.
   c. Sets the signature component object, WSSSignature.
   d. Sets the header in the SOAP message, specified by QName.
   e. Sets the generator security token.
   f. Adds the transform method, if needed.
3. Change from the default values for algorithm or message parts, as needed. For example: you could change one or more of the following items:
   - Change the data encryption algorithm from the default value of AES 128.
   - Change the key encryption algorithm from the default value of KW_RSA_OAEP.
   - Specify to not encrypt the key (false).
   - Change the security token type from default of X.509 token.
   - Change the security token reference type from the default value of SecurityToken.REF_STR.
   - Only use BODY_CONTENT as an encryption part and not use SIGNATURE also.
   - Turn MTOM optimization on (true).

### Results

The encryption information is configured for the generator binding.

### Example

The following is an example of the WSSEncryption API:

```
WSSFactory factory = WSSFactory.getInstance();
WSSGenerationContext gencont = factory.newWSSGenerationContext();

X509GenerateCallbackHandler callbackhandler = generateCallbackHandler();
SecurityToken token = factory.newSecurityToken(X509Token.class, callbackHandler);
WSSEncryption enc = factory.newWSSEncryption(token);

gencont.add(enc);
```

### What to do next

You must configure similar decryption information for the client-side response consumer (receiver) bindings, if you have not already configured the information.

Next, review the WSSEncryption API process.

*Encrypting the SOAP message using the WSSEncryption API:*

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure the client for request encryption on the generator side, use the WSSEncryption API to encrypt the SOAP message. The WSSEncryption API specifies which request SOAP message parts to encrypt when configuring the client.

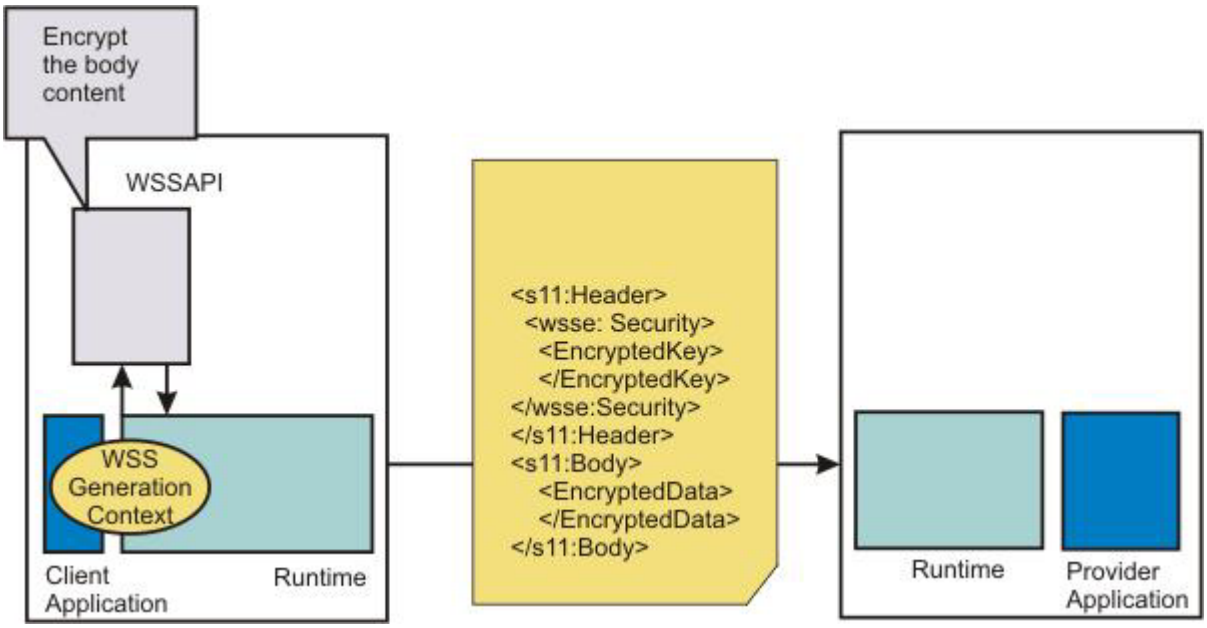
### Before you begin

You can use the WSS API or use policy sets on the administrative console to enable encryption and add generator security tokens in the SOAP message. To secure SOAP messages, use the WSS APIs to complete the following encryption tasks, as needed:

- Configure encryption and choose the encryption methods using the WSSEncryption API.
- Configure the encrypted parts, as needed, using the WSSEncryptPart API.

### About this task

The encryption information on the generator side is used for encrypting an outgoing SOAP message for the request generator (client side) bindings. The client generator configuration must match the configuration for the provider consumer.



Confidentiality settings require that confidentiality constraints be applied to generated messages. These constraints include specifying which message parts within the generated message must be encrypted, and which message parts to attach encrypted Nonce and timestamp elements to.

The following encryption parts can be configured:

*Table 272. Encryption parts. Use the encryption parts to enable encryption in messages.*

| Encryption parts | Description |
|---|---|
| part | Adds the WSSEncryptPart object as a target of the encryption part. |
| keyword | Adds the encryption parts using keywords. WebSphere Application Server supports the following keywords:<br>• BODY_CONTENT<br>• SIGNATURE |
| xpath | Adds the encryption part using an XPath expression. |
| signature | Adds the WSSignature component as a target of the encrypted part. |
| header | Adds the SOAP header, specified by QName, as a target of the encrypted part. |
| securityToken | Adds the SecurityToken object as a target of the encrypted part. |

For encryption, certain default behaviors occur. The simplest way to use the WSSEncryption API is to use the default behavior (see the example code).

WSSEncryption provides defaults for the key encryption algorithm, the data encryption algorithm, the security token reference method, and the encryption parts such as the SOAP body content and the signature. The encryption default behaviors include:

*Table 273. Encryption decisions. Use encryption default behavior to secure the message body content and signature.*

| Encryption decisions | Default behavior |
|---|---|
| Which SOAP message parts to encrypt using keywords | Sets the encryption parts that you can add using keywords. The default encryption parts are the BODY_CONTENT and SIGNATURE. WebSphere Application Server supports using these keywords:<br>• WSSEncryption.BODY_CONTENT<br>• WSSEncryption.SIGNATURE |

*Table 273. Encryption decisions (continued). Use encryption default behavior to secure the message body content and signature.*

| Encryption decisions | Default behavior |
|---|---|
| Which data encryption method to choose (algorithm) | Sets the data encryption method. Both data and key encryption methods can be specified. The default data encryption algorithm method is AES 128. WebSphere Application Server supports these data encryption methods:<br>• WSSEncryption.AES128: http://www.w3.org/2001/04/xmlenc#aes128-cbc<br>• WSSEncryption.AES192: http://www.w3.org/2001/04/xmlenc#aes192-cbc<br>• WSSEncryption.AES256: http://www.w3.org/2001/04/xmlenc#aes256-cbc<br>• WSSEncryption.TRIPLE_DES: http://www.w3.org.2001/04/xmlenc#tripledes-cbc |
| Whether to encrypt the key (isEncrypt) | Specifies whether to encrypt the key. The values are `true` or `false`. The default value is to encrypt the key (`true`). |
| Which key encryption method to choose (algorithm) | Sets the key encryption method. Both data and key encryption methods can be specified. The default key encryption algorithm method is key wrap RSA OAEP. WebSphere Application Server supports these key encryption methods:<br>• WSSEncryption.KW_AES128: http://www.w3.org/2001/04/xmlenc#kw-aes128<br>• WSSEncryption.KW_AES192: http://www.w3.org/2001/04/xmlenc#kw-aes192<br>• WSSEncryption.KW_AES256: http://www.w3.org/2001/04/xmlenc#kw-aes256<br>• WSSEncryption.KW_RSA_OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p<br>• WSSEncryption.KW_RSA15: http://www.w3.org/2001/04/xmlenc#rsa-1_5<br>• WSSEncryption.KW_TRIPLE_DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes |
| Which security token to specify (securityToken) | Sets the SecurityToken. The default security token type is the X509Token. WebSphere Application Server provides the following pre-configured consumer token types:<br>• Derived key token<br>• X.509 tokens |
| Which token reference to use (refType) | Sets the type of the security token reference. The default token reference is SecurityToken.REF_KEYID. WebSphere Application Server supports the following token reference types:<br>• SecurityToken.REF_KEYID<br>• SecurityToken.REF_STR<br>• SecurityToken.REF_EMBEDDED<br>• SecurityToken.REF_THUMBPRINT |
| Whether to use MTOM (mtomOptimize) | Sets Message Transmission Optimization Mechanism (MTOM) optimization for the encrypted part. |

### Procedure

1. To encrypt the SOAP message using the WSSEncryption API, first ensure that the application server is installed.
2. The WSS API process for encryption performs these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance
   b. Creates the WSSGenerationContext instance from the WSSFactory instance.
   c. Creates the SecurityToken from WSSFactory used for encryption.
   d. Creates WSSEncryption from the WSSFactory instance using the SecurityToken. The default behavior of WSSEncryption is to encrypt the body content and the signature.
   e. Adds a new part to be encrypted in WSSEncryption if the existing part is not appropriate. After addEncryptPart(), addEncryptHeader(), or addEncryptPartByXPath() is called, the default part is cleared.
   f. Calls the encryptKey(false) if the key is not to be encrypted.
   g. Sets the data encryption method if the default method is not appropriate.
   h. Sets the key encryption method if the default method is not appropriate.
   i. Sets the token reference if the default token reference is not appropriate.
   j. Adds WSSEncryption to WSSConsumingContext.
   k. Calls WSSGenerationContext.process() with the SOAPMessageContext.

### Results

If there is an error condition during encryption, a WSSException is provided. If successful, the API calls the WSSGenerationContext.process(), the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

### Example

The following example provides sample code using methods that are defined in WSSEncryption:

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance (step: a)
WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSGenerationContext instance (step: b)
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate the callback handler
X509GenerateCallbackHandler callbackHandler = new
          X509GenerateCallbackHandler(
     "",
     "enc-sender.jceks",
     "jceks",
     "storepass".toCharArray(),
     "bob",
     null,
     "CN=Bob, O=IBM, C=US",
     null);

// Generate the security token used for encryption (step: c)
SecurityToken token = factory.newSecurityToken(X509Token.class , callbackHandler);

// Generate WSSEncryption instance (step: d)
WSSEncryption enc = factory.newWSSEncryption(token);

// Set the part to be encrypted (step: e)
// DEFAULT: WSSEncryption.BODY_CONTENT and WSSEncryption.SIGNATURE

// Set the part specified by the keyword (step: e)
   enc.addEncryptPart(WSSEncryption.BODY_CONTENT);

// Set the part in the SOAP Header specified by QName (step: e)
   enc.addEncryptHeader(new QName("http://www.w3.org/2005/08/addressing",
                                  "MessageID"));

// Set the part specified by WSSSignature (step: e)
   SecurityToken sigToken = getSecurityToken();
      WSSSignature sig = factory.newWSSSignature(sigToken);
   enc.addEncryptPart(sig);

// Set the part specified by SecurityToken (step: e)
   UNTGenerateCallbackHandler untCallbackHandler =
          new UNTGenerateCallbackHandler("Chris", "sirhC");
      SecurityToken unt = factory.newSecurityToken(UsernameToken.class,
                                                   untCallbackHandler);
   enc.addEncryptPart(unt, false);

// sSt the part specified by XPath expression (step: e)
   StringBuffer sb = new StringBuffer();
      sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
         and local-name()='Envelope']");
      sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
         and local-name()='Body']");
      sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
         and local-name()='Ping']");
      sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
         and local-name()='Text']");
   enc.addEncryptPartByXPath(sb.toString());

// Set whether the key is encrypted (step: f)
// DEFAULT: true
   enc.encryptKey(true);

// Set the data encryption method (step: g)
// DEFAULT: WSSEncryption.AES128
   enc.setEncryptionMethod(WSSEncryption.TRIPLE_DES);

// Set the key encryption method (step: h)
// DEFAULT: WSSEncryption.KW_RSA_OAEP
   enc.setEncryptionMethod(WSSEncryption.KW_RSA15);

// Set the token reference (step: i)
// DEFAULT: SecurityToken.REF_KEYID
```

```
  enc.setTokenReference(SecurityToken.REF_STR);

// Add the WSSEncryption to the WSSGenerationContext (step: j)
  gencont.add(enc);

// Process the WS-Security header (step: k)
gencont.process(msgcontext);
```

**Note:** The X509GenerationCallbackHandler does not need the key password because the public key is used for encryption. You do not need a password to obtain the public key from the Java keystore.

**What to do next**

If you have not previously specified which encryption methods to choose, use the WSS API or configure the policy sets using the administrative console to choose the data and key encryption algorithm methods.

*Choosing encryption methods for generator bindings:*

To configure the client for request encryption for the generator binding, you must specify which encryption methods to use when the client encrypts the SOAP messages.

**Before you begin**

Prior to completing these steps, read the XML encryption information to become familiar with encrypting and decrypting SOAP messages.

To specify which algorithm methods are to be used when the client encrypts the SOAP messages, complete the following tasks:

- Use the WSSEncryption API to configure the data encryption algorithm and the key encryption algorithm methods.
- Use the WSSEncryptPart API to configure a transform algorithm method, if needed. The default is no transform algorithm.

**About this task**

Some of the encryption-related definitions are based on the XML-Encryption specification. The following information defines some data encryption-related terms:

**Data encryption method algorithm**

Data encryption algorithms specify the algorithm uniform resource identifier (URI) of the data encryption method. This algorithm encrypts and decrypts data in fixed size, multiple octet blocks.

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files.

For the AES256-cbc and the AES192-cbc algorithms, you must download the unrestricted Java™ Cryptography Extension (JCE) policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

**Key encryption method algorithm**

Key encryption algorithms specify the algorithm uniform resource identifier (URI) of the method to encrypt the key that is used to encrypt data. The algorithm represents public key encryption algorithms that are specified for encrypting and decrypting keys.

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property.

The property name is: com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod. The property value is one of the following URIs of the digest method:

- http://www.w3.org/2001/04/xmlenc#sha256
- http://www.w3.org/2001/04/xmlenc#sha512

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

**Important:** You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.

For the KW-AES256 and the KW-AES192 key encryption algorithms, you must download the unrestricted JCE policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

**Important:** Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

*Table 274. Encryption usage types. The encryption usage types describe encryptions methods.*

| Usage types | Description |
|---|---|
| Data encryption | Specifies the algorithm URI that is used for both encrypting and decrypting data. Encrypts and decrypts data in fixed size, multiple octet blocks. |
| Key encryption | Specifies the algorithm URI that is used for encrypting and decrypting the encryption key. |

### Data encryption

WebSphere Application Server supports the following pre-configured data encryption algorithms:

*Table 275. Data encryption algorithms. These pre-configuring encryption algorithms are supported by WebSphere Application Server.*

| Data encryption name | Algorithm URI |
|---|---|
| WSSEncryption.AES128 (the default value) | A URI of data encryption algorithm, AES 128: http://www.w3.org/2001/04/xmlenc#aes128-cbc |
| WSSEncryption.AES192 | A URI of data encryption algorithm, AES 192: http://www.w3.org/2001/04/xmlenc#aes192-cbc |
| WSSEncryption.AES256 | A URI of data encryption algorithm, AES 256: http://www.w3.org/2001/04/xmlenc#aes256-cbc |
| WSSEncryption.TRIPLE_DES | A URI of data encryption algorithm, 3DES: http://www.w3.org.2001/04/xmlenc#tripledes-cbc |

### Key encryption

WebSphere Application Server supports the following pre-configured key encryption algorithms:

*Table 276. Key encryption algorithms. These pre-configured encryption algorithms are supported by WebSphere Application Server.*

| Key encryption name | Algorithm URI |
|---|---|
| WSSEncryption.KW_AES128 | A URI of key encryption algorithm, key wrap AES 128: http://www.w3.org/2001/04/xmlenc#kw-aes128 |
| WSSEncryption.KW_AES192 | A URI of key encryption algorithm, key wrap AES 192: http://www.w3.org/2001/04/xmlenc#kw-aes192<br>**Restriction:** Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP). |
| WSSEncryption.KW_AES256 | A URI of key encryption algorithm, key wrap AES 256: http://www.w3.org/2001/04/xmlenc#kw-aes256 |

*Table 276. Key encryption algorithms (continued). These pre-configured encryption algorithms are supported by WebSphere Application Server.*

| Key encryption name | Algorithm URI |
|---|---|
| WSSEncryption.KW_RSA_OAEP (the default value) | A URI of key encryption algorithm, key wrap RSA OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p |
| WSSEncryption.KW_RSA15 | A URI of key encryption algorithm, key wrap RSA 1.5: http://www.w3.org/2001/04/xmlenc#rsa-1_5 |
| WSSEncryption.KW_TRIPLE_DES | http://www.w3.org/2001/04/xmlenc#kw-tripledes |

To configure the encryption and encrypted part algorithm methods, use the WSSEncryption API, or configure policy sets using the administrative console.

**Note:** Policy sets do not support symmetric key encryption. If you are using the WSS API for symmetric key encryption, you will not be able to interoperate with web services endpoints that use policy sets.

The WSS API process completes the following high-level steps to specify which encryption methods to use when configuring the client for request encryption:

### Procedure

1. Using the WSSEncryption API, adds the required data encryption algorithm. The data encryption algorithm is used for encrypting or decrypting parts of a SOAP message. Data encryption algorithms specify the algorithm uniform resource identifier (URI) of the data encryption method.

   The client generator configuration must match the configuration for the provider consumer.

   The default data encryption algorithm is AES 128. The data encryption name is AES128, and the URI of the data encryption algorithm, is http://www.w3.org/2001/04/xmlenc#aes128-cbc. WebSphere Application Server supports the following pre-configured data encryption algorithms:

   - AES 128: http://www.w3.org/2001/04/xmlenc#aes128-cbc

     The AES 128 algorithm is the default data algorithm method.
   - AES 192: http://www.w3.org/2001/04/xmlenc#aes192-cbc

     Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

     To use this AES 192-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
   - AES 256: http://www.w3.org/2001/04/xmlenc#aes256-cbc

     To use this AES 256-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
   - TRIPLEDES: http://www.w3.org/2001/04/xmlenc#tripledes-cbc
2. As needed, changes the WSSEncryption API method to specify another data encryption algorithm. For example, you might add the following code to change from the default AES 128 algorithm to the Triple DES algorithm:

```
// Default data encryption algorithm: AES128
WSSEncryption enc = factory.newWSSEncryption(x509t);
   enc.setEncryptionMethod(EncryptionMethod.TRIPLEDES_CBC);
gencont.add(enc);
```

3. Using the WSSEncryption API, adds the required key encryption algorithm. The key encryption algorithm is used for encrypting the key that is used for encrypting the message parts within the SOAP message. If the encryption key, which is the key that is used for encrypting the message parts, is not encrypted, then the decryption API selects `false` to match the encryption key.

   The client generator configuration must match the configuration for the provider consumer.

The default key encryption algorithm value is key wrap RSA OAP. The key encryption name is KW_RSA_OAEP, and the URI of the key encryption algorithm is http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p. WebSphere Application Server supports the following pre-configured key encryption algorithms:

- KW AES128: http://www.w3.org/2001/04/xmlenc#kw-aes128
- KW AES192: http://www.w3.org/2001/04/xmlenc#kw-aes192

  To use this key wrap AES 192 algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

  Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).KW AES 256: http://www.w3.org/2001/04/xmlenc#kw-aes256

  To use this key wrap AES 256-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
- KW RSA OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p.

  The KW RSA OAEP algorithm is the default key algorithm method.

  When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms does not include this algorithm. This algorithm appears in the list of supported key transport algorithms when running with SDK Version 1.5. See more information at http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p
- KW RSA15: http://www.w3.org/2001/04/xmlenc#rsa-1_5
- KW TRIPLE DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes

**Note:** For Web Services Secure Conversation, the WSSEncryption API might specify addition key-related information, such as the:
- algorithmName
- keyLength

### Results

If there is an error condition, a WSSException is provided. If successful, the API calls the WSSGenerationContext.process(), the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

### Example

The following example provides sample WSS API code using WSSEncryption.setEncryptionMethod() and WSSEncryption.setKeyEncryptionMethod().

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance
   WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSGenerationContext instance
   WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate callback handler
   X509GenerateCallbackHandler callbackHandler = new
       X509GenerateCallbackHandler(
                                   "",
                                   "enc-sender.jceks",
                                   "jceks",
                                   "storepass".toCharArray(),
                                   "bob",
                                   null,
                                   "CN=Bob, O=IBM, C=US",
                                   null);

// Generate the security token used for encryption
   SecurityToken token = factory.newSecurityToken(X509Token.class , callbackHandler);
```

```
// Generate WSSEncryption instance
   WSSEncryption enc = factory.newWSSEncryption(token);

// Set the data encryption method
// DEFAULT: WSSEncryption.AES128
      enc.setEncryptionMethod(WSSEncryption.TRIPLE_DES);

// Set the key encryption method
// DEFAULT: WSSEncryption.KW_RSA_OAEP
      enc.setEncryptionMethod(WSSEncryption.KW_RSA15);

// Add the WSSEncryption to the WSSGenerationContext
   gencont.add(enc);

// Generate the WS-Security header
gencont.process(msgcontext);
```

### What to do next

Next, if you want to add a transform algorithm, review the WSSEncryptPart API process task.

*Encryption methods:*

For request generator binding settings, the encryption methods include specifying the data and key encryption algorithms to use to encrypt the SOAP message. The WSS API for encryption (WSSEncryption) specifies the algorithm name and the matching algorithm uniform resource identifier (URI) for the data and key encryption methods. If the data and key encryption algorithms are specified, only elements that are encrypted with those algorithms are accepted.

### Data encryption algorithms

The data encryption algorithm is used to encrypt parts of the SOAP message, including the body and the signature. Data encryption algorithms specify the algorithm uniform resource identifier (URI) for each type of data encryption algorithms.

The following pre-configured data encryption algorithms are supported:

*Table 277. Data encryption algorithms. The algorithms are used to encrypt SOAP messages.*

| Data encryption algorithm name | Algorithm URI |
|---|---|
| WSSEncryption.AES128 (the default value) | A URI of data encryption algorithm, AES 128: http://www.w3.org/2001/04/xmlenc#aes128-cbc |
| WSSEncryption.AES192 | A URI of data encryption algorithm, AES 192: http://www.w3.org/2001/04/xmlenc#aes192-cbc |
| WSSEncryption.AES256 | A URI of data encryption algorithm, AES 256: http://www.w3.org/2001/04/xmlenc#aes256-cbc |
| WSSEncryption.TRIPLE_DES | A URI of data encryption algorithm, TRIPLE DES: http://www.w3.org/2001/04/xmlenc#tripledes-cbc |

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files.

**Important:** Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

For the AES256-cbc and the AES192-CBC algorithms, you must download the unrestricted Java™ Cryptography Extension (JCE) policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

The data encryption algorithm configured for encryption for the generator side must match the data encryption algorithm that is configured for decryption for the consumer side.

**Key encryption algorithms**

This algorithm is used to encrypt and decrypt keys. This key information is used to specify the configuration that is needed to generate the key for digital signature and encryption. The signing information and encryption information configurations can share the key information. The key information on the consumer side is used for specifying the information about the key that is used for validating the digital signature in the received message or for decrypting the encrypted parts of the message. The request generator is configured for the client.

**Note:** Policy sets do not support symmetric key encryption. If you are using the WSS API for symmetric key encryption, you will not be able to interoperate with web services endpoints using the policy sets.

Key encryption algorithms specify the algorithm uniform resource identifier (URI) of the key encryption method. The following pre-configured key encryption algorithms are supported:

*Table 278. Supported pre-configured key encryption algorithms. The algorithms are used to encrypt and decrypt keys.*

| WSS API | URI |
|---|---|
| WSSEncryption.KW_AES128 | A URI of key encryption algorithm, key wrap AES 128: http://www.w3.org/2001/04/xmlenc#kw-aes128 |
| WSSEncryption.KW_AES192 | A URI of key encryption algorithm, key wrap AES 192: http://www.w3.org/2001/04/xmlenc#kw-aes192<br>**Restriction:** Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP). |
| WSSEncryption.KW_AES256 | A URI of key encryption algorithm, key wrap AES 256: http://www.w3.org/2001/04/xmlenc#kw-aes256 |
| WSSEncryption.KW_RSA_OAEP (the default value) | A URI of key encryption algorithm, key wrap RSA OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p |
| WSSEncryption.KW_RSA15 | A URI of key encryption algorithm, key wrap RSA 1.5: http://www.w3.org/2001/04/xmlenc#rsa-1_5 |
| WSSEncryption.KW_TRIPLE_DES | A URI of key encryption algorithm, key wrap TRIPLE DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes |

For Secure Conversation, additional key-related information must be specified, such as:

- algorithmName
- keyLength

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. The property name is: `com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod`. The property value is one of the following URIs of the digest method:

- http://www.w3.org/2001/04/xmlenc#sha256
- http://www.w3.org/2001/04/xmlenc#sha512

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

**Important:** You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.

For the KW-AES256 and the KW-AES192 key encryption algorithms, you must download the unrestricted JCE policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

The key encryption algorithm for the generator must match the key decryption algorithm that is configured for the consumer.

This example provides sample code for encryption to use the Triple DES for the data encryption method and to use RSA1.5 for the key encryption method:

```
// get the message context
Object msgcontext = getMessageContext();

// generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

// generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// generate callback handler
X509GenerateCallbackHandler callbackHandler = new X509GenerateCallbackHandler(
  "",
  "enc-sender.jceks",
  "jceks",
  "storepass".toCharArray(),
  "bob",
  null,
  "CN=Bob, O=IBM, C=US",
  null);

// generate the security token used to the encryption
SecurityToken token = factory.newSecurityToken(X509Token.class,
     callbackHandler);

// generate WSSEncryption instance to encrypt the SOAP body content
WSSEncryption enc = factory.newWSSEncryption(token);
enc.addEncryptPart(WSSEncryption.BODY_CONTENT);

// set the data encryption method
// DEFAULT: WSSEncryption.AES128
enc.setEncryptionMethod(WSSEncryption.TRIPLE_DES);

// set the key encryption method
// DEFAULT: WSSEncryption.KW_RSA_OAEP
enc.setEncryptionMethod(WSSEncryption.KW_RSA15);

// add the WSSEncryption to the WSSGenerationContext
gencont.add(enc);

// generate the WS-Security header
gencont.process(msgcontext);
```

*Adding encrypted parts using the WSSEncryptPart API:*

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure encrypted parts for the request generator (client side) bindings, use the WSSEncryptPart API to define and add to the listing of elements in the encrypted part. WSSEncryptPart is an interface that is part of the com.ibm.websphere.wssecurity.wssapi.encryption package.

**Before you begin**

You can use the WSS APIs or configure policy sets using the administrative console to enable the encrypted parts. To secure SOAP messages, use the WSS APIs to complete the following encryption tasks, as needed:

- Configure encryption and choose the encryption methods using the WSSEncryption API.
- Configure the encrypted parts using the WSSEncryptpart API, as needed.

**About this task**

Confidentiality settings require that confidentiality constraints be applied to generated messages. These constraints include specifying which message parts within the generated message must be encrypted, and

which message parts to attach encrypted elements to. The encryption information on the generator side is used for encrypting an outgoing SOAP message. The request generator is configured for the client.

The WSSEncryptPart API specifies information related to encrypted parts and sets the encrypted parts that have been added for message confidentiality protection. Use the WSSEncryptPart to set the transform method and to specify the part to which the transform method is to be applied. Sets the transform method only if using SOAP with Attachments. The WSSEncryptPart is usually not needed except, in some case for tasks such as setting the transform method.

The encrypted parts and related information displayed in the following table are used to protect the confidentiality of messages.

*Table 279. Encrypted parts. Use encrypted parts to secure messages.*

| Encrypted parts | Description |
|---|---|
| part | Adds the WSSEncryptPart object as a target of the encryption part. |
| keyword | Adds the encrypted parts using keywords. The default encryption parts that you can add using keywords are the BODY_CONTENT and SIGNATURE. WebSphere Application Server supports using these keywords:<br>• BODY_CONTENT<br>• SIGNATURE |
| xpath | Adds the encrypted part by using an XPath expression. |
| signature | Adds the WSSSignature component as a target of the encrypted part.<br><br>WSSSignature is applicable only if the SOAP message contains a signature element. |
| header | Adds the SOAP header, specified by QName, as a target of the encrypted part. |
| securityToken | Adds the SecurityToken object as a target of the encrypted part. |

For encrypted parts, certain default behaviors occur. The simplest way to use the WSSEncryptPart API is to use the default behavior. The WSSEncryptPart API provides defaults for specifying the transform algorithm, setting objects as targets, specifying the encrypted parts, such as: the SOAP body content and the signature.

The encryption default behaviors include:

*Table 280. Encrypted part decisions. Several encrypted message parts are set by default.*

| Encrypted part decisions | Default behavior |
|---|---|
| Which SOAP message parts to encrypt using keywords | Specifies which keywords to use for the encrypted parts. WebSphere Application Server sets the following SOAP message parts by default for encryption:<br>• WSSEncryption.BODY_CONTENT<br>• WSSEncryption.SIGNATURE |
| Which transform method to add | WebSphere Application Server does not specify any transform method by default. Specify a transform method only if using SOAP with Attachments. |

### Procedure

1. To encrypt the SOAP message parts using the WSSEncryptPart API, first ensure that the application server is installed.
2. The WSS API process using WSSEncryptPart follows these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSGenerationContext instance from the WSSFactory instance.
   c. Creates the SecurityToken from WSSFactory to configure the encryption.
   d. Creates WSSEncryption from the WSSFactory instance using SecurityToken.
   e. Creates WSSEncryptPart from WSSFactory.
   f. Adds the parts to be encrypted and to be applied with the transform in WSSEncryptPart. WebSphere Application Server sets these encrypted parts by default for WSSEncryptPart: the BODY_CONTENT and SIGNATURE. After you add other encrypted parts, the default values are no

longer valid. For example, if you call addEncryptPart(securityToken, false), only the security token is encrypted, and not the signature and body content. So if you want to encrypt the security token, the signature, and the body content, you must call addEncryptPart(securityToken, false), addEncryptPart(WSSEncryption.SIGNATURE), and addEncryptPart(WSSEncrypyion.BODY_CONTENT).

g. Sets the transform method.
h. Adds WSSEncryptPart to WSSEncryption.
i. Adds WSSEncryption to WSSGenerationContext.
j. Calls WSSGenerationContext.process() with the SOAPMessageContext.

**Results**

If there is an error condition during encryption of the message parts, a WSSException is provided. If successful, the API calls the WSSGenerationContext.process(), the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

**What to do next**

After enabling encrypted parts for the request generator (client side) binding, you must specify the same parts to be decrypted for the response consumer (client side) bindings. Next, to configure decryption and decrypted parts, use the WSS APIs or configure policy sets using the administrative console.

*Configuring generator signing information to protect message integrity using the WSS APIs:*

You can configure the signing information to protect message integrity for the request (client side) generator binding. Signing information includes the signature and the signed parts. To keep the integrity of the message, digital signatures are typically applied.

**Before you begin**

In addition to using a digital signature and configuring the signing information, the following tasks should also be performed:

- Verify the signing information.
- Incorporate encryption.
- Attach security tokens.

**About this task**

Integrity refers to digital signature while confidentiality refers to encryption. Integrity is provided by applying a digital signature to a SOAP message. To configure the signing information to protect message integrity, you must first digitally sign and then verify the signature for the SOAP messages. Integrity decreases the risk of data modification when you transmit data across a network.

Also, message integrity is provided by digitally signing the body, time stamp, and WS-Addressing headers using the signature algorithm methods. The WSS APIs specify which algorithm is to be used to sign the certificate. The signature algorithms specify the Uniform Resource Identifiers (URI) of the signature method. WebSphere Application Server supports several pre-configured request signing algorithm methods.

You can use the following interfaces to configure Web Services Security and to protect SOAP message integrity:

- Use the administrative console to configure policy sets for the signing information.
- Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client).

Perform the following signing tasks, using the WSS APIs, to configure the signing information and to protect message integrity for the generator binding.

**Procedure**

- Configure the signing information using the WSSSignature API. Configure the signing information for the generator binding using the WSSSignature API. Signing information is used to sign parts of a message including the SOAP body, the time stamp, and the WS-Addressing headers. Both signing and encryption can be applied to the same message parts, such as the SOAP body.
- Add or change signed parts using the WSSSignPart API.
- Configure the client for request signing methods using the WSSSignature or WSSSignPart APIs. To configure the client for request signing, choose the signing methods. The request signing methods include the signature, the canonicalization, the digest, and the transform methods. Use the WSSSignature API to configure the signature and canonicalization methods. Use the WSSSignPart API to configure the digest and transform methods.

**Results**

The WSS APIs also specify the security token for the generator (client) binding and set the type of token reference to protect message authenticity. By completing the steps in these tasks, you have configured generator signing to protect the integrity of the SOAP message.

**What to do next**

Next, verify the consumer signing information by using the WSS APIs or by configuring policy sets using the administrative console.

*Configuring signing information using the WSS APIs:*

You can configure the signing information for the client-side request generator (sender) bindings. Signing information is used to sign and validate parts of a message including the SOAP body, the timestamp information, and the Username token. To configure the client for request signing, specify which message parts to digitally sign when configuring the client.

**Before you begin**

WebSphere Application Server uses XML digital signature with existing algorithms such as RSA, HMAC, and SHA1. XML signature defines many methods for describing key information and enables the definition of a new method. Prior to completing these steps, familiarize yourself with XML digital signature for signing and verifying digital signatures for digital content.

**About this task**

By including XML signature in SOAP messages, the following issues are realized: message integrity and authentication. *Integrity* refers to digital signature whereas confidentiality refers to encryption. Integrity decreases the risk of data modification while the data is transmitted across the Internet. WebSphere Application Server uses the signing information for the default generator to sign parts of the message, such as the body, time stamp, and Username token.

For the signing information, you must specify the following:

- Which parts of the message are to be signed.
- The key information that is referenced by the key information for the signing keys.
- The signing algorithms.

WebSphere Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

The WSSSignature API configures the following parts as signature parts:

*Table 281. Pre-configured signature parts. Use the signing information to validate parts of a message.*

| | |
|---|---|
| Security token object | This object authenticates the client. If this option is specified, then the message is signed. You can digitally sign the message using a security token if a login configuration authentication method is selected. |
| WSSTimestamp object | This object adds a time stamp to a message. The time stamp determines if the message is valid based on the time that the message is sent and then received. |
| WSSSignature Part object | This object adds the signature parts to a message. |
| SOAP header and the QName as a target | This signature part adds the header, specified by QName, as a verification part. |

The WSS APIs allow the use of keywords or an XPath expression to specify which parts of the message are to be signed. WebSphere Application Server supports the use of the following keywords:

*Table 282. Supported signature keywords. Key information is used to specify which parts of a message are signed.*

| Keyword | References |
|---|---|
| ADDRESSING_HEADERS | The Web Services Addressing (WS-Addressing) headers. |
| BODY | The SOAP message body. The body is the user data portion of the message. |
| TIMESTAMP | The creation and expiration timestamp information. |

The Web Services Security API (WSS API) are used to configure the signing information for the request generator (client side) section of the bindings file. To configure the signing information on the client side, use the WSS APIs or configure policy sets for signing using the administrative console.

If configuring using the WSS APIs, the WSSSignature and WSSSignPart APIs complete the following steps to specify which message parts to digitally sign when configuring the client for request generator signing:

**Procedure**

1. The WSSSignature API adds the required parts of the SOAP message to digitally sign. Either a keyword or an XPath expression can be used to specify the required encryption parts.
2. The WSSSignature API sets the signature method algorithm. The default signature method is RSA_SHA1. WebSphere Application Server supports the following pre-configured algorithms:
   - RSA SHA1: http://www.w3.org/2000/09/xmldsig#rsa-sha1
   - HMAC SHA1http://www.w3.org/2000/09/xmldsig#hmac-sha1

   WebSphere Application Server does not support the following algorithm for DSA-SHA1: http://www.w3.org/2000/09/xmldsig#dsa-sha1. You cannot use the DSA-SHA1 algorithm if you want to be compliant with the Basic Security Profile (BSP).

   Any ds:SignatureMethod/@Algorithm element in a signature is based on a symmetric key and must have a value of RSA-SHA1 or HMAC-SHA1.

   The algorithm that is specified for the request generator configuration must match the algorithm that is specified for the request consumer configuration.
3. The WSSSignature API sets the canonicalization method. The default signature method is EXC_C14N. WebSphere Application Server supports the following pre-configured algorithms:
   - The URI of the exclusive canonicalization algorithm, EXC_C14N: http://www.w3.org/2001/10/xml-exc-c14n#.
   - The URI of the inclusive canonicalization algorithm, C14N: http://www.w3.org/2001/10/xml-c14n#.

   The canonicalization algorithm that you specify for the generator must match the algorithm for the consumer.
4. The WSSSignature API adds a security token. The API adds information about the security token that is to be used for the signature, such as:
   - The class for security token.
   - The callback handler

- The name of the JAAS login configuration.

5. The WSSSignature API sets the type of security token and sets the type of token reference. WebSphere Application Server supports the following pre-configured token references:
   - SecurityToken.REF_STR

     Represents the security token reference as a token reference type.
   - SecurityToken.REF_KEYID

     Represents the key identifier reference as a token reference type.
   - SecurityToken.REF_EMBEDDED

     Represents the embedded reference as a token reference type.
   - SecurityToken.REF_THUMBPRINT

     Represents the thumbprint reference as a token reference type.
6. If SecurityToken.REF_KEYID is set as the type of token reference, the WSSSignature API sets the key information signature type and configures the key information that is referenced by the key information references. WebSphere Application Server supports the following:
   - Specifying that the KeyInfo element is not signed.
   - Specifying that the entire <KeyInfo> element is signed.
   - Specifying that the child elements <Keyinfochildelements> of the <KeyInfo> element are signed.

   If you do not specify one of the previous signature types, WebSphere Application Server specifies that the entire <KeyInfo> element is signed, by default.

   If you select Keyinfo or Keyinfochildelements and you select http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform as the transform algorithm in a subsequent step, WebSphere Application Server also signs the referenced token.

   The key information signature type for the generator must match the signature type for the consumer.
7. The WSSSignature API specifies whether to require signature confirmation. The OASIS Web Services Security (WS-Security) Version 1.1 specification defines the use of signature confirmation. If you are using WS-Security Version 1.0, this function is not available.

   The signature confirmation value is stored in order to validate the signature confirmation with it after the receiving message is returned. This method is called if the response message is expected to attach the signature confirmation into the SOAP message.
8. The WSSSignPart API specifies the part reference. The part reference specifies which parts of the message to digitally sign.

   The part reference refers to the message part that is digitally signed. The part attribute refers to the name of the <Integrity> element when the <PartReference> element is specified for the signature. You can specify multiple <PartReference> elements within the <SigningInfo> element. The <PartReference> element has two child elements when it is specified for the signature verification: <DigestTransform> and <Transform>.
9. The WSSSignPart API specifies the digest method algorithm. The digest method algorithm specified within the <DigestMethod> element is used in the <SigningInfo> element.

   WebSphere Application Server supports the following pre-configured digest algorithms:
   - http://www.w3.org/2000/09/xmldsig#sha1
   - http://www.w3.org/2001/04/xmlenc#sha256
   - http://www.w3.org/2001/04/xmlenc#sha512
10. The WSSSignPart API specifies the transform algorithm. The transform algorithm is that is specified within the <Transform> element and specifies the transform algorithm for the signature. WebSphere Application Server supports the following pre-configured transform algorithms:
    - http://www.w3.org/2001/10/xml-exc-c14n#
    - http://www.w3.org/TR/1999/REC-xpath-19991116

      Do not use this transform algorithm if you want to be compliant with the Basic Security Profile (BSP). Instead use http://www.w3.org/2002/06/xmldsig-filter2 to ensure compliance.

- http://www.w3.org/2002/06/xmldsig-filter2
- http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
- http://www.w3.org/2002/07/decrypt#XML
- http://www.w3.org/2000/09/xmldsig#enveloped-signature

The transform algorithm that you select for the generator must match the transform algorithm that you select for the consumer.

**Important:** If both of the following conditions are true, WebSphere Application Server signs the referenced token:

- You previously selected the Keyinfo or the Keyinfochildelements option
- You select http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform as the transform algorithm.

11. If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when running the client, you might need to configure the actor. Configure policy sets using the administrative console to configure the same actor strings for the web service on the server, which processes the request and sends the response back.

    The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The actor might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

### Results

After the WSSSignature and WSSSignPart APIs complete these steps, the signing information is configured for the generator sections of the bindings files.

### Example

The following example shows WSS API sample code to configure the signature, to generate the callback handler, and to specify the X.509 token type as the security token:

```
WSSFactory factory = WSSFactory.getInstance();
// Instantiate a generation context
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate the callback handler and specify the X.509 token
   X509GenerateCallbackHandler callbackhandler = generateCallbackHandler();
   SecurityToken token = factory.newSecurityToken(X509Token.class,
                                                  callbackHandler);

// Set the signature information
WSSSignature sig = factory.newWSSSignature(token);
// Add the header using QName
   sig.addSignHeader(new QName("http://www.w3.org/2005/08/addressing", "To"));
   sig.addSignHeader(new QName("http://www.w3.org/2005/08/addressing", "MessageID"));
   sig.addSignHeader(new QName("http://www.w3.org/2005/08/addressing", "Action"));
// Apply the signature
   gencont.add(sig);

// Secure the message
gencont.process(msgctx);
```

### What to do next

You must configure similar signature information for the client-side request consumer (receiver) bindings by completing the following verification tasks:

- Verify the signature
- Choose the signature algorithm methods.
- Change or add signed parts, as needed.

If signature verification is already configured, configure the encryption and decryption information, or configure the consumer and generator tokens.

*Configuring signing information using the WSSSignature API:*

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure the signing information for the generator binding sections for the client-side request, use the WSSSignature API. The WSSSignature API is part of the com.ibm.websphere.wssecurity.wssapi.signature package.

### Before you begin

Either you can use the WSS API or you can configure the policy sets by using the administrative console to enable the signing information. To secure SOAP messages, you must complete the following signing tasks:

- Configure the signing information.
- Choose the signing methods.
- Add or change signed parts, as needed.

### About this task

WebSphere Application Server uses the signing information for the default generator to sign parts of the message, and uses XML digital signature with existing algorithms such as RSA-SHA1 and HMAC-SHA1.

XML signature defines many methods for describing key information and enables the definition of a new method. XML canonicalization (C14N) is often needed when you use XML signature. Information can be represented in various ways within serialized XML documents. The C14N process is used to canonicalize XML information. Select an appropriate C14N algorithm because the information that is canonicalized depends on this algorithm.

The signing information specifies the integrity constraints that are applied to generated messages. The constraints include specifying which message parts within the generated message must be digitally signed, and the message parts to attach digitally signed Nonce and timestamp elements to. The following signature and related signature part information are configured:

*Table 283. Signature parts information. Use the signature parts to secure messages.*

| signature parts | Description |
|---|---|
| keyword | Adds a signature part using keywords. Use the following keywords for the signature parts:<br>• ADDRESSING_HEADERS<br>• BODY<br>• TIMESTAMP<br>The WS-Addressing headers are not encrypted but can be signed. |
| xpath | Adds a signature part by using an XPath expression. |
| part | Adds a WSSSignPart object as a target of the signature part. |
| timestamp | Adds a WSSTimestamp object as a target of the signature part. When specified, the timestamp information also specifies when the message is generated and when it expires. |

*Table 283. Signature parts information (continued). Use the signature parts to secure messages.*

| signature parts | Description |
|---|---|
| header | Adds the header, specified by QName, as a target of the signature part. |
| securityToken | Adds a SecurityToken object as a target of the signature part. |

For signing information, certain default behaviors occur. The simplest way to use the WSSSignature API is to use the default behavior (see the example code). The default values are defined by the WSS API for the signing method, the canonicalization method, the security token references, and the signature parts.

*Table 284. Signature default behaviors. Several signature behaviors are configured by default.*

| Signature decisions | Default behavior |
|---|---|
| Which keywords to use | Sets the keywords. WebSphere Application Server supports the following keywords by default:<br>• ADDRESSING_HEADERS<br>• BODY<br>• TIMESTAMP |
| Which signature method to use | Sets the signature algorithm. The default signature method is RSA SHA1. WebSphere Application Server supports the following pre-configured signature methods:<br>• WSSSignature.RSA_SHA1: http://www.w3.org/2000/09/xmldsig#rsa-sha1<br>• WSSSignature.HMAC_SHA1: http://www.w3.org/2000/09/xmldsig#hmac-sha1<br>The DSA-SHA1 digital signature method (http://www.w3.org/2000/09/xmldsig#dsa-sha1) is not supported. |
| Which canonicalization method to use | Sets the canonicalization algorithm. The default canonicalization method is EXC C14N. WebSphere Application Server supports the following pre-configured canonicalization methods:<br>• WSSSignature.EXC_C14N; http://www.w3.org/2001/10/xml-exc-c14n#<br>• WSSSignature.C14N: http://www.w3.org/2001/10/xml-c14n# |
| Whether signature confirmation is required | Sets whether to require signature confirmation. The default value is **false**. Signature confirmation is defined in the OASIS Web Services Security Version 1.1 specification. If required, the value of your signature confirmation is stored in order to use it to validate the signature confirmation after receiving back the message that generated the signature confirmation in the response message. This method is for the requestor side. |
| Which security token to use | Sets the SecurityToken. The token type specifies which type of token to use for signing and validating messages. The X.509 token is the default token type.<br>WebSphere Application Server provides the following pre-configured consumer token types:<br>• Derived Key Token<br>• X509 tokens<br>You can also create custom token types, as needed. |
| Which token reference to set | Sets the refType. SecurityToken.REF_STR is the default value for the type of token reference. WebSphere Application Server supports these pre-configured token references types:<br>• SecurityToken.REF_STR<br>• SecurityToken.REF_KEYID<br>• SecurityToken.REF_EMBEDDED<br>• SecurityToken.REF_THUMBPRINT |

If WSSSignature.requireSignatureConfirmation() is called, then the WSSSignature API expects that the response message will include the signature confirmation.

### Procedure

1. To configure the signing information in a SOAP message by using the WSS API, first ensure that the application server is installed.
2. Use the WSSSignature API to sign the message parts and specify the algorithms in a SOAP message. The WSS API process for signature follows these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSGenerationContext instance from the WSSFactory instance. WSSGenerationContext must be called in a JAX-WS client application.
   c. Creates the SecurityToken from WSSFactory to configure the key for signing.

d. Creates WSSSignature from the WSSFactory instance using the SecurityToken. The default behavior of WSSSignature is to sign these signature parts: BODY, ADDRESSING_HEADERS, and TIMESTAMP.
e. Adds the part to be signed, if the default part is not appropriate. If the digest method or transform method is changed, creates WSSSignPart and add it to WSSSignature.
f. Creates WSSSignaturePart to WSSSignature. Calls the requiredSignatureConfirmation() method, if the signature confirmation is to be applied.
g. Sets the canonicalization method, if the default is not appropriate.
h. Sets the signature method, if the default is not appropriate.
i. Sets the token reference, if the default is not appropriate.
j. Adds WSSSignature to WSSGenerationContext.
k. Calls WSSGenerationContext.process() with the SOAPMessageContext.

### Results

You have completed the steps to configure the signature for the generator section of the bindings. If there is an error condition when signing the message parts, a WSSException is provided. If successful, the WSSGenerationContext.process() is called, and Web Services Security is applied to the SOAP message.

### Example

The following example provides sample code that uses methods that are defined in the WSSignature API.

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the com.ibm.websphere.wssecurity.wssapi.WSSFactory instance  (step: a)
   WSSFactory factory = com.ibm.websphere.wssecurity.wssapi.WSSFactory.getInstance();

// Generate the WSSGenerationContext instance  (step: b)
   WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate the callback handler
   X509GenerateCallbackHandler callbackHandler = new
       X509GenerateCallbackHandler(
       "",
       "dsig-sender.ks",
       "jks",
       "client".toCharArray(),
       "soaprequester",
       "client".toCharArray(),
       "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP", null);

// Generate the security token to be used for the signature  (step: c)
   SecurityToken token = factory.newSecurityToken(X509Token.class,
        callbackHandler);

// Generate the WSSSignature instance (step: d)
   WSSSignature sig = factory.newWSSSignature(token);

// Set the part to be signed  (step: e)
// DEFAULT: WSSSignature.BODY, WSSSignature.ADDRESSING_HEADERS,
//          and WSSSignature.TIMESTAMP.

// Set the part in the SOAP Header specified by QName  (step: e)
      sig.addSignHeader(new
                        QName("http://www.w3.org/2005/08/addressing",
                        "MessageID"));

// Set the part specified by the keyword  (step: e)
      sig.addSignPart(WSSSignature.BODY);

// Set the part specified by SecurityToken  (step: e)
   UNTGenerateCallbackHandler untCallbackHandler = new
      UNTGenerateCallbackHandler("Chris", "sirhC");
      SecurityToken unt = factory.newSecurityToken(UsernameToken.class,
         untCallbackHandler);
      sig.addSignPart(unt);

// Set the part specified by WSSSignPart  (step: e)
   WSSSignPart sigPart = factory.newWSSSignPart();
      sigPart.setSignPart(WSSSignature.TIMESTAMP);
      sigPart.setDigestMethod(WSSSignPart.SHA256);
      sig.addSignPart(sigPart);
```

```
// Set the part specified by WSSTimestamp  (step: e)
   WSSTimestamp timestamp = factory.newWSSTimestamp();
      sig.addSignPart(timestamp);

// Set the part specified by XPath expression  (step: e)
   StringBuffer sb = new StringBuffer();
      sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
         and local-name()='Envelope']");
      sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
         and local-name()='Body']");
      sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
         and local-name()='Ping']");
      sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
         and local-name()='Text']");
      sig.addSignPartByXPath(sb.toString());

// Set to apply the signature confirmation  (step: f)
      sig.requireSignatureConfirmation();

// Set the canonicalization method  (step: g)
// DEFAULT: WSSSignature.EXC_C14N
      sig.setCanonicalizationMethod(WSSSignature.C14N);

// Set the signature method  (step: h)
// DEFAULT: WSSSignature.RSA_SHA1
      sig.setSignatureMethod(WSSSignature.HMAC_SHA1);

// Set the token reference  (step: i)
// DEFAULT: SecurityToken.REF_STR
      sig.setTokenReference(SecurityToken.REF_KEYID);

// Add the WSSSignature to WSSGenerationContext  (step: j)
   gencont.add(sig);

// Generate the WS-Security header  (step: k)
gencont.process(msgctx);
```

**Note:** The X509GenerationCallbackHandler needs the key password because the private key is used for signing.

### What to do next

Next, chose the algorithm methods if you want a method that is different from the default values. If the algorithm methods do not need to be changed, next use the WSSVerification API to verify the signature and specify the algorithm methods in the consumer section of the binding. Note that the WSSVerification API is only supported on the response consumer (client side).

*Adding signed parts using the WSSSignPart API:*

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure parts to be signed for the request generator (client side) bindings, use the WSSSignPart API to protect the integrity of messages and to configure the digest and transform algorithm methods. The WSSSignPart API is part of the com.ibm.websphere.wssecurity.wssapi.signature package.

### Before you begin

Either you can use the WSS API or you can configure the policy sets by using the administrative console to configure the signing information. To secure SOAP messages using the signing information, you must complete one of the following tasks:

- Configure the signature information
- Configure signed parts, as needed.

### About this task

WebSphere Application Server uses the signing information for the default generator to sign parts of the message, and uses XML digital signature with existing digest and transform algorithms (for example, SHA1 or TRANSFORM_EXC_C14N).

The signing information specifies the integrity constraints that are applied to generated messages. The signed parts are used to protect the integrity of messages. You can specify the signed parts to add for message integrity protection.

The following table shows the required signed parts when the digital signature security constraint (integrity) is defined:

*Table 285. Signed parts information. Use the signed parts to secure messages.*

| Signed parts | Description |
|---|---|
| keyword | Adds signed parts using keywords. WebSphere Application Server supports the following keywords for signed parts:<br>• BODY<br>• ADDRESSING_HEADERS<br>• TIMESTAMP<br>The WS-Addressing headers are not encrypted but can be signed. |
| xpath | Adds the required signed parts by using an XPath expression. |
| header | Adds the header, specified by QName, as a signed part. |
| timestamp | Adds a WSSTimestamp object as a signed part. If specified, the timestamp information specifies when the message is generated and when it expires. |

Different message parts can be specified in the message protection for request on the generator side. WSSSignPart allows for adding a transform algorithm, setting a digest method, setting objects as targets, specifying whether an element, and the signed parts, such as: the SOAP body, the WS-Addressing header, and timestamp information.

For signing information, certain default behaviors occur. The simplest way to use the WSSSignPart API is to use the default behavior (see the example code). The signed parts default behaviors include:

*Table 286. Default behavior of signed parts. Several signed part characteristics are configured by default.*

| Signature decisions | Default behavior |
|---|---|
| Which SOAP message parts to sign | WebSphere Application Server supports the following SOAP message parts to be signed and used for message protection:<br>• WSSSignature.BODY<br>• WSSSignature.ADDRESSING_HEADERS<br>• WSSSignature.TIMESTAMP |
| Which digest method to use | Sets the digest algorithm method. The digest method algorithm that is specified within the <DigestMethod> element is used in the <SigningInfo> element.<br>WebSphere Application Server supports the following pre-configured digest methods:<br>• WSSSignPart.SHA1 (the default value): http://www.w3.org/2000/09/xmldsig#sha1<br>• WSSSignPart.SHA256: http://www.w3.org/2001/04/xmlenc#sha256<br>• WSSSignPart.SHA512: http://www.w3.org/2001/04/xmlenc#sha512 |
| Which transform algorithms to use | Adds the transform method. The transform algorithm is specified within the <Transform> element and specifies the transform algorithm for the signature.<br>WebSphere Application Server supports the following pre-configured transform algorithms:<br>• WSSSignPart.TRANSFORM_EXC_C14N (the default value): http://www.w3.org/2001/10/xml-exc-c14n#<br>• WSSSignPart.TRANSFORM_XPATH2_FILTER: http://www.w3.org/2002/06/xmldsig-filter2<br>Use this transform method to ensure compliance with the Basic Security Profile (BSP).<br>• WSSSignPart.TRANSFORM_STRT10: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform<br>• WSSSignPart.TRANSFORM_ENVELOPED_SIGNATURE: http://www.w3.org/2000/09/xmldsig#enveloped-signature |

## Procedure

1. To enable Web Services Security by using the WSS API (WSSSignPart), first ensure that the application server is installed.

2. Use the WSSSignPart API to sign the message parts and specify the algorithms in a SOAP message. The WSS API process for signed parts follows these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSGenerationContext instance from the WSSFactory instance.
   c. Creates the SecurityToken from WSSFactory to configure the key for signing.
   d. Creates WSSSignature from the WSSFactory instance using the SecurityToken.
   e. Creates WSSSignPart from the WSSFactory instance.
   f. Sets the part to be signed and the digest method or transform method specified by step g or step h if the default is not appropriate.
   g. Sets the digest method if the default is not appropriate.
   h. Sets the transform method if the default is not appropriate.
   i. Adds WSSSignPart to WSSSignature. After any WSSSignPart is set to WSSSignature, the default parts to be signed, which are specified in WSSSignature, are ignored.
   j. Adds WSSSignature to WSSGenerationContext.
   k. Calls WSSGenerationContext.process() with the SOAPMessageContext.

### Results

You have completed the steps to configure the signed parts for the generator section of the bindings files. If there is an error condition, a WSSException is provided. If successful, the WSSGenerationContext.process() is called, and Web Services Security is applied to the SOAP message.

### Example

The following example provides sample code that uses all of methods that are defined in the WSSSignPart API:

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance  (step: a)
   WSSFactory factory = WSSFactory.getInstance();

// Generate WSSGenerationContext instance  (step: b)
   WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate callback handler
   X509GenerateCallbackHandler callbackHandler = new
      X509GenerateCallbackHandler
      "",
      "dsig-sender.ks",
      "jks",
      "client".toCharArray(),
      "soaprequester",
      "client".toCharArray(),
      "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP", null);

// Generate the security token used to the signature  (step: c)
   SecurityToken token = factory.newSecurityToken(X509Token.class, callbackHandler);

// Generate WSSSignature instance (step: d)
   WSSSignature sig = factory.newWSSSignature(token);

// Set the part specified by WSSSignPart  (step: e)
   WSSSignPart sigPart = factory.newWSSSignPart();

// Set the part specified by WSSSignPart  (step: f)
   sigPart.setSignPart(WSSSignature.BODY);

// Set the digest method specified by WSSSignPart  (step: g)
   sigPart.setDigestMethod(WSSSignPart.SHA256);

// Set the transform method specified by WSSSignPart  (step: h)
   sigPart.setTransformMethod(WSSSignPart.TRANSFORM_STRT10);

// Add the part specified by WSSSignPart  (step: i)
   sig.addSignPart(sigPart);

// Add the WSSSignature to the WSSGenerationContext  (step: j)
```

```
   gencont.add(sig);

// Generate the WS-Security header  (step: k)
gencont.process(msgcontext);
```

**Note:** The X509GenerationCallbackHandler needs the key password because the private key is used for signing.

### What to do next

Use the WSSVerifyPart API or configure policy sets using the administrative console to verify the signed parts on the consumer side.

*Configuring request signing methods for the client:*

Use the WSSSignature and WSSSignPart APIs to choose the signing methods. The request signing methods include the signature, canonicalization, digest, and transform methods.

### Before you begin

First, you must have specified which parts of the message sent by the client must be digitally signed using the WSS APIs or configuring policy sets using the administrative console.

### About this task

The following table describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following website http://www.w3.org/TR/xmldsig-core.

*Table 287. Signing methods. Use the signing methods to secure messages.*

| Name of method | Description |
|---|---|
| Canonicalization algorithm | Canonicalizes the <SignedInfo> element before the information is digested as part of the signature operation. |
| Signature algorithm | Calculates the signature value of the canonicalized <SignedInfo> element. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration. |
| Transform method | Transforms the parts to be signed before the information is digested as part of the signature operation. |
| Digest method | Calculates the digest value of the transformed parts. The algorithm selected for the client request sender configuration must match the algorithms selected in the server request receiver configuration. |

You can use the WSS APIs or configure policy sets using the administrative console to configure the signing algorithm methods. If using the WSS APIs, use the WSSSignature and WSSSignPart APIs to specify which message parts to digitally sign when configuring the client for request signing.

The WSSSignature and WSSSignPart APIs complete the following steps to configure the signature and signed part algorithm methods:

### Procedure

1. For the generator binding, the WSSSignature API specifies the signature method. WebSphere Application Server supports the following pre-configured signature methods:
   - WSSSignature.RSA_SHA1 (the default value): http://www.w3.org/2000/09/xmldsig#rsa-sha1
   - WSSSignature.HMAC_SHA1: http://www.w3.org/2000/09/xmldsig#hmac-sha1

   For the WSS APIs, WebSphere Application Server does not support the DSA-SHA1 digital signature method, http://www.w3.org/2000/09/xmldsig#dsa-sha1.
2. For the generator binding, the WSSSignature API specifies the canonicalization method. WebSphere Application Server supports the following pre-configured canonicalization algorithms:

- WSSSignature.EXC_C14N (the default value): The exclusive canonicalization algorithm, http://www.w3.org/2001/10/xml-exc-c14n#
- WSSSignature.C14N: The inclusive canonicalization algorithm, http://www.w3.org/2001/10/xml-c14n#

3. For the generator binding, the WSSSignPart API specifies the digest method. WebSphere Application Server supports the following pre-configured digest methods:
   - WSSSignPart.SHA1 (the default value): http://www.w3.org/2000/09/xmldsig#sha1
   - WSSSignPart.SHA256: http://www.w3.org/2001/04/xmlenc#sha256
   - WSSSignPart.SHA512: http://www.w3.org/2001/04/xmlenc#sha512
4. For the generator binding, the WSSSignPart API specifies the transform method. WebSphere Application Server supports the following pre-configured transform algorithms:
   - WSSSignPart.TRANSFORM_EXC_C14N (the default value): http://www.w3.org/2001/10/xml-exc-c14n#
   - WSSSignPart.TRANSFORM_XPATH2_FILTER: http://www.w3.org/2002/06/xmldsig-filter2
   - WSSSignPart.TRANSFORM_STRT10: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
   - WSSSignPart.TRANSFORM_ENVELOPED_SIGNATURE: http://www.w3.org/2000/09/xmldsig#enveloped-signature

   For the WSS APIs, WebSphere Application Server does not support the following transform algorithms:
   - http://www.w3.org/TR/1999/REC-xpath-19991116
   - http://www.w3.org/2002/07/decrypt#XML

### Results

Using the WSS APIs, you have specified which algorithm methods are used to digitally sign a message when the client sends a message to a server.

### Example

The following example is sample code for specifying the signature information, HMAC_SHA1 as signature method, C14N as a canonicalizaion method, SHA256 as a digest method, and EXC_C14N and TRANSFORM_STRT10 as the transform methods:

```
//get the message context
Object msgcontext = getMessageContext();

//generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

//generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

//generate callback handler
X509GenerateCallbackHandler callbackHandler = new X509GenerateCallbackHandler(
  "",
  "dsig-sender.ks",
  "jks",
  "client".toCharArray(),
  "soaprequester",
  "client".toCharArray(),
  "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP",
  null);

//generate the security token used to the signature
SecurityToken token = factory.newSecurityToken(X509Token.class, callbackHandler);

//generate WSSSignature instance
WSSSignature sig = factory.newWSSSignature(token);

//set the canonicalization method
// DEFAULT: WSSSignature.EXC_C14N
sig.setCanonicalizationMethod(WSSSignature.C14N);

//set the signature method
// DEFAULT: WSSSignature.RSA_SHA1
sig.setSignatureMethod(WSSSignature.HMAC_SHA1);
```

```
//set the part specified by WSSSignPart
WSSSignPart sigPart = factory.newWSSSignPart();

//set the digest method
 // DEFAULT: WSSSignPart.SHA1
sigPart.setDigestMethod(WSSSignPart.SHA256);

//add the transform method
// DEFAULT: WSSSignPart.TRANSFORM_EXC_C14N
sigPart.addTransformMethod(WSSSignPart.TRANSFORM_EXC_C14N);
sigPart.addTransformMethod(WSSSignPart.TRANSFORM_STRT10);

 // add the WSSSignPart to the WSSSignature
 sig.addSignPart(sigPart);

//add the WSSSignature to the WSSGenerationContext
gencont.add(sig);

//generate the WS-Security header
gencont.process(msgcontext);
```

### What to do next

After you configure the client to digitally sign the message and to choose the algorithm methods, you must configure the server to verify the digital signature for request signing and to choose the algorithm methods.

Configure policy sets using the administrative console to configure the signature verification information and methods on the server.

*Digital signing methods using the WSSSignature API:*

You can configure the signing information for the generator binding using the WSS API. To configure the client for request signing, choose the digital signing methods. The algorithm methods include the signing and canonicalization methods.

You must configure generator signing information to protect message integrity by digitally signing SOAP messages. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network.

After you have specified which message parts to digitally sign, you must specify which method is used to digitally sign the message.

### Methods

Methods that are used for the signing information include the:

**Signature method**
Sets the signature algorithm method.

**Canonicalization method**
Sets the canonicalization algorithm method.

### Signature algorithms

The signature algorithms specify the algorithm that is used to sign the certificate. The signature algorithms specify the Uniform Resource Identifiers (URI) of the signature method. WebSphere Application Server supports the following pre-configured algorithms:

*Table 288. Signature algorithms. The algorithms include the signing methods.*

| Algorithm | Description |
|---|---|
| WSSSignature.HMAC_SHA1 | A URI of the signature algorithm, HMAC: http://www.w3.org/2000/09/xmldsig#hmac-sha1 |
| WSSSignature.RSA_SHA1 (the default value) | A URI of the signature algorithm, RSA: http://www.w3.org/2000/09/xmldsig#rsa-sha1 |

For the WSS APIs, WebSphere Application Server does not support the DSA-SHA1 algorithm, http://www.w3.org/2000/09/xmldsig#dsa-sha1

The signing algorithm that is specified for the request generator configuration must match the algorithm that is specified for the request consumer configuration.

### Canonicalization algorithms

The canonicalization algorithms specify the Uniform Resource Identifiers (URI) of the canonicalization method. WebSphere Application Server supports the following pre-configured algorithms:

*Table 289. Signature canonicalization algorithms. The algorithms include the canonicalization methods.*

| Algorithm | Description |
|---|---|
| WSSSignature.EXC_C14N (the default value) | A URI of the exclusive canonicalization algorithm EXC_C14N: http://www.w3.org/2001/10/xml-exc-c14n# |
| WSSSignature.C14N | A URI of the inclusive canonicalization algorithm, C14N: http://www.w3.org/2001/10/xml-c14n# |

The canonicalization algorithm that is specified for the request generator configuration must match the algorithm that is specified for the request consumer configuration.

The following example provides sample WSS API code that specifies the HMAC_SHA1 as a signature method and C14n as a canonicalization method:

```
//generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

//generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

//generate callback handler
X509GenerateCallbackHandler callbackHandler = new
     X509GenerateCallbackHandler(
  "",
  "dsig-sender.ks",
  "jks",
  "client".toCharArray(),
  "soaprequester",
  "client".toCharArray(),
  "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP",
  null);

//generate the security token used to the signature
SecurityToken token = factory.newSecurityToken(X509Token.class,
     callbackHandler);

//generate WSSSignature instance
WSSSignature sig = factory.newWSSSignature(token);

//set the canonicalization method
// DEFAULT: WSSSignature.EXC_C14N
sig.setCanonicalizationMethod(WSSSignature.C14N);

//set the signature method
// DEFAULT: WSSSignature.RSA_SHA1
sig.setSignatureMethod(WSSSignature.HMAC_SHA1);

//add the WSSSignature to the WSSGenerationContext
gencont.add(sig);

//generate the WS-Security header
gencont.process(msgcontext);
```

*Signed parts methods using the WSSSignPart API:*

You can configure the signed parts information for the generator binding using the WSS API. The algorithms include the digest and transform methods.

You can protect message integrity by configuring signed parts and key information. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network.

### Methods

Methods that are used for the signed parts include the:

**Digest method**
Sets the digest algorithm method.

**Transform algorithm**
Sets the transform algorithm method.

### Digest algorithms

The digest method algorithm specified within the element is used in the element. WebSphere Application Server supports the following pre-configured algorithms:

*Table 290. Signed parts digest methods. The methods are used for the signed parts.*

| Digest method | Description |
|---|---|
| WSSSignPart.SHA1 (the default value) | A URI of the digest algorithm, SHA1: http://www.w3.org/2000/09/xmldsig#sha1 |
| WSSSignPart.SHA256 | A URI of the digest algorithm, SHA256: http://www.w3.org/2001/04/xmlenc#sha256 |
| WSSSignPart.SHA512 | A URI of the digest algorithm, SHA256: http://www.w3.org/2001/04/xmlenc#sha512 |

### Transform algorithms

The transform method algorithm specified within the element is used in the element. WebSphere Application Server supports the following pre-configured algorithms:

*Table 291. Signed parts transform methods. The methods are used for the signed parts.*

| Digest method | Description |
|---|---|
| WSSSignPart.TRANSFORM_ENVELOPED_SIGNATURE | A URI of the transform algorithm, enveloped signature: http://www.w3.org/2000/09/xmldsig#enveloped-signature |
| WSSSignPart.TRANSFORM_STRT10 | A URI of the transform algorithm, STR-Transform: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform |
| WSSSignPart.TRANSFORM_EXC_C14N (the default value) | A URI of the transform algorithm, Exc-C14N: http://www.w3.org/2001/10/xml-exc-c14n# |
| WSSSignPart.TRANSFORM_XPATH2_FILTER | A URI of the transform algorithm, XPath2 filter: http://www.w3.org/2002/06/xmldsig-filter2 |

The transform algorithm is specified within the <Transform> element and specifies the transform algorithm for the signed part.

For the WSS APIs, WebSphere Application Server does not support the following transform algorithms:

- http://www.w3.org/TR/1999/REC-xpath-19991116
- http://www.w3.org/2002/07/decrypt#XML

The following example provides sample WSS API code for specifying the signature and signed parts, setting the signing key and adding the STR-Transform transform algorithm as signed parts:

```
//get the message context
Object msgcontext = getMessageContext();

//generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

//generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

//generate callback handler
X509GenerateCallbackHandler callbackHandler = new
      X509GenerateCallbackHandler(
```

```
  "",
  "dsig-sender.ks",
  "jks",
  "client".toCharArray(),
  "soaprequester",
  "client".toCharArray(),
  "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP",
  null);

//generate the security token used to the signature
SecurityToken token = factory.newSecurityToken(X509Token.class,
     callbackHandler);

//generate WSSSignature instance
WSSSignature sig = factory.newWSSSignature(token);

//set the part specified by WSSSignPart
WSSSignPart sigPart = factory.newWSSSignPart();

//set the part specified by WSSSignPart
sigPart.setSignPart(WSSSignature.BODY);

//set the digest method specified by WSSSignPart
sigPart.setDigestMethod(WSSSignPart.SHA256);

//set the transform method specified by WSSSignPart
sigPart.addTransform(WSSSignPart.TRANSFORM_STRT10);

//set the part specified by WSSSignPart
sig.addSignPart(sigPart);

//add the WSSSignature to the WSSGenerationContext
gencont.add(sig);

//generate the WS-Security header
gencont.process(msgcontext);
```

*Attaching the generator token using WSS APIs to protect message authenticity:*

When you specify the token generator, the information is used on the generator side to generate the security token.

**Before you begin**

The token processing and pluggable token architecture in the Web Services Security run time reuses the same security token interface and Java Authentication and Authorization Service (JAAS) Login Module from the Web Services Security APIs (WSS API). The same implementation of token creation and validation can be used in both the WSS API and the WSS SPI in the Web Services Security run time.

**Restriction:** The `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` interface is not used with JAX-WS web services. If you are using JAX-RPC web services, this interface is still valid.

Note that the key name (KeyName) element is not supported in the application server because there is no KeyName policy assertion defined in the current OASIS Web Services Security draft specification.

**About this task**

The JAAS callback handler (CallbackHandler) and the JAAS login module (LoginModule) are responsible for creating the security token on the generator side and validating (authenticating) the security token on the consumer side.

For example, on the generator side, the Username token is created by the JAAS LoginModule and using the JAAS CallbackHandler to pass the authentication data. The JAAS LoginModule creates the Username SecurityToken object and passes it to the Web Services Security run time.

Then, on the consumer side, the Username Token XML format is passed to the JAAS LoginModule for validation or authentication and the JAAS CallbackHandler is used to pass authentication data from the Web Services Security run time to the LoginModule. After the token is authenticated, a Username SecurityToken object is created and passed it to the Web Services Security run time.

**Note:** WebSphere Application Server does not support a stackable login module with the WebSphere Application Server default login module implementation, meaning adding the login module before or after the WebSphere Application Server login module implementation. If you want to stack the login module implementations, you must develop the required login modules because there is no default implementation.

The com.ibm.websphere.wssecurity.wssapi.token package provided by WebSphere Application Server includes support for these classes:

- Security token (SecurityTokenImpl)
- Binary security token (BinarySecurityTokenImpl)

In addition, WebSphere Application Server provides the following pre-configured sub-interfaces for security tokens:

- Derived key token
- Security context token (SCT)
- Username token
- LTPA token propagation
- LTPA token
- X509PKCS7 token
- X509PKIPath token
- X509v3 token
- Kerberos v5 token

The Username token, the X.509 tokens, and the LTPA tokens are used by default for message authenticity. The derived key token and the X.509 tokens are used by default for signing and encryption.

The WSS API and WSS SPI are only supported on the client. To specify the security token type on the generator side, you can also configure policy sets using the administrative console. You can also use the WSS APIs or policy sets for matching consumer security tokens.

The default Login Module and Callback implementations are designed to be used as a pair, meaning both a generator and a consumer part. To use the default implementations, select the appropriate generator and consumer security token in a pair. For example, select `system.wss.generate.x509` in the token generator and `system.wss.consume.x509` in the token consumer when the X.509 token is required.

To configure the generator-side security token, use the appropriate pre-configured token generator interface from the WSS APIs to complete the following token configuration process steps:

**Procedure**

1. Generate the wssFactory instance.
2. Generate the wssGenerationContext instance.

   The WSSGenerationContext interface stores the components for generating Web Services Security (WS-Security), such as the signing and encryption information, the security token, and the time stamp. When the generate() method is called, all of these components are generated.
3. Create the generator-side components, such as the WSSSignature and the WSSEncryption objects.
4. Specify a JAAS configuration by specifying the name of the JAAS login configuration. The Java Authentication and Authorization Service (JAAS) configuration specifies the name of the JAAS configuration. The JAAS configuration specifies how the token logs in on the consumer side. Do not remove the predefined system or application login configurations. However, within these configurations, you can add module class names and specify the order in which WebSphere Application Server loads each module.

5. Specifiy a token generator class name. The token generator class name specifies the required information to generate the SecurityToken. The Username token, the X.509 tokens, and the LTPA tokens are used by default for message authenticity.
6. Specifiy the settings for the callback handler by specifying a callback handler class name and also specifies the callback handler keys. This class name is the name of the callback handler implementation class that is used for the plug-in to the security token framework.

   The callback handler implementation obtains the required security token and passes it to the token generator. The token generator inserts the security token in the Web Services Security header within the SOAP message. Also, the token generator is a plug-in point for the pluggable security token framework. Service providers can provide their own implementation, but the implementation must use the WSSGenerationContext interface.

   WebSphere Application Server provides the following default callback handler implementations for the generator side:

   **com.ibm.websphere.wssecurity.callbackhandler.PropertyCallback**
   This class is a callback for handling the name-value pair in elements in the Web Services Security (WS-Security) configuration XMI files.

   **com.ibm.websphere.wssecurity.callbackhandler.UNTGUIPromptCallbackHandler**
   This class is a callback handler for the Username token with the GUI prompt on the generator side. This instance is used to set the WSSGenerationContext object to generate a Username token.

   **com.ibm.websphere.wssecurity.callbackhandler.UNTGenerateCallbackHandler**
   This class is a callback handler for the Username token on the generator side. This instance is used to set into WSSGenerationContext object to attach a Username token. Use this implementation for a Java Platform, Enterprise Edition (Java EE) application client only.

   **com.ibm.websphere.wssecurity.callbackhandler.X509GenerateCallbackHandler**
   This class is a callback handler that is used to generate the X.509 certificate that is inserted in the Web Services Security header within the SOAP message as a binary security token on the generator side. This instance is used to generate the WSSSignature and WSSEncryption objects, set the objects into the WSSGenerationContext object to generate the X.509 binary security tokens. A keystore and a key definition are required for this callback handler. If you use this implementation, a key store password, path, and type must be provided on the generator side.

   **com.ibm.websphere.wssecurity.callbackhandler.LTPAGenerateCallbackHandler**
   This class is a callback handler for the Lightweight Third Party Authentication (LTPA) tokens on the generator side. This instance is used to generate WSSSignature object and WSSEncryption object to generate a LTPA token.

   This callback handler is used to validate the LTPA security token inserted in the Web Services Security header within the SOAP message as a binary security token. However, if the user name and password are specified, WebSphere Application Server authenticates the user name and password to obtain the LTPA security token rather than obtaining it from the Run As Subject. Use this callback handler only when the web service is acting as a client on the application server. It is recommended that you do not use this callback handler on a Java EE application client. If you use this implementation, a basic authentication user ID and password must have been provided on the generator side.

   **com.ibm.websphere.wssecurity.callbackhandler.KRBTokenConsumeCallbackHandler**
   This class is a callback handler for the Kerberos v5 token on the generator side. This instance is used to set the WSSGenerationContext object to generate the Kerberos v5 AP-REQ as a binary security token. The instance is also used to generate the WSSSignature and WSSEncryption objects to use the Kerberos session key or derived key in the SOAP message signature and encryption.
7. If a X.509 token is specified, additional token information is also specified.

*Table 292. Information for X.509 token. Use the X.509 token for signing and encryption.*

| | |
|---|---|
| storeRef | The reference name of the keystore. |
| storePath | The keystore file path from which the keystore is loaded, if needed. It is recommended that you use the `${USER_INSTALL_ROOT}` in the path name as this variable expands to the WebSphere Application Server path on your machine. This path is required when you use the X.509 tokens callback handler implementations. |
| storePassword | The password that is used to check the integrity of the keystore, or the keystore password that is used to unlock the keystore and to access the keystore file. The keystore and its configuration are used for some of the default callback handler implementations that are provided by WebSphere Application Server. |
| storeType | The keystore type of keystore that is used for the key locator. This selection indicates the format that is used by the keystore file. The following values are available for selection:<br>**JKS** Use this option if the keystore uses the Java Keystore (JKS) format.<br>**JCEKS** Use this option if the Java Cryptography Extension is configured in the software development kit (SDK). The default IBM JCE is configured in WebSphere Application Server. This option provides stronger protection for stored private keys by using Triple DES encryption.<br>**JCERACFKS** Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).<br>**PKCS11KS (PKCS11)** Use this format if your keystore uses the PKCS#11 file format. Keystores using this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.<br>**PKCS12KS (PKCS12)** Use this option if your keystore uses the PKCS#12 file format. |
| alias | The key alias name. The key alias is used by the key locator to find the key within the keystore file. |
| keyPassword | The key password that is used for recovering the key. This password is needed to access the key object within the keystore file. |
| keyName | The name of the key. For digital signatures, the key name is used by the request generator or response consumer signing information to determine which key is used to digitally sign the message. For encryption, the key name is used to determine the key used for encryption. The key name must be a fully qualified, distinguished name (DN). For example, `CN=Bob,O=IBM,C=US`. |
| certStores | A list of certificate stores. A collection certificate store includes a list of untrusted, intermediary certificates and certificate revocation lists (CRLs). This step configures a collection certificate store and certificate revocation lists for the generator bindings. |
| identityAssertion | Specifies whether identity assertion is used. Selects this item if identity assertion is defined. This option indicates that only the identity of the initial sender is required and inserted into the Web Services Security header within the SOAP message. For an X.509 token generator, the application server sends the original signer certification only. |
| requestorCertificate | Specifies whether the certificate of the requestor is used. |

The following can be specified for a X.509 token:

a. Without any keystore.

b. With a trust anchor. A trust anchor specifies a list of keystore configurations that contain trusted root certificates. These configurations are used to validate the certificate path of incoming X.509-formatted security tokens. For example, when you select the trust anchor or the certificate store of a trusted certificate, you must configure the trust anchor and the certificate store before setting the certificate path.

c. With a keystore that is used for the key locator.

First, you must have created the keystore file, by using a key tool utility, for example. The keystore is used to retrieve the X.509 certificate. This entry specifies the password that is used to access the keystore file. Keystore objects within trust anchors contain trusted root certificates that are used by the CertPath API to validate the trustworthiness of a certificate chain.

d. With keystore that is used for the key locator and the trust anchor.

e. With a map that includes key-value pairs. For example, you might specify the value type name and the value type Uniform Resource Identifier (URI). The value type specifies the namespace URI of the value type for the generated token, and represents the token type of this class:

**ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3**

Specifies an X.509 certificate token.

**ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1**

Specifies X.509 certificates in a public key infrastructure (PKI) path. This callback handler is used to create X.509 certificates encoded with the PkiPath format. The certificate is inserted in the Web Services Security header within the SOAP message as a binary security token. A keystore is required for this callback handler. A CRL is not supported by the callback handler; therefore, the collection certificate store is not required or used. If you use this implementation, you must provide a key store password, path, and type on this panel.

**ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7**

Specifies a list of X.509 certificates and certificate revocation lists in a PKCS#7 format. This callback handler is used to create X.509 certificates encoded with the PKCS#7 format. The certificate is inserted in the Web Services Security header in the SOAP message as a binary security token. A keystore is required for this callback handler. You can specify a certificate revocation list (CRL) in the collection certificate store. The CRL is encoded with the X.509 certificate in the PKCS#7 format. If you use this implementation, you must provide a key store password, path, and type.

For some tokens, WebSphere Application Server provides a predefined local name for the value type. When you specify the following local name, you do not need to specify a value type URI:

**ValueType: http://www.ibm.com/websphere/appserver/tokentype/5.0.2**

For an LTPA token, you can use `LTPA` for the value type local name. This local name causes `http://www.ibm.com/websphere/appserver/tokentype/5.0.2` to be specified for the value type Uniform Resource Identifier (URI).

**ValueType: http://www.ibm.com/websphere/appserver/tokentype/5.0.2**

For LTPA token propagation, you can use `LTPA_PROPAGATION` for the value type local name. This local name causes `http://www.ibm.com/websphere/appserver/tokentype` to be specified for the value type Uniform Resource Identifier (URI).

8. If the Username token is specified as the token generator class name, the following token information can be specified:
   a. Whether to use IdentityAssertion option. This option is selected if identity assertion is defined. This option indicates that only the identity of the initial sender is required and inserted into the Web Services Security header within the SOAP message. For example, WebSphere Application Server sends only the user name of the original caller for a Username token generator.
   b. Whether to use RunAsSubject identity option. This option is used if an identity assertion is defined and you want to use the Run As identity instead of the initial caller identity for identity assertion in a downstream call. This option is valid only if you have configured the Username token as the token generator.
   c. Whether to use sendRealm.
   d. Whether to specify the nonce.

      This option indicates whether a Nonce is included for the token generator. Nonce is a unique, cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of Username tokens. Nonce is valid only when the generated token type is a Username token, and it is available only for the request generator binding.
   e. Specifies the keyword of the time stamp. This option indicates whether to verify a time stamp in the Username token. The time stamp is valid only when the incorporated token type is a Username token.
   f. Specifies a map that includes key-value pairs. For example, you might specify the value type name and the value type Uniform Resource Identifier (URI). The value type specifies the namespace URI of the value type for the generated token, and represents the token type of this class:

**URI value type: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken**

Specifies a Username token.

9. If the Kerberos v5 token is specified as the token generator class name, the following token information can be specified:

| Token Information | Description | Default Value |
|---|---|---|
| name | Kerberos client principal name | |
| password | Kerberos client password | |
| realm | Kerberos realm associated with the Kerberos client | Default realm name in Kerberos configuration file.<br><br>Specify null to use the default value. |
| targetService | Kerberos service name associated with the target web services. | |
| targetHost | Kerberos realm name associated with the Kerberos service name. | |
| tokenValueType | Kerberos token value type in QName defined by Oasis Kerberos Token Profile v1.1 specification. | http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ |
| targetRealm | Kerberos realm name associated with the Kerberos service name. | Default realm name in the Kerberos configuration file |
| prompt | A boolean value to enable the login prompt. | false |
| supportTokenRequireSHA1 | A boolean value to require a SHA1 key that is used in subsequent request messages when the Kerberos token is used as a supporting token. | false<br><br>SHA1 key is consumed only if the supporting Kerberos token is protected. If set to true, the SHA1 key is always consumed. |
| alwaysAPREQ | A boolean value to indicate that the client should always send the Kerberos AP_REQ token in the request messages. | false<br><br>The SHA1 key is used instead in the subsequent messages. If set to true, the Kerberos AP_REQ token is always used. |
| requireDKT | A boolean value to require a derived key for message protection. | false |
| clabel | The client label for the derived key. | WS-SecureConversation<br><br>Specify null to use the default value. |
| slabel | The service label for the derived key. | WS-SecureConversation<br><br>Specify null to use the default value. |
| keylen | The length of the derived key. | 16<br><br>Specify zero to use the default value |
| noncelen | The length of the nonce. | 16<br><br>Specify zero to use the default value |

| Token Information | Description | Default Value |
|---|---|---|
| encComponent | An instance of WSSEncryption. | Set encComponent and sigComponent to null to initialize this first for either the encryption or signature component. Then, use the initialized component only in the callback handler constructor for the second component. |
| sigComponent | An instance of WSSSignature. | Set encComponent and sigComponent to null to initialize this first for either the encryption or signature component. Then, use the initialized component only in the callback handler constructor for the second component. |

Additional token value types are defined in the OASIS Kerberos Token Profile v1.1 specification. Specify the token value type as the local name. It is not necessary to specify the value type URI for the Kerberos v5 token.

- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ1510
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ1510
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ4120
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ4120

10. If Secure Conversation is used for message protection, the following information must be specified:

| Information | Description |
|---|---|
| bootstrapWSSGenerationContext | The bootstrap configuration used to secure the RequestSecurityToken (RST) token. |
| bootstrapWSSConmingContext | The bootstrap configuration used for consuming a secured RequestSecurityTokenResponse (RSTR). |
| ENDPOINT_URL | The service end point URL. |
| EncryptionAlgorithm | This determines the key size. |
| cLabel | The client label used when creating the derived key. |
| sLabel | The server label used when creating the derived key. |

11. Set the components into the wssGenerationContext object.
12. Invoke the wssGenerationContext.process() method.

### Results

Using the Web Services Security API (WSS API) process, you can configured the token generator.

### What to do next

Next, you must specify a similar token consumer configuration.

*Configuring generator security tokens using the WSS API:*

You can secure the SOAP messages, without using policy sets, by using the Web Services Security APIs. To configure the token on the generator side, use the Web Services Security APIs (WSS API). The generator security tokens are part of the `com.ibm.websphere.wssecurity.wssapi.token` interface package.

**Before you begin**

The pluggable token framework in WebSphere Application Server has been redesigned so that the same framework from the WSS API can be reused. The same implementation of creating and validating security token can be used both for the Web Services Security runtime and for the WSS API application code. The redesigned framework also simplifies the SPI programming model and will make it easier to add security token types.

You can use the WSS API or you can configure the tokens by using the administrative console. To configure tokens, you must complete the following token tasks:

- Configure the generator tokens.
- Configure the consumer tokens.

**About this task**

The JAAS CallbackHandler and JAAS LoginModule are responsible for creating the security token on the generator side.

On the generator side, the token is created by using the JAAS LoginModule and by using JAAS CallbackHandler to pass authentication data. Then, the JAAS LoginModule creates the securityToken object, such as the UsernameToken, and passes it to the Web Services Security run time.

On the consumer side, the XML format is passed to the JAAS LoginModule for validation or authentication. then the JAAS CallbackHandler is used to pass authentication data from the Web Services Security runtime to the LoginModule. After the token is authenticated, a security token object is created, and the token is passed it to the Web Services Security runtime.

When using the WSS API for generator token creation, certain default behaviors occur. The simplest way to use the WSS API is to use the default behavior (see the example code). The WSS API provide default values for the token type, the token value, and the JAAS confirmation name. The default token behaviors include:

*Table 293. Token decisions and default behaviors. Several token characteristics are configured by default.*

| Generator token decisions | Default behavior |
|---|---|
| Which token type to use | The token type specifies which type of token to use for message integrity, message confidentiality, or message authenticity.<br><br>WebSphere Application Server provides the following pre-configured generator token types for message integrity and message confidentiality:<br>• Derived key token<br>• X509 tokens<br><br>You can also create custom token types, as needed.<br><br>WebSphere Application Server also provides the following pre-configured generator token types for the message authenticity:<br>• Username token<br>• LTPA tokens<br>• X509 tokens<br><br>You can also create custom token types, as needed. |
| What JAAS login configuration name to specify | The JAAS login configuration name specifies which JAAS login configuration name to use. |
| Which configuration type to use | The JAAS login module specifies the configuration type. Only the pre-configured generator configuration types can be used for generator token types. |

The SecurityToken class (com.ibm.websphere.wssecurity.wssapi.token.SecurityToken) is the generic token class and represents the security token that has methods to get the identity, the XML format, and the cryptographic keys. Using the SecurityToken class, you can apply both the signature and encryption to the SOAP message. However, to apply both, you must have two SecurityToken objects, one for the signature and one for encryption, respectively.

The following tokens types are subclasses of the generic security token class:

*Table 294. Subclasses of the SecurityToken. Use the subclasses to represent the security token.*

| Token type | JAAS login configuration name |
|---|---|
| Username token | system.wss.generate.unt |
| Security context token | system.wss.generate.sct |
| Derived key token | system.wss.generate.dkt |

The following tokens types are subclasses of the binary security token class:

*Table 295. Subclasses of the BinarySecurityToken. Use the subclasses to represent the binary security token.*

| Token type | JAAS login configuration name |
|---|---|
| LTPA token | system.wss.generate.ltpa |
| LTPA propagation token | system.wss.generate.ltpaProp |
| X.509 token | system.wss.generate.x509 |
| X.509 PKI Path token | system.wss.generate.pkiPath |
| X.509 PKCS7 token | system.wss.generate.pkcs7 |

**Notes:**

- For each JAAS login token generator configuration name, there is a respective token consumer configuration name. For example, for the Username token, the respective token consumer configuration name is system.wss.consume.unt.
- The LTPA and LTPA propagation tokens are only available to a requester that is running as a server-based client. The LTPA and LTPA propagation tokens are not supported for the Java SE 6 or Java EE application client.

**Procedure**

1. To configure the securityToken package, `com.ibm.websphere.wssecurity.wssapi.token`, first ensure that the application server is installed.
2. Use the Web Services Security token generator process to configure the tokens. For each token type, the process is similar to the following process that demonstrates the UsernameToken token generator process:
   a. Use WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Create the WSSGenerationContext instance from the WSSFactory instance.
   c. Create a JAAS CallbackHandler. The authentication data, such as the user name and password are specified as part of the CallbackHandler. For example, the following code specifies Chris as the user name and sirhC as the password: UNTGenerationCallbackHandler("Chris", "sirhC");
   d. Call any JAAS CallbackHandler parameters and review the token class information for which parameters are required or optional. For example, for the UsernameToken, the following parameters can be configured also:

      **Nonce**

      Indicates whether a nonce is included in the user name token for the token generator. Nonce is a unique, cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of user name tokens. The nonce value is valid only when the generated token type is a UsernameToken and only when it applies to the request generator binding.

**Created timestamp**

Indicates whether to insert a time stamp into the UsernameToken. The timestamp value is valid only when the generated token type is a UsernameToken and only when it applies to the request generator binding.

e. Create the SecurityToken from WSSFactory.

   By default, the UsernameToken API specifies the ValueType as: "http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken"

   By default, the UsernameToken API provides the QName of this class and specifies the NamespaceURI as http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd and also specifies the LocalPart as UsernameToken.

f. Optional: Specify the JAAS login module configuration name. On the generator side, the configuration type is always `generate` (for example, `system.wss.generate.unt`).

g. Add the SecurityToken to the WSSGenerationContext.

h. Call WSSGenerationContext.process() and generate the WS-Security header.

### Results

If there is an error condition, a WSSException is provided. If successful, the WSSGenerationContext process() is called, and the security token for the generator binding is attached.

### Example

The following example code shows how to use WSS APIs to create a Username security token, attach the Username token to the SOAP message, and configure the Username token in the generator binding.

```
// import the packages
import javax.xml.ws.BindingProvider;
import com.ibm.websphere.wssecurity.wssapi.*;
import com.ibm.websphere.wssecurity.callbackhandler.*;
...
   // obtain the binding provider
   BindingProvider bp = ... ;

   // get the request context
   Map<String, Object> reqContext = bp.getRequestContext();

   // generate WSSFactory instance
   WSSFactory factory = WSSFactory.getInstance();

   // generate WSSGenerationContext instance
   WSSGenerationContext gencont = factory.newWSSGenerationContext();

   // generate callback handler
   UNTGenerateCallbackHandler untCallbackHandler =
   new UNTGenerateCallbackHandler("Chris", "sirhC");

   // generate the username token
   SecurityToken unt = factory.newSecurityToken(UsernameToken.class, untCallbackHandler);

   // add the SecurityToken to the WSSGenerationContext
   gencont.add(unt);

   // generate the WS-Security header
   gencont.process(reqContext);
```

The following example code shows how to modify the preceding Username token sample to create an LTPAv2 token from the runAs identity on the current thread. The two lines of code that instantiate the callback handler and create the security token are replaced with the following two lines of code:

```
// generate callback handler
LTPAGenerateCallbackHandler ltpaCallbackHandler = new LTPAGenerateCallbackHandler(null, null);

// generate the LTPAv2 token
SecurityToken ltpa = wssfactory.newSecurityToken(LTPAv2Token.class, ltpaCallbackHandler);
```

The instantiation of the LTPAGenerateCallbackHandler object with (null, null) indicates that the LTPA token should be generated from the current runAs identity. If the callback handler is instantiated with basicAuth information, ("userName", "password"), a new LTPA token is created using the specified basicAuth information.

The following example shows how to use secure conversation with the WSS APIs to configure the generator tokens, as well as the consumer tokens. In this example, the SecurityContextToken token is created using the WS-SecureConversation draft namespace: `http://schemas.xmlsoap.org/ws/2005/02/sc/sct`. To use the WS-SecureConversation version 1.3 namespace, `http://docs.oasis-open.org/ws-sx/ws-secureconversation/200512/sct`, specify SecurityContextToken13.class instead of SecurityContextToken.class.

```
// import the packages
import javax.xml.ws.BindingProvider;
import com.ibm.websphere.wssecurity.wssapi.*;
import com.ibm.websphere.wssecurity.callbackhandler.*;
...
   // obtain the binding provider
   BindingProvider bp = ... ;

   // get the request context
   Map<String, Object> reqContext = bp.getRequestContext();

   // generate WSSFactory instance
   WSSFactory wssFactory = WSSFactory.getInstance();

   WSSGenerationContext bootstrapGenCon = wssFactory.newWSSGenerationContext();

   // Create a Timestamp
   ...
   // Add Timestamp
   ...

   // Sign the SOAP Body, WS-Addressing headers, and Timestamp
   X509GenerateCallbackHandler btspReqSigCbHandler = new X509GenerateCallbackHandler(...);
   SecurityToken btspReqSigToken = wssFactory.newSecurityToken(X509Token.class,
                                                               btspReqSigCbHandler);
   WSSSignature bootstrapReqSig = wssFactory.newWSSSignature(btspReqSigToken);
   bootstrapReqSig.setCanonicalizationMethod(WSSSignature.EXC_C14N);

   // Add Sign Parts
   ...
   bootstrapGenCon.add(bootstrapReqSig);

   // Encrypt the SOAP Body and the Signature
   X509GenerateCallbackHandler btspReqEncCbHandler = new X509GenerateCallbackHandler(...);
   SecurityToken btspReqEncToken = wssFactory.newSecurityToken(X509Token.class,
                                                               btspReqEncCbHandler);
   WSSEncryption bootstrapReqEnc = wssFactory.newWSSEncryption(btspReqEncToken);
   bootstrapReqEnc.setEncryptionMethod(WSSEncryption.AES128);
   bootstrapReqEnc.setKeyEncryptionMethod(WSSEncryption.KW_RSA15);

   // Add Encryption parts
   ...
   bootstrapGenCon.add(bootstrapReqEnc);
   WSSConsumingContext bootstrapConCon = wssFactory.newWSSConsumingContext();
   X509ConsumeCallbackHandler btspRspVfyCbHandler = new X509ConsumeCallbackHandler(....);
   WSSVerification bootstrapRspVfy = wssFactory.newWSSVerification(X509Token.class,
                                                                   btspRspVfyCbHandler);
   bootstrapRspVfy.addAllowedCanonicalizationMethod(WSSVerification.EXC_C14N);

   // Add Verify parts
   ...
   bootstrapConCon.add(bootstrapRspVfy);
   X509ConsumeCallbackHandler btspRspDecCbHandler = new X509ConsumeCallbackHandler(...);
   WSSDecryption bootstrapRspDec = wssFactory.newWSSDecryption(X509Token.class,
                                                               btspRspDecCbHandler);
   bootstrapRspDec.addAllowedEncryptionMethod(WSSDecryption.AES128);
   bootstrapRspDec.addAllowedKeyEncryptionMethod(WSSDecryption.KW_RSA15);

   // Add Decryption parts
   ...
   bootstrapConCon.add(bootstrapRspDec);
   SCTGenerateCallbackHandler sctgch = new SCTGenerateCallbackHandler(bootstrapGenCon,
                                                                      bootstrapConCon,
                                                                      ENDPOINT_URL,
                                                                      WSSEncryption.AES128);
   SecurityToken[] scts = wssFactory.newSecurityTokens(new Class[]{SecurityContextToken.class},
                                                       sctgch);
   SecurityContextToken sct = (SecurityContextToken)scts[0];

   // Use the SCT to generate DKTs for Secure Conversation
   // Signature algorithm and client and service labels
   DerivedKeyToken dktSig = sct.getDerivedKeyToken(WSSSignature.HMAC_SHA1,
                                                   "WS-SecureConversation",
                                                   "WS-SecureConversation");

   // Encryption algorithm and client and service labels
   DerivedKeyToken dktEnc = sct.getDerivedKeyToken(WSSEncryption.AES128,
                                                   "WS-SecureConversation",
                                                   "WS-SecureConversation");
```

```
// Create the application generation context for the request message
WSSGenerationContext applicationGenCon = wssFactory.newWSSGenerationContext();

// Create and add Timestamp
...

// Add the derived key token and Sign the SOAP Body and WS-Addressing headers
WSSSignature appReqSig = wssFactory.newWSSSignature(dktSig);
appReqSig.setSignatureMethod(WSSSignature.HMAC_SHA1);
appReqSig.setCanonicalizationMethod(WSSSignature.EXC_C14N);
...
applicationGenCon.add(appReqSig);

// Add the derived key token and Encrypt the SOAP Body and the Signature
WSSEncryption appReqEnc = wssFactory.newWSSEncryption(dktEnc);
appReqEnc.setEncryptionMethod(WSSEncryption.AES128);
appReqEnc.setTokenReference(SecurityToken.REF_STR);
appReqEnc.encryptKey(false);
...
applicationGenCon.add(appReqEnc);

// Create the application consuming context for the response message
WSSConsumingContext applicationConCon = wssFactory.newWSSConsumingContext();

//client and service labels and decryption algorithm
SCTConsumeCallbackHandler sctCbHandler = new SCTConsumeCallbackHandler("WS-SecureConversation",
                                                                       "WS-SecureConversation",
                                                                       WSSDecryption.AES128);

// Derive the token from SCT and use it to Decrypt the SOAP Body and the Signature
WSSDecryption appRspDec = wssFactory.newWSSDecryption(SecurityContextToken.class,
                                                      sctCbHandler);
appRspDec.addAllowedEncryptionMethod(WSSDecryption.AES128);
appRspDec.encryptKey(false);
...
applicationConCon.add(appRspDec);

// Derive the token from SCT and use it to Verify the
// signature on the SOAP Body, WS-Addressing headers, and Timestamp
WSSVerification appRspVfy = wssFactory.newWSSVerification(SecurityContextToken.class,
                                                          sctCbHandler);
...
applicationConCon.add(appRspVfy);
...
applicationGenCon.process(reqContext);
applicationConCon.process(reqContext);
```

### What to do next

For each token type, configure the token using the WSS APIs or using the administrative console. Next, specify the similar consumer tokens if you have not done so.

If both the generator and consumer tokens are configured, continue securing SOAP messages either by signing the SOAP message or by encrypting the message, as needed. You can use either the WSS APIs or the administrative console to secure the SOAP messages.

*Sending self-issued SAML bearer tokens using WSS APIs:*

You can create self-issued SAML tokens with the bearer subject confirmation method and then send these tokens with Web services request messages using the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS API).

### Before you begin

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, and the use of policy sets to configure and administer web services settings.

### About this task

**Note:** You can build your web services client to use SAML tokens with the bearer subject confirmation method in SOAP request messages using the Web Services Security programming interfaces.

Using the programming interfaces in a web services client to specify the use of SAML tokens with bearer subject confirmation is an alternative approach to using policy sets and binding configurations.

You can create a self-issued SAML token and then send the SAML token in web services request messages from a web services client. The web services application client used in this task is a modified version of the client code that is contained in the JaxWSServicesSamples sample application that is available for download. Code snippets from the sample are described in the procedure section, and a complete, ready-to-use web services client sample is provided in the Example section.

**Procedure**

1. Identify and obtain the web services client that you want to use to invoke a web services provider.

   Use this client to insert SAML tokens in SOAP request messages programmatically using WSS APIs.

   The web services client used in this procedure is a modified version of the client code that is contained in the JaxWSServicesSamples web services sample application.

   To obtain and modify the sample web services client to add the Web Services Security API to pass SAML tokens in SOAP request messages programmatically using WSS APIs, complete the following steps:

   a. Download the JaxWSServicesSamples sample application. The JaxWSServicesSamples sample is not installed by default.

   b. Obtain the JaxWSServicesSamples client code.

      For example purposes, this procedure uses a modified version of the Echo thin client sample that is included in the JaxWSServicesSamples sample. The web services Echo thin client sample file, `SampleClient.java`, is located in the `src\SampleClientSei\src\com\ibm\was\wssample\sei\cli` directory. The sample class file is included in the `WSSampleClientSei.jar` file.

      The `JaxWSServicesSamples.ear` enterprise application and supporting Java archives (JAR) files are located in the `installableApps` directory within the JaxWSServicesSamples sample application.

   c. Deploy the `JaxWSServicesSamples.ear` file onto the application server. After you deploy the `JaxWSServicesSamples.ear` file, you are ready to test the sample web services client code against the sample application.

   Instead of using the web services client sample, you can choose to add the code snippets to pass SAML tokens in SOAP request messages programmatically using WSS APIs in your own web services client application. The example in this procedure uses a JAX-WS Web services thin client; however, you can also use a managed client.

2. Attach the SAML20 Bearer WSHTTPS default policy set to the web services provider. This policy set is used to protect messages using HTTPS transport. Read about configuring client and provider bindings for the SAML Bearer token for details on how to attach the SAML20 Bearer WSHTTPS default policy set to the Web services provider. The example in this procedure uses self-issued SAML tokens. When you configure the provider bindings, the truststore configuration and certificate must match the signing key of the self-issued token.

3. Assign the SAML Bearer Provider sample default general bindings to the sample web services provider. Read about configuring client and provider bindings for the SAML bearer token for details on assigning the SAML Bearer Provider sample default general bindings to your web services application.

4. Create the self-issued SAML token. The following code snippet illustrates creating the SAML token:

```
// Create the SAML token.
HashMap<Object, Object> map = new HashMap<Object, Object>();
map.put(SamlConstants.CONFIRMATION_METHOD, "Bearer");
map.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML20_VALUE_TYPE);
map.put(SamlConstants.SAML_NAME_IDENTIFIER, "Alice");
map.put(SamlConstants.SIGNATURE_REQUIRED, "true");
SAMLGenerateCallbackHandler callbackHandler = new SAMLGenerateCallbackHandler(map);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml");

System.out.println("SAMLToken id = " + samlToken.getId());
```

   a. Use the CallService() method to specify the Web services security configuration parameters that are required to invoke a target Web services provider using a self-issued SAML token.

The CallService() method sets the configuration parameters that are required by the Web Services Security runtime environment via the `com.ibm.websphere.wssecurity.wssapi.WSSGenerationContext` custom property to generate a self-issued SAMLToken.

Read about configuring a SAML token during token creation for more information about how you can specify configuration properties to control how the token is configured.

b. Add the Thin Client for JAX-WS JAR file to the class path. Add the *app_server_root*/runtimes/com.ibm.jaxws.thinclient_8.0.0.jar file to the class path. See the testing web services-enabled clients information for more information about adding this JAR file to the class path.

c. Use the WSSFactory newSecurityToken method to specify how to create the SAML token.

Specify the following method to create the SAML token:

```
WSSFactory  newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml")
```

Creating a SAML token requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken. Use the PolicyTool to add the following policy statement to the Java security policy file or the application client was.policy file:

```
permission java.security.SecurityPermission "wssapi.SAMLTokenFactory.newSAMLToken
```

The `SAMLToken.class` parameter specifies the type of security token to create.

The `callbackHandler` object contains parameters that define the characteristics of the SAMLToken that you are creating. This object points to a SAMLGenerateCallbackHandler object that specifies the configuration parameters described in the following table:

*Table 296. SAMLGenerateCallbackHandler properties. This table describes the configuration parameters for the SAMLGenerateCallbackHandler object using the bearer subject confirmation method.*

| Property | Description | Required |
|---|---|---|
| SamlConstants.CONFIRMATION_METHOD | Specifies to use the `Bearer` confirmation method. | Yes |
| SamlConstants.TOKEN_TYPE | Uses the constant value, `WSSConstants.SAML.SAML20_VALUE_TYPE`, to specify a SAML 2.0 token type.<br><br>When a web services client has policy set attachments, this property is not used by Web Services Security runtime environment. In this scenario, specify the token value type by the valueType attribute of the tokenGenerator binding configuration.<br><br>The example in this procedure uses a SAML 2.0 token; however, you can also use the `WSSConstants.SAML.SAML11_VALUE_TYPE` value. | Yes |
| SamlConstants.SAML_NAME_IDENTIFIER | Specifies a user identity such as `myname` as the NameID value in the SAML token.<br><br>If you do not define this parameter when using the Thin Client for JAX-WS, the NameID value does not contain useful information.<br><br>If you are using a web services managed client, such a Java Platform, Enterprise Edition (Java EE) application making a web services request invocation, the Web Services Security runtime environment tries to extract user security information from the security context. Similarly, if you do not define this parameter for a managed web services client, the NameID value contains an UNAUTHENTICATED name identifier.<br><br>This property is not used if your web services client has policy set attachments. Read about sending SAML tokens to learn more about sending the SAML token identity and attributes. | No |
| SamlConstants.SIGNATURE_REQUIRED | Specifies whether the issuer is required to digitally sign the SAML token.<br><br>A `true` value specifies that issuer is required to digitally sign the SAML token. This value is the default. | No |

The `system.wss.generate.saml` parameter specifies the Java Authentication and Authorization Service (JAAS) login module that is used to create the SAML token. You must specify a JVM property to define a JAAS configuration file that contains the required JAAS login configuration; for example:

```
-Djava.security.auth.login.config=profile_root/properties/wsjaas_client.conf
```

Alternatively, you can specify a JAAS login configuration file by setting a Java system property in the sample client code; for example:

```
System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas_client.conf ");
```

d. Obtain the token identifier of the created SAML token.

Use the following statement as a simple test for the SAML token that you created:

```
System.out.println("SAMLToken id = " + samlToken.getId())
```

5. Add the SAML token to the SOAP security header of a Web services request messages.

a. Initialize the web services client and configure the SOAPAction properties. The following code snippet illustrates these actions:

```
// Initialize web services client
EchoService12PortProxy echo = new EchoService12PortProxy();
echo._getDescriptor().setEndpoint(endpointURL);

// Configure SOAPAction properties
BindingProvider bp = (BindingProvider) (echo._getDescriptor().getProxy());
Map<String, Object> requestContext = bp.getRequestContext();
requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, endpointURL);
requestContext.put(BindingProvider.SOAPACTION_USE_PROPERTY, Boolean.TRUE);
requestContext.put(BindingProvider.SOAPACTION_URI_PROPERTY, "echoOperation");
```

b. Initialize the WSSGenerationContext. The following code illustrates the use of the WSSGenerationContext interface to initialize a generation context and enable you to insert the `SAMLToken` into the web services request message:

```
// Initialize WSSGenerationContext
WSSGenerationContext gencont = factory.newWSSGenerationContext();
gencont.add(samlToken);
```

Specifically, the `gencont.add(samlToken)` method call specifies to put the SAML token into a request message. Use the PolicyTool to add the following policy statement to the Java security policy file or the application client was.policy file:

```
 "permission javax.security.auth.AuthPermission "modifyPrivateCredentials"
```

c. Add the timestamp element in the SOAP messages security header. The SAML20 Bearer WSHTTPS default policy set requires web services requests and response messages to carry a timestamp element in SOAP messages Security header. In the following code snippet, the `factory.newWSSTimestamp()` method call generates the timestamp, and the `gencont.add(timestamp)` method call specifies the timestamp to put into a request message:

```
// Add a timestamp to the request message.
WSSTimestamp timestamp = factory.newWSSTimestamp();
gencont.add(timestamp);

gencont.process(requestContext);
```

d. Attach WSSGenerationContext object to the web services RequestContext object. The WSSGenerationContext object now contains all the security information that is required to format a request message. The `gencont.process(requestContext)` method call attaches the WSSGenerationContext object to the web services RequestContext object to enable the Web Services Security runtime environment to format the required SOAP security header; for example:

```
// Attaches WSSGenerationContext object to the web services RequestContext object.
gencont.process(requestContext);
```

e. Specify SSL transport level message protection using JVM properties.

The SAML20 Bearer WSHTTPS default policy set requires transport-level message protection using SSL. Specify SSL transport-level message protection using the following JVM property:

```
-Dcom.ibm.SSL.ConfigURL=file:profile_root\properties\ssl.client.props
```

Alternatively, you can define the SSL configuration file using a Java system property in the sample client code; for example:

```
System.setProperty("com.ibm.SSL.ConfigURL", "file:profile_root/properties/ssl.client.props");
```

### Results

You have created a self-issued SAML token with the bearer subject confirmation method and then sent this token with web services request messages using the JAX-WS programming model and WSS APIs.

## Example

The following code sample is a web services client application that demonstrates how to create a self-issued SAML token and send that SAML token in web services request messages. If your usage scenario requires SAML tokens, but does not require your application to pass the SAML tokens using web services messages, you only need to use the first part of the following sample code, up through the `// Initialize web services client` section.

```
/**
 * The following source code is sample code created by IBM Corporation.
 * This sample code is provided to you solely for the purpose of assisting you in the
 * use of the technology.  The code is provided 'AS IS', without warranty or condition of
 * any kind.  IBM shall not be liable for any damages arising out of your use of the
 * sample code, even if IBM has been advised of the possibility of such damages.

  private String urlPort = "9443";
  private static final String CONTEXT_BASE = "/WSSampleSei/";
  private static final String ECHO_CONTEXT12 = CONTEXT_BASE+"EchoService12";
  private String message = "HELLO";
  private String uriString = "https://" + urlHost + ":" + urlPort;
  private String endpointURL = uriString + ECHO_CONTEXT12;
  private String input = message;

  /**
   * main()
   *
   * see printusage() for command-line arguments
   *
   * @param args
   */
  public static void main(String[] args) {
    SampleClient sample = new SampleClient();
    sample.CallService();
  }

  /**
   * CallService Parms were already read. Now call the service proxy classes
   *
   */
  void CallService() {
    String response = "ERROR!:";
    try {
      System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas_client.conf ");
      System.setProperty("com.ibm.SSL.ConfigURL", "file:profile_root/properties/ssl.client.props");

      // Initialize WSSFactory object
      WSSFactory factory = WSSFactory.getInstance();
      // Initialize WSSGenerationContext
      WSSGenerationContext gencont = factory.newWSSGenerationContext();
      // Initialize SAML issuer configuration via custom properties
      HashMap<Object, Object> customProps = new HashMap<Object,Object>();

      customProps.put(SamlConstants.ISSUER_URI_PROP, "example.com");
      customProps.put(SamlConstants.TTL_PROP, "3600000");
      customProps.put(SamlConstants.KS_PATH_PROP, "keystores/saml-provider.jceks");
      customProps.put(SamlConstants.KS_TYPE_PROP, "JCEKS");
      customProps.put(SamlConstants.KS_PW_PROP, "{xor}LCswLTovPiws");
```

```
      customProps.put(SamlConstants.KEY_ALIAS_PROP, "samlissuer");
      customProps.put(SamlConstants.KEY_NAME_PROP, "CN=SAMLIssuer, O=EXAMPLE");
      customProps.put(SamlConstants.KEY_PW_PROP, "{xor}NDomLz4sLA==");
      customProps.put(SamlConstants.TS_PATH_PROP, "keystores/saml-provider.jceks");
      customProps.put(SamlConstants.TS_TYPE_PROP, "JCEKS");
      customProps.put(SamlConstants.TS_PW_PROP, "{xor}LCswLTovPiws");
      gencont.add(customProps); //Add custom properties

      // Create SAMLToken
      HashMap<Object, Object> map = new HashMap<Object, Object>();
      map.put(SamlConstants.CONFIRMATION_METHOD, "Bearer");
      map.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML20_VALUE_TYPE);
      map.put(SamlConstants.SAML_NAME_IDENTIFIER, "Alice");
      map.put(SamlConstants.SIGNATURE_REQUIRED, "true");
      SAMLGenerateCallbackHandler callbackHandler = new SAMLGenerateCallbackHandler(map);

      SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml");

      System.out.println("SAMLToken id = " + samlToken.getId());

      // Initialize web services client
      EchoService12PortProxy echo = new EchoService12PortProxy();
      echo._getDescriptor().setEndpoint(endpointURL);

      // Configure SOAPAction properties
      BindingProvider bp = (BindingProvider) (echo._getDescriptor().getProxy());
      Map<String, Object> requestContext = bp.getRequestContext();
      requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, endpointURL);
      requestContext.put(BindingProvider.SOAPACTION_USE_PROPERTY, Boolean.TRUE);
      requestContext.put(BindingProvider.SOAPACTION_URI_PROPERTY, "echoOperation");

      gencont.add(samlToken);

      // Add timestamp
      WSSTimestamp timestamp = factory.newWSSTimestamp();
      gencont.add(timestamp);

      gencont.process(requestContext);

      // Build the input object
      EchoStringInput echoParm =
        new com.ibm.was.wssample.sei.echo.ObjectFactory().createEchoStringInput();
      echoParm.setEchoInput(input);
      System.out.println(">> CLIENT: SEI Echo to " + endpointURL);

      // Prepare to consume timestamp in response message.
      WSSConsumingContext concont = factory.newWSSConsumingContext();
      concont.add(WSSConsumingContext.TIMESTAMP);
      concont.process(requestContext);

      // Call the service
      response = echo.echoOperation(echoParm).getEchoResponse();

      System.out.println(">> CLIENT: SEI Echo invocation complete.");
      System.out.println(">> CLIENT: SEI Echo response is: " + response);
    } catch (Exception e) {
      System.out.println(">> CLIENT: ERROR: SEI Echo EXCEPTION.");
      e.printStackTrace();
    }
  }
}
```

When this web services client application sample runs correctly, you receive messages like the following messages:

```
SAMLToken id = _191EBC44865015D9AB1270745072344
Retrieving document at 'file:profile_root/.../wsdl/'.
>> CLIENT: SEI Echo to https://localhost:9443/WSSampleSei/EchoService12
>> CLIENT: SEI Echo invocation complete.
>> CLIENT: SEI Echo response is: SOAP12==>>HELLO
```

*Inserting SAML attributes using WSS APIs:*

You can insert custom attributes into self-issued SAML tokens by using the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS APIs).

**Before you begin**

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, and the use of policy sets to configure and administer web services settings. Complete the following actions before you begin this task:

- Read about propagating self-issued SAML bearer tokens by using WSS APIs.
- Read about propagating self-issued SAML sender-vouches tokens by using WSS APIs with message level protection.
- Read about propagating self-issued SAML sender-vouches tokens by using WSS APIs with SSL transport protection.
- Read about propagating self-issued SAML holder-of-key tokens with symmetric key by using WSS APIs.
- Read about propagating self-issued SAML holder-of-key tokens with asymmetric key by using WSS APIs.

### About this task

This task shows example code that inserts custom attributes into self-issued SAML security tokens. This particular example uses the bearer subject confirmation method. You can add attributes to any SAML security tokens, and the same code can be used with other subject confirmation methods.

### Procedure

Insert custom attributes when creating SAML security tokens; for example:

```
import com.ibm.websphere.wssecurity.wssapi.token.SecurityToken;
import com.ibm.websphere.wssecurity.callbackhandler.SAMLGenerateCallbackHandler;
import com.ibm.websphere.wssecurity.wssapi.token.SAMLToken;
import com.ibm.wsspi.wssecurity.core.token.config.WSSConstants;
import com.ibm.wsspi.wssecurity.saml.config.SamlConstants;
import com.ibm.wsspi.wssecurity.saml.data.SAMLAttribute;

WSSFactory factory = WSSFactory.getInstance();
HashMap<Object, Object> map = new HashMap<Object, Object>();
map.put(SamlConstants.CONFIRMATION_METHOD, "Bearer");
map.put(SamlConstants.Token_REQUEST, "issue");
map.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML20_VALUE_TYPE);
map.put(SamlConstants.SAML_NAME_IDENTIFIER, "Alice");
map.put(SamlConstants.SIGNATURE_REQUIRED, "true");
ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
String groups[] = {"IBMer", "Texan"};
SAMLAttribute sattribute = new SAMLAttribute("Membership", groups, null,null, null, null);
al.add(sattribute);
String gender[] = {"Female"};
sattribute = new SAMLAttribute("Gender", gender, null,null, null, null);
al.add(sattribute);
map.put(SamlConstants.SAML_ATTRIBUTES, al);
SAMLGenerateCallbackHandler callbackHandler = new SAMLGenerateCallbackHandler(map);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, callbackHandler,
                                                   "system.wss.generate.saml");
```

### Results

You have inserted custom attributes to a SAML security token.

### Example

The following example shows the custom attributes in the SAML Assertion:

```
<saml2:Assertion xmlns:saml2="urn:oasis:names:tc:SAML:2.0:assertion"
                 Version="2.0"
                      ID="_E62A1CA3C2F21D9A9B1287772824570"
                      IssueInstant="2010-10-22T18:40:24.531Z">
    <saml2:Issuer>example.com</samls2:Issuer>
    <ds:Signature xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
    ...
    </ds:Signature>
    <saml2:Subject>
        <saml2:NameID>Alice</saml2:NameID>
        <saml2:SubjectConfirmation Method="urn:oasis:names:tc:SAML:2.0:cm:bearer"></saml2:SubjectConfirmation>
    </saml2:Subject>
    <saml2:Conditions NotBefore="2010-10-22T18:40:24.531Z"
                   NotOnOrAfter="2010-10-22T19:40:24.531Z">
    </saml2:Conditions>
```

```
    <saml2:AttributeStatement>
        <saml2:Attribute Name="Membership">
            <saml2:AttributeValue>IBMer</saml2:AttributeValue>
            <saml2:AttributeValue>Texan</saml2:AttributeValue>
        </saml2:Attribute>
        <saml2:Attribute Name="Gender">
            <saml2:AttributeValue>Female</saml2:AttributeValue>
        </saml2:Attribute>
    </saml2:AttributeStatement>
</saml2:Assertion>
```

**What to do next**

Merge the code with the example code listed in the “Propagating self-issued SAML bearer tokens by using WSS APIs” topic to generate SAML security tokens. You can see SAML attributes in the SAML Assertions.

*Sending self-issued SAML sender-vouches tokens using WSS APIs with message level protection:*

You can create self-issued SAML tokens with the sender-vouches subject confirmation method and then use the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS APIs) to send these tokens with web services request messages with message level protection.

**Before you begin**

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, and the use of policy sets to configure and administer web services settings.

**About this task**

**Note:** You can protect SOAP request messages and SAML tokens by using the Web Services Security programming interface to satisfy the sender-vouches subject confirmation method validation requirements with message level protection. Using the programming interfaces in web services client is an alternative approach to using policy set and binding configuration.

You can create a self-issued SAML token and then send the SAML token in web services request messages from a web services client. The web services application client used in this task is a modified version of the client code that is contained in the JaxWSServicesSamples sample application that is available for download. Code snippets from the sample are described in the procedure section, and a complete, ready-to-use web services client sample is provided in the Example section.

This product does not provide a default policy set that requires SAML tokens with sender-vouches subject confirmation method. Read about configuring client and provider bindings for the SAML sender-vouches token to learn more about how to create a Web Services Security policy to require SAML tokens with sender-vouches subject confirmation and how to create a custom binding configuration. You must attach the policy and binding to the web services provider. The code sample described in this task assumes that the web services provider policy requires that both the SAML tokens and the message bodies are digitally signed by using an X.509 security token.

**Procedure**

1. Identify and obtain the web services client that you want to use to invoke a web services provider.

   Use this client to insert SAML tokens in SOAP request messages programmatically using WSS APIs.

   The web services client used in this procedure is a modified version of the client code that is contained in the JaxWSServicesSamples web services sample application.

   To obtain and modify the sample web services client to add the Web Services Security API to pass SAML sender-vouches tokens in SOAP request messages programmatically using WSS APIs, complete the following steps:

a. Download the JaxWSServicesSamples sample application. The JaxWSServicesSamples sample is not installed by default.

b. Obtain the JaxWSServicesSamples client code.

For example purposes, this procedure uses a modified version of the Echo thin client sample that is included in the JaxWSServicesSamples sample. The web services Echo thin client sample file, `SampleClient.java`, is located in the `src\SampleClientSei\src\com\ibm\was\wssample\sei\cli` directory. The sample class file is included in the `WSSampleClientSei.jar` file.

The `JaxWSServicesSamples.ear` enterprise application and supporting Java archives (JAR) files are located in the `installableApps` directory within the JaxWSServicesSamples sample application.

c. Deploy the `JaxWSServicesSamples.ear` file onto the application server. After you deploy the `JaxWSServicesSamples.ear` file, you are ready to test the sample web services client code against the sample application.

Instead of using the web services client sample, you can choose to add the code snippets to pass SAML tokens in SOAP request messages programmatically using WSS APIs in your own web services client application. The example in this procedure uses a JAX-WS Web services thin client; however, you can also use a managed client.

2. Use the CallService() method to specify the Web services security configuration parameters that are required to invoke a target Web services provider using a self-issued SAML token.

The CallService() method sets configuration parameters that are required by the Web Services Security runtime environment via the `com.ibm.websphere.wssecurity.wssapi.WSSGenerationContext` custom property to generate a self-issued SAMLToken.

The following code snippet illustrates using the CallService() method to set the `SamlConstants.SAML_SELF_ISSUER_CONFIG` system property:

```
public static void main(String[] args) {
  SampleSamlSVClient sample = new SampleSamlSVClient();
  sample.CallService();
}

/**
 * CallService Parms were already read. Now call the service proxy classes
 *
 */
void CallService() {
  String response = "ERROR!:";
  try {
    System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas.conf");
```

Read about configuring a SAML token during token creation for more information about how you can specify configuration properties to control how the token is configured.

3. Add the Thin Client for JAX-WS JAR file to the class path. Add *app_server_root*/runtimes/com.ibm.jaxws.thinclient_8.0.0.jar file to the class path. See the testing web services-enabled clients information for more information about adding this JAR file to the class path.

4. Create the self-issued SAML token. The following code snippet illustrates creating the SAML token:

```
// Create SAMLToken
HashMap<Object, Object> map = new HashMap<Object, Object>();
map.put(SamlConstants.CONFIRMATION_METHOD, "sender-vouches");
map.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML20_VALUE_TYPE);
map.put(SamlConstants.SAML_NAME_IDENTIFIER, "Alice");
map.put(SamlConstants.SIGNATURE_REQUIRED, "true");
SAMLGenerateCallbackHandler callbackHandler = new SAMLGenerateCallbackHandler(map);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml");
System.out.println("SAMLToken id = " + samlToken.getId());
```

a. Use the WSSFactory newSecurityToken method to specify how to create the SAML token.

Specify the following method to create the SAML token:

```
WSSFactory  newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml")
```

Creating a SAML token requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken. Add the following policy statement to the Java security policy file or the application client was.policy file:

```
permission java.security.SecurityPermission "wssapi.SAMLTokenFactory.newSAMLToken
```

The `SAMLToken.class` parameter specifies the type of security token to create.

The `callbackHandler` object contains parameters that define the characteristics of the SAMLToken that you are creating. This object points to a SAMLGenerateCallbackHandler object that specifies the following configuration parameters described in the following table:

*Table 297. SAMLGenerateCallbackHandler properties. This table describes the configuration parameters for the SAMLGenerateCallbackHandler object using the sender-vouches confirmation method.*

| Property | Description | Required |
|---|---|---|
| SamlConstants.CONFIRMATION_METHOD | Specifies to use the `sender-vouches` confirmation method. | Yes |
| SamlConstants.TOKEN_TYPE | Uses the constant value, `WSSConstants.SAML.SAML20_VALUE_TYPE` to specify a SAML 2.0 token type.<br><br>When a web services client has policy set attachments, this property is not used by Web Services Security runtime environment. In this scenario, specify the token value type by the valueType attribute of the tokenGenerator binding configuration.<br><br>The example in this procedure uses a SAML 2.0 token; however, you can also use the `WSSConstants.SAML.SAML11_VALUE_TYPE` value. | Yes |
| SamlConstants.SAML_NAME_IDENTIFIER | Specifies a user identity such as `myname` as the NameID value in the SAMLToken.<br><br>If you do not define this parameter when using the Thin Client for JAX-WS, the NameID value does not contain useful information.<br><br>If you are using a web services managed client, such a Java Platform, Enterprise Edition (Java EE) application making a web services request invocation, the Web Services Security runtime environment tries to extract user security information from the security context. Similarly, if you do not define this parameter for a managed web services client, the NameID value contains an UNAUTHENTICATED name identifier.<br><br>This property is not used if your web services client has policy set attachments. Read about sending SAML tokens to learn more about sending the SAML token identity and attributes. | No |
| SamlConstants.SIGNATURE_REQUIRED | Specifies whether the issuer is required to digitally sign the SAML token.<br><br>A `true` value specifies that issuer is required to digitally sign the SAML token. This value is the default. | No |

The `system.wss.generate.saml` parameter specifies to use a Java Authentication and Authorization Service (JAAS) login configuration and specifies the login module that is invoked to create the SAML token. You must specify a JVM property to define a JAAS configuration file that contains the required JAAS login configuration; for example:

```
Djava.security.auth.login.config=profile_root/properties/wsjaas.conf
```

Alternatively, you can specify a JAAS login configuration file using a Java system property in the sample client code; for example:

```
System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas.conf");
```

b. Obtain the token identifier of the created SAML token.

Use the following statement as a simple test for the SAML token that you created:

```
System.out.println("SAMLToken id = " + samlToken.getId())
```

5. Add the SAML token to the SOAP security header of web services request messages.
   a. Initialize the web services client and configure the SOAPAction properties. The following code example illustrates these actions:

```
// Initialize web services client
EchoService12PortProxy echo = new EchoService12PortProxy();
echo._getDescriptor().setEndpoint(endpointURL);

// Configure SOAPAction properties
BindingProvider bp = (BindingProvider) (echo._getDescriptor().getProxy());
Map<String, Object> requestContext = bp.getRequestContext();
requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, endpointURL);
requestContext.put(BindingProvider.SOAPACTION_USE_PROPERTY, Boolean.TRUE);
requestContext.put(BindingProvider.SOAPACTION_URI_PROPERTY, "echoOperation");
```

```
// Initialize WSSGenerationContext
WSSGenerationContext gencont = factory.newWSSGenerationContext();
gencont.add(samlToken);
```

b. Initialize the WSSGenerationContext. The following code snippet illustrates the use of the gencont.object of the WSSGenerationContext type to initialize a generation context to enable you to insert the `SAMLToken` into a web services request message:

```
// Initialize WSSGenerationContext
WSSGenerationContext gencont = factory.newWSSGenerationContext();
gencont.add(samlToken);
```

Specifically, the `gencont.add(samlToken)` method call specifies to put the SAML token into a request message. This operation requires the client code to have the following Java 2 Security permission:

```
 "permission javax.security.auth.AuthPermission "modifyPrivateCredentials"
```

6. Add an X.509 token for message protection.

   This sample code uses the dsig-sender.ks key file and the SOAPRequester sample key. You must not use the sample key in a production environment. The following code snippet illustrates adding an X.509 token for message protection:

```
// Add an X.509 Token for message protection
X509GenerateCallbackHandler x509callbackHandler = new X509GenerateCallbackHandler(
        null,
        "profile_root/etc/ws-security/samples/dsig-sender.ks",
        "JKS",
        "client".toCharArray(),
        "soaprequester",
        "client".toCharArray(),
        "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP", null);

SecurityToken x509 = factory.newSecurityToken(X509Token.class,
        x509callbackHandler, "system.wss.generate.x509");

WSSSignature sig = factory.newWSSSignature(x509);
sig.setSignatureMethod(WSSSignature.RSA_SHA1);

WSSSignPart sigPart = factory.newWSSSignPart();
sigPart.setSignPart(samlToken);
sigPart.addTransform(WSSSignPart.TRANSFORM_STRT10);
sig.addSignPart(sigPart);
sig.addSignPart(WSSSignature.BODY);
```

a. Create a WSSSignature object with the X509 token. The following line of code creates a WSSSignature object with the X509 token:

```
WSSSignature sig = factory.newWSSSignature(x509);
```

b. Add the signed part to use for message protection. The following line of code specifies to add WSSSignature.BODY as the signed part:

```
sig.addSignPart(WSSSignature.BODY);
```

c. Add the timestamp element in the SOAP messages security header. The SAML20 SenderVouches WSHTTPS and SAML11 SenderVouches WSHTTPS policy sets require web services requests and response messages to carry a timestamp element in the SOAP messages Security header. In the following code snippet, the `factory.newWSSTimestamp()` method call generates the timestamp, and the `gencont.add(timestamp)` method call adds the timestamp into the request message:

```
// Add Timestamp
WSSTimestamp timestamp = factory.newWSSTimestamp();
gencont.add(timestamp);
sig.addSignPart(WSSSignature.TIMESTAMP);

gencont.add(sig);

WSSConsumingContext concont = factory.newWSSConsumingContext();
```

d. Configure the verification of the digital signature in the response message.

   A separate WSSSignPart is needed to specify the SecurityTokenReference transformation algorithm that is represented by the `WSSSignPart.TRANSFORM_STRT10` attribute. A SAML Token cannot be digitally signed directly. This attribute enables the Web Services Security runtime environment to generate a SecurityTokenReference element to reference the SAMLToken and to digitally sign the SAMLToken using the SecurityTokenReference transformation. The following line of code specifies to use the `WSSSignPart.TRANSFORM_STRT10` attribute:

```
WSSSignPart sigPart = factory.newWSSSignPart();
sigPart.setSignPart(samlToken);
sigPart.addTransform(WSSSignPart.TRANSFORM_STRT10);
```

e. Attach the WSSGenerationContext object to the web services RequestContext object. The WSSGenerationContext object now contains all the security information that is required to format a request message. The `gencont.process(requestContext)` method call attaches the WSSGenerationContext object to the web services RequestContext object to enable the Web Services Security runtime environment to format the required SOAP security header; for example:

```
// Attaches the WSSGenerationContext object to the web services RequestContext object.
gencont.process(requestContext);
```

7. Use the X.509 token to validate the digital signature and the integrity of the response message. If the provider policy requires the response message to be digitally signed, you must initialize the X.509 token.

   a. A X509ConsumeCallbackHandler object is initialized with a truststore, dsig-receiver.ks, and a certificate path object to validate the provider digital signature. The following line of code is used to initialize the X509ConsumeCallbackHandler object:

```
X509ConsumeCallbackHandler callbackHandlerVer = new X509ConsumeCallbackHandler(
        "profile_root/etc/ws-security/samples/dsig-receiver.ks",
        "JKS",
        "server".toCharArray(),
        certList,
        java.security.Security.getProvider("IBMCertPath"));
```

   b. A WSSVerification object is created and the message body is added to the verification object so that the Web Services Security runtime environment validates the digital signature.

      The following line of code is used to initialize the WSSVerification object:

```
WSSVerification ver = factory.newWSSVerification(X509Token.class, callbackHandlerVer);
```

      The WSSConsumingContext object now contains all the security information that is required to format a request message. The `concont.process(requestContext)` method call attaches the WSSConsumingContext object to the response method; for example:

```
// Attaches the WSSConsumingContext object to the web services RequestContext object.
concont.process(requestContext);
```

### Results

You have created a self-issued SAML token with the sender-vouches confirmation method and then sent this token with web services request messages using the JAX-WS programming model and WSS APIs.

### Example

The following code sample is a complete, ready-to-use web services client application that demonstrates how to create a self-issued SAML sender-vouches token and send that SAML token in web services request messages. This sample code illustrates the procedure steps described previously.

```
/**

```

When this web services client application sample runs correctly, you receive messages like the following messages:

```
SAMLToken id = _6CDDF0DBF91C044D211271166233407
Retrieving document at 'file:profile_root/.../wsdl/'.
>> CLIENT: SEI Echo to http://localhost:9080/WSSampleSei/EchoService12
>> CLIENT: SEI Echo invocation complete.
>> CLIENT: SEI Echo response is: SOAP12===>>HELLO
```

*Sending self-issued SAML sender-vouches tokens using WSS APIs with SSL transport protection:*

You can create self-issued SAML tokens with the sender-vouches subject confirmation method and then use the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS APIs) to send these tokens with web services request messages with transport protection.

**Before you begin**

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, SSL transport protection, and the use of policy sets to configure and administer web services settings.

**About this task**

**Note:** You can build your web services client to use SAML tokens with the sender-vouches subject confirmation method in SOAP request messages using the Web Services Security programming interfaces. Using the programming interfaces in a web services client to specify the use of SAML tokens with sender-vouches subject confirmation using message protection at the transport level is an alternative approach to using policy sets and binding configurations.

You can create a self-issued SAML token and then send the SAML token in web services request messages from a web services client. The web services client application used in this task is a modified version of the client code that is contained in the JaxWSServicesSamples sample application that is available for download. Code examples from the sample are described in the procedure section, and a complete, ready-to-use web services client sample is provided in the Example section.

**Procedure**

1. Identify and obtain the web services client that you want to use to invoke a web services provider.

   Use this client to insert SAML tokens in SOAP request messages programmatically using WSS APIs.

   The web services client used in this procedure is a modified version of the client code that is contained in the JaxWSServicesSamples web services sample application.

   To obtain and modify the sample web services client to use the Web Services Security API to pass SAML sender-vouches tokens in SOAP request messages programmatically using WSS APIs, complete the following steps:

   a. Download the JaxWSServicesSamples sample application. The JaxWSServicesSamples sample is not installed by default.

   b. Obtain the JaxWSServicesSamples client code.

For example purposes, this procedure uses a modified version of the Echo thin client sample that is included in the JaxWSServicesSamples sample. The web services Echo thin client sample file, `SampleClient.java`, is located in the `src\SampleClientSei\src\com\ibm\was\wssample\sei\cli` directory. The sample class file is included in the `WSSampleClientSei.jar` file.

The `JaxWSServicesSamples.ear` enterprise application and supporting Java archives (JAR) files are located in the `installableApps` directory within the JaxWSServicesSamples sample application.

c. Deploy the `JaxWSServicesSamples.ear` file onto the application server. After you deploy the `JaxWSServicesSamples.ear` file, you are ready to test the sample web services client code against the sample application.

Instead of using the web services client sample, you can choose to add the code snippets to pass SAML tokens in SOAP request messages programmatically using WSS APIs in your own web services client application. The example in this procedure uses a JAX-WS Web services thin client; however, you can also use a managed client.

2. Create a copy of either the SAML20 Bearer WSHTTPS default policy set or the SAML11 Bearer WSHTTPS default policy set.

   Provide a name for the copy of the policy set; for example SAML20 SenderVouches WSHTTPS or SAML11 SenderVouches WSHTTPS to help you identify that this new policy set uses the sender-vouches confirmation method.

   No additional change is required to the new policy file because the subject confirmation method is specified in the binding configuration and not in the policy.

   The new policy file contains either SAMLToken20Bearer or the SAMLToken11Bearer as the policy identifiers. Change the identifier of the SAMLToken20Bearer policy to SAMLToken20SV or change the identifier of the SAMLToken11Bearer policy to SAMLToken11SV to specify a more descriptive name. Changing the identifier of the policy does not change the policy enforcement in any way; however, adding a descriptive identifier helps you to identify that these policy identifiers use the sender-vouches confirmation method.

   If you want to view the settings of these policies, use the administrative console to complete the following actions:

   a. Click **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name***.
   b. Click the **WS-Security** policy in the policies table.
   c. Click the **Main policy** link or the **Bootstrap policy** link.
   d. Click **Request token policies** from the Policy Details section.

3. Attach the new SAML20 SenderVouches WSHTTPS or SAML11 SenderVouches WSHTTPS policy set to the web services provider application. Read about configuring client and provider bindings for the SAML sender-vouches token for details on attaching this policy set to your web services provider application.

4. Create a copy of the SAML Bearer Provider sample default general bindings.

   a. For the new copy of the default policy set, provide a name that includes sender-vouches, such as `SAML Sender-vouches provider binding`.
   b. Change the value of the confirmationMethod property to `sender-vouches` in the token consumer configuration for the intended SAML token version. Read about configuring client and provider bindings for the SAML sender-vouches token for details on modifying the sender-vouches bindings to satisfy the vouching requirement.

5. Assign the new provider binding to the JaxWSServicesSamples provider sample. Read about configuring client and provider bindings for the SAML sender-vouches for details on assigning the SAML sender-vouches provider sample, default general bindings to your web services provider application.

6. Enable the web services provider SSL configuration attribute, clientAuthentication, to require X.509 client certificate authentication.

   The clientAuthentication attribute determines whether SSL client authentication is required. To specify the clientAuthentication attribute, use the administrative console to complete the following actions:

a. Click **Security** > **SSL certificates and key management** > **Manage endpoint security configurations** > **{Inbound | Outbound}** > ***SSL_configuration***.

b. Click the **WC_defaulthost_secure** link.

c. Under Related Items, click the **SSL_configurations** link.

d. Select the **NodeDefaultSSLSettings** resource.

e. Click **Quality of protection (QoP) settings** link.

f. Select **Required** from the menu to specify client authentication.

Read about creating a secure sockets layer configuration to learn more about configuring the clientAuthentication attribute.

7. In the web services client code, use the CallService() method to specify the properties file that contains configuration parameters required to generate a self-issued SAML token.

   The CallService() method specifies configuration parameters that are required by the Web Services Security runtime environment to generate a self-issued SAMLToken.

   The following code snippet illustrates using the CallService() method to specify Web services security configuration parameters:

```
public static void main(String[] args) {
  SampleSamlSVClient sample = new SampleSamlSVClient();
  sample.CallService();
 }

/**
 * CallService Parms were already read. Now call the service proxy classes
 *
 */
void CallService() {
  String response = "ERROR!:";
  try {
    System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas_client.conf ");
    // Initialize WSSFactory object
    WSSFactory factory = WSSFactory.getInstance();

    // Initialize WSSGenerationContext
    WSSGenerationContext gencont = factory.newWSSGenerationContext();
    // Initialize SAML issuer configuration via custom properties
    HashMap <Object, Object> customProps = new HashMap<Object,Object>();

    customProps.put(SamlConstants.ISSUER_URI_PROP, "example.com");
    customProps.put(SamlConstants.TTL_PROP, "3600000");
    customProps.put(SamlConstants.KS_PATH_PROP, "keystores/saml-provider.jceks");
    customProps.put(SamlConstants.KS_TYPE_PROP, "JCEKS");
    customProps.put(SamlConstants.KS_PW_PROP, "{xor}LCswLTovPiws");
    customProps.put(SamlConstants.KEY_ALIAS_PROP, "samlissuer");
    customProps.put(SamlConstants.KEY_NAME_PROP, "CN=SAMLIssuer, O=EXAMPLE");
    customProps.put(SamlConstants.KEY_PW_PROP, "{xor}NDomLz4sLA==");
    customProps.put(SamlConstants.TS_PATH_PROP, "keystores/saml-provider.jceks");
    customProps.put(SamlConstants.TS_TYPE_PROP, "JCEKS");
    customProps.put(SamlConstants.TS_PW_PROP, "{xor}LCswLTovPiws");
    gencont.add(customProps); //Add custom properties
```

   Read about configuring a SAML token during token creation for more information about how you can specify configuration properties to control how the token is configured.

8. Add the Thin Client for JAX-WS JAR file to the classpath. Add *app_server_root*/runtimes/com.ibm.jaxws.thinclient_8.0.0.jar file to the classpath. See the testing web services-enabled clients information for more information about adding this JAR file to the classpath.

9. Create the self-issued SAML token. The following code snippet illustrates creating the SAML sender-vouches token:

```
// Create SAMLToken
HashMap<Object, Object> map = new HashMap<Object, Object>();
map.put(SamlConstants.CONFIRMATION_METHOD, "sender-vouches");
map.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML20_VALUE_TYPE);
map.put(SamlConstants.SAML_NAME_IDENTIFIER, "Alice");
map.put(SamlConstants.SIGNATURE_REQUIRED, "true");
SAMLGenerateCallbackHandler callbackHandler = new SAMLGenerateCallbackHandler(map);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml");
System.out.println("SAMLToken id = " + samlToken.getId());
```

   a. Use the WSSFactory newSecurityToken method to specify how to create the SAML token.

      Specify the following method to create the SAML token:

```
WSSFactory  newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml")
```

Creating a SAML token requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken. Use the PolicyTool to add the following policy statement to the Java security policy file or the application client was.policy file:

```
permission java.security.SecurityPermission "wssapi.SAMLTokenFactory.newSAMLToken
```

The `SAMLToken.class` parameter specifies the type of security token to create.

The `callbackHandler` object contains parameters that define the characteristics of the SAMLToken that you are creating. This object points to a SAMLGenerateCallbackHandler object that specifies the configuration parameters described in the following table:

*Table 298. SAMLGenerateCallbackHandler properties. This table describes the configuration parameters for the SAMLGenerateCallbackHandler object using the sender-vouches confirmation method.*

| Property | Description | Required |
|---|---|---|
| SamlConstants.CONFIRMATION_METHOD | Specifies to use the `sender-vouches` confirmation method. | Yes |
| SamlConstants.TOKEN_TYPE | Uses the constant value, `WSSConstants.SAML.SAML20_VALUE_TYPE` to specify a SAML 2.0 token type.<br><br>When a web services client has policy set attachments, this property is not used by Web Services Security runtime environment. In this scenario, specify the token value type by the valueType attribute of the tokenGenerator binding configuration.<br><br>The example in this procedure uses a SAML 2.0 token; however, you can also use the `WSSConstants.SAML.SAML11_VALUE_TYPE` value. | Yes |
| SamlConstants.SAML_NAME_IDENTIFIER | Specifies a user identity such as `myname` as the NameID value in the SAMLToken.<br><br>If you do not define this parameter when using the Thin Client for JAX-WS, the NameID value does not contain useful information.<br><br>If you are using a web services managed client, such a Java Platform, Enterprise Edition (Java EE) application making a web services request invocation, the Web Services Security runtime environment tries to extract user security information from the security context. Similarly, if you do not define this parameter for a managed web services client, the NameID value contains an UNAUTHENTICATED name identifier.<br><br>This property is not used if your web services client has policy set attachments. Read about sending SAML tokens to learn more about sending the SAML token identity and attributes. | No |
| SamlConstants.SIGNATURE_REQUIRED | Specifies whether the issuer is required to digitally sign the SAML token.<br><br>A `true` value specifies that issuer is required to digitally sign the SAML token. This value is the default. | No |

The `system.wss.generate.saml` parameter specifies the Java Authentication and Authorization Service (JAAS) login module that is used to create the SAML token. You must specify a JVM property to define a JAAS configuration file that contains the required JAAS login configuration; for example:

```
-Djava.security.auth.login.config=profile_root/properties/wsjaas_client.conf
```

Alternatively, you can specify a JAAS login configuration file by setting a Java system property in the sample client code; for example:

```
System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas_client.conf ");
```

b. Obtain the token identifier of the created SAML token.

Use the following statement as a simple test for the SAML token that you created:

```
System.out.println("SAMLToken id = " + samlToken.getId())
```

## Results

You have created a self-issued SAML token with the sender-vouches confirmation method with transport protection and then sent this token with web services request messages using the JAX-WS programming model and WSS APIs.

## Example

The following code sample is a complete, ready-to-use web services client application that demonstrates how to create a self-issued SAML sender-vouches token and send that SAML token in web services request messages. This sample code illustrates the procedure steps described previously.

```

}
```

When this web services client application sample runs correctly, you receive messages like the following messages:

```
SAMLToken id = _6CDDF0DBF91C044D211271166233407
Retrieving document at 'file:profile_root/.../wsdl/'.
>> CLIENT: SEI Echo to http://localhost:9443/WSSampleSei/EchoService12
>> CLIENT: SEI Echo invocation complete.
>> CLIENT: SEI Echo response is: SOAP12==>>HELLO
```

*Sending self-issued SAML holder-of-key tokens with symmetric key using WSS APIs:*

You can create self-issued SAML tokens with the holder-of-key subject confirmation method and then use the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS APIs) to send these tokens with web services request messages.

**Before you begin**

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, and the use of policy sets to configure and administer web services settings. Complete the following actions before you begin this task:

- Read about sending self-issued SAML bearer tokens by using WSS APIs.
- Read about sending self-issued SAML sender-vouches tokens by using WSS APIs with message level protection.

### About this task

This task focuses on using the symmetric key that is embedded in SAML security tokens to generate a digital signature of selected SOAP message elements in order to satisfy holder-of-key subject confirmation method security requirements. The Web Services Security policy attached to the web services provider is that of the *SAML20 HoK Symmetric WSSecurity default* policy set that is shipped in WebSphere Application Server 7.0.0.7 and later releases.

### Procedure

1. Create a SAML security token that contains holder-of-key subject confirmation method; for example:

```
WSSFactory factory = WSSFactory.getInstance();
// Initialize WSSGenerationContext
com.ibm.websphere.wssecurity.wssapi.WSSGenerationContext gencont = factory.newWSSGenerationContext();
// Initialize SAML issuer configuration via custom properties
HashMap<Object, Object> customProps = new HashMap<Object,Object>();

customProps.put(SamlConstants.ISSUER_URI_PROP, "example.com");
customProps.put(SamlConstants.TTL_PROP, "3600000");
customProps.put(SamlConstants.KS_PATH_PROP, "keystores/saml-provider.jceks");
customProps.put(SamlConstants.KS_TYPE_PROP, "JCEKS");
customProps.put(SamlConstants.KS_PW_PROP, "{xor}LCswLTovPiws");
customProps.put(SamlConstants.KEY_ALIAS_PROP, "samlissuer");
customProps.put(SamlConstants.KEY_NAME_PROP, "CN=SAMLIssuer, O=EXAMPLE");
customProps.put(SamlConstants.KEY_PW_PROP, "{xor}NDomLz4sLA==");
customProps.put(SamlConstants.TS_PATH_PROP, "keystores/saml-provider.jceks");
customProps.put(SamlConstants.TS_TYPE_PROP, "JCEKS");
customProps.put(SamlConstants.TS_PW_PROP, "{xor}LCswLTovPiws");
gencont.add(customProps); //Add custom properties
HashMap<Object, Object> map = new HashMap<Object, Object>();
map.put(SamlConstants.CONFIRMATION_METHOD, "holder-of-key");
map.put(SamlConstants.Token_REQUEST, "issue");
map.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML20_VALUE_TYPE);
map.put(SamlConstants.SAML_NAME_IDENTIFIER, "Alice");
map.put(SamlConstants.SIGNATURE_REQUIRED, "true");
map.put(SamlConstants.SERVICE_ALIAS, "soaprecipient");
map.put(SamlConstants.KEY_TYPE,
        "http://docs.oasis-open.org/ws-sx/ws-trust/200512/SymmetricKey");
map.put(SamlConstants.SAML_APPLIES_TO, "http://localhost:9080/your_Web_service");
map.put(RequesterConfiguration.RSTT.ENCRYPTIONALGORITHM,
        "http://www.w3.org/2001/04/xmlenc#aes256-cbc");
map.put(SamlConstants.KEY_SIZE, "256");
SAMLGenerateCallbackHandler callbackHandler = new
        SAMLGenerateCallbackHandler(map);
SAMLToken samlToken = (SAMLToken) factory.newSecurityToken(SAMLToken.class,
        callbackHandler, "system.wss.generate.saml");
```

   The embedded proof key in the SAML security token is encrypted for the target Web service. The public key of the target service that encrypts the proof key is specified by the `SamlConstants.SERVICE_ALIAS` property which specifies a public certificate in the trust file. The trust file location is specified by a `com.ibm.websphere.wssecurity.wssapi.WSSGenerationContext` custom property. In this example, you must import the Java Cryptography Extension (JCE) policy file because encryption uses 256 bit key size. For more information, read about using the unrestricted JCE policy files in the "Tuning Web Services Security applications" topic.

   If you prefer to use derived keys for digital signing and for encryption instead of using symmetric key directly, add the following name-value pair:

```
map.put(SamlConstants.REQUIRE_DKT, "true");
```

2. Use the `WSSGenerationContext` object to prepare for request message security header processing; for example:

```
gencon.add(samlToken); //this line of code can be omitted

WSSTimestamp timestamp = factory.newWSSTimestamp();
gencon.add(timestamp);

WSSSignature sig = factory.newWSSSignature(samlToken);

sig.setSignatureMethod(WSSSignature.HMAC_SHA1);
sig.setCanonicalizationMethod(WSSSignature.EXC_C14N);
sig.addSignPart(WSSSignature.BODY);
sig.addSignPart(WSSSignature.TIMESTAMP);
sig.addSignPart(WSSSignature.ADDRESSING_HEADERS);
sig.setTokenReference(SecurityToken.REF_KEYID);
//If the gencon.add(samlToken); line of code is omitted, or DerivedKey is used
//the above line of code must be replaced with
```

```
//sig.setTokenReference(SecurityToken.REF_STR);

gencon.add(sig);

WSSEncryption enc = factory.newWSSEncryption(samlToken);

enc.setEncryptionMethod(WSSEncryption.AES256);
enc.setTokenReference(SecurityToken.REF_KEYID);
//If the gencon.add(samlToken); line of code is omitted, or DerivedKey is used
//the above line of code must be replaced with
//enc.setTokenReference(SecurityToken.REF_STR);
enc.encryptKey(false);
enc.addEncryptPart(WSSEncryption.BODY_CONTENT);
enc.addEncryptPart(WSSEncryption.SIGNATURE);
gencon.add(enc);
```

3. Create the `WSSConsumingContext` object to prepare for response message, security header processing; for example:

```
WSSConsumingContext concont = factory.newWSSConsumingContext();

HashMap<Object, Object> map = new HashMap<Object, Object>();

SAMLConsumerCallbackHandler callbackHandler = new
        SAMLConsumerCallbackHandler(map);

WSSDecryption dec = factory.newWSSDecryption(SAMLToken.class, callbackHandler,
        "system.wss.consume.saml");
dec.addAllowedEncryptionMethod(WSSDecryption.AES256);
dec.encryptKey(false);
dec.addRequiredDecryptPart(WSSDecryption.BODY_CONTENT);

concont.add(dec);

callbackHandler = new SAMLConsumerCallbackHandler(map);
WSSVerification ver = factory.newWSSVerification(SAMLToken.class, callbackHandler,
        "system.wss.consume.saml");
ver.addAllowedSignatureMethod(WSSVerification.HMAC_SHA1);
ver.addRequiredVerifyPart(WSSVerification.BODY);
ver.addRequiredVerifyPart(WSSVerification.TIMESTAMP);

concont.add(ver);
```

4. Use the JDK `keytool` utility to generate the `saml-provider.jceks` and `recipient.jceks`files that are used to test the example code; for example:

```
keytool -genkey -alias samlissuer -keystore saml-provider.jceks -dname "CN=SAMLIssuer, O=ACME" -storepass issuerstorepass
 -keypass issuerkeypass -storetype jceks -validity 5000 -keyalg RSA -keysize 2048

keytool -genkey -alias soaprecipient -keystore recipient.jceks -dname "CN=SOAPRecipient, O=ACME" -storepass reciptstorepass
 -keypass reciptkeypass -storetype jceks -validity 5000 -keyalg RSA -keysize 2048

keytool -export -alias soaprecipient -file reciptpub.cer -keystore recipient.jceks -storepass reciptstorepass -storetype jceks

keytool -import -alias soaprecipient -file reciptpub.cer -keystore saml-provider.jceks -storepass issuerstorepass -storetype jceks
 -keypass issuerkeypass -noprompt
```

### Results

You have learned key building blocks to create a web services client application to send a SAML security token in a SOAP message and to use the symmetric key that is embedded in SAML security in message level protection.

*Sending self-issued SAML holder-of-key tokens with asymmetric key using WSS APIs:*

You can create self-issued SAML tokens with the holder-of-key subject confirmation method and then use the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS APIs) to send these tokens with web services request messages.

### Before you begin

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, and the use of policy sets to configure and administer web services settings. Complete the following actions before you begin this task:

- Read about sending self-issued SAML bearer tokens by using WSS APIs.
- Read about sending self-issued SAML sender-vouches tokens by using WSS APIs with message level protection.

### About this task

This task focuses on using the asymmetric key that is identified by SAML security tokens to generate a digital signature of selected SOAP message elements in order to satisfy holder-of-key subject confirmation method security requirements. The X.509 certificate of the sender is embedded in the SAML security token. The sender signs selected parts of request message elements by using its corresponding private key and encrypts the request message by using the public key of the recipient. The recipient signs the selected elements of the response message by using the private key of the recipient, and encrypts selected elements of the response message by using the public key of the sender in SAML security tokens. The Web services security policy attached to the web services provider is provided for your reference.

### Procedure

1. Create a SAML security token that contains the holder-of-key subject confirmation method; for example:

```
WSSFactory factory = WSSFactory.getInstance();
// Initialize WSSGenerationContext
com.ibm.websphere.wssecurity.wssapi.WSSGenerationContext gencont = factory.newWSSGenerationContext();
// Initialize SAML issuer configuration via custom properties
HashMap<Object, Object> customProps = new HashMap<Object,Object>();
customProps.put(SamlConstants.ISSUER_URI_PROP, "example.com");
customProps.put(SamlConstants.TTL_PROP, "3600000");
customProps.put(SamlConstants.KS_PATH_PROP, "keystores/saml-provider.jceks");
customProps.put(SamlConstants.KS_TYPE_PROP, "JCEKS");
customProps.put(SamlConstants.KS_PW_PROP, "{xor}LCswLTovPiws");
customProps.put(SamlConstants.KEY_ALIAS_PROP, "samlissuer");
customProps.put(SamlConstants.KEY_NAME_PROP, "CN=SAMLIssuer, O=EXAMPLE");
customProps.put(SamlConstants.KEY_PW_PROP, "{xor}NDomLz4sLA==");
customProps.put(SamlConstants.TS_PATH_PROP, "keystores/saml-provider.jceks");
customProps.put(SamlConstants.TS_TYPE_PROP, "JCEKS");
customProps.put(SamlConstants.TS_PW_PROP, "{xor}LCswLTovPiws");
gencont.add(customProps); //Add custom properties
HashMap<Object, Object> map = new HashMap<Object, Object>();
map.put(SamlConstants.CONFIRMATION_METHOD, "holder-of-key");
map.put(SamlConstants.Token_REQUEST, "issue");
map.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML20_VALUE_TYPE);
map.put(SamlConstants.SAML_NAME_IDENTIFIER, "Alice");
map.put(SamlConstants.SIGNATURE_REQUIRED, "true");
map.put(SamlConstants.KEY_TYPE,
        "http://docs.oasis-open.org/ws-sx/ws-trust/200512/PublicKey");
map.put(SamlConstants.SAML_APPLIES_TO, "http://localhost:9080/your_Web_service");
map.put(SamlConstants.KEY_ALIAS, "soapinitiator" );
map.put(SamlConstants.KEY_NAME, "CN=SOAPInitator, O=ACME");
map.put(SamlConstants.KEY_PASSWORD, "keypass");
map.put(SamlConstants.KEY_STORE_PATH, "keystores/initiator.jceks");
map.put(SamlConstants.KEY_STORE_PASSWORD, "storepass");
map.put(SamlConstants.KEY_STORE_TYPE, "jceks");
SAMLGenerateCallbackHandler callbackHandler = new SAMLGenerateCallbackHandler(map);
SAMLToken samlToken = (SAMLToken) factory.newSecurityToken(SAMLToken.class,
                      callbackHandler, "system.wss.generate.saml");
```

   The private key of the sender is specified by the `SamlConstants.KEY_ALIAS` property and is used to sign selected elements of the request message.

2. Use the `WSSGenerationContext` object to prepare for request message security header processing; for example:

```
gencon.add(samlToken); //this line of code can be omitted
WSSTimestamp timestamp = factory.newWSSTimestamp();
gencon.add(timestamp);
WSSSignature sig = factory.newWSSSignature(samlToken);
sig.setTokenReference(SecurityToken.REF_KEYID);
//If the gencon.add(samlToken); line of code is omitted,
//the above line of code must be replaced with
//sig.setTokenReference(SecurityToken.REF_STR);

sig.setSignatureMethod(WSSSignature.RSA_SHA1);
sig.setCanonicalizationMethod(WSSSignature.EXC_C14N);
sig.addSignPart(WSSSignature.BODY);
sig.addSignPart(WSSSignature.TIMESTAMP);
sig.addSignPart(WSSSignature.ADDRESSING_HEADERS);
gencon.add(sig);
X509GenerateCallbackHandler x509callbackHandler2 = new X509GenerateCallbackHandler(
        null,
        "keystores/initiator.jceks",
        "jceks",
        "storepass".toCharArray(),
        "soaprecipient",
        null,
        "", null);
SecurityToken st2 = factory.newSecurityToken(X509Token.class, x509callbackHandler2);
WSSEncryption enc = factory.newWSSEncryption(st2);
enc.addEncryptPart(WSSEncryption.BODY_CONTENT);
enc.addEncryptPart(WSSEncryption.SIGNATURE);
enc.setEncryptionMethod(WSSEncryption.AES256);
enc.setKeyEncryptionMethod(WSSEncryption.KW_RSA_OAEP);
gencon.add(enc);
```

In this example, encryption uses a 256 bit key size so you must import the Java Cryptography Extension (JCE) policy file. For more information, read about using the unrestricted JCE policy files in the "Tuning Web Services Security applications" topic.

3. Create the `WSSConsumingContext` object to prepare for response message security header processing; for example:

```
WSSConsumingContext concont = factory.newWSSConsumingContext();

HashMap<Object, Object> map = new HashMap<Object, Object>();

SAMLConsumerCallbackHandler callbackHandler = new SAMLConsumerCallbackHandler(map);
WSSDecryption dec = factory.newWSSDecryption(SAMLToken.class, callbackHandler,
                           "system.wss.consume.saml");
dec.addAllowedEncryptionMethod(WSSDecryption.AES256);
dec.addAllowedKeyEncryptionMethod(WSSDecryption.KW_RSA_OAEP);
dec.encryptKey(false);
dec.addRequiredDecryptPart(WSSDecryption.BODY_CONTENT);
concont.add(dec);
X509ConsumeCallbackHandler verHandler = new X509ConsumeCallbackHandler(null,
            "keystores/initiator.jceks",
            "jceks",
            "storepass".toCharArray(),
            "soaprecipient",
            null, null);
WSSVerification ver = factory.newWSSVerification(X509Token.class, verHandler);
ver.addRequiredVerifyPart(WSSVerification.BODY);
concont.add(ver);
```

4. Use the JDK keytool utility to generate the `saml-provider.jceks`, `initiator.jceks`, and `recipient.jceks`files that are used to test the example code; for example:

```
keytool -genkey -alias samlissuer -keystore saml-provider.jceks -dname "CN=SAMLIssuer, O=ACME" -storepass storepass -keypass keypass
 -storetype jceks -validity 5000 -keyalg RSA -keysize 2048

keytool -genkey -alias soaprecipient -keystore recipient.jceks -dname "CN=SOAPRecipient, O=ACME" -storepass storepass -keypass keypass
 -storetype jceks -validity 5000 -keyalg RSA -keysize 2048

keytool -genkey -alias soapinitiator -keystore initiator.jceks -dname "CN=SOAPInitator, O=ACME" -storepass storepass -keypass keypass
 -storetype jceks -validity 5000 -keyalg RSA -keysize 2048

keytool -export -alias samlissuer -file issuerpub.cer -keystore saml-provider.jceks -storepass storepass -storetype jceks
keytool -export -alias soaprecipient -file reciptpub.cer -keystore recipient.jceks -storepass storepass -storetype jceks
keytool -export -alias soapinitiator -file initatpub.cer -keystore initiator.jceks -storepass storepass -storetype jceks

keytool -import -alias samlissuer -file issuerpub.cer -keystore initiator.jceks -storepass storepass -storetype jceks -keypass keypass -noprompt
keytool -import -alias soaprecipient -file reciptpub.cer -keystore initiator.jceks -storepass storepass -storetype jceks -keypass keypass -noprompt

keytool -import -alias samlissuer -file issuerpub.cer -keystore recipient.jceks -storepass storepass -storetype jceks -keypass keypass -noprompt
```

```
keytool -import -alias soapinitiator -file initatpub.cer -keystore recipient.jceks -storepass storepass -storetype jceks -keypass keypass -noprompt

keytool -import -alias soapinitiator -file initatpub.cer -keystore saml-provider.jceks -storepass storepass -storetype jceks -keypass keypass -noprompt
```

### Results

You have learned key building blocks to create a web services client application to send a SAML security token in a SOAP message and to use the asymmetric key that is embedded in SAML security in message level protection.

### Example

The following example illustrates the web services provider Web services security policy:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<wsp:Policy xmlns:wsp="http://schemas.xmlsoap.org/ws/2004/09/policy"
  xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd"
  xmlns:sp="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200512" xmlns:wsa="http://schemas.xmlsoap.org/ws/2004/08/addressing"
  xmlns:spe="http://www.ibm.com/xmlns/prod/websphere/200605/ws-securitypolicy-ext">
    <wsp:Policy wsu:Id="response:app_encparts">
        <sp:EncryptedElements>
            <sp:XPath>/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
             and local-name()='Envelope']/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
             and local-name()='Header']/*[namespace-uri()='http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd'
             and local-name()='Security']/*[namespace-uri()='http://www.w3.org/2000/09/xmldsig#' and local-name()='Signature']</sp:XPath>
            <sp:XPath>/*[namespace-uri()='http://www.w3.org/2003/05/soap-envelope'

</wsp:Policy>
```

*Requesting SAML bearer tokens from an external STS using WSS APIs and transport level protection:*

You can request SAML tokens with the bearer subject confirmation method from an external Security Token Service (STS). After obtaining the SAML bearer token, you can then send these tokens with web services request messages using the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS API).

**Before you begin**

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, and the use of policy sets to configure and administer web services settings.

**About this task**

**Note:**

> You can request a SAML token with the bearer subject confirmation method from an external STS and then send the SAML token in web services request messages from a web services client using WSS APIs.

The web services application client used in this task is a modified version of the client code that is contained in the JaxWSServicesSamples sample application that is available for download. Code snippets from the sample are described in the procedure section, and a complete, ready-to-use web services client sample is provided in the Example section.

**Procedure**

1. Identify and obtain the web services client that you want to use to invoke a web services provider.

   Use this client to insert SAML tokens in SOAP request messages programmatically using WSS APIs.

   The web services client used in this procedure is a modified version of the client code that is contained in the JaxWSServicesSamples web services sample application.

   To obtain and modify the sample web services client to add the Web Services Security API to pass SAML tokens in SOAP request messages programmatically using WSS APIs, complete the following steps:

   a. Download the JaxWSServicesSamples sample application. The JaxWSServicesSamples sample is not installed by default.

   b. Obtain the JaxWSServicesSamples client code.

      For example purposes, this procedure uses a modified version of the Echo thin client sample that is included in the JaxWSServicesSamples sample. The web services Echo thin client sample file, `SampleClient.java`, is located in the `src\SampleClientSei\src\com\ibm\was\wssample\sei\cli` directory. The sample class file is included in the `WSSampleClientSei.jar` file.

      The `JaxWSServicesSamples.ear` enterprise application and supporting Java archives (JAR) files are located in the `installableApps` directory within the JaxWSServicesSamples sample application.

   c. Deploy the `JaxWSServicesSamples.ear` file onto the application server. After you deploy the `JaxWSServicesSamples.ear` file, you are ready to test the sample web services client code against the sample application.

Instead of using the web services client sample, you can choose to add the code snippets to pass SAML tokens in SOAP request messages programmatically using WSS APIs in your own web services client application. The example in this procedure uses a JAX-WS web services thin client; however, you can also use a managed client.

2. Attach the SAML20 Bearer WSHTTPS default policy set to the web services provider. This policy set is used to protect messages using HTTPS transport. Read about configuring client and provider bindings for the SAML Bearer token for details on how to attach the SAML20 Bearer WSHTTPS default policy set to the web services provider.
3. Assign the SAML Bearer Provider sample default general bindings to the sample web services provider. Read about configuring client and provider bindings for the SAML bearer token for details on assigning the SAML Bearer Provider sample default general bindings to your web services application.
4. Verify that the trustStoreType, trustStorePassword and trustStorePath custom properties correspond to the trust store containing the STS signer certificate. Using the administrative console, complete the following steps:
   a. Click **Services** > **Policy sets** > **General provider policy set bindings** > **Saml Bearer Provider sample** > **WS-Security** > **Authentication and protection**.
   b. Click **gen_saml11token** in the Authentication tokens table.
   c. Click **Callback handler**.
   d. In the Custom Properties section, ensure that the trustStoreType, trustStorePassword and trustStorePath custom properties correspond to the trust store containing the STS signer certificate.
5. Request the SAML token from an external STS. The following code snippet illustrates how to request the SAML token and assumes that an external STS is configured to accept a UsernameToken, and to issue a SAML 2.0 token after validation:

```
//Request the SAML Token from external STS
WSSFactory factory = WSSFactory.getInstance();
String STS_URI  = "https://externalstsserverurl:port/TrustServerWST13/services/RequestSecurityToken";
String ENDPOINT_URL = "http://localhost:9080/WSSampleSei/EchoService";
WSSGenerationContext gencont1 = factory.newWSSGenerationContext();
WSSConsumingContext concont1 = factory.newWSSConsumingContext();
HashMap<Object, Object> cbackMap1 = new HashMap<Object, Object>();
cbackMap1.put(SamlConstants.STS_ADDRESS, STS_URI);
cbackMap1.put(SamlConstants.SAML_APPLIES_TO, ENDPOINT_URL);
cbackMap1.put(SamlConstants.TRUST_CLIENT_WSTRUST_NAMESPACE, "http://docs.oasis-open.org/ws-sx/ws-trust/200512");
cbackMap1.put(SamlConstants.TRUST_CLIENT_COLLECTION_REQUEST, "false");
cbackMap1.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML20_VALUE_TYPE);
cbackMap1.put(SamlConstants.CONFIRMATION_METHOD, "Bearer");

SAMLGenerateCallbackHandler cbHandler1 = new SAMLGenerateCallbackHandler(cbackMap1);

// Add UNT to trust request
UNTGenerateCallbackHandler utCallbackHandler = new UNTGenerateCallbackHandler("testuser", "testuserpwd");
SecurityToken ut = factory.newSecurityToken(UsernameToken.class, utCallbackHandler);

gencont1.add(ut);

cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, cbHandler1, "system.wss.generate.saml");

System.out.println("SAMLToken id = " + samlToken.getId());
```

   a. Add the Thin Client for JAX-WS JAR file to the class path. Add the *app_server_root*/runtimes/com.ibm.jaxws.thinclient_8.0.0.jar file to the class path. See the testing web services-enabled clients information for more information about adding this JAR file to the class path.
   b. Use the WSSFactory newSecurityToken method to request a SAML token from an external STS.

      Specify the following method to request the SAML token:

```
WSSFactory  newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml")
```

      Requesting a SAML token requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken. Use the Policy Tool to add the following policy statement to the Java security policy file or the application client was.policy file:

```
permission java.security.SecurityPermission "wssapi.SAMLTokenFactory.newSAMLToken"
```

      The `SAMLToken.class` parameter specifies the type of security token to create.

The `callbackHandler` object contains parameters that define the characteristics of the SAML token that you are requesting and other parameters required to reach the STS and obtain the SAML token. The SAMLGenerateCallbackHandler object specifies the configuration parameters described in the following table:

*Table 299. SAMLGenerateCallbackHandler properties. This table describes the configuration parameters for the SAMLGenerateCallbackHandler object using the bearer subject confirmation method.*

| Property | Description | Required |
|---|---|---|
| SamlConstants.CONFIRMATION_METHOD | Specifies to use the `Bearer` confirmation method. | Yes |
| SamlConstants.TOKEN_TYPE | Specifies the token type.<br><br>When a web services client has policy set attachments, this property is not used by Web Services Security runtime environment.<br><br>Specify the token value type by using the `valueType` attribute of the tokenGenerator binding configuration.<br><br>The example in this procedure uses a SAML 2.0 token; however, you can also use the `WSSConstants.SAML.SAML11_VALUE_TYPE` value. | Yes |
| SamlConstants.STS_ADDRESS | Specifies the Security Token Service address.<br><br>For the example used in this task topic, the value of this property is set to `https` to specify to use SSL to protect the SAML Token request.<br><br>You must set the -Dcom.ibm.SSL.ConfigURL property to enable the use of SSL to protect the SAML token request with the STS. | Yes |
| SamlConstants.SAML_APPLIES_TO | Specifies the target STS address for where you want to use the SAML token. | No |
| SamlConstants.TRUST_CLIENT_COLLECTION_REQUEST | Specifies whether to request from the STS a single token that is enclosed in a RequestSecurityToken (RST) element or multiple tokens in a collection of RST elements that are enclosed in a single RequestSecurityTokenCollection (RSTC) element.<br><br>The default behavior is to request a single token that is enclosed in a RequestSecurityToken (RST) element from the STS.<br><br>Specifying a `true` value for this property indicates to request multiple tokens in a collection of RST elements that are enclosed in a single RequestSecurityTokenCollection (RSTC) element from the STS. | No |
| SamlConstants.TRUST_CLIENT_WSTRUST_NAMESPACE | Specifies the WS-Trust namespace that is included in the WS-Trust request. | No |

A WSSGenerationContext instance and a WSSConsumingContext instance are also set in the SAMLGenerateCallbackHandler object. The WSSGenerationContext instance must contain a UNTGenerateCallbackHandler object with the information to create the UsernameToken that you want to send to the STS.

The `system.wss.generate.saml` parameter specifies the Java Authentication and Authorization Service (JAAS) login module that is used to create the SAML token. You must specify a JVM property to define a JAAS configuration file that contains the required JAAS login configuration; for example:

```
-Djava.security.auth.login.config=profile_root/properties/wsjaas_client.conf
```

Alternatively, you can specify a JAAS login configuration file by setting a Java system property in the sample client code; for example:

```
System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas_client.conf");
```

c. Obtain the token identifier of the created SAML token.

Use the following statement as a simple test for the SAML token that you created:

```
System.out.println("SAMLToken id = " + samlToken.getId())
```

6. Add the SAML token to the SOAP security header of a web services request messages.
   a. Initialize the web services client and configure the SOAPAction properties. The following code snippet illustrates these actions:

```
// Initialize web services client
EchoService12PortProxy echo = new EchoService12PortProxy();
echo._getDescriptor().setEndpoint(endpointURL);

// Configure SOAPAction properties
BindingProvider bp = (BindingProvider) (echo._getDescriptor().getProxy());
Map<String, Object> requestContext = bp.getRequestContext();
requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, endpointURL);
requestContext.put(BindingProvider.SOAPACTION_USE_PROPERTY, Boolean.TRUE);
requestContext.put(BindingProvider.SOAPACTION_URI_PROPERTY, "echoOperation");
```

   b. Initialize the WSSGenerationContext. The following code illustrates the use of the WSSGenerationContext interface to initialize a generation context and enable you to insert the `SAMLToken` into the web services request message:

```
// Initialize WSSGenerationContext
WSSGenerationContext gencont = factory.newWSSGenerationContext();
gencont.add(samlToken);
```

      Specifically, the `gencont.add(samlToken)` method call specifies to put the SAML token into a request message. Use the Policy Tool to add the following policy statement to the Java security policy file or the application client was.policy file:

```
permission javax.security.auth.AuthPermission "modifyPrivateCredentials"
```

   c. Add the timestamp element in the SOAP messages security header. The SAML20 Bearer WSHTTPS default policy set requires web services requests and response messages to carry a timestamp element in SOAP messages Security header. In the following code snippet, the `factory.newWSSTimestamp()` method call generates the timestamp, and the `gencont.add(timestamp)` method call specifies the timestamp to put into a request message:

```
// Add a timestamp to the request message.
WSSTimestamp timestamp = factory.newWSSTimestamp();
gencont.add(timestamp);

gencont.process(requestContext);
```

   d. Attach WSSGenerationContext object to the web services RequestContext object. The WSSGenerationContext object now contains all the security information that is required to format a request message. The `gencont.process(requestContext)` method call attaches the WSSGenerationContext object to the web services RequestContext object to enable the Web Services Security runtime environment to format the required SOAP security header; for example:

```
// Attaches WSSGenerationContext object to the web services RequestContext object.
gencont.process(requestContext);
```

   e. Specify SSL transport level message protection using JVM properties.

      The SAML20 Bearer WSHTTPS default policy set requires transport-level message protection using SSL. In addition, you can use this same property to enable protection of the SAML token request to the STS using SSL. Specify SSL transport-level message protection using the following JVM property:

```
-Dcom.ibm.SSL.ConfigURL=file:profile_root\properties\ssl.client.props
```

      Alternatively, you can define the SSL configuration file using a Java system property in the sample client code; for example:

```
System.setProperty("com.ibm.SSL.ConfigURL", "file:profile_root/properties/ssl.client.props");
```

### Results

You have requested a SAML token with the bearer subject confirmation method with transport level protection from an external STS. After obtaining the token, you sent the token with web services request messages using the JAX-WS programming model and WSS APIs.

If you want to request a SAML token with the bearer subject confirmation method with message level protection from an external STS, see the documentation for requesting SAML sender-vouches tokens from an external STS using WSS APIs and message level protection. To use message level protection for

SAML tokens with the bearer subject confirmation method, in the step to request the SAML token from an external STS, specify a confirmation method of `Bearer` instead of `sender-vouches`; for example:

```
//Request the SAML Token from external STS
WSSFactory factory = WSSFactory.getInstance();
String STS_URI  = "https://externalstsserverurl:port/TrustServerWST13/services/RequestSecurityToken";
String ENDPOINT_URL = "http://localhost:9080/WSSampleSei/EchoService";
WSSGenerationContext gencont1 = factory.newWSSGenerationContext();
WSSConsumingContext concont1 = factory.newWSSConsumingContext();
HashMap<Object, Object> cbackMap1 = new HashMap<Object, Object>();
cbackMap1.put(SamlConstants.STS_ADDRESS, STS_URI);
cbackMap1.put(SamlConstants.SAML_APPLIES_TO, ENDPOINT_URL);
cbackMap1.put(SamlConstants.TRUST_CLIENT_WSTRUST_NAMESPACE, "http://docs.oasis-open.org/ws-sx/ws-trust/200512");
cbackMap1.put(SamlConstants.TRUST_CLIENT_COLLECTION_REQUEST, "false");
cbackMap1.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML11_VALUE_TYPE);
cbackMap1.put(SamlConstants.CONFIRMATION_METHOD, "Bearer");

SAMLGenerateCallbackHandler cbHandler1 = new SAMLGenerateCallbackHandler(cbackMap1);

// Add UNT to trust request
UNTGenerateCallbackHandler utCallbackHandler = new UNTGenerateCallbackHandler("testuser", "testuserpwd");
SecurityToken ut = factory.newSecurityToken(UsernameToken.class, utCallbackHandler);

gencont1.add(ut);

cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, cbHandler1, "system.wss.generate.saml");

System.out.println("SAMLToken id = " + samlToken.getId());
```

Additionally, the step to configure the verification of the digital signature in the response message is optional in the case of the bearer token.

### Example

The following code sample is a web services client application that demonstrates how to request a SAML token from an external STS and send that SAML token in web services request messages. If your usage scenario requires SAML tokens, but does not require your application to pass the SAML tokens using web services messages, you only need to use the first part of the following sample code, up through the `// Initialize web services client` section.

```
/**
 * The following source code is sample code created by IBM Corporation.
 * This sample code is provided to you solely for the purpose of assisting you in the
 * use of the technology.  The code is provided 'AS IS', without warranty or condition of
 * any kind.  IBM shall not be liable for any damages arising out of your use of the
 * sample code, even if IBM has been advised of the possibility of such damages.
 */

SAMLGenerateCallbackHandler cbHandler1 = new SAMLGenerateCallbackHandler(cbackMap1);

// Add UNT to trust request
UNTGenerateCallbackHandler utCallbackHandler = new UNTGenerateCallbackHandler("testuser", "testuserpwd");
SecurityToken ut = factory.newSecurityToken(UsernameToken.class, utCallbackHandler);

gencont1.add(ut);

cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, cbHandler1, "system.wss.generate.saml");

System.out.println("SAMLToken id = " + samlToken.getId());

        // Initialize web services client
   EchoService12PortProxy echo = new EchoService12PortProxy();
   echo._getDescriptor().setEndpoint(endpointURL);

   // Configure SOAPAction properties
   BindingProvider bp = (BindingProvider) (echo._getDescriptor().getProxy());
   Map<String, Object> requestContext = bp.getRequestContext();
   requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, endpointURL);
   requestContext.put(BindingProvider.SOAPACTION_USE_PROPERTY, Boolean.TRUE);
   requestContext.put(BindingProvider.SOAPACTION_URI_PROPERTY, "echoOperation");

   // Initialize WSSGenerationContext
   WSSGenerationContext gencont = factory.newWSSGenerationContext();
         gencont.add(samlToken);

         // Add timestamp
         WSSTimestamp timestamp = factory.newWSSTimestamp();
   gencont.add(timestamp);

         gencont.process(requestContext);

         // Build the input object
   EchoStringInput echoParm =
    new com.ibm.was.wssample.sei.echo.ObjectFactory().createEchoStringInput();
   echoParm.setEchoInput(input);
   System.out.println(">> CLIENT: SEI Echo to " + endpointURL);

   // Prepare to consume timestamp in response message.
   WSSConsumingContext concont = factory.newWSSConsumingContext();
       concont.add(WSSConsumingContext.TIMESTAMP);
       concont.process(requestContext);

   // Call the service
```

```
   response = echo.echoOperation(echoParm).getEchoResponse();

   System.out.println(">> CLIENT: SEI Echo invocation complete.");
   System.out.println(">> CLIENT: SEI Echo response is: " + response);
  } catch (Exception e) {
   System.out.println(">> CLIENT: ERROR: SEI Echo EXCEPTION.");
   e.printStackTrace();
  }
 }
}
```

When this web services client application sample runs correctly, you receive messages like the following messages:

```
SAMLToken id = _191EBC44865015D9AB1270745072344
Retrieving document at 'file:profile_root/.../wsdl/'.
>> CLIENT: SEI Echo to https://localhost:9443/WSSampleSei/EchoService12
>> CLIENT: SEI Echo invocation complete.
>> CLIENT: SEI Echo response is: SOAP12==>>HELLO
```

*Requesting SAML sender-vouches tokens from an external STS using WSS APIs and message level protection:*

You can request SAML tokens with the sender-vouches subject confirmation method from an external Security Token Service (STS). After obtaining the SAML sender-vouches token, you can then send these tokens with web services request messages using the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS API) with message level protection.

**Before you begin**

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, SSL transport protection, X.509 security token, and the use of policy sets to configure and administer web services settings.

**About this task**

**Note:**

> You can request a SAML token with the sender-vouches subject confirmation method from an external STS and then send the SAML token in web services request messages from a web services client using WSS APIs with message level protection.

This product does not provide a default policy set that requires SAML tokens with sender-vouches subject confirmation method. Read about configuring client and provider bindings for the SAML sender-vouches token to learn more about how to create a Web Services Security policy to require SAML tokens with sender-vouches subject confirmation and how to create a custom binding configuration. You must attach the policy and binding to the web services provider. The code sample described in this task assumes that the web services provider policy requires that both the SAML tokens and the message bodies are digitally signed by using an X.509 security token.

The web services client application used in this task is a modified version of the client code that is contained in the JaxWSServicesSamples sample application that is available for download. Code examples from the sample are described in the procedure, and a complete, ready-to-use web services client sample is provided.

**Procedure**

1. Identify and obtain the web services client that you want to use to invoke a web services provider.

   Use this client to insert SAML tokens in SOAP request messages programmatically using WSS APIs.

   The web services client used in this procedure is a modified version of the client code that is contained in the JaxWSServicesSamples web services sample application.

To obtain and modify the sample web services client to add the Web Services Security API to pass SAML sender-vouches tokens in SOAP request messages programmatically using WSS APIs, complete the following steps:

a. Download the JaxWSServicesSamples sample application. The JaxWSServicesSamples sample is not installed by default.

b. Obtain the JaxWSServicesSamples client code.

   For example purposes, this procedure uses a modified version of the Echo thin client sample that is included in the JaxWSServicesSamples sample. The web services Echo thin client sample file, `SampleClient.java`, is located in the `src\SampleClientSei\src\com\ibm\was\wssample\sei\cli` directory. The sample class file is included in the `WSSampleClientSei.jar` file.

   The `JaxWSServicesSamples.ear` enterprise application and supporting Java archives (JAR) files are located in the `installableApps` directory within the JaxWSServicesSamples sample application.

c. Deploy the `JaxWSServicesSamples.ear` file onto the application server. After you deploy the `JaxWSServicesSamples.ear` file, you are ready to test the sample web services client code against the sample application.

Instead of using the web services client sample, you can choose to add the code snippets to pass SAML tokens in SOAP request messages programmatically using WSS APIs in your own web services client application. The example in this procedure uses a JAX-WS web services thin client; however, you can also use a managed client.

2. Specify to use SSL message-level message protection. Use the following JVM property to specify to use SSL to protect the SAML token request with the STS:

```
-Dcom.ibm.SSL.ConfigURL=file:profile_root\properties\ssl.client.props
```

   Alternatively, you can define the SSL configuration file using a Java system property in the sample client code; for example:

```
System.setProperty("com.ibm.SSL.ConfigURL", "file:profile_root/properties/ssl.client.props");
```

3. Add the Thin Client for JAX-WS JAR file to the class path. Add the *app_server_root*/runtimes/com.ibm.jaxws.thinclient_8.0.0.jar file to the class path. See the testing web services-enabled clients information for more information about adding this JAR file to the class path.

4. Request the SAML token from an external STS. The following code snippet illustrates how to request the SAML sender-vouches token and assumes that an external STS is configured to accept a Username token, and to issue a SAML 2.0 token using sender-vouches after validation:

```
//Request the SAML Token from external STS
WSSFactory factory = WSSFactory.getInstance();
String STS_URI  = "https://externalstsserverurl:port/TrustServerWST13/services/RequestSecurityToken";
String ENDPOINT_URL = "http://localhost:9080/WSSampleSei/EchoService";
WSSGenerationContext gencont1 = factory.newWSSGenerationContext();
WSSConsumingContext concont1 = factory.newWSSConsumingContext();
HashMap<Object, Object> cbackMap1 = new HashMap<Object, Object>();
cbackMap1.put(SamlConstants.STS_ADDRESS, STS_URI);
cbackMap1.put(SamlConstants.SAML_APPLIES_TO, ENDPOINT_URL);
cbackMap1.put(SamlConstants.TRUST_CLIENT_WSTRUST_NAMESPACE, "http://docs.oasis-open.org/ws-sx/ws-trust/200512");
cbackMap1.put(SamlConstants.TRUST_CLIENT_COLLECTION_REQUEST, "false");
cbackMap1.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML11_VALUE_TYPE);
cbackMap1.put(SamlConstants.CONFIRMATION_METHOD, "sender-vouches");

SAMLGenerateCallbackHandler cbHandler1 = new SAMLGenerateCallbackHandler(cbackMap1);

// Add UNT to trust request
UNTGenerateCallbackHandler utCallbackHandler = new UNTGenerateCallbackHandler("testuser", "testuserpwd");
SecurityToken ut = factory.newSecurityToken(UsernameToken.class, utCallbackHandler);

gencont1.add(ut);

cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, cbHandler1, "system.wss.generate.saml");

System.out.println("SAMLToken id = " + samlToken.getId());
```

   a. Use the WSSFactory newSecurityToken method to specify how to request the SAML token from an external STS.

      Specify the following method to create the SAML token:

```
WSSFactory  newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml")
```

Requesting a SAML token requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken. Use the Policy Tool to add the following policy statement to the Java security policy file or the application client was.policy file:

```
permission java.security.SecurityPermission "wssapi.SAMLTokenFactory.newSAMLToken"
```

The `SAMLToken.class` parameter specifies the type of security token to create.

The `callbackHandler` object contains parameters that define the characteristics of the SAMLToken that you are requesting and other parameters required to reach the STS and obtain the SAML token. The SAMLGenerateCallbackHandler object specifies the configuration parameters described in the following table:

*Table 300. SAMLGenerateCallbackHandler properties. This table describes the configuration parameters for the SAMLGenerateCallbackHandler object using the sender-vouches confirmation method.*

| Property | Description | Required |
|---|---|---|
| SamlConstants.CONFIRMATION_METHOD | Specifies to use the `sender-vouches` confirmation method. | Yes |
| SamlConstants.TOKEN_TYPE | Specifies the token type.<br><br>When a web services client has policy set attachments, this property is not used by the Web Services Security runtime environment.<br><br>Specify the token value type by using the `valueType` attribute of the tokenGenerator binding configuration.<br><br>The example in this procedure uses a SAML 1.1 token; however, you can also use the `WSSConstants.SAML.SAML20_VALUE_TYPE` value. | Yes |
| SamlConstants.STS_ADDRESS | Specifies the Security Token Service address.<br><br>For the example used in this task topic, the value of this property is set to `https` to specify to use SSL to protect the SAML Token request.<br><br>You must set the -Dcom.ibm.SSL.ConfigURL property to enable the use of SSL to protect the SAML token request with the STS. | Yes |
| SamlConstants.SAML_APPLIES_TO | Specifies the target STS address for where you want to use the SAML token. | No |
| SamlConstants.TRUST_CLIENT_COLLECTION_REQUEST | Specifies whether to request from the STS a single token that is enclosed in a RequestSecurityToken (RST) element or multiple tokens in a collection of RST elements that are enclosed in a single RequestSecurityTokenCollection (RSTC) element.<br><br>The default behavior is to request a single token that is enclosed in a RequestSecurityToken (RST) element from the STS.<br><br>Specifying a `true` value for this property indicates to request multiple tokens in a collection of RST elements that are enclosed in a single RequestSecurityTokenCollection (RSTC) element from the STS. | No |
| SamlConstants.TRUST_CLIENT_WSTRUST_NAMESPACE | Specifies the WS-Trust namespace that is included in the WS-Trust request.<br><br>The default value is WSTrust 1.3. | No |

A WSSGenerationContext instance and a WSSConsumingContext instance are also set in the SAMLGenerateCallbackHandler object. The WSSGenerationContext instance must contain a UNTGenerateCallbackHandler object with the information to create the UsernameToken that you want to send to the STS.

The `system.wss.generate.saml` parameter specifies the Java Authentication and Authorization Service (JAAS) login module that is used to create the SAML token. You must specify a JVM property to define a JAAS configuration file that contains the required JAAS login configuration; for example:

```
-Djava.security.auth.login.config=profile_root/properties/wsjaas_client.conf
```

Alternatively, you can specify a JAAS login configuration file by setting a Java system property in the sample client code; for example:

```
System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas_client.conf");
```

b. Obtain the token identifier of the created SAML token.

Use the following statement as a simple test for the SAML token that you created:

```
System.out.println("SAMLToken id = " + samlToken.getId())
```

5. Add the SAML token to the SOAP security header of web services request messages.

a. Initialize the web services client and configure the SOAPAction properties. The following code example illustrates these actions:

```
// Initialize web services client
EchoService12PortProxy echo = new EchoService12PortProxy();
echo._getDescriptor().setEndpoint(endpointURL);

// Configure SOAPAction properties
BindingProvider bp = (BindingProvider) (echo._getDescriptor().getProxy());
Map<String, Object> requestContext = bp.getRequestContext();
requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, endpointURL);
requestContext.put(BindingProvider.SOAPACTION_USE_PROPERTY, Boolean.TRUE);
requestContext.put(BindingProvider.SOAPACTION_URI_PROPERTY, "echoOperation");

// Initialize WSSGenerationContext
WSSGenerationContext gencont = factory.newWSSGenerationContext();
gencont.add(samlToken);
```

b. Initialize the WSSGenerationContext. The following code snippet illustrates the use of the gencont.object of the WSSGenerationContext type to initialize a generation context to enable you to insert the `SAMLToken` into a web services request message:

```
// Initialize WSSGenerationContext
WSSGenerationContext gencont = factory.newWSSGenerationContext();
gencont.add(samlToken);
```

Specifically, the `gencont.add(samlToken)` method call specifies to put the SAML token into a request message. This operation requires the client code to have the following Java 2 Security permission:

```
 permission javax.security.auth.AuthPermission "modifyPrivateCredentials"
```

6. Add an X.509 token for message protection using the Web Services Security API.

This sample code uses the dsig-sender.ks key file and the SOAPRequester sample key. You must not use the sample key in a production environment. The following code snippet illustrates adding an X.509 token for message protection:

```
// Add an X.509 Token for message protection
    X509GenerateCallbackHandler x509callbackHandler = new X509GenerateCallbackHandler(
         null,
         "profile_root/etc/ws-security/samples/dsig-sender.ks",
         "JKS",
         "client".toCharArray(),
         "soaprequester",
         "client".toCharArray(),
         "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP", null);

   SecurityToken x509 = factory.newSecurityToken(X509Token.class,
   x509callbackHandler, "system.wss.generate.x509");

   WSSSignature sig = factory.newWSSSignature(x509);
   sig.setSignatureMethod(WSSSignature.RSA_SHA1);

   WSSSignPart sigPart = factory.newWSSSignPart();
   sigPart.setSignPart(samlToken);
   sigPart.addTransform(WSSSignPart.TRANSFORM_STRT10);
   sig.addSignPart(sigPart);
   sig.addSignPart(WSSSignature.BODY);
```

a. Create a WSSSignature object with the X509 token. The following line of code creates a WSSSignature object with the X509 token:

```
WSSSignature sig = factory.newWSSSignature(x509);
```

b. Add the signed part to use for message protection. The following line of code specifies to add WSSSignature.BODY as the signed part:

```
sig.addSignPart(WSSSignature.BODY);
```

c. Add the timestamp element in the SOAP messages security header. The SAML20 SenderVouches WSHTTPS and SAML11 SenderVouches WSHTTPS policy sets require web services requests and

response messages to carry a timestamp element in the SOAP messages Security header. In the following code snippet, the `factory.newWSSTimestamp()` method call generates the timestamp, and the `gencont.add(timestamp)` method call adds the timestamp into the request message:

```
// Add Timestamp
WSSTimestamp timestamp = factory.newWSSTimestamp();
   gencont.add(timestamp);
sig.addSignPart(WSSSignature.TIMESTAMP);

gencont.add(sig);

WSSConsumingContext concont = factory.newWSSConsumingContext();
```

d. Configure the SAML token signature using STR-Transform transform algorithm.

   A separate WSSSignPart is needed to specify the SecurityTokenReference transformation algorithm that is represented by the `WSSSignPart.TRANSFORM_STRT10` attribute. A SAML Token cannot be digitally signed directly. This attribute enables the Web Services Security runtime environment to generate a SecurityTokenReference element to reference the SAMLToken and to digitally sign the SAMLToken using the SecurityTokenReference transformation. The following line of code specifies to use the `WSSSignPart.TRANSFORM_STRT10` attribute:

```
WSSSignPart sigPart = factory.newWSSSignPart();
sigPart.setSignPart(samlToken);
sigPart.addTransform(WSSSignPart.TRANSFORM_STRT10);
```

e. Attach the WSSGenerationContext object to the web services RequestContext object. The WSSGenerationContext object now contains all the security information that is required to format a request message. The `gencont.process(requestContext)` method call attaches the WSSGenerationContext object to the web services RequestContext object to enable the Web Services Security runtime environment to format the required SOAP security header; for example:

```
// Attaches the WSSGenerationContext object to the web services RequestContext object.
gencont.process(requestContext);
```

7. Use the X.509 token to validate the digital signature and the integrity of the response message. If the provider policy requires the response message to be digitally signed, you must initialize the X.509 token.

   a. A X509ConsumeCallbackHandler object is initialized with a truststore, dsig-receiver.ks, and a certificate path object to validate the provider digital signature. The following line of code is used to initialize the X509ConsumeCallbackHandler object:

```
X509ConsumeCallbackHandler callbackHandlerVer = new X509ConsumeCallbackHandler(
 "profile_root/etc/ws-security/samples/dsig-receiver.ks",
          "JKS",
           "server".toCharArray(),
            certList,
                 java.security.Security.getProvider("IBMCertPath"));
```

   b. A WSSVerification object is created and the message body is added to the verification object so that the Web Services Security runtime environment validates the digital signature.

      The following line of code is used to initialize the WSSVerification object:

```
WSSVerification ver = factory.newWSSVerification(X509Token.class, callbackHandlerVer);
```

      The WSSConsumingContext object now contains all the security information that is required to format a request message. The `concont.process(requestContext)` method call attaches the WSSConsumingContext object to the response method; for example:

```
// Attaches the WSSConsumingContext object to the web services RequestContext object.
concont.process(requestContext);
```

### Results

You have requested a SAML token with the sender-vouches confirmation method from an external STS. After obtaining the token, you sent the token with web services request messages using message level protection using the JAX-WS programming model and WSS APIs.

## Example

The following code sample is a complete, ready-to-use web services client application that demonstrates how to request a SAML token from an external STS and send that SAML token in web services request messages with message level protection. This sample code illustrates the procedure steps described previously.

```

        ver.addRequiredVerifyPart(WSSVerification.BODY);
        concont.add(ver);

        gencont.process(requestContext);
        concont.process(requestContext);

        // Build the input object
   EchoStringInput echoParm =
    new com.ibm.was.wssample.sei.echo.ObjectFactory().createEchoStringInput();
   echoParm.setEchoInput(input);
   System.out.println(">> CLIENT: SEI Echo to " + endpointURL);

   // Call the service
   response = echo.echoOperation(echoParm).getEchoResponse();

   System.out.println(">> CLIENT: SEI Echo invocation complete.");
   System.out.println(">> CLIENT: SEI Echo response is: " + response);
  } catch (Exception e) {
   System.out.println(">> CLIENT: ERROR: SEI Echo EXCEPTION.");
   e.printStackTrace();
  }
 }
}
```

When this web services client application sample runs correctly, you receive messages like the following messages:

```
SAMLToken id = _6CDDF0DBF91C044D211271166233407
Retrieving document at 'file:profile_root/.../wsdl/'.
>> CLIENT: SEI Echo to http://localhost:9443/WSSampleSei/EchoService12
>> CLIENT: SEI Echo invocation complete.
>> CLIENT: SEI Echo response is: SOAP12==>>HELLO
```

*Requesting SAML sender-vouches tokens from an external STS using WSS APIs and transport level protection:*

You can request SAML tokens with the sender-vouches subject confirmation method from an external Security Token Service (STS). After obtaining the SAML sender-vouches token, you can then send these tokens with web services request messages using the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS API) with transport level protection.

**Before you begin**

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, SSL transport protection, and the use of policy sets to configure and administer web services settings.

**About this task**

**Note:**

> You can request a SAML token with the sender-vouches subject confirmation method from an external STS and then send the SAML token in web services request messages from a web services client using WSS APIs with transport level protection.

The web services client application used in this task is a modified version of the client code that is contained in the JaxWSServicesSamples sample application that is available for download. Code examples from the sample are described in the procedure, and a complete, ready-to-use web services client sample is provided.

**Procedure**

1. Identify and obtain the web services client that you want to use to invoke a web services provider.

   Use this client to insert SAML tokens in SOAP request messages programmatically using WSS APIs.

   The web services client used in this procedure is a modified version of the client code that is contained in the JaxWSServicesSamples web services sample application.

   To obtain and modify the sample web services client to add the Web Services Security API to pass SAML sender-vouches tokens in SOAP request messages programmatically using WSS APIs, complete the following steps:

   a. Download the JaxWSServicesSamples sample application. The JaxWSServicesSamples sample is not installed by default.

   b. Obtain the JaxWSServicesSamples client code.

      For example purposes, this procedure uses a modified version of the Echo thin client sample that is included in the JaxWSServicesSamples sample. The web services Echo thin client sample file, `SampleClient.java`, is located in the `src\SampleClientSei\src\com\ibm\was\wssample\sei\cli` directory. The sample class file is included in the `WSSampleClientSei.jar` file.

      The `JaxWSServicesSamples.ear` enterprise application and supporting Java archives (JAR) files are located in the `installableApps` directory within the JaxWSServicesSamples sample application.

   c. Deploy the `JaxWSServicesSamples.ear` file onto the application server. After you deploy the `JaxWSServicesSamples.ear` file, you are ready to test the sample web services client code against the sample application.

   Instead of using the web services client sample, you can choose to add the code snippets to pass SAML tokens in SOAP request messages programmatically using WSS APIs in your own web services client application. The example in this procedure uses a JAX-WS Web services thin client; however, you can also use a managed client.

2. Create a copy of either the SAML20 Bearer WSHTTPS default policy set or the SAML11 Bearer WSHTTPS default policy set.

   Provide a name for the copy of the policy set; for example SAML20 SenderVouches WSHTTPS or SAML11 SenderVouches WSHTTPS to help you identify that this new policy set uses the sender-vouches confirmation method.

   No additional change is required to the new policy file because the subject confirmation method is specified in the binding configuration and not in the policy.

   The new policy file contains either SAMLToken20Bearer or the SAMLToken11Bearer as the policy identifiers. Change the identifier of the SAMLToken20Bearer policy to SAMLToken20SV or change the identifier of the SAMLToken11Bearer policy to SAMLToken11SV to specify a more descriptive name. Changing the identifier of the policy does not change the policy enforcement in any way; however, adding a descriptive identifier helps you to identify that these policy identifiers use the sender-vouches confirmation method.

   If you want to view the settings of these policies, use the administrative console to complete the following actions:

a. Click **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name***.
b. Click the **WS-Security** policy in the policies table.
c. Click the **Main policy** link or the **Bootstrap policy** link.
d. Click **Request token policies** from the Policy Details section.

3. Attach the new SAML20 SenderVouches WSHTTPS or SAML11 SenderVouches WSHTTPS policy set to the web services provider application. Read about configuring client and provider bindings for the SAML sender-vouches token for details on attaching this policy set to your web services provider application.
4. Create a copy of the SAML Bearer Provider sample default general bindings.
   a. For the new copy of the default policy set, provide a name that includes sender-vouches, such as `SAML Sender-vouches provider binding`.
   b. In the callback handler of your SAML11 or SAML20 token consumer, change the value of the confirmationMethod property to `sender-vouches` in the token consumer configuration for the intended SAML token version. Ensure that the custom properties trustStoreType, trustStorePassword and trustStorePath correspond to the trust store containing the STS signer certificate. Read about configuring client and provider bindings for the SAML sender-vouches token for details on modifying the sender-vouches bindings to satisfy the vouching requirement.
5. Assign the new provider binding to the JaxWSServicesSamples provider sample. Read about configuring client and provider bindings for the SAML sender-vouches for details on assigning the SAML sender-vouches provider sample, default general bindings to your web services provider application.
6. Enable the web services provider SSL configuration attribute, clientAuthentication, to require X.509 client certificate authentication.

   The clientAuthentication attribute determines whether SSL client authentication is required. To specify the clientAuthentication attribute, use the administrative console to complete the following actions:
   a. Click **Security** > **SSL certificates and key management** > **Manage endpoint security configurations** > **{Inbound | Outbound}** > ***SSL_configuration***.
   b. Click the **WC_defaulthost_secure** link in the inbound topology.
   c. From Related Items, click the **SSL_configurations** link.
   d. Select the **NodeDefaultSSLSettings** resource.
   e. Click **Quality of protection (QoP) settings** link.
   f. Select **Required** from the menu to specify client authentication.

   Read about creating a secure sockets layer configuration to learn more about configuring the clientAuthentication attribute.
7. Specify to use SSL transport-level message protection. Use the following JVM property to specify to use SSL to protect the SAML token request with the STS:

```
-Dcom.ibm.SSL.ConfigURL=file:profile_root\properties\ssl.client.props
```

   Alternatively, you can define the SSL configuration file using a Java system property in the sample client code; for example:

```
System.setProperty("com.ibm.SSL.ConfigURL", "file:profile_root/properties/ssl.client.props");
```

8. Add the Thin Client for JAX-WS JAR file to the class path. Add the *app_server_root*/runtimes/com.ibm.jaxws.thinclient_8.0.0.jar file to the class path. See the testing web services-enabled clients information for more information about adding this JAR file to the class path.
9. Request the SAML token from an external STS. The following code snippet illustrates how to request the SAML sender-vouches token and assumes that an external STS is configured to accept a UsernameToken, and to issue a SAML 1.1 token using sender-vouches after validation:

```
//Request the SAML Token from external STS
WSSFactory factory = WSSFactory.getInstance();
String STS_URI  = "https://externalstsserverurl:port/TrustServerWST13/services/RequestSecurityToken";
String ENDPOINT_URL = "http://localhost:9080/WSSampleSei/EchoService";
WSSGenerationContext gencont1 = factory.newWSSGenerationContext();
WSSConsumingContext concont1 = factory.newWSSConsumingContext();
```

```
HashMap<Object, Object> cbackMap1 = new HashMap<Object, Object>();
cbackMap1.put(SamlConstants.STS_ADDRESS, STS_URI);
cbackMap1.put(SamlConstants.SAML_APPLIES_TO, ENDPOINT_URL);
cbackMap1.put(SamlConstants.TRUST_CLIENT_WSTRUST_NAMESPACE, "http://docs.oasis-open.org/ws-sx/ws-trust/200512");
cbackMap1.put(SamlConstants.TRUST_CLIENT_COLLECTION_REQUEST, "false");
cbackMap1.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML11_VALUE_TYPE);
cbackMap1.put(SamlConstants.CONFIRMATION_METHOD, "sender-vouches");

SAMLGenerateCallbackHandler cbHandler1 = new SAMLGenerateCallbackHandler(cbackMap1);

// Add UNT to trust request
UNTGenerateCallbackHandler utCallbackHandler = new UNTGenerateCallbackHandler("testuser", "testuserpwd");
SecurityToken ut = factory.newSecurityToken(UsernameToken.class, utCallbackHandler);

gencont1.add(ut);

cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, cbHandler1, "system.wss.generate.saml");

System.out.println("SAMLToken id = " + samlToken.getId());
```

a. Use the WSSFactory newSecurityToken method to specify how to request the SAML token from an external STS.

   Specify the following method to create the SAML token:

```
WSSFactory  newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml")
```

   Requesting a SAML token requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken. Use the Policy Tool to add the following policy statement to the Java security policy file or the application client was.policy file:

```
permission java.security.SecurityPermission "wssapi.SAMLTokenFactory.newSAMLToken"
```

   The `SAMLToken.class` parameter specifies the type of security token to create.

   The `callbackHandler` object contains parameters that define the characteristics of the SAMLToken that you are requesting and other parameters required to reach the STS and obtain the SAML token. The SAMLGenerateCallbackHandler object specifies the configuration parameters described in the following table:

*Table 301. SAMLGenerateCallbackHandler properties. This table describes the configuration parameters for the SAMLGenerateCallbackHandler object using the sender-vouches confirmation method.*

| Property | Description | Required |
|---|---|---|
| SamlConstants.CONFIRMATION_METHOD | Specifies to use the `sender-vouches` confirmation method. | Yes |
| SamlConstants.TOKEN_TYPE | Specifies the token type.<br><br>When a web services client has policy set attachments, this property is not used by the Web Services Security runtime environment.<br><br>Specify the token value type by using the `valueType` attribute of the tokenGenerator binding configuration.<br><br>The example in this procedure uses a SAML 1.1 token; however, you can also use the `WSSConstants.SAML.SAML20_VALUE_TYPE` value. | Yes |
| SamlConstants.STS_ADDRESS | Specifies the Security Token Service address.<br><br>For the example used in this task topic, the value of this property is set to `https` to specify to use SSL to protect the SAML Token request.<br><br>You must set the -Dcom.ibm.SSL.ConfigURL property to enable the use of SSL to protect the SAML token request with the STS. | Yes |
| SamlConstants.SAML_APPLIES_TO | Specifies the target STS address for where you want to use the SAML token. | No |
| SamlConstants.TRUST_CLIENT_COLLECTION_REQUEST | Specifies whether to request from the STS a single token that is enclosed in a RequestSecurityToken (RST) element or multiple tokens in a collection of RST elements that are enclosed in a single RequestSecurityTokenCollection (RSTC) element.<br><br>The default behavior is to request a single token that is enclosed in a RequestSecurityToken (RST) element from the STS.<br><br>Specifying a `true` value for this property indicates to request multiple tokens in a collection of RST elements that are enclosed in a single RequestSecurityTokenCollection (RSTC) element from the STS. | No |

*Table 301. SAMLGenerateCallbackHandler properties (continued). This table describes the configuration parameters for the SAMLGenerateCallbackHandler object using the sender-vouches confirmation method.*

| Property | Description | Required |
|---|---|---|
| SamlConstants.TRUST_CLIENT_WSTRUST_NAMESPACE | Specifies the WS-Trust namespace that is included in the WS-Trust request.<br><br>The default value is WSTrust 1.3. | No |

A WSSGenerationContext instance and a WSSConsumingContext instance are also set in the SAMLGenerateCallbackHandler object. The WSSGenerationContext instance must contain a UNTGenerateCallbackHandler object with the information to create the UsernameToken that you want to send to the STS.

The `system.wss.generate.saml` parameter specifies the Java Authentication and Authorization Service (JAAS) login module that is used to create the SAML token. You must specify a JVM property to define a JAAS configuration file that contains the required JAAS login configuration; for example:

```
-Djava.security.auth.login.config=profile_root/properties/wsjaas_client.conf
```

Alternatively, you can specify a JAAS login configuration file by setting a Java system property in the sample client code; for example:

```
System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas_client.conf");
```

b. Obtain the token identifier of the created SAML token.

Use the following statement as a simple test for the SAML token that you created:

```
System.out.println("SAMLToken id = " + samlToken.getId())
```

### Results

You have requested a SAML token with the sender-vouches confirmation method from an external STS. After obtaining the token, you sent the token with web services request messages using transport protection using the JAX-WS programming model and WSS APIs.

### Example

The following code sample is a complete, ready-to-use web services client application that demonstrates how to request a SAML token from an external STS and send that SAML token in web services request messages with transport level protection. This sample code illustrates the procedure steps described previously.

```

        gencont.add(samlToken);

        // Add timestamp
        WSSTimestamp timestamp = factory.newWSSTimestamp();
   gencont.add(timestamp);

        gencont.process(requestContext);

        // Build the input object
   EchoStringInput echoParm =
    new com.ibm.was.wssample.sei.echo.ObjectFactory().createEchoStringInput();
   echoParm.setEchoInput(input);
   System.out.println(">> CLIENT: SEI Echo to " + endpointURL);

   // Prepare to consume timestamp in response message
```

```
   WSSConsumingContext concont = factory.newWSSConsumingContext();
       concont.add(WSSConsumingContext.TIMESTAMP);
       concont.process(requestContext);

   // Call the service
   response = echo.echoOperation(echoParm).getEchoResponse();

   System.out.println(">> CLIENT: SEI Echo invocation complete.");
   System.out.println(">> CLIENT: SEI Echo response is: " + response);
  } catch (Exception e) {
   System.out.println(">> CLIENT: ERROR: SEI Echo EXCEPTION.");
   e.printStackTrace();
     }
 }
}
```

When this web services client application sample runs correctly, you receive messages like the following messages:

```
SAMLToken id = _6CDDF0DBF91C044D211271166233407
Retrieving document at 'file:profile_root/.../wsdl/'.
>> CLIENT: SEI Echo to http://localhost:9443/WSSampleSei/EchoService12
>> CLIENT: SEI Echo invocation complete.
>> CLIENT: SEI Echo response is: SOAP12===>>HELLO
```

*Requesting SAML holder-of-key tokens with symmetric key from external security token service using WSS APIs:*

You can request an external security token service (STS) to issue SAML tokens with the holder-of-key subject confirmation method with symmetric key that is encrypted for a target service. Use the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS APIs) to complete this task.

**Before you begin**

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, and the use of policy sets to configure and administer web services settings. Complete the following actions before you begin this task:

- Read about propagating self-issued SAML holder-of-key tokens with symmetric key by using WSS APIs.
- Become familiar with using embedded key materials in SAML tokens for message protection by using WSS APIs. Your usage scenario requires requesting SAML tokens from an external STS instead of using self-issued SAML tokens.
- Read about requesting SAML sender-vouches tokens from an external STS to propagate by using WSS APIs with message level protection.
- Read about requesting SAML sender-vouches tokens from an external STS to propagate by using WSS APIs with transport level protection.
- Read about requesting SAML bearer tokens from an external STS to propagate by using WSS APIs with transport level protection.
- Be familiar with accessing an external STS by using WSS APIs.

**About this task**

This task shows example code to request SAML tokens from an external STS, with holder-of-key subject confirmation method and embedded symmetric key that is encrypted for the target service by using WSS APIs. This task focuses on sending a WS-Trust request message to an external STS to request SAML holder-of-key tokens with symmetric keys.

**Procedure**

1. Specify an STS from which to request a SAML security token that contains holder-of-key subject confirmation method; for example:

```
com.ibm.websphere.wssecurity.wssapi.WSSFactory factory =
    com.ibm.websphere.wssecurity.wssapi.WSSFactory.getInstance();
WSSGenerationContext gencont1 = factory.newWSSGenerationContext();
```

```
WSSConsumingContext concont1 = factory.newWSSConsumingContext();
HashMap<Object, Object> cbackMap1 = new HashMap<Object, Object>();
cbackMap1.put(SamlConstants.STS_ADDRESS, "https://www.example.com/sts");  //STS URL
cbackMap1.put(SamlConstants.SAML_APPLIES_TO, "http://myhost:9080/myService");  //Target Service
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_SOAP_VERSION, "1.1");
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_WSTRUST_NAMESPACE,
                  "http://docs.oasis-open.org/ws-sx/ws-trust/200512");
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_COLLECTION_REQUEST,
              "true");   //RST or RSTC
cbackMap1.put(SamlConstants.TOKEN_TYPE,
              "http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV2.0");
cbackMap1.put(SamlConstants.CONFIRMATION_METHOD, "holder-of-key");
```

To request a holder-of-key SAML security token from the STS, you must specify whether to embed a symmetric key or a public key by way of a `KeyType` element in a trust request. This example requires a symmetric key type as shown in the next step.

2. Specify the symmetric key to be embedded in SAML security tokens; for example:

```
cbackMap1.put(SamlConstants.KEY_TYPE,
             "http://docs.oasis-open.org/ws-sx/ws-trust/200512/SymmetricKey");

SAMLGenerateCallbackHandler cbHandler1 = new SAMLGenerateCallbackHandler(cbackMap1);
cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);

SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class,
                                                   cbHandler1, "system.wss.generate.saml");
```

The requested SAML token contains a symmetric key that is encrypted for the target service. The STS also returns the unencrypted symmetric key through the `WS-Trust RequestedProofToken` element. See the following example.

```
<wst:RequestedProofToken>
    <wst:BinarySecret
      xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd"
      wsu:Id="_27325D34CE4BCC83141288966548620">n68rFQba+XTZLNBfEc4prg==</wst:BinarySecret>
</wst:RequestedProofToken>
```

The `RequestedProofToken` element is shown here for your information. The detailed processing is not exposed to WSS APIs users. The `RequestedProofToken` element and the symmetric key are handled by the Web Services Security runtime environment, or more precisely by the `SAMLGenerateLoginModule` that is specified in the `system.wss.geenrate.saml` JAAS login configuration.

### Results

You have learned key building blocks for requesting SAML tokens with holder-of-key subject confirmation method and symmetric key from an external STS by using WSS APIs. To use the SAML token to sign request messages, review the example code in the “Propagating self-issued SAML holder-of-key tokens with symmetric key by using WSS APIs” topic.

*Requesting SAML holder-of-key tokens with asymmetric key from External Security Token Service using WSS APIs:*

You can request an external Security Token Service (STS) to issue SAML tokens with the holder-of-key subject confirmation method with a public key in an X.509 certificate with the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS APIs).

### Before you begin

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, and the use of policy sets to configure and administer web services settings. Complete the following actions before you begin this task:

- Read about propagating self-issued SAML holder-of-key tokens with asymmetric key by using WSS APIs.
- Become familiar with using embedded key materials in SAML tokens for message protection by using WSS APIs. Your usage scenario requires requesting SAML tokens from an external STS instead of using self-issued SAML tokens.

- Read about requesting SAML sender-vouches tokens from an external STS to propagate by using WSS APIs with message level protection.
- Read about requesting SAML sender-vouches tokens from an external STS to propagate by using WSS APIs with transport level protection.
- Read about requesting SAML bearer tokens from an external STS, which you propagate by using WSS APIs with transport level protection.
- Become familiar with accessing an external STS by using WSS APIs.

### About this task

This task shows example code to request SAML tokens with the holder-of-key subject confirmation method and the embedded public key in an X.509 certificate by using WSS APIs, from an external STS. This task focuses on sending an X.509 certificate to an external STS when requesting SAML holder-of-key tokens.

### Procedure

1. Specify an STS from which to request a SAML security token that contains holder-of-key subject confirmation method; for example:

```
com.ibm.websphere.wssecurity.wssapi.WSSFactory factory =
    com.ibm.websphere.wssecurity.wssapi.WSSFactory.getInstance();
WSSGenerationContext gencont1 = factory.newWSSGenerationContext();
WSSConsumingContext concont1 = factory.newWSSConsumingContext();
HashMap<Object, Object> cbackMap1 = new HashMap<Object, Object>();
cbackMap1.put(SamlConstants.STS_ADDRESS, "https://www.example.com/sts");
cbackMap1.put(SamlConstants.SAML_APPLIES_TO, "http://myhost:9080/myService");
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_SOAP_VERSION, "1.1");
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_WSTRUST_NAMESPACE,
              "http://docs.oasis-open.org/ws-sx/ws-trust/200512");
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_COLLECTION_REQUEST,
              "true");   //RST or RSTC
cbackMap1.put(SamlConstants.TOKEN_TYPE,
              "http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV2.0");
cbackMap1.put(SamlConstants.CONFIRMATION_METHOD, "holder-of-key");
```

   For the holder-of-key subject confirmation method, you must specify whether a public key or a symmetric key is embedded in SAML tokens. This example specifies a public key type. It then specifies the location of a certificate that contains the public key, and the location of the corresponding private key for the sender to digitally sign elements of SOAP messages to satisfy the holder-of-key subject confirmation requirements.

2. Specify the location of an X.509 certificate to embed in SAML tokens and a corresponding private key for using to digitally sign message elements; for example:

```
cbackMap1.put(SamlConstants.KEY_TYPE,
              "http://docs.oasis-open.org/ws-sx/ws-trust/200512/PublicKey");
cbackMap1.put(SamlConstants.KEY_ALIAS, "soapinitiator" );
cbackMap1.put(SamlConstants.KEY_NAME, "CN=SOAPInitator, O=Example");
cbackMap1.put(SamlConstants.KEY_PASSWORD, "keypass");
cbackMap1.put(SamlConstants.KEY_STORE_PATH, "keystores/initiator.jceks");
cbackMap1.put(SamlConstants.KEY_STORE_PASSWORD, "storepass");
cbackMap1.put(SamlConstants.KEY_STORE_TYPE, "jceks");

SAMLGenerateCallbackHandler cbHandler1 = new SAMLGenerateCallbackHandler(cbackMap1);
cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);

SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class,
                                                   cbHandler1, "system.wss.generate.saml");
```

   The specified X.509 certificate is sent in WS-Trust requests to the external STS in the `trust:UseKey` element. For more information read about SAML assertions defined in the SAML Token Profile standard. SSL is used to protect integrity and confidentiality of WS-Trust request and response messages in this example.

### Results

You have learned key building blocks to request SAML tokens with the holder-of-key subject confirmation method and asymmetric key from an external STS using WSS APIs. To use the SAML token to sign request messages, become familiar with the example code in the "Propagating self-issued SAML holder-of-key tokens with asymmetric key by using WSS APIs" topic.

*Sending a security token using WSSAPIs with a generic security token login module:*

You can request an authentication token from an external *Security Token Service (STS)*, and then send the token with web service request messages using the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS API), with message or transport level protection.

### Before you begin

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, WebSphere web service security generic security token login modules, SSL transport protection, message level protection, and the use of policy sets to configure and administer web services settings.

### About this task

The web service client application used in this task is a modified version of the client code that is contained in the JaxWSServicesSamples sample application that is available for download. Code examples from the sample are described in the procedure, and a complete, ready-to-use web service client sample is provided.

Complete the following steps to request a SAML Bearer authentication token from an external STS and send the token:

### Procedure

1. Identify and obtain the web service client that you want to use to invoke a web service provider. Use this client to request and to insert authentication tokens in the SOAP request messages programmatically using WSS APIs. The web service client used in this procedure is a modified version of the client code that is contained in the JaxWSServicesSamples web service sample application.

   Complete the following steps to obtain and modify the sample web service client to add the Web Services Security API to pass a security token in the SOAP request message programmatically using WSS APIs:

   a. Download the JaxWSServicesSamples sample application. The JaxWSServicesSamples sample is not installed by default.

   b. Obtain the JaxWSServicesSamples client code. For the purpose of this example, the procedure uses a modified version of the Echo thin client sample that is included in the JaxWSServicesSamples sample. The web service Echo thin client sample file, `SampleClient.java`, is located in the `src\SampleClientSei\src\com\ibm\was\wssample\sei\cli` directory. The sample class file is included in the `WSSampleClientSei.jar` file.

      The `JaxWSServicesSamples.ear` enterprise application and supporting Java archives (JAR) files are located in the `installableApps` directory within the JaxWSServicesSamples sample application.

   c. Deploy the `JaxWSServicesSamples.ear` file onto the application server. After you deploy the `JaxWSServicesSamples.ear` file, you are ready to test the sample web service client code against the sample application.

      Instead of using the PolicySet for the protection of the web service client sample, you can choose to add the code snippets to pass authentication tokens in the SOAP request message programmatically using WSS APIs in your own web service client application. The example in this procedure uses a JAX-WS web service thin client; however, you can also use a managed client.

d. Attach the SAML11 Bearer WSHTTPS default policy set to the web services provider. This policy set is used to protect messages using HTTPS transport. Read about configuring client and provider bindings for the SAML Bearer token for details on how to attach the SAML11 Bearer WSHTTPS default policy set to the web services provider.

e. Assign the SAML Bearer Provider sample default general bindings to the sample web services provider. Read about configuring client and provider bindings for the SAML bearer token for details on assigning the SAML Bearer Provider sample default general bindings to your web services application.

f. Verify that the trustStoreType, trustStorePassword and trustStorePath custom properties correspond to the trust store containing the STS signer certificate. Complete the following steps by using the administrative console:

   1) Click **Services** > **Policy sets** > **General provider policy set bindings** > **Saml Bearer Provider sample** > **WS-Security** > **Authentication and protection**.

   2) Click **con_saml11token** in the Authentication tokens table.

   3) Click **Callback handler**.

   4) In the Custom Properties section, ensure that the trustStoreType, trustStorePassword and trustStorePath custom properties correspond to the trust store containing the STS signer certificate.

2. If you are using SSL Transport-level protection to protect the web service request or the WS-Trust request, use the following Java virtual machine (JVM) property to set up the SSL configuration.

```
-Dcom.ibm.SSL.ConfigURL=file:<profile_root>\properties\ssl.client.props
```

   Alternatively, you can define the SSL configuration file using a Java system property in the sample client code:

```
System.setProperty("com.ibm.SSL.ConfigURL", "file:profile_root/properties/ssl.client.props");
```

3. Add the JAR file for the JAX-WS thin client to the class path: `app_server_root/runtimes/com.ibm.jaxws.thinclient_8.0.0.jar`. See the testing web service-enabled clients information for more information about adding this JAR file to the class path.

4. Request the authentication token from an external STS. The following code snippet illustrates how to request the authentication token to be used with WebSphere generic SecurityToken login module, and assumes that an external STS is configured to accept a Username token as authentication token, and to issue a SAML 1.1 token.

```
//Request SecurityToken from external STS:
WSSFactory factory = WSSFactory.getInstance();
//STS URL that issues the requested token
String STS_URI  = "https://externalstsserverurl:port/TrustServerWST13/services/RequestSecurityToken";
//Web services endpoint that receives the issued token
String ENDPOINT_URL = "http://localhost:9080/WSSampleSei/EchoService";

//Begin sample code 1 (Using WS-Trust Issue to request the token from
//the STS in which authentication token is send over WS-Security head):
HashMap<Object, Object> cbackMap1 = new HashMap<Object, Object>();
cbackMap1.put(IssuedTokenConfigConstants.STS_ADDRESS, STS_URI);
cbackMap1.put(IssuedTokenConfigConstants.APPLIES_TO, ENDPOINT_URL);
//The following property specifies that the ws-trust request should be
//compliance with WS-Trust 1.3 spec
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_WSTRUST_NAMESPACE,
"http://docs.oasis-open.org/ws-sx/ws-trust/200512");
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_COLLECTION_REQUEST, "false");
//This request is made with WS-TRust Issue only (without the use of
//WS-Trust Validate)
cbackMap1.put(IssuedTokenConfigConstants.USE_RUN_AS_SUBJECT, "false");

GenericIssuedTokenGenerateCallbackHandler cbHandler1 =
new GenericIssuedTokenGenerateCallbackHandler (cbackMap1);

//Create the context object for WS-Trust request:
WSSGenerationContext gencont1 = factory.newWSSGenerationContext();
WSSConsumingContext concont1 = factory.newWSSConsumingContext();
// Use UNT for trust request authentication
UNTGenerateCallbackHandler utCallbackHandler = new UNTGenerateCallbackHandler("testuser", "testuserpwd");
SecurityToken ut = factory.newSecurityToken(UsernameToken.class, utCallbackHandler);
gencont1.add(ut);
cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);
//End of sample code 1.

//Begin sample code 2 (using WS-Trust Validate to request a token by
```

```
//exchanging a token in RunAs Subject).
//If web service client has RunAs Subject , for example an
//authenticated intermediate server acts as a client to invoke the
//downstream service, you can program the client to use the token from
//the RunAs subject to exchange with the STS by using WS-Trust validate.
//To do so, you replace sample code 1 with the following:
HashMap<Object, Object> cbackMap1 = new HashMap<Object, Object>();
cbackMap1.put(IssuedTokenConfigConstants.STS_ADDRESS, STS_URI);
cbackMap1.put(IssuedTokenConfigConstants.APPLIES_TO, ENDPOINT_URL);
//This request is made with WS-Trust 1.3
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_WSTRUST_NAMESPACE,
"http://docs.oasis-open.org/ws-sx/ws-trust/200512");
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_COLLECTION_REQUEST, "false");

//add the next line if you do not want to fallback to WS-Trust Issue if
//token exchange fails.
cbackMap1.put(IssuedTokenConfigConstants.USE_RUN_AS_SUBJECT_ONLY, "true");

//add the next line to specify the token type in the RunAs subject that
//will be used to exchange the requested token. For example, you use
//the LTPA token to exchange for a SAML token. If the exchanged token
//in the RunAs subject has the same value type as the requested token,
//setting IssuedTokenConfigConstants.USE_TOKEN is not required.
cbackMap1.put(IssuedTokenConfigConstants.USE_TOKEN, LTPAToken.ValueType);

GenericIssuedTokenGenerateCallbackHandler cbHandler1 =
    new GenericIssuedTokenGenerateCallbackHandler (cbackMap1);
//The following codes are added if Authentication token in ws-security
//head or Message level security protection is required. If there is no
//Message level protection or additional authentication token for
//WS-Trust Validate, do not create the context object shown below.
//Context object for WS-Trust request:
WSSGenerationContext gencont1 = factory.newWSSGenerationContext();
WSSConsumingContext concont1 = factory.newWSSConsumingContext();
// Use UNT for trust request authentication
UNTGenerateCallbackHandler utCallbackHandler =
    new UNTGenerateCallbackHandler("testuser", "testuserpwd");
SecurityToken ut = factory.newSecurityToken(UsernameToken.class, utCallbackHandler);
gencont1.add(ut);
cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);

//End of sample code 2.

GenericSecurityToken token = (GenericSecurityToken) factory.newSecurityToken
(GenericSecurityToken.class, cbHandler1, "system.wss.generate.issuedToken");

//The following step to set ValueType is required..
//The parameter is always the QName of the requested token's valueType.
//QName for SAML1.1:
QName Saml11ValueType = new QName(WSSConstants.SAML.SAML11_VALUE_TYPE);
            token.setValueType(Saml11ValueType);

//This article includes QName definitions for  SAML11, SAML20, TAM
//token, and Pass ticket token.
//QName for SAML 2.0:
QName Saml20ValueType = new QName(WSSConstants.SAML.SAML20_VALUE_TYPE);
token.setValueType(Saml11ValueType);
//QName for TAM token:
QName TamValueType = new QName("http://ibm.com/2004/01/itfim/ivcred");
//QName for PassTicket token:
QName PassTicketValueType = new QName("http://docs.oasis-open.org/wss/
2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken");

//You can use the Token interface to get the token ValueType QName for
//all other tokens. For example, a Username Token's QName is //UsernameToken.ValueType.
```

The `GenericIssuedTokenGenerateCallbackHandler` object contains parameters that define the characteristics of the security token that you are requesting, as well as other parameters required to reach the STS and to obtain the security token. The `GenericIssuedTokenGenerateCallbackHandler` object specifies the configuration parameters described in the following table:

*Table 302. `GenericIssuedTokenGenerateCallbackHandler` properties. This table describes the configuration parameters for the `GenericIssuedTokenGenerateCallbackHandler` object, and specifies whether or not the property is required.*

| Property | Description | Required |
|---|---|---|
| `IssuedTokenConfigConstants.STS_ADDRESS` | Specifies the http address of the STS.<br><br>When communication to the STS is protected with SSL, you must set the `-Dcom.ibm.SSL.ConfigURL` property. SSL connection to the STS is indicated with an `https://` address prefix. | Yes |

*Table 302. `GenericIssuedTokenGenerateCallbackHandler` properties (continued). This table describes the configuration parameters for the `GenericIssuedTokenGenerateCallbackHandler` object, and specifies whether or not the property is required.*

| Property | Description | Required |
|---|---|---|
| `IssuedTokenConfigConstants.APPLIES_TO` | Specifies the target service address for where you want to use the token. | No |
| `IssuedTokenConfigConstants.TRUST_CLIENT_COLLECTION_REQUEST` | Specifies whether to request a single token from the STS that is enclosed in a `RequestSecurityToken (RST)` element or multiple tokens in a collection of RST elements that are enclosed in a single `RequestSecurityTokenCollection (RSTC)` element.<br><br>The default behavior is to request a single token that is enclosed in a `RequestSecurityToken (RST)` element from the STS.<br><br>Specifying a `true` value for this property indicates a request for multiple tokens in a collection of RST elements that are enclosed in a single `RequestSecurityTokenCollection (RSTC)` element from the STS.<br><br>The default value is `false`. | No |
| `IssuedTokenConfigConstants.TRUST_CLIENT_WSTRUST_NAMESPACE` | Specifies the WS-Trust namespace that is included in the WS-Trust request.<br><br>The default value is `WSTrust 1.3`. | No |
| `IssuedTokenConfigConstants.USE_RUN_AS_SUBJECT` | Specify if you want WS-Security to use the token from the RunAs subject to exchange the requested token first by using WS-Trust Validate. If set to `false`, WS-Security will use WS-Trust Issue to request the token.<br><br>The default value is `true`. | No |
| `IssuedTokenConfigConstants.USE_RUN_AS_SUBJECT_ONLY` | Specify if you do not want WS-Security to use WS-Trust Issue to the requested token if token exchange fails.<br><br>The default value is `false`. | No |
| `IssuedTokenConfigConstants.USE_TOKEN` | Use this value to choose a token from the RunAs subject to exchange the requested token.<br><br>The default value is the requested token's `ValueType`. | No |

A `WSSGenerationContext` instance and a `WSSConsumingContext` instance are also set in the `GenericIssuedTokenGenerateCallbackHandler` object. In this example, the `WSSGenerationContext` instance contains a `UNTGenerateCallbackHandler` object with the information to create the `UsernameToken` that you want to send to the STS.

The `system.wss.generate.issuedToken` parameter specifies the Java Authentication and Authorization Service (JAAS) login module that is used to create the generic security token. You must specify a JVM property to define a JAAS configuration file that contains the required JAAS login configuration; for example:

```
-Djava.security.auth.login.config=profile_root/properties/wsjaas_client.conf
```

Alternatively, you can specify a JAAS login configuration file by setting a Java system property in the sample client code; for example:

```
System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas_client.conf");
```

5. Add the requested authentication token from the STS to the SOAP security header of web services request messages.
   a. Initialize the web service client and configure the `SOAPAction` properties. The following code illustrates these actions:

```
// Initialize web service client
EchoService12PortProxy echo = new EchoService12PortProxy();
echo._getDescriptor().setEndpoint(endpointURL);

// Configure SOAPAction properties
BindingProvider bp = (BindingProvider) (echo._getDescriptor().getProxy());
Map<String, Object> requestContext = bp.getRequestContext();
```

```
requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, endpointURL);
requestContext.put(BindingProvider.SOAPACTION_USE_PROPERTY, Boolean.TRUE);
requestContext.put(BindingProvider.SOAPACTION_URI_PROPERTY, "echoOperation");

// Initialize WSSGenerationContext
WSSGenerationContext gencont = factory.newWSSGenerationContext();
gencont.add(token);
```

b. Initialize the `WSSGenerationContext` object. The following code illustrates using the `WSSFactory.newWSSGenerationContext` method to obtain a `WSSGenerationContext` object. The `WSSGenerationContext` object is then used to insert the token into a web service request message:

```
// Initialize WSSGenerationContext
WSSGenerationContext gencont = factory.newWSSGenerationContext();
gencont.add(token);
```

The `WSSGenerationContext.add` method requires the client code to have the following Java 2 Security permission:

```
permission javax.security.auth.AuthPermission "modifyPrivateCredentials"
```

6. Add an X.509 token for message protection (skip this step if the web service is protected with SSL Transport level protection only). The following sample code uses the `dsig-sender.ks` key file and the `SOAPRequester` sample key. You must not use the sample key in a production environment. The following code illustrates adding an X.509 token for message protection:

```
//Add an X.509 Token for message protection
X509GenerateCallbackHandler x509callbackHandler = new X509GenerateCallbackHandler(
    null,
    "profile_root/etc/ws-security/samples/dsig-sender.ks",
    "JKS",
    "client".toCharArray(),
    "soaprequester",
    "client".toCharArray(),
    "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP", null);

SecurityToken x509 = factory.newSecurityToken(X509Token.class,
x509callbackHandler, "system.wss.generate.x509");

WSSSignature sig = factory.newWSSSignature(x509);
sig.setSignatureMethod(WSSSignature.RSA_SHA1);

WSSSignPart sigPart = factory.newWSSSignPart();
sigPart.setSignPart(token);
sigPart.addTransform(WSSSignPart.TRANSFORM_STRT10);
sig.addSignPart(sigPart);
sig.addSignPart(WSSSignature.BODY);
```

a. Create a `WSSSignature` object with the X.509 token. The following line of code creates a `WSSSignature` object with the X.509 token:

```
WSSSignature sig = factory.newWSSSignature(x509);
```

b. Add the signed part to use for message protection. The following line of code specifies to add `WSSSignature.BODY` as the signed part:

```
sig.addSignPart(WSSSignature.BODY);
```

c. Add the `Timestamp` element in the SOAP Security header. The `SAML20 SenderVouches WSHTTPS` and `SAML11 SenderVouches WSHTTPS` policy sets require web service requests and responses to contain a `Timestamp` element in the SOAP Security header. In the following code, the `WSSFactory.newWSSTimestamp()` method generates a `Timestamp` element, and the `WSSGenerationContext.add(timestamp)` method adds the `Timestamp` element to the request message:

```
// Add Timestamp element
WSSTimestamp timestamp = factory.newWSSTimestamp();
    gencont.add(timestamp);
sig.addSignPart(WSSSignature.TIMESTAMP);

gencont.add(sig);

WSSConsumingContext concont = factory.newWSSConsumingContext();
```

d. Skip this step if token signature is not required. If the requested security token needs to be signed with the *STR Dereference Transform* reference option, follow step 1. Otherwise, follow step 2. The *STR Dereference Transform* reference option is commonly known as *STR-Transform*.

Step 1: Some tokens, including SAML Tokens, cannot be digitally signed directly. You must sign the token using *STR-Transform*. In order for a token to be signed with *STR-Transform*, it must be referenced by a `<wsse:SecurityTokenReference>` element in the `<wsse:Security>` header block. To

sign a security token with *STR-Transform*, a separate `WSSSignPart` is created to specify the `SecurityTokenReference` with a transformation algorithm that is represented by the `WSSSignPart.TRANSFORM_STRT10` attribute. This attribute enables the WS-Security runtime environment to generate a `SecurityTokenReference` element to reference the token, and to digitally sign the token using the *STR Dereference* reference option. The following code illustrates the use of the `WSSSignPart.TRANSFORM_STRT10` attribute:

```
WSSSignPart sigPart = factory.newWSSSignPart();
sigPart.setSignPart(token);
sigPart.addTransform(WSSSignPart.TRANSFORM_STRT10);
```

Step 2: If the requested signed token is not a SAML token, or *STR-Transform* is not used, use the following code instead:

```
sig.addSignPart(token);
```

e. Attach the `WSSGenerationContext` object to the web service `RequestContext` object. The `WSSGenerationContext` object now contains all of the security information required to format a request message. The `WSSGenerationContext.process(requestContext)` method attaches the `WSSGenerationContext` object to the web service `RequestContext` object to enable the WS-Security runtime environment to format the required SOAP Security header; for example:

```
// Attaches the WSSGenerationContext object to the web service RequestContext object.
gencont.process(requestContext);
```

7. Use the X.509 token to validate the digital signature and the integrity of the response message if the provider policy requires the response message to be digitally signed. Skip this step if using SSL Transport level protection.
   a. An `X509ConsumeCallbackHandler` object is initialized with a trust store and a `List` of certificate path objects to validate the digital signature in a response message. The following code initializes the `X509ConsumeCallbackHandler` object with `dsig-receiver.ks` trust store and a certificate path object called `certList`:

```
ArrayList certList = new ArrayList();
java.security.cert.CertStore certStore = java.security.cert.CertStore.getDefaultType();
certList.add(certStore);

X509ConsumeCallbackHandler callbackHandlerVer = new
    X509ConsumeCallbackHandler("profile_root/etc/ws-security/samples/dsig-receiver.ks",
    "JKS",
    "server".toCharArray(),
    certList,
    java.security.Security.getProvider("IBMCertPath"));
```

   b. A `WSSVerification` object is created and the message body is added to the verification object so that the WS-Security runtime environment validates the digital signature. The following code is used to initialize the `WSSVerification` object:

```
WSSVerification ver = factory.newWSSVerification(X509Token.class, callbackHandlerVer);
```

The `WSSConsumingContext` object now contains all the security information that is required to format a request message. The `WSSConsumingContext.process(requestContext)` method attaches the `WSSConsumingContext` object to the response method; for example:

```
// Attaches the WSSConsumingContext object to the web service RequestContext object.
concont.process(requestContext);
```

### Results

You have requested a security token from an external STS. After obtaining the token, you sent the token with web services request messages using message level protection using the JAX-WS programming model and WSS APIs.

### Example

The following code example is a web service client application that demonstrates how to request a SAML Bearer token from an external STS and send that SAML token in a web service request message. If your

usage scenario requires SAML tokens, but does not require your application to pass the SAML tokens using web service messages, you only need to use the first part of the following sample code, up through the `// Initialize web service client` section.

```

            concont.process(requestContext);

            // Call the service
            response = echo.echoOperation(echoParm).getEchoResponse();

            System.out.println(">> CLIENT: SEI Echo invocation complete.");
            System.out.println(">> CLIENT: SEI Echo response is: " + response);
        } catch (Exception e) {
            System.out.println(">> CLIENT: ERROR: SEI Echo EXCEPTION.");
            e.printStackTrace();
        }
    }
}
```

### *Securing messages at the response consumer using WSS APIs:*

You can secure SOAP messages with signature verification, decryption, and consumer tokens to protect message integrity, confidentiality, and authenticity, respectively. The response consumer (client-side) configuration defines the Web Services Security requirements for the incoming SOAP response.

#### About this task

To secure web services with WebSphere Application Server, you must configure the generator and the consumer security constraints. You must specify several different configurations. Although there is no specific sequence to specify these different configurations, some configurations reference other configurations. For example, decryption configurations reference encryption configurations.

The response consumer (client-side) configuration requirements involve verifying that the integrity parts are signed and that the signature is verified, verifying that the required confidential parts are encrypted and that the parts are decrypted; and validating the security tokens.

You can use the following methods to configure Web Services Security and to define policy types to secure the SOAP messages:

- Use the administrative console to configure policy sets.
- Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client)

The following high-level steps use the WSS APIs:

### Procedure

- Verify consumer signing information to protect message integrity.
- Configure decryption to protect message confidentiality.
- Validate consumer tokens to protect message authenticity.

### Results

After completing these procedures, you have secured messages at the response consumer level.

### What to do next

Next, if not already configured, secure messages with signing information, encryption, and generator tokens at the response (client-side) generator level.

*Configuring decryption methods to protect message confidentiality using the WSS APIs:*

You can configure decryption method information for the response consumer (client side) section of the binding file. Decryption information is used to specify how the consumers (receivers) decrypt incoming SOAP messages. To configure decryption, specify which message parts to decrypt and specify which algorithm methods and security tokens are to be used for decryption.

### Before you begin

Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone understanding the message flowing across the Internet. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the correct target. Prior to configuring decryption, familiarize yourself with XML encryption.

### About this task

For decryption, you must specify the following:

- Which parts of the message are to be decrypted.
- Which decryption algorithms to specify.

To configure decryption and decrypted parts on the client side, use the WSSDecryption and WSSDecryptPart APIs, or configure policy sets using the administrative console.

WebSphere Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

WebSphere Application Server uses decryption information for the default consumer to decrypt parts of the SOAP message. The WSSDecryption API configures the following required parts as decrypted parts.

*Table 303. Required decrypted parts. Use the decryption information to specify how incoming messages are decrypted.*

| Decryption parts | Description |
|---|---|
| Keywords | Keywords are used to add the decrypted parts to the SOAP message. |
| XPath expression | XPath expressions are used to add the decrypted parts to the SOAP message. |
| WSSDencryptPart object | This object adds the decrypted parts to the SOAP message. |
| WSSVerification object | This object adds the signature verification component as a decrypted part. |
| Header | This part adds the header in the SOAP header, specified by QName, as a decrypted part. |
| Security token object | This object adds the security token as a decrypted part. |

Web Services Security API (WSS API) supports symmetric encryption, by using a shared key, only when Web Services Secure Conversation (WS-SecureConversation) is used.

The WSS APIs allow the use of either keywords or an XPath expression to specify the parts of the SOAP message that are to be decrypted. WebSphere Application Server supports the use of the following keywords:

*Table 304. Supported decryption keywords. Use the keywords to decrypt incoming messages.*

| Keyword | References |
|---|---|
| BODY_CONTENT | The keyword for the body contents of the SOAP message body as a decryption target. |
| SIGNATURE | The keyword for the signature element as a decryption target. |
| USERNAME_TOKEN, | The keyword for the Username token element as a decryption target. |

If configuring using the WSS APIs, the WSSDecryption and WSSDecryptPart APIs complete these high-level steps:

**Procedure**

1. Use the WSSDecryption API to configure encryption. The WSSDecryption API performs these tasks by default:
   a. Generates the callback handler.
   b. Generates the consumer security token object.
   c. Adds the security token reference type.
   d. Adds the WSSEncryptPart object.
   e. Adds the parts to be encrypted. Adds the default parts for decryption by using keywords and XPath expressions.
   f. Adds the verification component.
   g. Adds the header in the SOAP message, specified by QName.
   h. Sets the default data encryption method.
   i. Specifies whether the key is to be decrypted using a Boolean value. Calls this method when the shared key is encrypted.
   j. Sets the default key encryption method.
2. Use the WSSEncryptPart API to configure encrypted parts or add a transform method. The WSSEncryptPart API performs these tasks by default:
   a. Sets the encrypted parts specified by using keywords or an XPath expression.
   b. Sets the encrypted parts specified by an XPath expression.
   c. Sets the signature component object, WSSSignature.
   d. Sets the header in the SOAP message, specified by QName.
   e. Sets the generator security token.
   f. Adds the transform method, if needed.
3. Change from the default values for algorithm or message parts, as needed. For example: you could change one or more of the following items:
   - Add USERNAME_TOKEN as a target of decryption.
   - Change the data encryption algorithm from the default value of AES 128.
   - Change the key encryption algorithm from the default value of KW_RSA_OAEP.
   - Specify to not encrypt the encryption key (false).
   - Change the security token type from the default value of X.509 token.
   - Only use BODY_CONTENT as an encryption part and not use SIGNATURE also.

### Results

The decryption information is configured for the consumer binding.

### Example

The following is an example of the WSSDecryption API:

```
WSSFactory factory = WSSFactory.getInstance();
WSSConsumingContext concont = factory.newWSSConsumingContext();
    X509ConsumeCallbackHandler callbackhandler = generateCallbackHandler();
// see X509ConsumeCallbackHandler
    WSSDecryption dec = factory.newWSSDecryption(X509Token.class,
        callbackhandler);

 concont.add(dec);
```

### What to do next

You must configure similar encryption information for the client-side request generator (sender) bindings, if you have not already configured the information.

Next, review the WSSDecryption API process.

*Decrypting SOAP messages using the WSSDecryption API:*

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure the client for decryption on the response (client) consumer side, use the WSSDecryption API to decrypt the SOAP messages. The WSSDecryption API specifies which request SOAP message parts to decrypt when configuring the client.

### Before you begin

You can use the WSS API or use policy sets on the administrative console to enable decryption and add consumer security tokens in the SOAP message. To secure SOAP messages, you must have completed the following decryption tasks:

- Encrypted the SOAP message.
- Chosen the decryption method.

### About this task

The decryption information on the consumer side is used for decrypting an incoming SOAP message for the response consumer (client side) bindings. The client consumer configuration must match the configuration for the provider generator.

Confidentiality settings require that confidentiality constraints be applied to generated messages.

The following decryption parts can be configured:

*Table 305. Decryption parts. Use the decryption parts to secure messages.*

| Decryption parts | Description |
|---|---|
| part | Adds the WSSDecryptPart object as a target of the decryption part. |
| keyword | Adds the decryption part using keywords. WebSphere Application Server supports the following keywords:<br>• BODY_CONTENT<br>• SIGNATURE<br>• USERNAME_TOKEN |
| xpath | Adds the decryption part using an XPath expression. |
| verification | Adds the WSSVerification instance as a target of the decryption part. |
| header | Adds the SOAP header, specified by QName, as a target of the decryption part. |

For decryption, certain default behaviors occur. The simplest way to use the WSS API for decryption is to use the default behavior (see the example code). WSSDecryption provides defaults for the key encryption algorithm, the data encryption algorithm, and the decryption parts such as the SOAP body content and the signature. The decryption default behaviors include:

*Table 306. Decryption decisions. Several decryption part characteristics are configured by default.*

| Decryption decisions | Default behavior |
|---|---|
| Which parts to decrypt | The default decryption parts are the BODY_CONTENT and SIGNATURE. WebSphere Application Server supports using these keywords:<br>• WSSDecryption.BODY_CONTENT<br>• WSSDecryption.SIGNATURE<br>• WSSDecryption.USERNAME_TOKEN<br><br>After you specify which message parts to decrypt, you must specify which method to use when decrypting the consumer request message. For example, if both signature and body content are applied for encryption, then the SOAP message parts that are decrypted include the same parts. |
| Whether to encrypt the key (isEncrypt) | The default value is to encrypt the key (`true`). |
| Which data decryption algorithm to choose (method) | The default data decryption algorithm method is AES128. WebSphere Application Server supports these data encryption methods:<br>• WSSDecryption.AES128: http://www.w3.org/2001/04/xmlenc#aes128-cbc<br>• WSSDecryption.AES192: http://www.w3.org/2001/04/xmlenc#aes192-cbc<br>• WSSDecryption.AES256: http://www.w3.org/2001/04/xmlenc#aes256-cbc<br>• WSSDecryption.TRIPLE_DES: http://www.w3.org/2001/04/xmlenc#tripledes-cbc |
| Which key decryption method to choose (algorithm) | The default key decryption algorithm method is key wrap RSA OAEP. WebSphere Application Server supports these key encryption methods:<br>• WSSDecryption.KW_AES128: http://www.w3.org/2001/04/xmlenc#kw-aes128<br>• WSSDecryption.KW_AES192: http://www.w3.org/2001/04/xmlenc#kw-aes192<br>• WSSDecryption.KW_AES256: http://www.w3.org/2001/04/xmlenc#kw-aes256<br>• WSSDecryption.KW_RSA_OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p<br>• WSSDecryption.KW_RSA15: http://www.w3.org/2001/04/xmlenc#rsa-1_5<br>• WSSDecryption.KW_TRIPLE_DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes |
| Which security token to specify | The default security token type is the X509 token. WebSphere Application Server provides the following pre-configured consumer token types:<br>• Derived key token<br>• X509 tokens |

### Procedure

1. To decrypt the SOAP message using the WSSDecryption API, first ensure that the application server is installed.
2. The WSS API process for decryption performs these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSConsumingContext instance from the WSSFactory instance. The WSSConsumingContext must always be called in a JAX-WS client application.
   c. Creates the callback handler for the consumer side.
   d. Creates WSSDecryption with the class for the security token and the callback handler from the WSSFactory instance. The default behavior of WSSDecryption is to assume that the body content and the signature are encrypted.
   e. Adds the parts to be decrypted, if the default is not appropriate.
   f. Adds the candidates of the data encryption methods to use for decryption.
   g. Adds the candidates of the key encryption methods to use for decryption.
   h. Adds the candidates of the security token to use for decryption.
   i. Calls WSSDecryption.encryptKey(false) if the application does not want the key to be encrypted in the incoming message.

j. Adds WSSDecryption to WSSConsumingContext.
k. Calls WSSConsumingContext.process() with the SOAPMessageContext

### Results

If there is an error condition during decryption, a WSSException is provided. If successful, the WSSConsumingContext.process() is called, and Web Services Security is applied to the SOAP message.

### Example

The following example provides sample code for decrypting the SOAP message body content:

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance (step: a)
   WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSConsumingContext instance (step: b)
   WSSConsumingContext gencont = factory.newWSSConsumingContext();

// Generate the callback handler (step: c)
   X509ConsumeCallbackHandler callbackHandler = new
       X509ConsumeCallbackHandler(
                                 "",
                                 "enc-sender.jceks",
                                 "jceks",
                                 "storepass".toCharArray(),
                                 "alice",
                                 "keypass".toCharArray(),
 "CN=Alice, O=IBM, C=US");

// Generate the WSSDecryption instance (step: d)
   WSSDecryption dec = factory.newWSSDecryption(X509Token.class,
                                                callbackHandler);

// Set the part to be encrypted (step: e)
// DEFAULT: WSSEncryption.BODY_CONTENT and WSSEncryption.SIGNATURE

// Set the part to be encrypted (step: e)
// DEFAULT: WSSEncryption.BODY_CONTENT and WSSEncryption.SIGNATURE

// Set the part specified by the keyword (step: e)
      dec.addRequiredDecryptPart(WSSDecryption.BODY_CONTENT);

// Set the part in the SOAP Header specified by QName (step: e)
    dec.addRequiredDecryptHeader(new
       QName("http://www.w3.org/2005/08/addressing",
       "MessageID"));

// Set the part specified by WSSVerification  (step: e)
   X509ConsumeCallbackHandler verifyCallbackHandler =
      getCallbackHandler();
   WSSVerification ver = factory.newWSSVerification(X509Token.class,
                                                    verifyCallbackHandler);
      dec.addRequiredDecryptPart(ver);

// Set the part specified by XPath expression (step: e)
      StringBuffer sb = new StringBuffer();
         sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
            and local-name()='Envelope']");
         sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
            and local-name()='Body']");
         sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
            and local-name()='Ping']");
         sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
            and local-name()='Text']");
      dec.addRequiredDecryptPartByXPath(sb.toString());

// Set the part in the SOAP header to be decrypted specified by QName (step: e)
      dec.addRequiredDecryptHeader(new
          QName("http://www.w3.org/2005/08/addressing",
          "MessageID"));

// Set the candidates for the data encryption method (step: f)
// DEFAULT : WSSDecryption.AES128
      dec.addAllowedEncryptionMethod(WSSDecryption.AES128);
      dec.addAllowedEncryptionMethod(WSSDecryption.AES192);

// Set the candidates for the key encryption method (step: g)
// DEFAULT : WSSDecryption.KW_RSA_OAEP
      dec.addAllowedKeyEncryptionMethod(WSSDecryption.KW_TRIPLE_DES);

// Set the candidate security token to used for the decryption (step: h)
```

```
   X509ConsumeCallbackHandler callbackHandler2 = getCallbackHandler2();
      dec.addToken(X509Token.class, callbackHandler2);

// Set whether or not the key should be encrypted in the incoming SOAP message (step: i)
// DEFAULT: true
      dec.encryptKey(true);

// Add the WSSDecryption to the WSSConsumingContext (step: j)
   concont.add(dec);

// Validate the WS-Security header (step: k)
concont.process(msgcontext);
```

### What to do next

Next, use the WSSDecryptPart API or configure the policy sets using the administrative console to add decrypted parts for the consumer message.

*Choosing decryption methods for the consumer binding:*

To configure the client for response decryption for the consumer binding, specify which data and transform algorithm methods to use when the client decrypts the SOAP messages.

### Before you begin

Prior to completing these steps, read the XML encryption information to become familiar with encrypting and decrypting SOAP messages.

To complete decryption configuration to secure SOAP messages, you must complete the following tasks:

- Configure decryption of the SOAP message parts
- Specify the decryption methods.

You can configure the decryption methods using the WSSDecryption and WSSDecryptPart APIs. Or you can also configure policy sets using the administrative console to configure the decryption methods.

### About this task

Some of the encryption-related definitions are based on the XML-Encryption specification. The following information defines some data encryption-related terms:

**Data encryption method algorithm**

Data encryption algorithms specify the algorithm uniform resource identifier (URI) of the data encryption method. This algorithm encrypts and decrypts data in fixed size, multiple octet blocks.

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files.

For the AES256-cbc and the AES192-cbc algorithms, you must download the unrestricted Java™ Cryptography Extension (JCE) policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

**Key encryption method algorithm**

Key encryption algorithms specify the algorithm uniform resource identifier (URI) of the key encryption method. The algorithm represents public key encryption algorithms that are specified for encrypting and decrypting keys.

By default, the RSA_OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. The property name is: `com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod`. The property value is one of the following URIs of the digest method:

- http://www.w3.org/2001/04/xmlenc#sha256
- http://www.w3.org/2001/04/xmlenc#sha512

By default, the RSA_OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

**Important:** You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.

For the KW_AES256 and the KW_AES192 key encryption algorithms, you must download the unrestricted JCE policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

**Important:** Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

To complete the decryption configuration, you must specify the algorithm uniform resource identifier (URI) and its usage type. If the URI is used for multiple usage types, then you must define the URI to each usage type. WebSphere Application Server supports the following decryption usage types:

*Table 307. Decryption usage types. These decryption types are supported by WebSphere Application Server.*

| Usage types | Description |
|---|---|
| Data encryption | Specifies the algorithm URI that is used for both encrypting and decrypting data. Encrypts and decrypts data in fixed size, multiple octet blocks. |
| Key encryption | Specifies the algorithm URI that is used for encrypting and decrypting the encryption key. |

To configure the decryption and decrypted part algorithms, use the WSSDecryption and WSSDecryptPart APIs, or configure policy sets using the administrative console.

**Note:** Policy sets do not support symmetric key encryption. If you are using the WSS API for symmetric key encryption, you will not be able to interoperate with web services endpoints that use policy sets.

If you are using the WSS APIs, the WSSDecryption and WSSDecryptPart APIs specify which algorithm methods are used when the client decrypts the SOAP messages.

- Use the WSSDecryption API to configure the data encryption algorithm and the key encryption algorithm methods.
- Use the WSSDecryptPart API to configure a transform algorithm method.

The WSS API process completes the following high-level steps to specify which decryption and decrypted part algorithm methods to use when configuring the client for response decryption:

**Procedure**

1. Using the WSSDecryption API, adds the required data encryption algorithm. The data encryption algorithm is used for encrypting or decrypting parts of a SOAP message. Data decryption algorithms specify the algorithm uniform resource identifier (URI) of the data encryption method.

   The default data encryption algorithm is AES 128. The data encryption name is AES128, and the URI of the data encryption algorithm, is http://www.w3.org/2001/04/xmlenc#aes128-cbc. WebSphere Application Server supports the following pre-configured data decryption algorithms:

- AES128: http://www.w3.org/2001/04/xmlenc#aes128-cbc

  The AES 128 algorithm is the default data algorithm method.
- AES256: http://www.w3.org/2001/04/xmlenc#aes256-cbc

  To use this AES 256-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
- AES192: http://www.w3.org/2001/04/xmlenc#aes192-cbc

  Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

  To use this AES 192-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
- TRIPLE_DES: http://www.w3.org/2001/04/xmlenc#tripledes-cbc

2. As needed, changes the WSSEncryption API method to specify another data encryption algorithm. For example, you might add the following code to change from the default AES 128 algorithm to the Triple DES algorithm:

```
dec.addAllowedKeyEncryptionMethod(WSSDecryption.TRIPLE_DES);
```

3. Using the WSSDecryption API, adds the required key encryption algorithm. The key encryption algorithm is used for encrypting the key that is used for encrypting the message parts within the SOAP message. If no key for encrypting the data is needed, then you must specify WSSDecryption.encryptKey(false).

   The key encryption algorithm that you select for the consumer side must match the key encryption method that you select for the generator side.

   The default key encryption algorithm value is key wrap RSA_OAEP. The key encryption name is KW_RSA_OAEP, and the URI of the key encryption algorithm is http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p. WebSphere Application Server supports the following pre-configured key encryption algorithms:
   - KW_AES128: http://www.w3.org/2001/04/xmlenc#kw-aes128
   - KW_AES192: http://www.w3.org/2001/04/xmlenc#kw-aes192

     To use this key wrap AES 192 algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

     **Restriction:** Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).
   - KW_AES256: http://www.w3.org/2001/04/xmlenc#kw-aes256

     To use this key wrap AES 256-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
   - KW_RSA_OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p.

     The KW_RSA_OAEP algorithm is the default key algorithm method.

     When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms does not include this algorithm. This algorithm appears in the list of supported key transport algorithms when running with SDK Version 1.5. See more information at http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p
   - KW_RSA_15: http://www.w3.org/2001/04/xmlenc#rsa-1_5
   - KW_TRIPLE_DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes

   **Note:** For Web Services Secure Conversation, the WSSEncryption API might specify addition key-related information, such as the:
   - algorithmName

- keyLength

4. As needed, uses the WSSDecryption API method to change to other key encryption algorithms. For example, you might add the following code to change from the default key encryption algorithm KW_RSA_OAEP to the TRIPLE_DES algorithm:

```
dec.addAllowedKeyEncryptionMethod(WSSDecryption.KW_TRIPLE_DES);
```

5. Using the WSSDecryptPart API, adds a transform algorithm, as needed. There is no default transform algorithm. However, WebSphere Application Server provides a pre-configured decrypted part, `WSSDecryptPart.TRANSFORM_ATTACHMENT_CIPHERTEXT`, that can be added.

### Results

If there is an error condition, a WSSException is provided. If successful, the API calls the `WSSConsumerContext.process()` method, the WS-Security header is validated, and the SOAP message is now secured using Web Services Security.

### Example

The following example provides sample WSS API code for decrypting the body content as well as changing the data encryption and key encryption algorithms from the default values:

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance
   WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSConsumingContext instance
   WSSConsumingContext gencont = factory.newWSSConsumingContext();

// Generate the callback handler
   X509ConsumeCallbackHandler callbackHandler = new
      X509ConsumeCallbackHandler(
                                "",
                                "enc-sender.jceks",
                                "jceks",
                                "storepass".toCharArray(),
                                "alice",
                                "keypass".toCharArray(),
                                "CN=Alice, O=IBM, C=US");

// Generate WSSDecryption instance
   WSSDecryption dec = factory.newWSSDecryption(X509Token.class,
                                                callbackHandler);

// Set the candidates for the data encryption method
// DEFAULT : WSSDecryption.AES128
   dec.addAllowedEncryptionMethod(WSSDecryption.AES128);
   dec.addAllowedEncryptionMethod(WSSDecryption.AES192);

// Set the candidates for the key encryption method
// DEFAULT : WSSDecryption.KW_RSA_OAEP
   dec.addAllowedKeyEncryptionMethod(WSSDecryption.KW_TRIPLE_DES);

// Add the WSSDecryption to WSSConsumingContext
   concont.add(dec);

// Validate the WS-Security header
concont.process(msgcontext);
```

*Adding decrypted parts using the WSSDecryptPart API:*

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure decrypted parts for the response consumer (client side) bindings, use the WSSDecryptPart API to define and add to the listing of elements in the decrypted part. WSSDecryptPart is an interface that is part of the com.ibm.websphere.wssecurity.wssapi.decryption package.

### Before you begin

You can use either the WSS APIs or configure the policy sets using the administrative console to configure and add new encrypted parts. To secure SOAP messages using the WSSDecryptPart APIs, you must configure the decrypted parts for the response consumer bindings.

### About this task

Confidentiality settings require that confidentiality constraints be applied to generated messages. These constraints include specifying which message parts within the generated message must be encrypted and decrypted, and which message parts to attach encrypted elements to.

The WSSDecryptPart API specifies information related to decryption and sets the decrypted parts that have been added for message confidentiality protection. Use the WSSDecryptPart to set the transform method and to specify the part to which the transform method is to be applied. Sets the transform method only if using SOAP with Attachments. The WSSDecryptPart is usually not needed except, in some case for tasks such as setting the transform method.

The decrypted parts displayed in the following table are used to protect the confidentiality of messages.

*Table 308. Decrypted Parts. Use the decrypted parts to secure messages.*

| Decrypted parts | Description |
|---|---|
| keyword | Sets the decrypted part using keywords. The default decrypted parts that you can add using keywords are the BODY_CONTENT and SIGNATURE. WebSphere Application Server supports the following keywords:<br>• BODY_CONTENT<br>• SIGNATURE<br>• USERNAME_TOKEN |
| xpath | Sets the decrypted part by using an XPath expression. |
| verification | Sets the WSSVerification component as a decrypted part.<br><br>The WSSVerification part is applicable only if the SOAP message contains a signature element. |
| header | Sets the header, specified by QName, as a decrypted part. |

For decrypted parts, certain default behaviors occur. The simplest way to use the WSSDecryptPart API is to use the default behavior (see the example code).

WSSDecryptPart provides defaults for setting the transform algorithm, adding a transform method, setting objects as targets, whether an element, and the encrypted parts, such as: the SOAP body content and the signature.

*Table 309. Decrypted part decisions. Several characteristics of decrypted parts are configured by default.*

| Decryption decisions | Default behavior |
|---|---|
| Which SOAP message parts to decrypt using keywords | Specifies which keywords to use for the decrypted parts. WebSphere Application Server sets the following SOAP message parts by default for decryption:<br>• WSSDecryption.BODY_CONTENT<br>• WSSDecryption.SIGNATURE |
| Which transform algorithm to use (algorithm) | WebSphere Application Server does not specify any transform algorithm by default. Specify a transform method only if using SOAP with Attachments. |

### Procedure

1. To decrypt the SOAP message parts using the WSSDecryptPart API, first ensure that the application server is installed.
2. The WSS API process using WSSDecryptPart follows these steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.

b. Creates the WSSConsumingContext instance from the WSSFactory instance. Note that the WSSConsumingContext must always be called in a JAX-WS client application.
c. Creates the SecurityToken from WSSFactory to configure decryption.
d. Creates WSSDecryption from the WSSFactory instance using SecurityToken.
e. Creates WSSDecryptPart from the WSSFactory instance. The default behavior of WSSDecryptPart is to assume that the body content and signature are encrypted.
f. Adds the parts to be decrypted and to be applied with the transform in WSSDecryptPart. WebSphere Application Server sets these encrypted parts by default for WSSDecryptPart: the BODY_CONTENT and SIGNATURE. After you add other decrypted parts, the default values are no longer valid. For example, if you call addDecryptPart(securityToken, false), only the security token is encrypted, and not the signature and body content. So if you want to decrypt the security token, the signature, and the body content, you must call addDecryptPart(securityToken, false), addDecryptPart(WSSDecryption.SIGNATURE), and addDecryptPart(WSSDecryption.BODY_CONTENT).
g. Sets the transform method.
h. Adds WSSDecryptPart to WSSDecryption.
i. Adds WSSDecryption to WSSConsumingContext.
j. Calls WSSConsumingContext.process() with the SOAPMessageContext

**Results**

If there is an error condition when decrypting the message, a WSSException is provided. If successful, the API calls the WSSConsumingContext.process(), the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

**What to do next**

After enabling decrypted parts for the response consumer (client side) binding, specify the generator and consumer tokens, if the security tokens have not already been specified.

*Decryption methods:*

The decryption algorithms specify the data and key encryption algorithms that are used to decrypt the SOAP message. The WSS API for decryption (WSSDecryption) specifies the algorithm uniform resource identifier (URI) of the data and key encryption methods. The WSSDecryption interface is part of the `com.ibm.websphere.wssecurity.wssapi.decryption` package.

**Data encryption algorithms**

The data encryption algorithms are the algorithms that are used to encrypt and decrypt data. This algorithm type is used for encrypting data to encrypt and decrypt various parts of the message, including the body content and the signature.

Data decryption algorithms specify the algorithm uniform resource identifier (URI) of the data encryption method. WebSphere Application Server supports the following pre-configured data decryption algorithms:

*Table 310. Supported pre-configured data decryption algorithms. The algorithms are used to decrypt SOAP messages.*

| WSS API | URI |
|---|---|
| WSSDecryption.AES128 (the default value) | A URI of data encryption algorithm, AES 128: http://www.w3.org/2001/04/xmlenc#aes128-cbc |
| WSSDecryption.AES192 | A URI of data encryption algorithm, AES 192: http://www.w3.org/2001/04/xmlenc#aes192-cbc |
| WSSDecryption.AES256 | A URI of data encryption algorithm, AES 256: http://www.w3.org/2001/04/xmlenc#aes256-cbc |

*Table 310. Supported pre-configured data decryption algorithms (continued). The algorithms are used to decrypt SOAP messages.*

| WSS API | URI |
|---|---|
| WSSDecryption.TRIPLE_DES | A URI of data encryption algorithm, TRIPLE DES: http://www.w3.org/2001/04/xmlenc#tripledes-cbc |

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files.

**Important:** Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

For the AES256-cbc and the AES192-cbc algorithms, you must download the unrestricted Java™ Cryptography Extension (JCE) policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

The data encryption algorithm must match the data decryption algorithm that is configured for the consumer.

### Key encryption algorithms

The key encryption algorithms are the algorithms that are used to encrypt and decrypt keys.

This key information is used to specify the configuration that is needed to generate the key for digital signature and encryption. The signing information and encryption information configurations can share the key information. The key information on the consumer side is used for specifying the information about the key that is used for validating the digital signature in the received message or for decrypting the encrypted parts of the message. The request generator is configured for the client.

Key encryption algorithms specify the algorithm uniform resource identifier (URI) of the key encryption method. WebSphere Application Server supports the following pre-configured key encryption algorithms:

*Table 311. Supported pre-configured key encryption algorithms. The algorithms are used to decrypt SOAP messages.*

| WSS API | URI |
|---|---|
| WSSDecryption.KW_AES128 | A URI of key encryption algorithm, key wrap AES 128: http://www.w3.org/2001/04/xmlenc#kw-aes128 |
| WSSDecryption.KW_AES192 | A URI of key encryption algorithm, key wrap AES 192: http://www.w3.org/2001/04/xmlenc#kw-aes192<br>**Restriction:** Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP). |
| WSSDecryption.KW_AES256 | A URI of key encryption algorithm, key wrap AES 256: http://www.w3.org/2001/04/xmlenc#kw-aes256 |
| WSSDecryption.KW_RSA_OAEP (the default value) | A URI of key encryption algorithm, key wrap RSA OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p |
| WSSDecryption.KW_RSA15 | A URI of key encryption algorithm, key wrap RSA 1.5: http://www.w3.org/2001/04/xmlenc#rsa-1_5 |
| WSSDecryption.KW_TRIPLE_DES | A URI of data encryption algorithm, key wrap TRIPLE DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes |

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. The property name is:

com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod. The property value is one of the following URIs of the digest method: http://www.w3.org/2001/04/xmlenc#sha256 http://www.w3.org/2001/04/xmlenc#sha512

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPparams. The property value is the base 64-encoded value of the octet string.

**Important:** You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.

For the kw-aes256 and the kw-aes192 key encryption algorithms, you must download the unrestricted JCE policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

The key encryption algorithm for the generator and the consumer must match.

The following example provides a sample of the WSS API code for the default algorithms that are used for WebSphere Application Server decryption:

```
WSSFactory factory = WSSFactory.getInstance();
WSSConsumingContext concont = factory.newWSSConsumingContext();

// Required to attach username token into the message.
X509ConsumeCallbackHandler callbackHandler =
       new X509ConsumeCallbackHandler("",
                                      "enc-sender.jceks",
                                      "JCEKS",
                                      "storepass".toCharArray(),
                                      "alice",
                                      "keypass".toCharArray(),
                                      "CN=Alice, O=IBM, C=US");
// Set the decrypt component.
// Default encrypted part: Body-Content
// Default data encryption algorithm: AES128
// Default key encryption algorithm: KW-RSA-OAEP
WSSDecryption dec = factory.newWSSDecryption(X509Token.Type,
callbackHandler);
concont.add(dec);

// validate the WS-Security header.
concont.process(msgctx);
```

*Verifying consumer signing information to protect message integrity using WSS APIs:*

You can verify the signing information to protect message integrity for the response (client side) consumer binding. Signing information includes the signature and the signed parts for the generator side as well as signature verification and verify parts for the consumer side. To keep the integrity of the message, digital signatures are typically applied.

**Before you begin**

Ensure that the signature and signed parts information has been configured. The signature verification information must match what was configured on the generator side.

**About this task**

Integrity refers to digital signature while confidentiality refers to encryption. Integrity is provided by applying a digital signature to a SOAP message. To configure the signing information to protect message integrity, you must first digitally sign and then verify the signature for the SOAP messages. Integrity decreases the risk of data modification when you transmit data across a network.

Also, message integrity is provided by verifying the digitally signed body, time stamp, and WS-Addressing headers using the signature verification algorithm methods. The WSS APIs specify which algorithm is to be

used to verify the certificate. The signature algorithms specify the Uniform Resource Identifiers (URI) of the signature verification method. WebSphere Application Server supports several pre-configured verification algorithm methods.

You can use the following interfaces to configure Web Services Security and to protect SOAP message integrity:

- Use the administrative console to configure policy sets for signature verification.
- Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client)

Perform the following verification tasks, using the WSS APIs, to configure the signing information and to protect message integrity for the consumer binding.

**Procedure**

- Configure the signing information using the WSSSignature API. Configure the signature verification information for the consumer binding using the WSSVerification API. Signature verification information is used to verify parts of a message including the SOAP body, the time stamp, and the WS-Addressing headers. Both verifying and decryption can be applied to the same message parts, such as the SOAP body.
- Add or change verify parts using the WSSVerifyPart API.
- Configure the client for request signing methods using the WSSVerification or WSSVerifyPart APIs. To configure the client for response verification, choose the verification methods. Use the WSSVerification API to configure the canonicalization and signature methods. Use the WSSVerifyPart API to configure the digest and transform methods.

**Results**

By completing the steps in these tasks, you have configured the consumer verification information to protect the integrity of messages.

*Verifying signing information for the consumer binding using the WSS APIs:*

You can configure the signing information for the client-side response consumer (receiver) bindings. Signing information is used to sign and validate parts of a message including the SOAP body, the timestamp information, and the Username token.

**Before you begin**

WebSphere Application Server uses XML digital signature with existing algorithms such as RSA, HMAC, and SHA1. XML signature defines many methods for describing key information and enables the definition of a new method. Prior to completing these steps, read the information about XML digital signature to become familiar with signing and verifying digital signatures for digital content.

By including XML signature in SOAP messages, the following issues are realized: message integrity and authentication. *Integrity* refers to digital signature whereas confidentiality refers to encryption. Integrity decreases the risk of data modification while the data is transmitted across the Internet.

Before you can verify the signature and SOAP message signed parts, you must have completed the following tasks:

- Configured the signature.
- Added signed parts, as needed.
- Chosen the signature and signed parts methods.

### About this task

Use the Web Services Security APIs (WSS API) to configure the signing verification information for the response consumer (client side) section of the bindings file. Use the WSSVerification or WSSVerifyPart APIs to configure the client for request signature verification and to specify which digitally signed message parts to verify.

WebSphere Application Server uses the signing information on the consumer side to verify the integrity of the received SOAP message by validating that the message parts (such as the body, time stamp, and Username token) are signed.

On the client side, use the WSS APIs, or configure policy sets using the administrative console to specify which parts of the message are signed and to configure the key information that is referenced by the key information references. To verify the signature and signed parts, use the WSSVerification and WSSVerifyPart APIs.

WebSphere Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

The WSSVerification and WSSVerifyPart APIs complete the following steps to specify which digitally signed message parts to verify when configuring the client for response consumer signing:

### Procedure

1. The WSSVerification API adds the required verify parts of the SOAP message.

   The part reference refers to the message part that is digitally signed. The part attribute refers to the name of the <Integrity> element when the <PartReference> element is specified for the signature. You can specify multiple <PartReference> elements within the <SigningInfo> element. The <PartReference> element has two child elements when it is specified for the signature: <DigestTransform> and <Transform>.

   The WSSVerification API configures the following parts as verification parts:

| | |
|---|---|
| Security token | Adds information for the security token that is used for the signature verification. |
| SOAP header and the QName as a target | Adds the SOAP header, specified by QName, as a verification part. |

   The WSS APIs allow the use of keywords or an XPath expression to specify which parts of the message are to be verified. WebSphere Application Server supports the use of the following keywords:

| Keyword | References |
|---|---|
| WSSVerification.ADDRESSING_HEADERS | The Web Services Addressing (WS-Addressing) headers. |
| WSSVerification.BODY | The SOAP message body. The body is the user data portion of the message. |
| WSSVerification.TIMESTAMP | The creation and expiration timestamp information. |

2. The WSSVerification API adds the required header to the SOAP message. The header, specified by QName, is a required verification header.
3. The WSSVerification API adds a security token. Adds information about the security token that is to be used for the signature verification, such as:
   - The class for security token.
   - The callback handler
   - The name of the JAAS login configuration.

4. The WSSVerification API adds the signature method algorithm. The signature method is the algorithm that is used to convert the canonicalized <SignedInfo> element in the binding file into the <SignatureValue> element. The algorithm that is specified for the consumer, which is the response consumer configuration, must match the algorithm specified for the request generator configuration. WebSphere Application Server supports the following pre-configured signature algorithms:
   - WSSVerification.RSA_SHA1:http://www.w3.org/2000/09/xmldsig#rsa-sha1
   - WSSVerification.HMAC_SHA1:http://www.w3.org/2000/09/xmldsig#hmac-sha1

   WebSphere Application Server does not support the following algorithm for DSA-SHA1: http://www.w3.org/2000/09/xmldsig#dsa-sha1. You cannot use the DSA-SHA1 algorithm if you want to be compliant with the Basic Security Profile (BSP).
5. The WSSVerification API adds a canonicalization method. The canonicalization method algorithm is used to canonicalize the <SignedInfo> element before it is incorporated as part of the digital signature operation. The canonicalization algorithm that you specify for the generator must match the algorithm for the consumer.

   WebSphere Application Server supports the following pre-configured canonicalization algorithms:
   - WSSVerification.EXC_C14N: http://www.w3.org/2001/10/xml-exc-c14n#
   - WSSVerification.C14N: http://www.w3.org/TR/xml-c14n
6. The WSSVerification API verifies whether a signature confirmation is required. The OASIS Web Services Security (WS-Security) Version 1.1 specification defines the use of signature confirmation. If you are using WS-Security Version 1.0, this function is not available.

   The signature confirmation value is stored in order to validate the signature confirmation with it after the receiving message is returned. This method is called if the response message is expected to attach the signature confirmation into the SOAP message.
7. The WSSVerifyPart API adds a digest method. For each part reference in the signing information, the API specifies both a digest method algorithm and a transform algorithm.

   WebSphere Application Server supports the following pre-configured digest algorithms:
   - WSSVerifyPart.SHA1: http://www.w3.org/2000/09/xmldsig#sha1
   - WSSVerifyPart.SHA256: http://www.w3.org/2001/04/xmlenc#sha256
   - WSSVerifyPart.SHA512: http://www.w3.org/2001/04/xmlenc#sha512
8. The WSSVerifyPart API adds a transform method. For each part reference in the signing information, the API specifies both a digest method algorithm and a transform algorithm.

   WebSphere Application Server supports the following pre-configured transform algorithms:
   - WSSVerifyPart.TRANSFORM_EXC_C14N (the default value): http://www.w3.org/2001/10/xml-exc-c14n#
   - WSSVerifyPart.TRANSFORM_XPATH2_FILTER: http://www.w3.org/2002/06/xmldsig-filter2
   - WSSVerifyPart.TRANSFORM_STRT10: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
   - WSSVerifyPart.TRANSFORM_ENVELOPED_SIGNATURE: http://www.w3.org/2000/09/xmldsig#enveloped-signature

   For the WSS APIs, WebSphere Application Server does not support these algorithms:
   - http://www.w3.org/2002/07/decrypt#XML
   - http://www.w3.org/TR/1999/REC-xpath-19991116

   The transform algorithm for the consumer must match the transform algorithm for the generator.

**Results**

You have completed the steps to configure the signing information for the client-side response consumer sections of the bindings files.

### Example

The following example shows WSS API sample code to verify the signature and to verify the X.509 token type as the security token:

```
WSSFactory factory = WSSFactory.getInstance();
WSSConsumingContext concont = factory.newWSSConsumingContext();
// Generate the X.509 Callback Handler on the consumer side
    X509ConsumeCallbackHandler callbackhandler = generateCallbackHandler();
    WSSVerification ver = factory.newWSSVerification(X509Token.class,
        callbackhandler);
concont.add(ver);
```

### What to do next

If not already configured, specify a similar signing information configuration for the generator bindings.

Next, if already configured, configure the encryption and decryption information, or configure the consumer and generator tokens.

*Verifying the signature using the WSSVerification API:*

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To verify the signing information for the consumer binding sections for the client side request, use the WSSVerification API. You must also specify which algorithm methods and which signature parts of the SOAP message are to be verified. The WSSVerification API is part of the com.ibm.websphere.wssecurity.wssapi.verification package.

### Before you begin

Use the WSS APIs, or configure the policy sets by using the administrative console to verify the signing information. To secure SOAP messages, you must complete the following signature tasks:

- Configure the signature information.
- Choose the algorithm methods for signature and signature verification.
- Verify the signature information.

### About this task

WebSphere Application Server uses the signing information for the default generator to sign parts of the message, and uses XML digital signature with existing algorithms such as RSA-SHA1 and HMAC-SHA1.

XML signature defines many methods for describing key information and enables the definition of a new method. XML canonicalization (C14N) is often needed when you use XML signature. Information can be represented in various ways within serialized XML documents. The C14N process is used to canonicalize XML information. Select an appropriate C14N algorithm because the information that is canonicalized depends on this algorithm.

The following table shows the required and optional binding information when the digital signature security constraint (integrity) is defined.

*Table 312. Signature verification parts. Use the signature verification parts to secure messages.*

| Verification parts | Description |
|---|---|
| keywords | Adds required signature parts as targets of verification by using keywords . Different message parts can be specified in the message protection for request on the generator side. Use the following keywords for the required signature verification parts:<br>• ADDRESSING_HEADERS<br>• BODY<br>• TIMESTAMP<br>The WS-Addressing headers are not encrypted but can be signed. |

*Table 312. Signature verification parts (continued). Use the signature verification parts to secure messages.*

| Verification parts | Description |
|---|---|
| xpath | Adds verification parts by using an XPath expression. |
| part | Adds the WSSVerifyPart object as a verification part. |
| header | Adds the header, specified by QName, as a verification part. |

For signature verification information, certain default behaviors occur. The simplest way to use the WSSVerification API is to use the default behavior.

The default values are defined by the WSS API for the digest method, the transform method, the security token, and the required verification parts.

*Table 313. Signature verification default behaviors. Several characteristics of the signature verification parts are configured by default.*

| Signature verification decisions | Default behavior |
|---|---|
| Which signature method to use (algorithm) | Sets the signature algorithm method. Both the data encryption and the signature and the canonicalization can be specified. The default signature method is RSA SHA1. WebSphere Application Server supports the following pre-configured signature methods:<br>• WSSVerification.RSA_SHA1: http://www.w3.org/2000/09/xmldsig#rsa-sha1<br>• WSSVerification.HMAC_SHA1: http://www.w3.org/2000/09/xmldsig#hmac-sha1<br>The DSA-SHA1 digital signature method (http://www.w3.org/2000/09/xmldsig#dsa-sha1) is not supported. |
| Which canonicalization method to use (algorithm) | Sets the canonicalization algorithm method. Both the data encryption and the signature and the canonicalization can be specified. The default signature method is EXC_C14N. WebSphere Application Server supports the following pre-configured canonicalization methods:<br>• WSSVerification.EXC_C14N: http://www.w3.org/2001/10/xml-exc-c14n#<br>• WSSVerification.C14N: http://www.w3.org/2001/10/xml-c14n# |
| Whether signature confirmation is required | If the WSSSignature API specifies that signature confirmation is required, then the WSSVerification API verifies the signature confirmation value in the response message that has the signature confirmation value attached to it when received. Signature confirmation is defined in the OASIS Web Services Security Version 1.1 specification.<br>The default signature confirmation is false. |
| Which security token to specify (securityToken) | Adds the securityToken object as a signature part. WebSphere Application Server sets the token information to use for verification.<br>WebSphere Application Server supports the following pre-configured tokens for signing:<br>• X.509 Token<br>• Derived Key Token<br>Information required for tokens include the class for the token, the callback handler information, and the name of the JAAS login module. |

### Procedure

1. To verify the signature in a SOAP message by using the WSSVerification API, first ensure that the application server is installed.
2. Use the WSSVerification API to set the message parts to be verified and to specify the algorithms in a SOAP message. The WSS API process for signature verification follows these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSConsumingContext instance from the WSSFactory instance.
   c. Ensures that WSSConsumingContext is called in the JAX-WS Provider implementation class. Due to the nature of the JAX-WS programming model, a JAX-WS provider needs to be implemented and must call the WSSConsumingContext to verify the SOAP message signature.
   d. Creates WSSVerification from the WSSFactory instance.
   e. Adds the part to be verified. If the digest method or the transform method are changed, create WSSVerifyPart and set it into WSSVerification.
   f. Sets the candidates of the canonicalization method, if the default is not appropriate.

g. Sets the candidates of the signature method, if the default is not appropriate.
h. Sets the candidate security token, if the default is not appropriate.
i. Calls the requireSignatureConfirmation(), if the signature confirmation is applied.
j. Adds WSSVerification to WSSConsumingContext.
k. Calls WSSConsumingContext.process() with the SOAP message context.

### Results

You have completed the steps to verify the signature for the consumer section of the bindings. If there is an error condition, a WSSException is provided. If successful, the WSSConsumingContext.process() is called, and Web Services Security is applied to the SOAP message.

### Example

The following example provides sample code that uses methods that are defined in the WSSVerification API:

```
// Get the message context
  Object msgcontext = getMessageContext();

// Generate the WSSFactory instance (step: a)
   WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSConsumingContext instance (step: b)
   WSSConsumingContext concont = factory.newWSSConsumingContext();

// Generate the certificate list
  String certpath = "c:/WebSphere/AppServer/etc/ws-security/samples/intca2.cer";
// The location of the X509 certificate file
  X509Certificate x509cert = null;
     try {
      InputStream is = new FileInputStream(certpath);
      CertificateFactory cf = CertificateFactory.getInstance("X.509");
      x509cert = (X509Certificate)cf.generateCertificate(is);
       } catch(FileNotFoundException e1){
        throw new WSSException(e1);
       } catch (CertificateException e2) {
        throw new WSSException(e2);
       }
      Set<Object> eeCerts = new HashSet<Object>();
       eeCerts.add(x509cert);
// Create the certificate store
   java.util.List<CertStore> certList = new java.util.ArrayList<CertStore>();
   CollectionCertStoreParameters certparam = new CollectionCertStoreParameters(eeCerts);
   CertStore cert = null;
   try {
    cert = CertStore.getInstance("Collection", certparam, "IBMCertPath");
   } catch (NoSuchProviderException e1) {
    throw new WSSException(e1);
   } catch (InvalidAlgorithmParameterException e2) {
    throw new WSSException(e2);
   } catch (NoSuchAlgorithmException e3) {
    throw new WSSException (e3);
   }
   if(certList != null ){
    certList.add(cert);
   }
// Generate the callback handler
   X509ConsumeCallbackHandler callbackHandler = new X509ConsumeCallbackHandler(
     "dsig-receiver.ks",
     "jks",
     "server".toCharArray(),
     certList,
     java.security.Security.getProvider("IBMCertPath")
   );

// Generate the WSSVerification instance (step: d)
  WSSVerification ver = factory.newWSSVerification(X509Token.class, callbackHandler);

// Set the part to be verified (step: e)
// DEFAULT: WSSVerification.BODY, WSSSignature.ADDRESSING_HEADERS,
// and WSSSignature.TIMESTAMP.

// Set the part in the SOAP header to be specified by QName (step: e)
     ver.addRequiredVerifyHeader(new QName("http://www.w3.org/2005/08/addressing", "MessageID"));

// Set the part to be specified by the keyword (step: e)
     ver.addRequiredVerifyPart(WSSVerification.BODY);
```

```
// Set the part to be specified by WSSVerifyPart (step: e)
  WSSVerifyPart verPart = factory.newWSSVerifyPart();
     verPart.setRequiredVerifyPart(WSSVerification.BODY);
     verPart.addAllowedDigestMethod(WSSVerifyPart.SHA256);
     ver.addRequiredVerifyPart(verPart);

// Set the part specified by XPath expression (step: e)
  StringBuffer sb = new StringBuffer();
        sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
            and local-name()='Envelope']");
        sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
            and local-name()='Body']");
        sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
            and local-name()='Ping']");
        sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
            and local-name()='Text']");
     ver.addRequiredVerifyPartByXPath(sb.toString());

// Set one or more canonicalization method candidates for verification (step: f)
// DEFAULT : WSSVerification.EXC_C14N
    ver.addAllowedCanonicalizationMethod(WSSVerification.C14N);
    ver.addAllowedCanonicalizationMethod(WSSVerification.EXC_C14N);

// Set one or more signature method candidates for verification (step: g)
// DEFAULT : WSSVerification.RSA_SHA1
    ver.addAllowedSignatureMethod(WSSVerification.HMAC_SHA1);

// Set the candidate security token to used for the verification (step: h)
  X509ConsumeCallbackHandler callbackHandler2 = getCallbackHandler2();
    ver.addToken(X509Token.class, callbackHandler2);

// Set the flag to require the signature confirmation (step: i)
   ver.requireSignatureConfirmation();

// Add the WSSVerification to the WSSConsumingContext (step: j)
  concont.add(ver);

//Validate the WS-Security header (step: k)
concont.process(msgcontext);
```

### What to do next

After verifying the signature and setting algorithm methods for the SOAP message, you can set either the digest method or the transform method. If you want to set these methods, use the WSSVerifyPart API, or configure policy sets using the administrative console.

*Verifying signed parts using the WSSVerifyPart API:*

To secure SOAP messages on the consumer side, use the Web Services Security APIs (WSS API) to configure the verify parts information for the consumer binding on the response consumer (client side). You can specify which algorithm methods and which parts of the SOAP message are to be verified. Use the WSSVerifyPart API to change the digest method or the transform method. The WSSVerifyPart API is part of the com.ibm.websphere.wssecurity.wssapi.verification package.

### Before you begin

To secure SOAP messages using the signing verification information, you must complete one of the following tasks:

- Configure the signature verification information using the WSSVerification API.
- Configure verify parts using the WSSVerifyPart API, as needed.

The WSSVerifyPart is used for specify the transform or digest methods for the verification. Use the WSSVerifyPart API or configure policy sets using the administrative console.

### About this task

WebSphere Application Server uses the signing information for the default consumer to verify the signed parts of the message. The WSSVerifyPart API is only supported on the response consumer (requester).

The following table shows the required verification parts when the digital signature security constraint (integrity) is defined:

*Table 314. Verify parts information. Use the verify parts to secure messages with signing verification information.*

| Verify parts information | Description |
|---|---|
| keyword | Sets the verify parts using the following keywords:<br>• BODY<br>• ADDRESSING_HEADERS<br>• TIMESTAMP<br><br>The WS-Addressing headers are not decrypted but can be signed and verified. |
| xpath | Sets the verify parts using an XPath expression. |
| header | Sets the header, specified by QName, as a required verify part. |

For signature verification, certain default behaviors occur. The simplest way to use the WSSVerification API is to use the default behavior (see the example code). The default values are defined by the WSS API for the signing algorithm and the canonicalization algorithm, and the verify parts.

*Table 315. Verify parts default behaviors. Several characteristics of verify parts are configured by default.*

| Verify parts decisions | Default behavior |
|---|---|
| Which keywords to specify | The different SOAP message parts to be signed and used for message protection. WebSphere Application Server supports the following keywords:<br>• WSSVerification.BODY<br>• WSSVerification.ADDRESSING_HEADERS<br>• WSSVerification.TIMESTAMP |
| Which transform method to use (algorithm) | Adds the transform method. The transform algorithm is specified within the <Transform> element and specifies the transform algorithm for the signature. The default transform method is TRANSFORM_EXC_C14N.<br><br>WebSphere Application Server supports the following pre-configured transform algorithms:<br>• WSSVerifyPart.TRANSFORM_EXC_C14N (the default value): http://www.w3.org/2001/10/xml-exc-c14n#<br>• WSSVerifyPart.TRANSFORM_XPATH2_FILTER: http://www.w3.org/2002/06/xmldsig-filter2<br>Use this transform method to ensure compliance with the Basic Security Profile (BSP).<br>• WSSVerifyPart.TRANSFORM_STRT10: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform<br>• WSSVerifyPart.TRANSFORM_ENVELOPED_SIGNATURE: http://www.w3.org/2000/09/xmldsig#enveloped-signature |
| Which digest method to use (algorithm) | Sets the digest algorithm method. The digest method algorithm that is specified within the <DigestMethod> element is used in the <SigningInfo> element. The default digest method is SHA1.<br><br>WebSphere Application Server supports the following digest method algorithms:<br>• WSSVerifyPart.SHA1: http://www.w3.org/2000/09/xmldsig#sha1<br>• WSSVerifyPart.SHA256: http://www.w3.org/2001/04/xmlenc#sha256<br>• WSSVerifyPart.SHA512: http://www.w3.org/2001/04/xmlenc#sha512 |

### Procedure

1. To verify signed parts by using the WSSVerifyPart API, first ensure that the application server is installed.
2. Use the Web Services Security API to verify the verification in a SOAP message. The WSS API process for verifying the signature follows these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSConsumingContext instance from the WSSFactory instance. Ensures that WSSConsumingContext is called in the JAX-WS Provider implementation class. Due to the nature of the JAX-WS programming model, a JAX-WS provider needs to be implemented and must call the WSSConsumingContext to verify the SOAP message signature.
   c. Creates the CallbackHandler to use for verification.

d. Create the WSSVerification object from the WSSFactory instance.
e. Creates WSSVerifyPart from the WSSFactory instance.
f. Sets the part to be verified, if the default is not appropriate.
g. Sets the candidates for the digest method, if the default is not appropriate.
h. Sets the candidates for the transform method, if the default is not appropriate.
i. Adds WSSVerifyPart to WSSVerification.
j. Adds WSSVerification to WSSConsumingContext.
k. Calls WSSConsumingContext.process() with the SOAPMessageContext.

### Results

You have completed the steps to verify to verify the signed parts on the consumer side. If there is an error condition when verifying the signing information, a WSSException is provided. If successful, the WSSConsumingContext.process() is called, and Web Services Security is verified for the SOAP message.

### Example

The following example provides sample code for the WSSVerification API process for verifying the signing information in a SOAP message:

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance (step: a)
   WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSConsumingContext instance (step: b)
   WSSConsumingContext concont = factory.newWSSConsumingContext();

// Generate the certificate list
   String certpath =
   "c:/WebSphere/AppServer/etc/ws-security/samples/intca2.cer";
// The location of the X509 certificate file
   X509Certificate x509cert = null;
      try {
          InputStream is = new FileInputStream(certpath);
          CertificateFactory cf = CertificateFactory.getInstance("X.509");
          x509cert = (X509Certificate)cf.generateCertificate(is);
      } catch(FileNotFoundException e1){
            throw new WSSException(e1);
      } catch (CertificateException e2) {
            throw new WSSException(e2);
      }

      Set<Object> eeCerts = new HashSet<Object>();
      eeCerts.add(x509cert);
// create certStore
      java.util.List<CertStore> certList = new
          java.util.ArrayList<CertStore>();
      CollectionCertStoreParameters certparam = new
          CollectionCertStoreParameters(eeCerts);
      CertStore cert = null;
      try {
         cert = CertStore.getInstance("Collection",
              certparam, "IBMCertPath");
      } catch (NoSuchProviderException e1) {
           throw new WSSException(e1);
      } catch (InvalidAlgorithmParameterException e2) {
           throw new WSSException(e2);
      } catch (NoSuchAlgorithmException e3) {
           throw new WSSException (e3);
      }
      if(certList != null ){
      certList.add(cert);
      }

// generate callback handler (step: c)
   X509ConsumeCallbackHandler callbackHandler = new
       X509ConsumeCallbackHandler(
                                  "dsig-receiver.ks",
                                  "jks",
                                  "server".toCharArray(),
                                  certList,
       java.security.Security.getProvider("IBMCertPath")
);
```

```
// Generate the WSSVerification instance (step: d)
   WSSVerification ver = factory.newWSSVerification(X509Token.class,
       callbackHandler);

// Set the part to be specified by WSSVerifyPart (step: e)
   WSSVerifyPart verPart = factory.newWSSVerifyPart();

// Set the part to be specified by the keyword (step: f)
   verPart.setRequiredVerifyPart(WSSVerification.BODY);

// Set the candidates for the digest method for verification (step: g)
// DEFAULT : WSSVerifyPart.SHA1
   verPart.addAllowedDigestMethod(WSSVerifyPart.SHA256);

// Set the candidates for the transform method for verification (step: h)
// DEFAULT : WSSVerifypart.TRANSFORM_EXC_C14N : String
   verPart.addAllowedTransform(WSSVerifyPart.TRANSFORM_STRT10);

// Set WSSVerifyPart to WSSVerification (step: i)
   ver.addRequiredVerifyPart(verPart);

// Add WSSVerification to WSSConsumingContext (step: j)
   concont.add(ver);

//Validate the WS-Security header (step: k)
concont.process(msgcontext);
```

### What to do next

You have completed configuring the signed part to be verified.

*Configuring response signature verification methods for the client:*

Use the WSSVerification and WSSVerifyPart APIs to choose the signing verification methods. The request signing verification methods include the digest algorithm and the transport methods.

### Before you begin

To complete configuration of the signature verification information to secure SOAP messages, you must perform the following algorithm tasks:

- Use the WSSVerification API to configure the canonicalization and signature methods.
- Use the WSSVerifyPart API to configure the digest and transform methods.

to configure the algorithm methods to use when configuring the client for request signing.

### About this task

The following table describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following website http://www.w3.org/TR/xmldsig-core.

*Table 316. Signing verification methods. Use signing verification information to secure messages.*

| Name of method | Purpose |
|---|---|
| Digest algorithm | Applies to the data after transforms are applied, if specified, to yield the <DigestValue> element. Signing the <DigestValue> element binds the resource content to the signer key. The algorithm selected for the client request sender configuration must match the algorithm selected in the client request receiver configuration. |
| Transform algorithm | Applies to the <Transform> element. |
| Signature algorithm | Specifies the Uniform Resource Identifiers (URI) of the signature verification method. |
| Canonicalization algorithm | Specifies the Uniform Resource Identifiers (URI) of the canonicalization method. |

After configuring the client to digitally sign the message, you must configure the client to verify the digital signature. You can use the WSS APIs or configure policy sets using the administrative console to verify the digital signature and to choose the verification and verify part algorithms. If using the WSS APIs to

configure, use the WSSVerification and WSSVerifyPart APIs to specify which digitally signed message parts to verify and to specify which algorithm methods to use when configuring the client for request signing.

The WSSVerification and WSSVerifyPart APIs perform the following steps to configure the signature verification and verify parts algorithm methods:

**Procedure**

1. For the consumer binding, the WSSVerification API specifies the signature methods to allow for the signature verification. WebSphere Application Server supports the following pre-configured signature methods:
   - WSSVerification.RSA_SHA1 (the default value): http://www.w3.org/2000/09/xmldsig#rsa-sha1
   - WSSVerification.HMAC_SHA1: http://www.w3.org/2000/09/xmldsig#hmac-sha1

   The DSA-SHA1 digital signature method (http://www.w3.org/2000/09/xmldsig#dsa-sha1) is not supported.
2. For the consumer binding, the WSSVerification API specifies the canonicalization method to allow for the signature verification. WebSphere Application Server supports the following pre-configured canonicalization methods by default:
   - WSSVerification.EXC_C14N (the default value): http://www.w3.org/2001/10/xml-exc-c14n#
   - WSSVerification.C14N: http://www.w3.org/2001/10/xml-c14n#
3. For the consumer binding, the WSSVerifyPart API specifies the digest method, as needed. WebSphere Application Server supports the following digest method algorithms for signed parts verification:
   - WSSVerifyPart.SHA1 (the default value): http://www.w3.org/2000/09/xmldsig#sha1
   - WSSVerifyPart.SHA256: http://www.w3.org/2001/04/xmlenc#sha256
   - WSSVerifyPart.SHA512: http://www.w3.org/2001/04/xmlenc#sha512
4. For the consumer binding, the WSSVerifyPart API specifies the transform method. WebSphere Application Server supports the following transform algorithms for verify parts:
   - WSSVerifyPart.TRANSFORM_EXC_C14N (the default value): http://www.w3.org/2001/10/xml-exc-c14n#
   - WSSVerifyPart.TRANSFORM_XPATH2_FILTER: http://www.w3.org/2002/06/xmldsig-filter2
   - WSSVerifyPart.TRANSFORM_STRT10: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
   - WSSVerifyPart.TRANSFORM_ENVELOPED_SIGNATURE: http://www.w3.org/2000/09/xmldsig#enveloped-signature

   For the WSS APIs, WebSphere Application Server does not support these algorithms:
   - http://www.w3.org/2002/07/decrypt#XML
   - http://www.w3.org/TR/1999/REC-xpath-19991116

**Results**

You have specified which method to use when verifying a digital signature when the client sends a message.

**Example**

The following example provides sample WSS API code that specifies the verification information, the body as a part to be verified, the HMAC_SHA1 as a signature method, C14N and EXC_C14N as the candidates of canonicalization methods, TRANSFORM_STRT10 as a transform method, and SHA256 as a digest method.

```
// Get the message context
   Object msgcontext = getMessageContext();
```

```
// Generate the WSSFactory instance
   WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSConsumingContext instance
   WSSConsumingContext concont = factory.newWSSConsumingContext();

// Generate the certificate list
   String certpath = "intca2.cer";
// The location of the X509 certificate file
      X509Certificate x509cert = null;
      try {
            InputStream is = new FileInputStream(certpath);
            CertificateFactory cf = CertificateFactory.getInstance("X.509");
           x509cert = (X509Certificate)cf.generateCertificate(is);
      } catch(FileNotFoundException e1){
          throw new WSSException(e1);
      } catch (CertificateException e2) {
          throw new WSSException(e2);
      }

      Set<Object> eeCerts = new HashSet<Object>();
      eeCerts.add(x509cert);
// Create the certStore
   java.util.List<CertStore> certList = new
         java.util.ArrayList<CertStore>();
   CollectionCertStoreParameters certparam = new
        CollectionCertStoreParameters(eeCerts);
   CertStore cert = null;
      try {
            cert = CertStore.getInstance("Collection",
                                         certparam,
                                        "IBMCertPath");
      } catch (NoSuchProviderException e1) {
          throw new WSSException(e1);
      } catch (InvalidAlgorithmParameterException e2) {
          throw new WSSException(e2);
      } catch (NoSuchAlgorithmException e3) {
          throw new WSSException (e3);
      }
      if(certList != null ){
            certList.add(cert);
      }

// Generate the callback handler
   X509ConsumeCallbackHandler callbackHandler = new
      X509ConsumeCallbackHandler(
                                "dsig-receiver.ks",
                                "jks",
                                "server".toCharArray(),
                                certList,
                                java.security.Security.getProvider(
                                      "IBMCertPath")
                                );

// Generate the WSSVerification instance
   WSSVerification ver = factory.newWSSVerification(X509Token.class,
                                                    callbackHandler);

// Set one or more candidates of the signature method used for
//    verification (step. 1)
// DEFAULT : WSSVerification.RSA_SHA1
      ver.addAllowedSignatureMethod(WSSVerification.HMAC_SHA1);

// Set one or more candidates of the canonicalization method used for
//    verification (step. 2)
// DEFAULT : WSSVerification.EXC_C14N
      ver.addAllowedCanonicalizationMethod(WSSVerification.C14N);
      ver.addAllowedCanonicalizationMethod(WSSVerification.EXC_C14N);

// Set the part to be specified by WSSVerifyPart
   WSSVerifyPart verPart = factory.newWSSVerifyPart();

// Set the part to be specified by the keyword
      verPart.setRequiredVerifyPart(WSSVerification.BODY);

// Set the candidates of digest methods to use for verification (step. 3)
// DEFAULT : WSSVerifypart.TRANSFORM_EXC_C14N : String
      verPart.addAllowedTransform(WSSVerifyPart.TRANSFORM_STRT10);

// Set the candidates of digest methods to use for verification (step. 4)
// DEFAULT : WSSVerifyPart.SHA1
      verPart.addAllowedDigestMethod(WSSVerifyPart.SHA256);

// Set WSSVerifyPart to WSSVerification
      ver.addRequiredVerifyPart(verPart);

// Add the WSSVerification to the WSSConsumingContext
```

```
   concont.add(ver);

// Validate the WS-Security header
concont.process(msgcontext);
```

### What to do next

You have completed configuring the signature verification algorithms. Next, configure the encryption or decryption algorithms, if not already configured. Or, configure the security token information, as needed.

*Signature verification methods using the WSSVerification API:*

You can verify the signing or signature information using the WSS API for the consumer binding. The signature and canonicalization algorithm methods are used for the generator binding. The WSSVerification API is provided in the com.ibm.websphere.wssecurity.wssapi.verification package.

To configure consumer signing information to protect message integrity, you must first digitally sign and then verify the signature for the SOAP messages. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network.

### Methods

Methods that are used for the signature verification include the:

**Signature method**
Sets the signature algorithm method.

**Canonicalization method**
Sets the canonicalization algorithm method.

The algorithm that is specified for the request generator configuration must match the algorithm that is specified for the response consumer configuration.

### Signature algorithms

The signature algorithms specify the signature verification algorithm that is used to sign the certificate. The signature algorithms specify the Uniform Resource Identifiers (URI) of the signature verification method. WebSphere Application Server supports the following pre-configured algorithms:

*Table 317. Signature verification algorithms. The algorithms include the signature methods.*

| Algorithm | Description |
|---|---|
| WSSVerification.HMAC_SHA1 | A URI of the signature algorithm, HMAC: http://www.w3.org/2000/09/xmldsig#hmac-sha1 |
| WSSVerification.RSA_SHA1 (the default value) | A URI of the signature algorithm, RSA: http://www.w3.org/2000/09/xmldsig#rsa-sha1 |

WebSphere Application Server does not support the algorithm for DSA-SHA1: http://www.w3.org/2000/09/xmldsig#dsa-sha1

### Canonicalization algorithms

The canonicalization algorithms specify the Uniform Resource Identifiers (URI) of the canonicalization method. WebSphere Application Server supports the following pre-configured algorithms:

*Table 318. Verification canonicalization algorithms. The algorithms include the canonicalization methods.*

| Algorithm | Description |
|---|---|
| WSSVerification.C14N | A URI of the inclusive canonicalization algorithm, C14N: http://www.w3.org/2001/10/xml-c14n# |

*Table 318. Verification canonicalization algorithms (continued). The algorithms include the canonicalization methods.*

| Algorithm | Description |
|---|---|
| WSSVerification.EXC_C14N (the default value) | A URI of the exclusive canonicalization algorithm EXC_C14N: http://www.w3.org/2001/10/xml-exc-c14n# |

The following example provides sample WSS API code that specifies the X.509 token security token for signature verification:

```
WSSFactory factory = WSSFactory.getInstance();
WSSConsumingContext concont = factory.newWSSConsumingContext();

// X509ConsumeCallbackHandler
X509ConsumeCallbackHandler callbackHandler = new
   X509ConsumeCallbackHandler("dsig-receiver.ks",
                              "jks",
                              "server".toCharArray(),
                              certList,
   java.security.Security.getProvider("IBMCertPath")46 );

// Set the verification component
// DEFAULT verification parts: Body, WS-Addressing header, and Timestamp
// DEFAULT data encryption algorithm: RSA-SHA1
// DEFAULT digest algorithm: SHA1
// DEFAULT canonicalization algorithm: exc-c14n
WSSVerification ver = factory.newWSSVerification(X509Token.class,
                                                 callbackhandler);
concont.add(ver);

// Validate the WS-Security header
concont.validate(msgctx);
```

*Choosing the verify parts methods using the WSSVerifyPart API:*

You can configure the signing verification information for the consumer binding using the WSS API. The transform algorithm and digest methods are used for the consumer binding. Use the WSSVerifyPart API to configure the algorithm methods. The WSSVerifyPart API is provided in the com.ibm.websphere.wssecurity.wssapi.verification package.

To configure consumer verify parts information to protect message integrity, you must first digitally sign and then verify the signature and signed parts for the SOAP messages. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network.

### Methods

Methods that are used for the signing information include the:

**Digest method**
Sets the digest method.

**Transform method**
Sets the transform algorithm method.

### Digest algorithms

The digest method algorithm is specified within the element is used in the <Digest> element. WebSphere Application Server supports the following pre-configured digest algorithms:

*Table 319. Verify parts digest methods. Use the verify parts to protect message integrity.*

| Digest method | Description |
|---|---|
| WSSVerifyPart.SHA1 (the default value) | A URI of the digest algorithm, SHA1: http://www.w3.org/2000/09/xmldsig#sha1 |
| WSSVerifyPart.SHA256 | A URI of the digest algorithm, SHA256: http://www.w3.org/2001/04/xmlenc#sha256 |
| WSSVerifyPart.SHA512 | A URI of the digest algorithm, SHA256: http://www.w3.org/2001/04/xmlenc#sha512 |

### Transform algorithms

The transform algorithm is specified within the <Transform> element and specifies the transform algorithm for the signed part. WebSphere Application Server supports the following pre-configured transform algorithms:

*Table 320. Verify parts transform methods. Use the verify parts to protect message integrity.*

| Digest method | Description |
|---|---|
| WSSVerifyPart.TRANSFORM_ENVELOPED_SIGNATURE | A URI of the transform algorithm, enveloped signature: http://www.w3.org/2000/09/xmldsig#enveloped-signature |
| WSSVerifyPart.TRANSFORM_STRT10 | A URI of the transform algorithm, STR-Transform: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform |
| WSSVerifyPart.TRANSFORM_EXC_C14N (the default value) | A URI of the transform algorithm, Exc-C14N: http://www.w3.org/2001/10/xml-exc-c14n# |
| WSSVerifyPart.TRANSFORM_XPATH2_FILTER | A URI of the transform algorithm, XPath2 filter: http://www.w3.org/2002/06/xmldsig-filter2 |

For the WSS APIs, WebSphere Application Server does not support the following transform algorithms:

- http://www.w3.org/TR/1999/REC-xpath-19991116
- http://www.w3.org/2002/07/decrypt#XML

The following example provides sample WSS API code that verifies the body using SHA256 as the digest method and TRANSFORM_EXC_14N and TRANSFORM_STRT10 as the transform methods:

```
// get the message context
Object msgcontext = getMessageContext();

// generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

// generate WSSConsumingContext instance
WSSConsumingContext concont = factory.newWSSConsumingContext();

// generate the cert list
String certpath = "intca2.cer";// The location of the X509
   certificate file X509Certificate x509cert = null;
try {
 InputStream is = new FileInputStream(certpath);
 CertificateFactory cf = CertificateFactory.getInstance("X.509");
 x509cert = (X509Certificate)cf.generateCertificate(is);
} catch(FileNotFoundException e1){
 throw new WSSException(e1);
} catch (CertificateException e2) {
 throw new WSSException(e2);
}

Set<Object> eeCerts = new HashSet<Object>();
eeCerts.add(x509cert);
// create certStore
java.util.List<CertStore> certList = new java.util.ArrayList<CertStore>();
CollectionCertStoreParameters certparam = new
      CollectionCertStoreParameters(eeCerts);
CertStore cert = null;
try {
 cert = CertStore.getInstance("Collection", certparam, "IBMCertPath");
} catch (NoSuchProviderException e1) {
 throw new WSSException(e1);
} catch (InvalidAlgorithmParameterException e2) {
 throw new WSSException(e2);
} catch (NoSuchAlgorithmException e3) {
 throw new WSSException (e3);
}
if(certList != null ){
 certList.add(cert);
}

// generate callback handler
X509ConsumeCallbackHandler callbackHandler = new
      X509ConsumeCallbackHandler(
  "dsig-receiver.ks",
  "jks",
  "server".toCharArray(),
  certList,
  java.security.Security.getProvider("IBMCertPath")
);
```

```
//generate WSSVerification instance
WSSVerification ver = factory.newWSSVerification(X509Token.class,
     callbackHandler);

//set one or more candidates of the signature method used for the
 //verification (step. 1)
// DEFAULT : WSSVerification.RSA_SHA1
ver.addAllowedSignatureMethod(WSSVerification.HMAC_SHA1);

//set one or more candidates of the canonicalization method used
 //for the verification (step. 2)
// DEFAULT : WSSVerification.EXC_C14N
ver.addAllowedCanonicalizationMethod(WSSVerification.C14N);
ver.addAllowedCanonicalizationMethod(WSSVerification.EXC_C14N);

//set the part to be specified by WSSVerifyPart
WSSVerifyPart verPart = factory.newWSSVerifyPart();

//set the part to be specified by the keyword
verPart.setRequiredVerifyPart(WSSVerification.BODY);

//set the candidates of digest methods to use for verification (step. 3)
// DEFAULT : WSSVerifypart.TRANSFORM_EXC_C14N
verPart.addAllowedTransform(WSSVerifyPart.TRANSFORM_EXC_C14N);
verPart.addAllowedTransform(WSSVerifyPart.TRANSFORM_STRT10);

//set the candidates of digest methods to use for verification (step. 4)
// DEFAULT : WSSVerifyPart.SHA1
verPart.addAllowedDigestMethod(WSSVerifyPart.SHA256);

//set WSSVerifyPart to WSSVerification
ver.addRequiredVerifyPart(verPart);

//add the WSSVerification to the WSSConsumingContext
concont.add(ver);

//validate the WS-Security header
concont.process(msgcontext);
```

*Validating the consumer token to protect message authenticity:*

The token consumer information is used on the consumer side to incorporate and validate the security token. The Username token, X509 tokens, and LTPA tokens by default are used for message authenticity.

**Before you begin**

The token processing and pluggable token architecture in the Web Services Security run time reuses the same security token interface and Java Authentication and Authorization Service (JAAS) Login Module from the Web Services Security APIs (WSS API). The same implementation of token creation and validation can be used in both the WSS API and the WSS SPI in the Web Services Security run time.

**Restriction:** The `com.ibm.wsspi.wssecurity.token.TokenConsumingComponent` interface is not used with JAX-WS web services. If you are using JAX-RPC web services, this interface is still valid.

Note that the key name (KeyName) element is not supported because there is no KeyName policy assertion defined in the current OASIS Web Services Security draft specification.

**About this task**

The JAAS callback handler (CallbackHandler) and the JAAS login module (LoginModule) are responsible for creating the security token on the generator side and validating (authenticating) the security token on the consumer side.

For example, on the generator side, the Username token is created by the JAAS LoginModule and using the JAAS CallbackHandler to pass the authentication data. The JAAS LoginModule creates the Username SecurityToken object and passes it to the Web Services Security run time.

Then, on the consumer side, the Username Token XML format is passed to the JAAS LoginModule for validation or authentication and the JAAS CallbackHandler is used to pass authentication data from the

Web Services Security run time to the LoginModule. After the token is authenticated, a Username SecurityToken object is created and passed it to the Web Services Security run time.

**Note:** WebSphere Application Server does not support a stackable login module with the WebSphere Application Server default login module implementation, meaning adding the login module before or after the WebSphere Application Server login module implementation. If you want to stack the login module implementations, you must develop the required login modules because there is no default implementation.

The com.ibm.websphere.wssecurity.wssapi.token package provided by WebSphere Application Server includes support for these classes:

- Security token (SecurityTokenImpl)
- Binary security token (BinarySecurityTokenImpl)

In addition, WebSphere Application Server provides the following pre-configured sub-interfaces for security tokens:

- Derived key token
- Security context token (SCT)
- Username token
- LTPA token propagation
- LTPA token
- X509PKCS7 token
- X509PKIPath token
- X509v3 token
- Kerberos v5 token

The Username token, the X.509 tokens, and the LTPA tokens are used by default for message authenticity. The derived key token and the X.509 tokens are used by default for signing and encryption.

The WSS API and WSS SPI are only supported on the client. To specify the security token type on the consumer side, you can also configure policy sets using the administrative console. You can also use the WSS APIs or policy sets for matching generator security tokens.

The default Login Module and Callback implementations are designed to be used as a pair, meaning both a generator and a consumer part. To use the default implementations, select the appropriate generator and consumer security token in a pair. For example, select `system.wss.generate.x509` in the token generator and `system.wss.consume.x509` in the token consumer when the X.509 token is required.

To configure the consumer-side security token, use the appropriate pre-configured token consumer interface from the WSS APIs to complete the following token configuration process steps:

**Procedure**

1. Generate the wssFactory instance.
2. Generate the wssConsumingContext instance.

   The WSSConsumingContext interface stores the components for consuming Web Services Security (WS-Security), such as verification, decryption, the security token, and the time stamp. When the validate() method is called, all of these components are validated.
3. Create the consumer-side components, such as the WSSVerification and the WSSDecryption objects.
4. Specify a JAAS configuration by specifying the name of the JAAS login configuration. The Java Authentication and Authorization Service (JAAS) configuration specifies the name of the JAAS configuration. The JAAS configuration specifies how the token logs in on the consumer side. Do not

remove the predefined system or application login configurations. However, within these configurations, you can add module class names and specify the order in which WebSphere Application Server loads each module.

5. Specify a token consumer class name. The token consumer class name specifies the required information to validate the SecurityToken. The Username token, the X.509 tokens, and the LTPA tokens are used by default for message authenticity.
6. Specify the settings for the callback handler by specifying a callback handler class name and also specifies the callback handler keys. This class name is the name of the callback handler implementation class that is used for the plug-in to the security token framework.

   WebSphere Application Server provides the following default callback handler implementations for the consumer side:

   **com.ibm.websphere.wssecurity.callbackhandler.PropertyCallback**
   This class is a callback for handling the name-value pair in elements in the Web Services Security (WS-Security) configuration XMI files.

   **ccom.ibm.websphere.wssecurity.callbackhandler.UNTConsumeCallbackHandler**
   This class is a callback handler for the Username token on the consumer side. This instance is used to set into WSSConsumingContext object to validate a Username token. Use this implementation for a Java Platform, Enterprise Edition (Java EE) application client only.

   **com.ibm.websphere.wssecurity.callbackhandler.X509ConsumeCallbackHandler**
   This class is a callback handler that is used to validate the X.509 certificate that is inserted in the Web Services Security header within the SOAP message as a binary security token on the consumer side. This instance is used to generate the WSSVerification object and WSSDecryption objects, set the objects into WSSConsumingContext object to validate the X.509 binary security tokens. A keystore and a key definition are required for this callback handler. If you use this implementation, a key store password, path, and type must have been provided on the generator side.

   **com.ibm.websphere.wssecurity.callbackhandler.LTPAConsumeCallbackHandler**
   This class is a callback handler for the Lightweight Third Party Authentication (LTPA) tokens on the consumer side. This instance is used to generate the WSSVerification and WSSDecryption objects to validate an LTPA token.

   This callback handler is used to validate the LTPA security token inserted in the Web Services Security header within the SOAP message as a binary security token. However, if the user name and password are specified, WebSphere Application Server authenticates the user name and password to obtain the LTPA security token rather than obtaining it from the Run As Subject. Use this callback handler only when the web service is acting as a client on the application server. It is recommended that you do not use this callback handler on a Java EE application client. If you use this implementation, a basic authentication user ID and password must have been provided on the generator side.

   **com.ibm.websphere.wssecurity.callbackhandler.KRBTokenConsumeCallbackHandler**
   This class is a callback handler for the Kerberos v5 token on the consumer side. This instance is used to set the WSSConsumingContext object to consume the Kerberos v5 AP-REQ as a binary security token. The instance is also used to generate the WSSVerification and WSSDecryption objects to use the Kerberos session key or derived key in the SOAP message verification and decryption.
7. If a X.509 token is specified, additional token information is also specified.

*Table 321. Information for the X.509 token. Use the X.509 token to authenticate messages.*

| | |
|---|---|
| keyStoreRef | The reference name of the keystore that is used for the key locator. |
| keyStorePath | The keystore file path from which the keystore is loaded, if needed. It is recommended that you use the `${USER_INSTALL_ROOT}` in the path name as this variable expands to the WebSphere Application Server path on your machine. This path is required when you use the X.509 tokens callback handler implementations. |

*Table 321. Information for the X.509 token (continued). Use the X.509 token to authenticate messages.*

| | |
|---|---|
| keyStorePassword | The password that is used to check the integrity of the keystore, or the keystore password that is used to unlock the keystore and to access the keystore file. The keystore and its configuration are used for some of the default callback handler implementations that are provided by WebSphere Application Server. |
| keyStoreType | The keystore type of keystore that is used for the key locator. This selection indicates the format that is used by the keystore file. The following values are available for selection:<br>**JKS** Use this option if the keystore uses the Java Keystore (JKS) format.<br>**JCEKS** Use this option if the Java Cryptography Extension is configured in the software development kit (SDK). The default IBM JCE is configured in WebSphere Application Server. This option provides stronger protection for stored private keys by using Triple DES encryption.<br>**JCERACFKS** Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).<br>**PKCS11KS (PKCS11)** Use this format if your keystore uses the PKCS#11 file format. Keystores using this format might contain RSA keys on cryptographic hardware or might contain encrypt keys that use cryptographic hardware to ensure protection.<br>**PKCS12KS (PKCS12)** Use this option if your keystore uses the PKCS#12 file format. |
| alias | The key alias name. The key alias is used by the key locator to find the key within the keystore file. |
| keyPassword | The key password that is used for recovering the key. This password is needed to access the key object within the keystore file. |
| keyName | The name of the key. For digital signatures, the key name is used by the request generator or response consumer signing information to determine which key is used to digitally sign the message. For encryption, the key name is used to determine the key used for encryption. The key name must be a fully qualified, distinguished name (DN). For example, `CN=Bob,O=IBM,C=US`. |
| trustAnchorPath | The file path from which the trust anchor is loaded. |
| trustAnchorType | The type of trust anchor. |
| trustAnchorPassword | The password that is used to check the integrity of the trust anchor or the password used to unlock the keystore. |
| certStores | A list of certificate stores. A collection certificate store includes a list of untrusted, intermediary certificates and certificate revocation lists (CRLs). The collection certificate store is used to validate the certificate path of the incoming X.509-formatted security tokens. |
| provider | The security provider. |

The following can be specified for a X.509 token:

a. Without any keystore.

b. With a trust anchor. A trust anchor specifies a list of keystore configurations that contain trusted root certificates. These configurations are used to validate the certificate path of incoming X.509-formatted security tokens. For example, when you select the trust anchor or the certificate store of a trusted certificate, you must configure the trust anchor and the certificate store before setting the certificate path.

c. With a keystore that is used for the key locator.

First, you must have created the keystore file, by using a key tool utility, for example. The keystore is used to retrieve the X.509 certificate. This entry specifies the password that is used to access the keystore file. Keystore objects within trust anchors contain trusted root certificates that are used by the CertPath API to validate the trustworthiness of a certificate chain. The names of the trust anchor and the collection certificate store are created in the certificate path under your token consumer.

d. With a keystore that is used for the key locator and the trust anchor.

e. With a map that includes key-value pairs. For example, you might specify the value type name and the value type Uniform Resource Identifier (URI). The value type specifies the namespace URI of the value type for the consumer token, and represents the token type of this class:

**ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3**

Specifies an X.509 certificate token.

**ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1**

Specifies X.509 certificates in a public key infrastructure (PKI) path. This callback handler is used to create X.509 certificates encoded with the PkiPath format. The certificate is inserted in the Web Services Security header within the SOAP message as a binary security token. A keystore is required for this callback handler. A CRL is not supported by the callback handler; therefore, the collection certificate store is not required or used. If you use this implementation, you must provide a key store password, path, and type on this panel.

**ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7**

Specifies a list of X.509 certificates and certificate revocation lists in a PKCS#7 format. This callback handler is used to create X.509 certificates encoded with the PKCS#7 format. The certificate is inserted in the Web Services Security header in the SOAP message as a binary security token. A keystore is required for this callback handler. You can specify a certificate revocation list (CRL) in the collection certificate store. The CRL is encoded with the X.509 certificate in the PKCS#7 format. If you use this implementation, you must provide a key store password, path, and type.

For some tokens, WebSphere Application Server provides a predefined local name for the value type. When you specify the following local name, you do not need to specify a value type URI:

**ValueType: http://www.ibm.com/websphere/appserver/tokentype/5.0.2**

For an LTPA token, you can use `LTPA` for the value type local name. This local name causes `http://www.ibm.com/websphere/appserver/tokentype/5.0.2` to be specified for the value type Uniform Resource Identifier (URI).

**ValueType: http://www.ibm.com/websphere/appserver/tokentype/5.0.2**

For LTPA token propagation, you can use `LTPA_PROPAGATION` for the value type local name. This local name causes`http://www.ibm.com/websphere/appserver/tokentype` to be specified for the value type Uniform Resource Identifier (URI).

8. If the Username token is specified as the token consumer class name, the following token information can be specified:
   a. Whether to specify the nonce.

      This option indicates whether a Nonce is included for the token consumer. Nonce is a unique, cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of Username tokens. Nonce is valid only when the validating token type is a Username token, and it is available only for the response consumer binding.

   b. Specifies the keyword of the time stamp. This option indicates whether to verify a time stamp in the Username token. The time stamp is valid only when the incorporated token type is a Username token.

   c. Specifies a map that includes key-value pairs. For example, you might specify the value type name and the value type Uniform Resource Identifier (URI). The value type specifies the namespace URI of the value type for the consumer token, and represents the token type of this class:

      **URI value type: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken**

      Specifies a Username token.

9. If a Kerberos v5 token is specified as the token generator class name, the following token information can be specified:

| Token Information | Description | Default Value |
|---|---|---|
| tokenValueType | Kerberos token value type in QName defined by Oasis Kerberos Token Profile v1.1 specification. | http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ |

| Token Information | Description | Default Value |
|---|---|---|
| requireDKT | A boolean value to require a derived key for message protection. | false |
| clabel | The client label for the derived key. | WS-SecureConversation<br><br>Specify null to use the default value. |
| slabel | The service label for the derived key. | WS-SecureConversation<br><br>Specify null to use the default value. |
| keylen | The length of the derived key. | 16<br><br>Specify zero to use the default value |
| supportTokenRequireSHA1 | A boolean value to require a SHA1 key that is used in subsequent request messages when the Kerberos token is used as a supporting token. | false<br><br>SHA1 key is consumed only if the supporting Kerberos token is protected. If set to true, the SHA1 key is always consumed. |
| decComponent | An instance of WSSDecryption . | Set decComponent and verComponent to null to initialize this first for either the decryption or verification component. Then, use the initialized component only in the callback handler constructor for the second component. |
| verComponent | An instance of WSSVerfication. | Set decComponent and verComponent to null to initialize this first for either the decryption or verification component. Then, use the initialized component only in the callback handler constructor for the second component. |

Additional token value types are defined in the OASIS Kerberos Token Profile v1.1 specification. Specify the token value type as the local name. It is not necessary to specify the value type URI for the Kerberos v5 token.

- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ1510
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ1510
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ4120
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ4120

10. If secure conversation is used for message protection, then the following information must be specified:

| Information | Description |
|---|---|
| EncryptionAlgorithm | This determines the key size. |
| cLabel | The client label used when creating the derived key. |
| sLabel | The server label used when creating the derived key. |

11. Set the components into the wssConsumingContext object.
12. Invoke the wssConsumingContext.process() method.

### Results

Using the WSS APIs, you have configured the token consumer.

### What to do next

You must specify a similar token generator configuration, if not already completed.

*Configuring the consumer security tokens using the WSS API:*

You can secure the SOAP messages, without using policy sets, by using the Web Services Security APIs. To configure the token on the consumer side, use the Web Services Security APIs (WSS API). The consumer security tokens are part of the com.ibm.websphere.wssecurity.wssapi.token interface package.

### Before you begin

The pluggable token framework in WebSphere Application Server has been redesigned so that the same framework from the WSS API can be reused. The same implementation of creating and validating security token can be used both for the Web Services Security run time and for the WSS API application code. The redesigned framework also simplifies the SPI programming model and will make it easier to add security token types.

You can use the WSS API or you can configure the tokens by using the administrative console. To configure tokens, you must have completed the following token task: configure the generator tokens, as needed.

### About this task

On the generator side, the JAAS CallbackHandler and JAAS LoginModule are responsible for creating the security token. The token is created by using the JAAS LoginModule and by using JAAS CallbackHandler to pass authentication data. Then, the JAAS LoginModule creates the securityToken object, such as the UsernameToken, and passes it to the Web Services Security run time.

On the consumer side, the XML format is passed to the JAAS LoginModule for validation or authentication. then the JAAS CallbackHandler is used to pass authentication data from the Web Services Security run time to the LoginModule. After the token is authenticated and a security token object is created, then the token is passed it to the Web Services Security run time.

When using the WSS API for consumer token validation, certain default behaviors occur. The simplest way to use the WSS API is to use the default JAAS login module and callback handler. The example uses the default for them so the example does not specify the JAAS login module name.

The simplest way to use the WSS API is to use the default behavior (see the example code). The WSS API provide defaults for the token type, the token value, and the JAAS configuration name. The default token behaviors include:

*Table 322. Default token behaviors. Several token characteristics are configured by default.*

| Consumer token decisions | Default behavior |
|---|---|
| Which token type to use | The token type specifies which type of token to use for signing and validating messages. The X.509 token is the default token type.<br><br>WebSphere Application Server provides the following pre-configured consumer token types:<br>• Security context token<br>• Derived key token<br>• X509 tokens<br><br>You can also create custom token types, as needed. |

*Table 322. Default token behaviors (continued). Several token characteristics are configured by default.*

| Consumer token decisions | Default behavior |
|---|---|
| What JAAS login configuration name to specify | The JAAS login configuration name specifies which JAAS login configuration name to use. |
| Which configuration type to use | The JAAS login module configuration type. Only the pre-configured consumer configuration types can be used for consumer token types. |

The SecurityToken class (com.ibm.websphere.wssecurity.wssapi.token.SecurityToken) is the generic token class and represents the security token that has methods to get the identity, XML format, and cryptographic keys. Using the SecurityToken class, you can apply both the signature and encryption to the SOAP message. However, to apply both, you must have two SecurityToken objects, one for the signature and one for encryption, respectively.

The following token types are subclasses of the generic security token class:

*Table 323. Subclasses of the SecurityToken. Use the subclasses to represent the security token.*

| Token type | JAAS login configuration name |
|---|---|
| Security context token | system.wss.consume.sct |
| Derived key token | system.wss.consume.dkt |

The following token types are subclasses of the binary security token class:

*Table 324. Subclasses to the BinarySecurityToken. Use the subclasses to represent the binary security token.*

| Token type | JAAS login configuration name |
|---|---|
| X.509 token | system.wss.consume.x509 |
| X.509 PKI Path token | system.wss.consume.pkiPath |
| X.509 PKCS7 token | system.wss.consume.pkcs7 |

**Notes:**

- For each JAAS login token consumer configuration name, there is a respective token generator configuration name. For example, for the X509Token, the respective token generator configuration name is system.wss.generate.x509.
- The LTPA and LTPA propagation tokens are only available to a requester that is running as a server-based client. The LTPA and LTPA propagation tokens are not supported for the Java SE 6 or Java EE application client.

To validate the X509Token to the SOAP message on the consumer side, the <X509Token> element must be in the <wsse:Security> element.

**Procedure**

1. To validate the securityToken package, com.ibm.websphere.wssecurity.wssapi.token, first ensure that the application server is installed.
2. *If using the default values*, configures the tokens for the Web Services Security token consumer process. , for each token type, the process is similar to the following token consumer process:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSConsumingContext instance from the WSSFactory instance. Note that the WSSConsumingContext must always be called in a JAX-WS client application.
   c. Creates a JAAS CallbackHandler with information that is required to validate the security token. Review the token class information for which parameters are required or optional. For example, for an X.509 token, you could configure the following:

*Table 325. X.509 token options. Use the X.509 configuration options to control the behavior of the token.*

| | |
|---|---|
| keyStoreRef | Indicates the reference name of the keystore that is stored in the cryptographic card. It can be specified when the card is set to the hardware. |

*Table 325. X.509 token options (continued). Use the X.509 configuration options to control the behavior of the token.*

| | |
|---|---|
| keyStorePath | Indicates the path of the keystore file. It is not necessary to specify the keyStorePath if the keyStoreRef is set. |
| keyStorePassword | Indicates the password of the keystore file. |
| keyStoreType | Indicates the type of keystore file. |
| alias | Indicates the alias of the key. |
| keyPassword | Indicates the password of the key. |
| keyName | Indicates the subject name of the key. |

d. Sets the callback handler into WSSDecryption, WSSVerification, or WSSConsumingContext.

e. If the callback handler is set into the WSSDecryption or WSSVerification, adds either one into WSSConsumingContext.

f. Calls WSSConsumingContext.process().

3. *If using other than the default values*, configures the tokens for the Web Services Security token consumer process. For each token type, the process is similar to the following token consumer process:

   a. If you do not use the default JAAS login module and callback handler, you need to prepare a custom one and register the name of JAAS login configuration using the administrative console in advance.

   b. Uses WSSFactory.getInstance() to get the WSS API implementation instance.

   c. Creates the WSSConsumingContext instance from the WSSFactory instance. Note that the WSSConsumingContext must always be called in a JAX-WS client application.

   d. Creates a callback handler with information that is required to validate the security token. Review the token class information for which parameters are required or optional. For example, for a X.509 token, you can configure the following:

*Table 326. X.509 token options. Use the X.509 configuration options to control the behavior of the token.*

| | |
|---|---|
| keyStoreRef | Indicates the reference name of the keystore that is stored in the cryptographic card. It can be specified when the card is set to the hardware. |
| keyStorePath | Indicates the path of the keystore file. It is not necessary to specify the keyStorePath if the keyStoreRef is set. |
| keyStorePassword | Indicates the password of the keystore file. |
| keyStoreType | Indicates the type of keystore file. |
| alias | Indicates the alias of the key. |
| keyPassword | Indicates the password of the key. |
| keyName | Indicates the subject name of the key. |

   e. Sets JAAS configuration name and callback handler into WSSDecryption or WSSVerification, or WSSConsumingContext.

   f. If JAAS configuration name and callback handler are set into the WSSDecryption or WSSVerification, adds either one into WSSConsumingContext.

   g. Calls WSSConsumingContext.process().

**Results**

If there is an error condition, a WSSException is provided. If successful, the WSSConsumingContext.process() is called, and the security token on the consumer side is validated (authenticated).

**Example**

The following sample code provides the WSS API example code for decryption using the default JAAS login module and callback handler:

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance (step: a)
   WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSConsumingContext instance (step: b)
   WSSConsumingContext gencont = factory.newWSSConsumingContext();

// Generate the callback handler (step: c)
   X509ConsumeCallbackHandler callbackHandler = new
        X509ConsumeCallbackHandler(
                                    "",
                                    "enc-sender.jceks",
                                    "jceks",
                                    "storepass".toCharArray(),
                                    "alice",
                                    "keypass".toCharArray(),
                                    "CN=Alice, O=IBM, C=US");

// Generate the WSSDecryption instance (step: d)
   WSSDecryption dec = factory.newWSSDecryption(X509Token.class,
                                                callbackHandler);

// Add WSSDecryption to WSSConsumingContext (step: e)
   concont.add(dec);

// Validate the WS-Security header (step: f)
concont.process(msgcontext);
```

### What to do next

For each token type, configure the token using the WSS APIs or using the administrative console. Next, specify the similar generator tokens if you have not done so.

If both the generator and consumer tokens are configured, continue securing SOAP messages at the response consumer using the WSS APIs or configure the tokens using the administrative console.

If both the generator and consumer tokens are configured, continue securing SOAP messages either by verifying the signature or by decrypting the message, as needed. You can use either the WSS APIs or the administrative console to secure the SOAP messages.

#### *Configuring Web Services Security using the WSS APIs:*

The Web Services Security application programming interfaces (WSS API) provide support for securing SOAP message.

### Before you begin

Web Service Security supports the following programming models:

- Programming API for securing SOAP message with Web Services Security (WSS API).

  The API programming model design has been redesigned. The new design is an interface-based programming model and is based on Web Services Security Version 1.1 standards but the design also includes support for Web Services Security Version 1.0 for securing the SOAP message. The WSS API programming model implementation is a simplified version, which is based on an early draft proposal of JSR-183, which is the JSR for defining Java API binding for Web Services Security. By design, because the application code is programmed to the interface, any application code that is programmed with the open source implementation should be able to run on the WebSphere Application Server with minimal changes or no changes at all.
- Service Programming Interfaces (SPI) for a service provider

  Similarly, the Web Services Security run time token generation and token consuming SPI have been redesign so that the same security token interface and JAAS Login Module implementation can be used for both the WSS API and the SPI. The WSS SPI for the service provider extend the security token types and provide keys and deriving keys for signing, signature verification, encryption and decryption.

**Usage statement:** You must use the IBM implementation of the WS-Security standards in the context of web services.

**About this task**

These programming models extend the following functions :

- Security token types and deriving keys for signing
- Signature and verification
- Encryption and decryption

The following figure demonstrates how to use the simplified WSS APIs to secure a SOAP message by using XML digital signature and XML encryption.

The configuration model for web services has also been redesigned from a deployment descriptor model to a policy set model. The configuration programming model is based on configuring policy sets using a security policy to specify security constraints.

The functions provided by the policy set configurations are the same as the functions supported by the WSS API for the Web Services Security run time. However, the security policy that is defined using policy sets has a higher priority over the WSS API. When the WSS API and the policy set are both used in the application, the default behavior is for the security policy from the policy set to be enforced and the WSS API to be ignored. To use the WSS API in the application, you must make sure that there is no policy set attached to the application or to the application resources, or make sure there is no security policy in the attached policy set.

Web Service Security can be enabled by either using a policy set that is configured by using the administrative console, or by using the WSS API for configuration.

Using the WSS API, complete the following high-level steps to secure the SOAP message:

**Procedure**

1. Use the WSSSignature API to configure the signing information for the request generator (client side) binding. Different message parts can be specified in the message protection for a request on the generator side. The default required parts are BODY, ADDRESSING_HEADERS, and TIMESTAMP.

   The WSSSignature API also specifies the different algorithm methods to be used with the signature for message protection. The default signature method is RSA_SHA1. The default canonicalization method is EXC_C14N.
2. Use the WSSSignPart API if you want to add or change the signed parts to be used for message protection. The default signed parts are WSSSignature.BODY, WSSSignature.ADDRESSING_HEADERS, and WSSSignature.TIMESTAMP.

   The WSSSignPart API also specifies the different algorithm methods to be used if you added or changed the signed parts. The default digest method is SHA1. The default transform method is TRANSFORM_EXC_C14N. For example, use the WSSSignPart API if you want to generate the signature for the SOAP message using the SHA256 digest method instead of the default value of SHA1.
3. Use the WSSEncryption API to configure the encryption information on the request generator side. The encryption information on the generator side is used for encrypting an outgoing SOAP message for the request generator (client side) bindings. The default targets of encryption are BODY_CONTENT and SIGNATURE

   The WSSEncryption API also specifies the different algorithm methods to be used to protect message confidentiality. The default data encryption method is AES128. The default key encryption method is KW_RSA_OAEP.

4. Use the WSSEncryptPart API if you want to add or change the encrypted parts to be used for message confidentiality. For example, if you want to change the data encryption method from the default value of AES128 to TRIPLE_DES.

   No algorithm methods are required for encrypted parts.
5. Use the WSS API to attach the token on the generator side. The requirements for the security token depend on the token type. The JAAS Login Module and the JAAS CallbackHandler are responsible for creating the security token on the generator side. Different stand-alone tokens can be sent in request or response. The default token is the X509Token. The other token that can be used for signing is the DerivedKeyToken, which is used only with Web Services Secure Conversation (WS-SecureConversation).
6. Use the WSSVerification API to verify the signature for the response consumer (client side) binding. Different message parts can be specified in the message protection for a response on the consumer side. The required targets for verification are BODY, ADDRESSING_HEADERS, and TIMESTAMP.

   The WSSVerification API also specifies the different algorithm methods to be used for verifying the signature and for message protection. The default signature method is RSA_SHA1. The default canonicalization method is EXC_C14N.
7. Use the WSSVerifyPart API to add or change the verify signed parts to be used for message protection. The required verify parts are WSSVerification.BODY, WSSVerification.ADDRESSING_HEADERS, and WSSVerification.TIMESTAMP.

   The WSSVerifyPart API also specifies the different algorithm methods to be used if you added or changed the verification parts. The default digest method is SHA1. The default transform method is TRANSFORM_EXC_C14N.
8. Use the WSSDecryption API to configure the decryption information for the response consumer (client side) binding. The decryption information on the consumer side is used for decrypting an incoming SOAP message. The default targets of decryption are BODY_CONTENT and SIGNATURE. The default data encryption method is AES128. The default key encryption method is KW_RSA_OAEP.

   No algorithm methods are required for decryption.
9. Use the WSSDecryptPart API if you want to add or change the decrypted parts to be used for message confidentiality. For example, if you want to change the data encryption method from the default value of AES128 to TRIPLE_DES.

   No algorithm methods are required for decrypted parts.
10. Use the WSS API to configure the token on the consumer side. The requirements for the security token depend on the token type. The JAAS Login Module and the JAAS CallbackHandler are responsible for validating (authenticating) the security token on the consumer side. Different stand-alone tokens can be sent in request or response.

    The WSS API adds the information for the candidate token that is used for decryption. The default token is X509Token.

**Results**

**What to do next**

The Web Services Security run time token generation and token consuming Service Programming Interfaces (SPI) have been redesign so that the same Security Token interface and JAAS Login Module implementation can be used in both the WSS API and the SPI. See the SPI information for detail descriptions.

*Web Services Security APIs:*

The Web Services Security programming model provides application programming interfaces (WSS API) for securing the SOAP message. The WSS API model is based on Web Services Security Version 1.1 standards but also includes support for Web Services Security Version 1.0.

The Web Services Security APIs (WSS APIs) can generate and process the following SOAP-related bindings for XML security:

- XML signature and signature verification
- XML encryption and decryption

The token processing and pluggable token architecture in the Web Service Security run time has been redesign to reuse the same Security Token interface and the JAAS Login Module as those used for the WSS APIs.

The following table lists the WSS API interfaces that are provided with WebSphere Application Server and used to configure signing and encryption information in the SOAP bindings for the generator and consumer bindings.

*Table 327. WSS API interfaces. Use the interfaces to configure security information in the bindings.*

| WSS API interfaces | Description |
|---|---|
| WSSDecryption | Package: com.ibm.websphere.wssecurity.wssapi.decryption<br><br>This interface is responsible for specifying decryption. The default values for decryption include:<br>• Targets: BODY_CONTENT, SIGNATURE<br>• Data encryption method: AES128<br>• Key encryption method: KW_RSA_OAEP<br>• Security token: X.509 |
| WSSDecryptPart | Package: com.ibm.websphere.wssecurity.wssapi.decryption<br><br>This interface is responsible for adding decrypted parts, as needed. If specified, the default values for decrypted parts include:<br>• Security token: X.509<br>• Transform method: N/A (not applicable) |
| WSSEncryption | Package: com.ibm.websphere.wssecurity.wssapi.encryption<br><br>This interface is responsible for the encryption component. The default values for encryption include:<br>• Targets: BODY_CONTENT, SIGNATURE<br>• Data encryption method: AES128<br>• Key encryption method: KW_RSA_OAEP<br>• Security token: X.509<br>• refType: SecurityToken.REF_KEYID<br>• mtomOptimize: false |
| WSSEncryptPart | Package: com.ibm.websphere.wssecurity.wssapi.encryption<br><br>This interface is responsible for adding encrypted parts, as needed. If specified, the default values for encrypted parts include:<br>• Transform method: N/A (not applicable) |
| WSSSignature | Package: com.ibm.websphere.wssecurity.wssapi.signature<br><br>This interface is responsible for specifying the signature. The default values for signature include:<br>• Targets: BODY, ADDRESSING_HEADERS, TIMESTAMP<br>• Signature method: RSA_SHA1<br>• Canonicalization method: EXC_C14N<br>• Security token: X.509<br>• Type of token reference: SecurityToken.REF_STR |
| WSSSignPart | Package: com.ibm.websphere.wssecurity.wssapi.signature<br><br>This interface is responsible for adding signed parts, as needed. If specified, the default values for signed parts include:<br>• Transform method : TRANSFORM_EXC_C14N<br>• Digest method: SHA1 |

*Table 327. WSS API interfaces (continued). Use the interfaces to configure security information in the bindings.*

| WSS API interfaces | Description |
|---|---|
| WSSVerification | Package: com.ibm.websphere.wssecurity.wssapi.verification<br><br>This interface is responsible for specifying the signature verification. The default values for verification include:<br>• Targets: BODY, ADDRESSING_HEADERS, TIMESTAMP<br>• Signature method: RSA_SHA1<br>• Canonicalization method: EXC_C14N<br>• Security token: X.509 |

Also see the information about pre-configured generator and consumer tokens.

*Web Services Security configuration considerations when using the WSS API:*

To secure Web Services Security for WebSphere Application Server, you can specify several different configurations using the Web Services Security APIs (WSS API). The Web Services Security specification provides a flexible way to secure web services messages using XML digital signature, XML encryption, and attaching security tokens. You can enable Web Services Security by either configuring a policy set or by using the Web Services Security APIs (WSS API). The implementation for WSS API has default values for which message parts are to be signed or encrypted. The default values for the WSS APIs help end users to enable Web Services Security quickly.

Different message parts can be specified in the message protection for request or response, and different stand-alone tokens can be sent in request or response. However, there is only one symmetric or one asymmetric binding assertion to describe the token type and the algorithm that is used for message protection.

Using the WSS API, you can override any default values. However, when you alter the protection parts, note that all the default protection parts are cleared. For example, if you specify that you want to encrypt the Username token instead of the default X.509 token, all the default values of the encrypting protection parts are cleared.

The following table shows an example of the relationships between each of the configurations:

*Table 328. Request generator and response consumer configurations. Use the table to determine the mapping between the configurations and the default values.*

| Type of configuration | Configuration name | Configurations and default values |
|---|---|---|
| Request generator | Signing information | • Canonicalization method: WSSSignature.EXC_C14N<br>• Signature method: WSSSignature.RSA_SHA1<br>• Digest method: WSSSignPart.SHA1<br>• Transform method: WSSSignPart.TRANSFORM_EXC_C14N<br>• Signed part - Body: WSSSignature.BODY<br>• Signed part - Addressing: WSSSignature.ADDRESSING_HEADERS<br>• Signed part - Timestamp: WSSSignature.TIMESTAMP<br>• Token reference: SecurityToken.REF_STR<br>• Token - Value type: X509Token.ValueType<br>• Token - JAAS login configuration name: system.wss.generate.x509 |

*Table 328. Request generator and response consumer configurations (continued). Use the table to determine the mapping between the configurations and the default values.*

| Type of configuration | Configuration name | Configurations and default values |
|---|---|---|
| Response consumer | Signature verification information | • Canonicalization method: WSSVerification.EXC_C14N<br>• Signature method: WSSVerification.RSA_SHA1<br>• Transform method: WSSVerifyPart.TRANSFORM_EXC_C14N<br>• Signed part - Body: WSSVerification.BODY<br>• Signed part - Addressing: WSSVerification.ADDRESSING_HEADERS<br>• Signed part - Timestamp: WSSVerification.TIMESTAMP<br>• Token - Value type: X509Token.ValueType<br>• Token - JAAS login configuration name: system.wss.consume.x509 |
| Request generator | Encryption information | • Encrypted key: true<br>• Key encryption method: WSSEncryption.KW_RSA_OAEP<br>• Data encryption method: WSSEncryption.AES128<br>• Encryption part: WSSEncryption.BODY_CONTENT<br>• Token reference: SecurityToken.REF_KEYID<br>• Token - Value type: X509Token.ValueType<br>• Token - JAAS login configuration name: system.wss.generate.x509 |
| Response consumer | Decryption information | • Encrypted key: true<br>• Key decryption method: WSSDecryption.KW_RSA_OAEP<br>• Data decryption method: WSSDecryption.AES128<br>• Decryption part: WSSDecryption.BODY_CONTENT<br>• Token - Value type: 509Token.ValueType<br>• Token - JAAS login configuration name: system.wss.consume.x509 |

### *Encrypted SOAP headers:*

The encrypted header element provides a standard way of encrypting SOAP headers. As one of the extensions to the OASIS SOAP message security specification, the encrypted header element indicates that the responder has processed the request. Encrypting SOAP headers and parts help to provide more secure message-level security.

The EncryptedHeader or <wsse11:EncryptedHeader> element is a part of the updated Web Services Security Version 1.1 standard and enables interoperability with other vendors that support the Version 1.1 standards, such as Microsoft .NET.

Use the EncryptedHeader element for encrypting SOAP header blocks. The EncryptedHeader element allows Web Services Security to be compliant with the SOAP mustUnderstand processing guidelines and to prevent disclosure of information that is contained in attributes on a SOAP header block.

The <wsse11:EncryptedHeader> element must contain one <xenc:EncryptedData> element. Only one <xenc:EncryptedData> element per encrypted header element is permitted.

#### Encrypted data element

Normally, the programming model, such as JAX-WS, deserializes the SOAP message to a Java binding object before dispatching the call to the application code. However, if the SOAP message is encrypted, the deserialization fails because, before encryption, the original content is replaced with the EncryptedData XML element from the XML Encryption standard.

In certain cases, it might be desirable for the token that is included in the <wsse:Security> header to be encrypted for the recipient processing role.

Follow these guidelines when using the EncryptedData element:

- The EncryptedHeader element must contain one EncryptedData element.
- The <xenc:EncryptedData> element may be used to contain a security token and include it in the <wsse:Security> header.
- The <xenc:EncryptedData> must not include an XML ID for referencing the contained security token.
- All <xenc:EncryptedData> tokens must either have an embedded encryption key or must be referenced by a separate encryption key.
- If compliance with Basic Security Profile 1.1 is desired, the <xenc:EncryptedData> element must have an Id attribute.

### Policy assertion for encrypted parts

The EncryptedParts policy assertion specifies which header is to be encrypted in the security policy. The following table describes the elements and attributes that can be used for EncryptedParts.

*Table 329. Attributes and elements of the EncryptedParts element. Use encrypted parts to provide more secure message-level security.*

| Element or attribute | Description |
|---|---|
| /sp:EncryptedParts/sp:Header | Optional. Presence of this optional element indicates that a specific SOAP header (or set of such headers) must be protected. You can have multiple sp:Header elements within a single EncryptedParts element.<br><br>Each header (or set of headers) must be encrypted, and this encryption will encrypt the elements by using Web Services Security Version 1.1 encrypted headers. As such, if WS-Secuirty 1.1 Encrypted Headers are not supported by a service, then the headers cannot be encrypted by using message-level security.<br><br>If multiple SOAP headers with the same local name but different namespace names are to be encrypted, multiple sp:Header elements are required, either as part of a single sp:EncryptedParts assertion or as part of separate sp:EncryptedParts assertions. |
| /sp:EncryptedParts/sp:Header/@Name | Optional. This attribute indicates the local name of the SOAP header to be confidentiality protected. If this attribute is not specified, all SOAP headers whose namespace matches the Namespace attribute are to be protected. |
| /sp:EncryptedParts/sp:Header/@Namespace | Required. This attribute indicates the namespace of the SOAP headers to be confidentiality protected. |

The following message example shows what the EncryptedHeader element looks like on a message where the EncryptedParts policy assertion for the encrypted header has been specified on the policy:

```
<S:Envelope xmlns:S="..." xmlns:wsse="..." xmlns:wsse11="..." xmlns:wsu="..."
   xmlns:xenc="..." xmlns:ds="...">
   <S:Header>
     <wsse:Security>
      <!-- Tokens etc. -->
       <xenc:EncryptedKey>
         <xenc:EncryptionMethod Algorithm="..."/>
           <ds:KeyInfo>
             ... ...
           </ds:KeyInfo>
          <xenc:CipherData>
            <xenc:CipherValue>...</xenc:CipherValue>
          </xenc:CipherData>
          <xenc:ReferenceList>
            <xenc:DataReference URI="#hdrID"/>
          </xenc:ReferenceList>
        </xenc:EncryptedKey>
     </wsse:Security>
     <wsse11:EncryptedHeader wsu:Id="hdrID">
       <xenc:EncryptedData Id="encDataID">
         <xenc:CipherData>
           <xenc:CipherValue>...</xenc:CipherValue>
         </xenc:CipherData>
         ...
       </xenc:EncryptedData>
     </wsse11:EncryptedHeader>
   </S:Header>
   <S:Body>
     ...
   </S:Body>
</S:Envelope>
```

To encrypt headers in the Web Services Security Version 1.0 specification format, specify the com.ibm.wsspi.wssecurity.encryptedHeader.generate.WSS1.0 property with a value of `true` on the <encryptionInfo> element in the binding. When this property is specified, the target header for encryption is replaced by an <EncryptedData> element, instead of an <EncryptedHeader> element that contains an <EncryptedData> element.

For Web Services Security Version 1.1 behavior that is equivalent to WebSphere Application Server versions prior to version 7.0, specify the com.ibm.wsspi.wssecurity.encryptedHeader.generate.WSS1.1.pre.V7 property with a value of `true` on the <encryptionInfo> element in the binding. When this property is specified, the <EncryptedHeader> element includes a wsu:Id parameter and the <EncryptedData> element omits the Id parameter. This property should only be used if compliance with Basic Security Profile 1.1 is not required.

For complete information about the EncryptedHeader element and the EncryptedData element, see the Web Services Security Version 1.1 specification.

***Signature confirmation:***

Web Services Security signature confirmation is an enhanced XML digital signature, and it is included in the Web Services Security standard. XML digital signature is used for signing elements of the SOAP envelope.

As one of the extensions to the OASIS SOAP message security specification, the signature confirmation element incorporates the elements that are needed within the response message in order to confirm the signature that is contained in a request message. XML digital signature and signature confirmation help to provide more secure message-level security.

Web Services Security Version 1.0 for SOAP message security did not provide any guidance on how to confirm mutual understanding of the request that prompted this response. The SignatureConfirmation or <wsse11:SignatureConfirmation> element has been added to the Web Services Security Version 1.1 specification. The <wsse11:SignatureConfirmation> element ensures that the signature is processed by the intended recipient and indicates that the responder has processed the signature in the request. The signature confirmation element is part of the updated Web Services Security standard and enables interoperability with other vendors that support the Version 1.1 standards, such as Microsoft .NET.

Because of the stateless nature of web services and due to different message exchange patterns (MEPs), consider the following assumptions:

- Assume that session affinity is enabled if a cluster is enabled for the clients that are running in WebSphere Application Server. When session affinity is enabled, it implies that the response is sent back to the initiating client of the server.
- Assume WS-Addressing is enabled for asynchronous message exchange patterns. When WS-Addressing is enabled, it allows the run time to relate the response back to the request. An asynchronous response is sent back to the application of the initiating WebSphere Application Server.

**Syntax**

The SignatureConfirmation element indicates that the responder has processed the signature in the request. When this element is not present in a response, the initiator interprets that the responder is not compliant.

The format for the signature confirmation element is as follows:

```
<wsse11:SignatureConfirmation wsu:Id="..." Value="..." />
```

where:

**wsu:Id**
The identifier that is used when referencing this element in the <ds:SignedInfo> reference list of the signature of the associated response message. This attribute is required so that unambiguous references are made to this <wsse11:SignatureConfirmation> element.

**Value** This attribute is optional and contains the contents of a <ds:SignatureValue> that is copied from the associated request. If the request is unsigned, this attribute must not be present. If this attribute is specified without a value (empty), the initiator interprets this as incorrect behavior and processes it accordingly. When this attribute is not present, the initiator interprets this to mean that the response is based on a request that was not signed.

#### Configuration

To configure signature confirmation, configure the policy file using the administrative console, and select **Require signature confirmation**. To process Signature Confirmation correctly, the initiator of the request needs to preserve the signatures during request generator processing and later needs to retrieve the signatures for confirmation checks.

#### Response generation rules

Additional SOAP security elements for the SOAP responder are used to confirm that the response is in relationship to a particular request. The responder must include the contents of the <ds:SignatureValue> element of the request signature as the value of the @Value attribute of the <wsse11:SignatureConfirmation> element.

The following response generation rules apply when using the SignatureConfirmation policy assertion:

- If there are no signatures on the request, the response contains one SignatureConfirmation element, without a value. For MEPs where there are multiple requests (all without signatures) and one response, the response contains one SignatureConfirmation element without a value.
- If there are signatures on the request, the response contains a SignatureConfirmation element for each signature, with a value that matches the signature value on the request. For MEPs where there are multiple requests, with at least one containing a signature, and one response, the response contains a SignatureConfirmation element for each signature that is found on the requests, with a value that matches the signature value on the request.
- For MEPs where there is one request and multiple responses, each response contains the appropriate SignatureConfirmation elements as noted in the first and second bullets.
- If the SOAP request contains multiple signatures, the requester will find all of the signature confirmation elements contained in the response, and will check the values of the value fields of the signature confirmation elements against the values of the signatures in the original SOAP request.

## Developing JAX-WS based web services client applications that retrieve security tokens

The security handlers are responsible for propagating security tokens. These security tokens are embedded in the SOAP security header and passed to downstream servers.

### About this task

This information applies only to Java API for XML-based Web Services (JAX-WS) .

The security tokens are encapsulated in the implementation classes for the com.ibm.wsspi.wssecurity.auth.token.Token interface. You can retrieve the security token data from either a server application or a client application.

With a client application, the application serves as the request generator and the response consumer and runs as the Java Platform, Enterprise Edition (Java EE) client application. The consumer component for Web Services Security stores the security tokens that it receives in one of the properties of the

MessageContext object for the current web services call. You can retrieve a set of token objects through the javax.xml.rpc.Stub interface of that web services call. You must know which security tokens to retrieve and their token IDs in case multiple security tokens are included in the SOAP security header. Complete the following steps to retrieve the security token data from a client application:

### Procedure

1. Use the com.ibm.wsspi.wssecurity.token.tokenPropergation key string to obtain the Hashtable for the tokens through a property value in the javax.xml.ws.Stub interface. The following example shows how to obtain the Hashtable:

```
java.util.Hashtable t;

javax.xml.ws.Service serv = ...;
serv.addPort(...);
javax.xml.ws.Dispatch<Object> dispatch = svc.createDispatch(...);

Map<String, Object> requestContext = dispatch.getRequestContext();
requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, ..);
requestContext.put(BindingProvider.SOAPACTION_USE_PROPERTY, ..);
requestContext.put(BindingProvider.SOAPACTION_URI_PROPERTY, ..);

String response = dispatch.invoke(body.toString());

Map<String, Object> responseContext = dispatch.getResponseContext();

t = (Hashtable) responseContext.get(
com.ibm.wsspi.wssecurity.Constants.WSSECURITY_TOKEN_PROPERGATION);
```

2. Search the targeting token objects in the Hashtable. Each token object in the Hashtable is set with its token ID as a key. You must have prior knowledge of the security token IDs to retrieve the security tokens. The following example shows how to retrieve a username token from the security header with a certain token ID value:

```
com.ibm.wsspi.wssecurity.auth.token.UsernameToken unt;
if (t != null) {
  unt = (com.ibm.wsspi.wssecuty.auth.token.UsernameToken)t.get("...");
}
```

### Results

After completing these steps, you have retrieved the security tokens that are processed by the Web Services Security handler in a client application.

## Developing JAX-WS based web services server applications that retrieve security tokens

With a server application, the application acts as the request consumer, and the response generator is deployed and runs in the Java Platform, Enterprise Edition (Java EE) container. The consumer component for Web Services Security stores the security tokens that it receives in the Java Authentication and Authorization Service (JAAS) Subject of the current thread. You can retrieve the security tokens from the JAAS Subject that is maintained as a local thread in the container.

### About this task

This information applies only to Java API for XML-based Web Services (JAX-WS).

The security handlers are responsible for propagating security tokens. These security tokens are embedded in the SOAP security header and passed to downstream servers. The security tokens are encapsulated in the implementation classes for the com.ibm.wsspi.wssecurity.auth.token.Token interface. You can retrieve the security token data from either a server application or a client application.

Complete the following steps to retrieve the security token data from a server application:

### Procedure

1. Obtain the JAAS Subject of the current thread using the WSSubject API. If you enable Java 2 Security on the Global security panel in the administrative console, access to the JAAS Subject is denied if the application code is not granted the javax.security.auth.AuthPermission("wssecurity.getCallerSubject") permission. The following code sample shows how to obtain the JAAS subject:

   ```
   javax.security.auth.Subject subject;

   try {
   subject = com.ibm.websphere.security.auth.WSSubject.getCallerSubject();
   } catch (com.ibm.websphere.security.WSSecurityException e) {
     ...
   }
   ```

2. Obtain a set of private credentials from the Subject. For more information, see the application programming interface (API) com.ibm.websphere.security.auth.WSSubject class through the information center . To access this information within the information center, click **Reference > Developer > API Documentation > Application Programming Interfaces**. In the Application Programming Interfaces article, click **com.ibm.websphere.security.auth > WSSubject**.

   **Attention:** When Java 2 Security is enabled, you might need to use the AccessController class to avoid a security violation that is caused by operating the security objects in the Java EE container.

   The following code sample shows how to set the AccessController class and obtain the private credentials:

   ```
   Set s = (Set) AccessController.doPrivileged(new PrivilegedAction() {
      public Object run() {
      return subj.getPrivateCredentials();
      }
         });
   ```

3. Search the targeting token class in the private credentials. You can search the targeting token class by using the java.util.Iterator interface. The following example shows how to retrieve a username token with a certain token ID value in the security header. You can also use other method calls to retrieve security tokens. For more information, see the application programming interface (API) documents for the com.ibm.wsspi.wssecurity.auth.token.Token interface or custom token classes.

   ```
   com.ibm.wsspi.wssecurity.auth.token.UsernameToken unt;
   Iterator it = s.iterator();
   while (it.hasNext()) {
     Object obj = it.next();
     if (obj != null &&
   obj instanceOf com.ibm.wsspi.wssecurity.auth.token.UsernameToken) {
       unt =(com.ibm.wsspi.wssecurity.auth.token.UsernameToken) obj;
   if (unt.getId().equals("...")) break;
   else continue;
     }
   }
   ```

### Results

After completing these steps, you have retrieved the security tokens from the JAAS Subject in a server application.

# Developing message-level security for JAX-RPC web services

IBM® WebSphere® Application Server supports the Java™ API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model.

## Developing web services clients that retrieve tokens from the JAAS Subject in an application

The security handlers are responsible for propagating security tokens. These security tokens are embedded in the SOAP security header and passed to downstream servers.

### About this task

This information applies only to Java API for XML-based RPC (JAX-RPC) Web services.

The security tokens are encapsulated in the implementation classes for the com.ibm.wsspi.wssecurity.auth.token.Token interface. You can retrieve the security token data from either a server application or a client application.

With a client application, the application serves as the request generator and the response consumer and runs as the Java Platform, Enterprise Edition (Java EE) client application. The consumer component for Web Services Security stores the security tokens that it receives in one of the properties of the MessageContext object for the current Web services call. You can retrieve a set of token objects through the javax.xml.rpc.Stub interface of that web services call. You must know which security tokens to retrieve and their token IDs in case multiple security tokens are included in the SOAP security header. Complete the following steps to retrieve the security token data from a client application:

### Procedure

1. Use the com.ibm.wsspi.wssecurity.token.tokenPropergation key string to obtain the Hashtable for the tokens through a property value in the javax.xml.rpc.Stub interface. The following example shows how to obtain the Hashtable:

   ```
   java.util.Hashtable t;
   javax.xml.rpc.Service serv = ...;
   MyWSPortType pt = (MyWSPortType)serv.getPort(MyWSPortType.class);
   t = (Hashtable)((javax.xml.rpc.Stub)pt)._getProperty(
   com.ibm.wsspi.wssecurity.Constants.WSSECURITY_TOKEN_PROPERGATION);
   ```

2. Search the targeting token objects in the Hashtable. Each token object in the Hashtable is set with its token ID as a key. You must have prior knowledge of the security token IDs to retrieve the security tokens. The following example shows how to retrieve a username token from the security header with a certain token ID value:

   ```
   com.ibm.wsspi.wssecurity.auth.token.UsernameToken unt;
   if (t != null) {
     unt = (com.ibm.wsspi.wssecuty.auth.token.UsernameToken)t.get("...");
   }
   ```

### Results

After completing these steps, you have retrieved the security tokens from the JAAS Subject in a client application

## Developing web services applications that retrieve tokens from the JAAS Subject in a server application

With a server application, the application acts as the request consumer, and the response generator is deployed and runs in the Java Platform, Enterprise Edition (Java EE) container. The consumer component for Web Services Security stores the security tokens that it receives in the Java Authentication and Authorization Service (JAAS) Subject of the current thread. You can retrieve the security tokens from the JAAS Subject that is maintained as a local thread in the container.

### About this task

This information applies only to Java API for XML-based RPC (JAX-RPC) Web services.

The security handlers are responsible for propagating security tokens. These security tokens are embedded in the SOAP security header and passed to downstream servers. The security tokens are encapsulated in the implementation classes for the com.ibm.wsspi.wssecurity.auth.token.Token interface. You can retrieve the security token data from either a server application or a client application.

Complete the following steps to retrieve the security token data from a server application:

### Procedure

1. Obtain the JAAS Subject of the current thread using the WSSubject utility class. If you enable Java 2 Security on the Global security panel in the administrative console, access to the JAAS Subject is denied if the application code is not granted the javax.security.auth.AuthPermission("wssecurity.getCallerAsSubject") permission. The following code sample shows how to obtain the JAAS subject:

   ```
   javax.security.auth.Subject subj;
   try {
   subj = com.ibm.websphere.security.auth.WSSubject.getCallerSubject();
   } catch (com.ibm.websphere.security.WSSecurityException e) {
     ...
   }
   ```

2. Obtain a set of private credentials from the Subject. For more information, see the application programming interface (API) com.ibm.websphere.security.auth.WSSubject class through the information center . To access this information within the information center, click **Reference > Developer > API Documentation > Application Programming Interfaces**. In the Application Programming Interfaces article, click **com.ibm.websphere.security.auth > WSSubject**.

   **Attention:** When Java 2 Security is enabled, you might need to use the AccessController class to avoid a security violation that is caused by operating the security objects in the Java EE container.

   The following code sample shows how to set the AccessController class and obtain the private credentials:

   ```
   Set s = (Set) AccessController.doPrivileged(new PrivilegedAction() {
      public Object run() {
      return subj.getPrivateCredentials();
      }
         });
   ```

3. Search the targeting token class in the private credentials. You can search the targeting token class by using the java.util.Iterator interface. The following example shows how to retrieve a username token with a certain token ID value in the security header. You can also use other method calls to retrieve security tokens. For more information, see the application programming interface (API) documents for the com.ibm.wsspi.wssecurity.auth.token.Token interface or custom token classes.

   ```
   com.ibm.wsspi.wssecurity.auth.token.UsernameToken unt;
   Iterator it = s.iterator();
   while (it.hasNext()) {
     Object obj = it.next();
     if (obj != null &&
   obj instanceOf com.ibm.wsspi.wssecurity.auth.token.UsernameToken) {
       unt =(com.ibm.wsspi.wssecurity.auth.token.UsernameToken) obj;
   if (unt.getId().equals("...")) break;
   else continue;
     }
   }
   ```

### Results

After completing these steps, you have retrieved the security tokens from the JAAS Subject in a server application

## Web Services Security service provider programming interfaces

Several Service Provider Interfaces (SPIs) are provided to extend the capability of the Web Services Security runtime.

## About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

The following list contains the SPIs that are available for WebSphere Application Server:

## Procedure

- com.ibm.wsspi.wssecurity.config.KeyLocator is an abstract for obtaining the keys for digital signature and encryption. The following list contains the default implementations:
  1. com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator implements the Java key store.
  2. com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator povides a mapping of the authenticated identity to a key for encryption or, the implementation uses the default key that is specified.
  3. com.ibm.wsspi.wssecurity.config.CertInRequestKeyLocator Provides the capability of using the signer key for encryption in the response message. This implementation is typically used in the response sender configuration.
- com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator is an interface that is used to evaluate the trust for identity assertion. The default implementation is com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl, which enables you to define a list of trusted identities.
- The Java Authentication and Authorization Service (JAAS) CallbackHandler application programming interfaces (APIs) are used for token generation by the request sender. This interface can be extended to generate a custom token that can be inserted in the Web Services Security header. The following list contains the default implementations that are provided by WebSphere Application Server:
  1. com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler presents a login prompt to gather the basic authentication data. Use this implementation in the client environment only.
  2. com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler collects the basic authentication data in the standard in (stdin) prompt. Use this implementation in the client environment only.

     **Restriction:** If you have a multi-threaded client and multiple threads attempt to read from standard in at the same time, all the threads will not successfully obtain the user name and password information. Therefore, you cannot use the com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler implementation with a multi-threaded client where multiple threads might attempt to obtain data from standard in concurrently.
  3. com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler reads the basic authentication data from the application binding file. This implementation might be used on the server side to generate a user name token.
  4. com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler Generates a Lightweight Third Party Authentication (LTPA) token in the Web Services Security header as a binary security token. If basic authentication data is defined in the application binding file, it is used to perform a login, to extract the LTPA token from the WebSphere credentials, and to insert the token in the Web Services Security header. Otherwise, it will extract the LTPA security token from the invocation credentials (RunAs identity) and insert the token in the Web Services Security header.

## What to do next

The JAAS LoginModule API is used for token validation on the request receiver side of the message. You can implement a custom LoginModule API to perform validation of the custom token on the request receiver of the message. After the token is verified and validated, the token is set as the caller and then

run as the identity in the WebSphere Application Server runtime. The identity is used for authorization checks by the containers before a Java Platform, Enterprise Edition (Java EE) resource is invoked. The following list presents the default AuthMethod configurations provided by WebSphere Application Server:

**BasicAuth**
Validates a user name token.

**Signature**
Maps the distinguished name (DN) of a verified certificate to a Java Authentication and Authorization Service (JAAS) subject.

**IDAssertion**
Maps a trusted identity to a JAAS subject.

**LTPA** Validates an LTPA token that is received in the message and creates a JAAS subject.

## Configuring Web Services Security during application assembly

If you configure Web Services Security with an assembly tool, the Web Services Security binding information is modified

## Configuring HTTP outbound transport level security with an assembly tool

You can configure the HTTP outbound transport level security with an assembly tool.

### Before you begin

You can configure HTTP outbound transport level security with assembly tools provided with WebSphere Application Server.

This task is one of several ways that you can configure the HTTP outbound transport level security for a web service acting as a client to another web service server. You can also configure the HTTP outbound transport level security with the administrative console or by using the Java properties. If you do not configure the HTTP outbound transport level security, the web services runtime defers to the Java Platform, Enterprise Edition (Java EE) security runtime in the WebSphere product for an effective Secure Sockets Layer (SSL) configuration. If there is no SSL configuration with the Java EE security runtime in the WebSphere product, the Java Secure Socket Extension (JSSE) system properties are used.

### About this task

If you configure the HTTP outbound transport level security with assembly tool or with the administrative console, the Web Services Security binding information is modified. If you have not yet installed the web services application into WebSphere Application Server, you can configure the HTTP SSL configuration with an assembly tool. This task assumes that you have not deployed the web services application into the WebSphere product.

If you configure the HTTP outbound transport level security using the standard Java properties for JSSE, the properties are configured as system properties. The configuration that is specified in the binding takes precedence over the Java properties. However, the configurations that are specified by the Java EE security programming model, or are associated with the Dynamic selection, have a higher precedence.

To learn more, see the secure communications using Secure Sockets Layer information.

### Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.

2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.
4. Configure the HTTP outbound transport level security. Read about enabling web service endpoints in the Rational Application Developer documentation.

### Results

You have configured the HTTP outbound transport level security for a web service acting as a client to another web service with an assembly tool.

## Configuring HTTP basic authentication for JAX-RPC web services with an assembly tool

You can configure HTTP basic authentication for Java API for XML-based RPC (JAX-RPC) web services with an assembly tool.

### Before you begin

You can configure HTTP basic authentication with assembly tools provided with WebSphere Application Server.

### About this task

This task is one of three ways that you can configure HTTP basic authentication. You can also configure HTTP basic authentication with the administrative console or by modifying the HTTP properties programmatically.

If you choose to configure the HTTP basic authentication with an assembly tool or with the administrative console, the Web Services Security binding information is modified. You can use an assembly tool to configure HTTP basic authentication before you deploy or install the web services application into WebSphere Application Server. This task assumes that you have not deployed the web services application into the WebSphere product.

If you configure HTTP basic authentication programmatically, the properties are configured in the Stub or Call instance. The values set programmatically take precedence over the values defined in the binding.

The HTTP basic authentication that is discussed in this topic is orthogonal to WS-Security and is distinct from basic authentication that WS-Security supports. WS-Security supports basic authentication token, not HTTP basic authentication.

To configure HTTP basic authentication, use the WebSphere Application Server tools to modify the binding information.

### Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.

3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.
4. Configure the HTTP basic authentication in the Web Services Client Port Binding page for a web service or a web service client. The Web Services Client Port Binding page is available after double-clicking the client deployment descriptor file. Read about Web Services Client Port Bindings in the Rational Application Developer documentation.

# Configuring XML digital signature for Version 5.x web services with an assembly tool

XML digital signature is one of the methods WebSphere® Application Server provides to secure your web services. It provides message integrity and authentication capabilities when used with SOAP messages.

## Configuring trust anchors using an assembly tool

Use an assembly tool to configure trust anchors (that specify keystores which contain trusted root certificates to validate the signer certificate) or trust stores at the application level.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

This document describes how to configure trust anchors or trust stores at the application level. It does not describe how to configure trust anchors at the server or cell level. Trust anchors defined at the application level have a higher precedence over trust anchors defined at the server or cell level. You can configure an application-level trust anchor using an assembly tool or the administrative console. This document describes how to configure the application-level trust anchor using an assembly tool.

### About this task

A trust anchor specifies keystores that contain trusted root certificates, which validate the signer certificate. These keystores are used by the request receiver (as defined in the `ibm-webservices-bnd.xmi` file) and the response receiver (as defined in the `application-client.xml` file when web services are acting as client) to validate the signer certificate of the digital signature. The keystores are critical to the integrity of the digital signature validation. If they are tampered with, the result of the digital signature verification is doubtful and comprised. Therefore, it is recommended that you secure these keystores. The binding configuration specified for the request receiver in the `ibm-webservices-bnd.xmi` file must match the binding configuration for the response receiver in the `application-client.xml` file.

Complete the following steps to configure trust anchors using an assembly tool.

### Procedure

1. Configure an assembly tool to work with a Java Platform, Enterprise Edition (Java EE) enterprise application. For more information, see the related information on Assembly Tools.
2. Create a web services-enabled Java EE enterprise application.
3. Configure the client-side response receiver, which is defined in the `ibm-webservicesclient-bnd.xmi` bindings extensions file.
   a. Use an assembly tool to import your Java EE application.
   b. Click **Window** > **Open Perspective** > **Other** > **J2EE**.
   c. Click **Application Client projects** > ***application_name*** > **appClientModule** > **META-INF**

d. Right-click the `application-client.xml` file, select **Open with** > **Deployment Descriptor Editor**, and click the **WS Binding** tab. The Client Deployment Descriptor is displayed.
e. Locate the Port qualified name binding section and either select an existing entry or click **Add**, to add a new port binding. The web services client port binding editor displays for the selected port.
f. Locate the Trust anchor section and click **Add**. The Trust anchor window is displayed.
   1) Enter a unique name within the port binding for the **Trust anchor name**.
      The name is used to reference the trust anchor that is defined.
   2) Enter the keystore password, path, and keystore type.
      The supported keystore types are the Java Cryptography Extension (JCE) and Java Cryptography Extension Keystores (JCEKS) types.

   Click **Edit** to edit the selected trust anchor.

   Click **Remove** to remove the selected trust anchor.

   When you start the application, the configuration is validated in the run time while the binding information is loading.
g. Save the changes.

4. Configure the server-side request receiver, which is defined in the `ibm-webservices-bnd.xmi` bindings extensions file.
   a. Click **Window** > **Open perspective** > **J2EE**.
   b. Select the web services enabled Enterprise JavaBeans (EJB) or web module.
   c. In the Package Explorer window, click the `META-INF` directory for an EJB module or the `WEB-INF` directory for a web module.
   d. Right-click the `webservices.xml` file, select **Open with** > **Web services editor**, and click the bindings tab. The web services bindings editor is displayed.
   e. Locate the web service description bindings section and either select an existing entry or click **Add** to add a new web services descriptor.
   f. Click **Binding configurations**. The web services binding configurations editor is displayed for the selected web services descriptor.
   g. Locate the Trust anchor section and click **Add**. The Trust anchor dialog box is displayed.
      1) Enter a unique name within the binding for the **Trust anchor name**.
         This unique name is used to reference the trust anchor defined.
      2) Enter the keystore password, path, and keystore type. The supported keystore types are `JCE` and `JCEKS`.

      Click **Edit** to edit the selected trust anchor.

      Click **Remove** to remove the selected trust anchor.

      When you start the application, the configuration is validated in the run time while the binding information is loading.
   h. Save the changes.

## Results

This procedure defines trust anchors that can be used by the request receiver or the response receiver (if the web services is acting as client) to verify the signer certificate.

## Example

The request receiver or the response receiver (if the web service is acting as a client) uses the defined trust anchor to verify the signer certificate. The trust anchor is referenced using the trust anchor name.

### What to do next

To complete the signing information configuration process for request receiver, complete the following tasks:

1. “Configuring the server for request digital signature verification: Verifying the message parts” on page 2028
2. “Configuring the server for request digital signature verification: choosing the verification method” on page 2030

To complete the process for the response receiver, if the web services is acting as a client, complete the following tasks:

1. “Configuring the client for response digital signature verification: verifying the message parts” on page 2035
2. “Configuring the client for response digital signature verification: choosing the verification method” on page 2037

## Configuring the client-side collection certificate store using an assembly tool

You can configure the client-side collection certificate store using the assembly tool.

### About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6 and later applications.

A collection certificate store is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs are used to check the signature of a digitally signed SOAP message.

You can configure the collection certificate either by using an assembly tool or the WebSphere Application Server administrative console. Complete the following steps to configure the client-side collection certificate store using the assembly tool.

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment Descriptor Editor**, and click the **WS Binding** tab, which is located at the bottom of deployment descriptor editor within the assembly tool. The Client Deployment Descriptor is displayed.
5. Click the **Port binding** tab in deployment descriptor editor within the assembly tool. The web services client port binding window is displayed.
6. Select one of the port-qualified name binding entries.
7. Expand the **Security response receiver binding configuration** > **certificate store list** > **Collection certificate store** section.
8. Click **Add** to create a new collection certificate store, click **Edit** to edit an existing certificate store, or click **Remove** to delete an existing certificate store.
9. Enter a name in the **Name** field. This name is referenced in the Certificate store reference field in the Signing info dialog box.
10. Leave the Provider field as `IBMCertPath`.

11. Click **Add** to enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`. If you have additional certificate store paths, click **Add** to add the paths.
12. Click **OK** when you finish adding paths.

## Configuring the server-side collection certificate store using an assembly tool

A *collection certificate store* is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collections of CA certificates and CRLs are used to check the signature of a digitally signed SOAP message. You can configure the server-side collection certificate store by using an assembly tool.

### About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

You can configure the collection certificate either by using an assembly tool or by using the WebSphere Application Server administrative console. Complete the following steps to configure the server-side collection certificate store using an assembly tool.

### Procedure

1. Start an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, select **Open with** > **Web Services Editor**.
5. Click the Binding configurations tab in the web services editor within the assembly tool. The Web Service Binding Configuration window is displayed.
6. Select one of the web service description binding entries under the Port Component Binding section.
7. Expand the **Request receiver binding configuration details** > **Certificate store list** > **Collection certificate store** section.
8. Click **Add** to create a new collection certificate store, click **Edit** to edit an existing certificate store, or click **Remove** to delete an existing certification store.
9. Enter a name in the **Name** field. This name is referenced in the **Certificate store reference** field in the Signing info dialog.
10. Leave the **Provider** field as `IBMCertPath`.
11. Click **Add** to enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT]/etc/ws-security/samples/intca2.cer`. If you have additional certificate store paths, click **Add** to add the paths.
12. Click **OK** when you finish adding paths.

## Configuring key locators using an assembly tool

The following information provides instructions on how to configure key locators using an assembly tool.

### About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

You can configure key locators in various locations within the assembly tool. The following procedure provides instructions on how to configure key locators at any of these locations because the concept is the same.

## Procedure

1. Start an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment Descriptor Editor**, and click the **WS Binding** tab. The Client Deployment Descriptor is displayed.
5. Click the **WS Binding** tab in deployment descriptor editor within the assembly tool or the **Binding configurations** tab in the Web services editor within the assembly tool.
6. Expand one of the **Binding configuration** sections.
7. Expand the **Key locators** section.
8. Click **Add** to create a new key locator, click **Edit** to edit an existing key locator, or click **Remove** to delete an existing key locator.
9. Enter a key locator name. The name entered for the **Key locator name** is used to refer to the key locator from the Encryption information and Signing Information sections.
10. Enter a key locator class. The key locator class is the implementation of the `KeyLocator` interface. When using default implementations, select a class from the menu.
11. Determine whether to click **Use key store**. Select this option when you use the default implementations as they use key stores. If you click **Use key store**, complete the following steps:
    a. Enter a value in the key store storepass field. The key store storepass is the password used to access the key store.
    b. Enter a path name in the key store path field. The key store path is the location on the file system where the key store resides. Make sure that the location can be found wherever you deploy the application.
    c. Enter a type value in the key store type field. The valid types to enter are JKS and JCEKS. JKS is used when you are not using the Java Cryptography Extensions (JCE) policy. JCEKS is used when you are using JCE. Although the JCEKS type is more secure, it might decrease performance.
    d. Click **Add** to create an entry for a key in the key store.
        1) Enter a value in the Alias field.

           The key alias is a reference to this particular key from the Signing Information section.
        2) Enter a value in the Key pass field.

           The key pass is the password associated with the certificate which is created using the Java SE Development Kit 6 `keytool.exe` file.
        3) Enter a value in the Key name field.

           The key name refers to the alias of the certificate as found in the key store.
12. Click **Add** to create a custom property. The property can be used by custom key locator implementations. For example, you can use properties with the `WSIdKeyStoreMapKeyLocator` default implementation. The key locator implementation has the following property names:
    - *id_*, which maps to a credential user ID.
    - *mappedName_* , which maps to the key alias to use for this user name.
    - *default*, which maps to a key alias to use when a credential does not have an associated *id_* entry.

A typical set of properties for this key locator might be: `id_1=user1`, `mappedName_1=key1`, `id_2=user2`, `mappedName_2=key2`, `default=key3`. If `user1` or `user2` authenticates, then the associated `key1` or `key2` is used, respectively. However, if none of the user properties authenticate or the user is not `user1` or `user2`, then `key3` is used.

a. Enter a name in the Name field. The name entered is the property name.

b. Enter a value in the Value field. This value entered is the property value.

## Securing web services for Version 5.x applications using XML digital signature

XML digital signature is one of the methods WebSphere Application Server provides to secure your web services. It provides message integrity and authentication capabilities when used with SOAP messages.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

WebSphere Application Server provides several different methods to secure your web services; XML digital signature is one of these methods. You can secure your web services by using any of the following methods:

- XML digital signature
- XML encryption
- Basicauth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

### About this task

XML digital signature provides both message integrity and authentication capabilities when it is used with SOAP messages. A message receiver can verify that attackers or accidents have not altered parts of the message after the message was signed by a key. If a message has a digital certificate issued by a certificate authority (CA) and a signature in the message is validated successfully by a public key in the certificate, it is proof that the signer has the corresponding private key. To use XML digital signature to secure web services, complete the following steps:

### Procedure

1. Define the security constraints or extensions. To configure the security constraints, you must use an assembly tool. For more information, see the related information on Assembly Tools.
   a. Configure the client to digitally sign a message request. To configure the client, complete the following steps to specify which parts of the SOAP message to digitally sign and define the method used to digitally sign the message. The client in these steps is the request sender.
      1) Specify the message parts by following the steps found in “Configuring the client for request signing: digitally signing message parts” on page 2024.
      2) Select the method used to digitally sign the request message. You can select the digital signature method by following the steps in “Configuring the client for request signing: choosing the digital signature method” on page 2026.
   b. Configure the server to verify the digital signature that is used in the message request. To configure the server, you must specify which parts of the SOAP message, sent by the request sender, contain digitally signed information and which method was used to digitally sign the message. The settings chosen for the request receiver, or the server in this step, must match the settings chosen for the request sender in the previous step.

1) Define the message parts by following the steps found in “Configuring the server for request digital signature verification: Verifying the message parts” on page 2028.
2) Select the same method used by the request sender to digitally sign the message. You can select the digital signature method by following the steps in “Configuring the server for request digital signature verification: choosing the verification method” on page 2030

c. Configure the server to digitally sign a message response. To configure the server, complete the following steps to specify which parts of the SOAP message to digitally sign and define the method used to digitally sign the message. The sender in these steps is the response sender.
1) Specify which message parts to digitally sign by following the steps found in “Configuring the server for response signing: digitally signing message parts” on page 2032.
2) Select the method used to digitally sign the response message. You can select the digital signature method by following the steps in “Configuring the server for response signing: choosing the digital signature method” on page 2034

d. Configure the client to verify the digital signature that is used in the message response. To configure the client, you must specify which parts of the SOAP message sent by the response sender contain digitally signed information and which method was used to digitally sign the message. The settings chosen for the response receiver, or client in this step, must match the settings chosen for the response sender in the previous step.
1) Define the message parts by following the steps found in “Configuring the client for response digital signature verification: verifying the message parts” on page 2035
2) Select the same method used by the response sender to digitally sign the message. You can select the digital signature method by following the steps in “Configuring the client for response digital signature verification: choosing the verification method” on page 2037

2. Define the client security bindings. To configure the client security bindings, complete the steps in either of the following topics:
   - “Configuring the client security bindings using an assembly tool” on page 2039
   - Configuring the security bindings on a server acting as a client using the administrative console
3. Define the server security bindings. To configure the server security bindings, complete the steps in either of the following topics:
   - “Configuring the server security bindings using an assembly tool” on page 2042
   - Configuring the server security bindings using the administrative console

### Results

After completing these steps, you have secured your web services using XML digital signature.

## Configuring the client for request signing: digitally signing message parts

To configure the client for request signing, specify which message parts to digitally sign when configuring the client.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **Security Extensions** tab and the **Port Binding** tab in the Web Services Client Editor within an assembly tool.

- “Configuring the client security bindings using an assembly tool” on page 2039
- Configuring the security bindings on a server acting as a client using the administrative console

These two tabs are used to configure the Web Services Security extensions and the Web Services Security bindings, respectively.

### About this task

Complete the following steps to specify which message parts to digitally sign when configuring the client for request signing:

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Click **Window** > **Open perspective** > **Other** > **J2EE**.
3. Click **Application Client projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment Descriptor Editor**, and click the **WS Extension** tab. The Client Deployment Descriptor is displayed.
5. Expand **Request sender configuration** > **Integrity**. *Integrity* refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification while the data is transmitted across the Internet.
6. Indicate which parts of the message to sign by clicking **Add** and selecting **body**, **timestamp**, or **SecurityToken**. The following list contains descriptions of the message parts

   **body** The body is the user data portion of the message.

   **timestamp**
   The time stamp determines if the message is valid based on the time that the message is sent and then received. If **timestamp** is selected, proceed to the next step and select **Add created time stamp** to add a time stamp to a message.

   **SecurityToken**
   The security token authenticates the client. If this option is selected, the message is signed.

   You can choose to digitally sign the message using a time stamp if **Add created time stamp** is selected and configured. You can digitally sign the message using a security token if a login configuration authentication method is selected.
7. Optional: Expand the **Add created time stamp** section and select this option if you want a time stamp added to the message. You can specify an expiration time for the time stamp, which helps defend against replay attacks. The lexical representation for duration is the [ISO 8601] extended format *PnYnMnDTnHnMnS*, where:
   - *nY* represents the number of years
   - *nM* represents the number of months
   - *nD* represents the number of days
   - *T* is the date and time separator
   - *nH* represents the number of hours
   - *nM* represents the number of minutes
   - *nS* represents the number of seconds. The number of seconds can include decimal digits to arbitrary precision.

   For example, to indicate a duration of 1 year, 2 months, 3 days, 10 hours, and 30 minutes, the format is: `P1Y2M3DT10H30M`. Typically, you configure a message time stamp for about 10 to 30 minutes, for example, 10 minutes is represented as: `P0Y0M0DT0H10M0S`. The *P* character precedes time and date values.

### Results

**Important:** If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when executing the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the Web Services Client Editor within an assembly tool:

- Click **Security extensions** > **Client service configuration details** and indicate the actor information in the **Actor URI** field.
- Click **Security extensions** > **Request sender configuration** > **Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the web service on the server, which processes the request and sends the response back. Configure the actor in the following locations:

- Click **Security extensions** > **Server service configuration**.
- Click **Security extensions** > **Response sender service configuration details** > **Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the **Actor** fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The **Actor** fields might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server **Actor** fields are synchronized.

### What to do next

After you have specified which message parts to digitally sign, you must specify which method is used to digitally sign the message. See “Configuring the client for request signing: choosing the digital signature method” for more information.

## Configuring the client for request signing: choosing the digital signature method

To configure the client for request signing, specify which message parts to digitally sign when configuring the client.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **Security extensions** tab and the **Port binding** tab in the web services client editor within an assembly tool:

- “Configuring the client security bindings using an assembly tool” on page 2039
- Configuring the server security bindings using the administrative console

These two tabs are used to configure the Web Services Security extensions and the Web Services Security bindings, respectively. You must specify which parts of the message sent by the client must be digitally signed. See “Configuring the client for request signing: digitally signing message parts” on page 2024 for more information.

## About this task

Complete the following steps to specify which message parts to digitally sign when configuring the client for request signing:

## Procedure

1. Launch an assembly tool. For more information, see the related information on assembly tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open perspective** > **Other** > **J2EE**.
3. Click **Application Client projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment Descriptor Editor**, and click the **WS Binding** tab. The Client Deployment Descriptor is displayed.
5. Expand **Security request sender binding configuration** > **Signing information**.
6. Select **Edit** to view the signing information and select a digital signature method from the **Signature method algorithm** field. The following table describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following website http://www.w3.org/TR/xmldsig-core.

*Table 330. Digital signature methods. The digital signature method information is stored in the client deployment descriptor.*

| Name | Purpose |
|---|---|
| **Canonicalization method algorithm** | Canonicalizes the `<SignedInfo>` element before the information is digested as part of the signature operation. |
| **Digest method algorithm** | Applies to the data after transforms are applied, if specified, to yield the `<DigestValue>` element. Signing the `<DigestValue>` element binds the resource content to the signer key. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration. |
| **Signature method algorithm** | Converts the canonicalized `<SignedInfo>` element into the `<SignatureValue>` element. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration. |
| **Signing key name** | Represents the key entry associated with the signing key locator. The key entry refers to an alias of the key, which is found in the key store and is used to sign the request. |
| **Signing key locator** | Represents a reference to a key locator implementation class that locates the correct hey store where the alias and the certificate exist. |

7. Optional: Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the **Digest method algorithm** and **Signature method algorithm** drop-down lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the WebSphere administrative console.

## Results

**Important:** If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when running the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the web services client editor within an assembly tool:

- Click **Security extensions** > **Client service configuration details** and indicate the actor information in the **Actor URI** field.
- Click **Security extensions** > **Request sender configuration > Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the web services editor within an assembly tool:

- Click **Security extensions** > **Server service configuration**.

- Click **Security extensions** > **Response sender service configuration details** > **Details** and indicate the actor information in the **Actor** field.

  The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The **Actor** fields might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which method is used to digitally sign a message when the client sends a message to a server.

### What to do next

After you configure the client to digitally sign the message, you must configure the server to verify the digital signature. See "Configuring the server for request digital signature verification: Verifying the message parts" for more information.

## Configuring the server for request digital signature verification: Verifying the message parts

Configure the server for request digital signature verification by modifying the extensions to indicate which parts of the request to verify.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **Extensions** tab and the **Binding Configurations** tab in the web services editor within the assembly tools:

- "Configuring the server security bindings using an assembly tool" on page 2042
- Configuring the server security bindings using the administrative console

You can use these two tabs to configure the Web Services Security extensions and the Web Services Security bindings, respectively. Also, you must specify which parts of the message sent by the client must be digitally signed. See "Configuring the client for request signing: digitally signing message parts" on page 2024 to determine which message parts are digitally signed. The message parts specified for the client request sender must match the message parts specified for the server request receiver.

### About this task

Complete the following steps to configure the server for request digital signature verification. The steps describe how to modify the extensions to indicate which parts of the request to verify.

### Procedure

1. Launch an assembly tool. For more information, see the related information on assembly tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open perspective** > **Other** > **J2EE**.

3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the Extensions tab in the web services editor.
6. Expand the **Request receiver service configuration details** > **Required integrity** section. Required integrity refers to the parts of the message that require digital signature verification. The purpose of digital signature verification is to make sure that the message parts have not been modified while transmitting across the Internet.
7. Indicate parts of the message to verify by clicking **Add**, and selecting one of the following three parts: **body**, **Timestamp**, or **SecurityToken**. You can determine which parts of the message to verify by looking at the web service request sender configuration in the client application. To view the web service request sender configuration information in the web services client editor, click the Security extensions tab and expand **Request sender configuration** > **Integrity**. The following includes a list and description of the message parts:

   **Body** This is the user data portion of the message.

   **Timestamp**
   The time stamp determines if the message is valid based on the time that the message is sent and then received. If **Timestamp** is selected, proceed to the next step to `Add Created Time Stamp` to the message.

   **SecurityToken**
   The security token authenticates the client. If **SecurityToken** is selected, the message is signed.
8. Optional: Expand the **Add received time stamp** section. The Add Received Time Stamp value indicates to validate the Add Created Time Stamp option configured by the client. You must select this option if you selected the Add Created Time Stamp on the client. The time stamp ensures message integrity by indicating the timeliness of the request. This option helps defend against replay attacks.

## Results

**Important:** If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when running the client, you might need to configure the actor. You can configure the actor in the following locations:

- Click **Security extensions** > **Client service configuration details** and indicate the actor information in the **Actor URI** field.
- Click **Security extensions** > **Request sender configuration** > **Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the web service on the server, which processes the request and sends the response back. Configure the actor in the following locations:

- Click **Security extensions** > **Server service configuration**.
- Click **Security extensions** > **Response sender service configuration details** > **Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The actor fields might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which message parts are digitally signed and must be verified by the server when the client sends a message to a server.

### What to do next

After you specify which message parts contain a digital signature that must be verified by the server, you must configure the server to recognize the digital signature method used to digitally sign the message. See “Configuring the server for request digital signature verification: choosing the verification method” for more information.

## Configuring the server for request digital signature verification: choosing the verification method

To configure the server for request digital signature verification, use an assembly tool to modify the extensions and indicate which digital signature method the server will use during verification.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the Extensions tab and the Binding Configurations tab in the Web Services Editor within the IBM assembly tools:

- “Configuring the server security bindings using an assembly tool” on page 2042
- Configuring the server security bindings using the administrative console

You can use these two tabs to configure the Web Services Security extensions and Web Services Security bindings, respectively. You must specify which message parts contain digital signature information that must be verified by the server. See “Configuring the server for request digital signature verification: Verifying the message parts” on page 2028. The message parts specified for the client request sender must match the message parts specified for the server request receiver. Likewise, the digital signature method chosen for the client must match the digital signature method used by the server.

### About this task

Complete the following steps to configure the server for request digital signature verification. The steps describe how to modify the extensions to indicate which digital signature method the server will use during verification.

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open perspective** > **Other** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the **Binding Configurations** tab.
6. Expand the **Security request receiver binding configuration details** > **Signing information** section.
7. Click **Edit** to edit the signing information. The signing information dialog is displayed, select or enter the following information:
   - Canonicalization method algorithm
   - Digest method algorithm
   - Signature method algorithm

- Use certificate path reference
- Trust anchor reference
- Certificate store reference
- Trust any certificate

For more conceptual information on digitally signing SOAP messages, see XML digital signature. The following table describes the purpose for each of these selections. Some of the following definitions are based on the XML-Signature specification, which is located at the following web address: http://www.w3.org/TR/xmldsig-core.

*Table 331. Digital signature methods. The digital signature method is part of the binding configuration.*

| Name | Purpose |
|---|---|
| **Canonicalization method algorithm** | Canonicalizes the <SignedInfo> element before it is digested as part of the signature operation. The algorithm selected for the server request receiver configuration must match the algorithm selected in the client request sender configuration. |
| **Digest method algorithm** | Applies to the data after transforms are applied, if specified, to yield the <DigestValue> element. The signing of the <DigestValue> element binds resource content to the signer key. The algorithm selected for the server request receiver configuration must match the algorithm selected in the client request sender configuration. |
| **Signature method algorithm** | Converts the canonicalized <SignedInfo> element into the <SignatureValue> element. The algorithm selected for the server request receiver configuration must match the algorithm selected in the client request sender configuration. |
| **Use certificate path reference** or **Trust any certificate** | Validates a certificate or signature sent with a message. When a message is signed, the public key used to sign it is sent with the message. This public key or certificate might not be validated at the receiving end. By selecting **User certificate path reference**, you must configure a trust anchor reference and a certificate store reference to validate the certificate sent with the message. By selecting **Trust any certificate**, the signature is validated by the certificate sent with the message without the certificate itself being validated. |
| **Use certificate path reference: Trust anchor reference** | Refers to a key store that contains trusted, self-signed certificates and certificate authority (CA) certificates. These certificates are trusted certificates that you can use with any applications in your deployment. |
| **Use certificate path reference: Certificate store reference** | Contains a collection of X.509 certificates. These certificates are not trusted for all applications in your deployment, but might be used as an intermediary to validate certificates for an application. |

8. Optional: Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Signature method algorithm and Digest method algorithm dropdown lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console.

## Results

**Important:** If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when running the client, you might need to configure the actor. You can configure the actor in the following locations on the client:

- Click **Security extensions** > **Client service configuration details** and indicate the actor information in the Actor URI field.
- Click **Security extensions** > **Request sender configuration > Details** and indicate the actor information in the Actor field.

You must configure the same actor strings for the web service on the server, which processes the request and sends the response back. Configure the actor in the following locations:

- Click **Security extensions** > **Server service configuration**.
- Click **Security extensions** > **Response sender service configuration details** > **Details** and indicate the actor information in the Actor field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The **actor** fields might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified the method that the server uses to verify the digital signature in the message parts.

### What to do next

After you configure the client for request signing and the server for request digital signature verification, you must configure the server and the client to handle the response. Next, specify the response signing for the server. See "Configuring the server for response signing: digitally signing message parts" for more information.

## Configuring the server for response signing: digitally signing message parts

Use an assembly tool to specify which message parts to digitally sign when configuring the server for response signing.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this topic supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **Extensions** tab and the **Binding** configurations tab in the web services editor within the IBM assembly tools:

- "Configuring the server security bindings using an assembly tool" on page 2042
- Configuring the server security bindings using the administrative console

These two tabs are used to configure the Web Services Security extensions and the Web Services Security bindings, respectively.

### About this task

Complete the following steps to specify which message parts to digitally sign when configuring the server for response signing:

### Procedure

1. Launch an assembly tool. For more information, see the related information on assembly tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open perspective** > **Other** > **J2EE**.
3. Click **EJB Projects** > ***application _name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file and click **Open with** > **Web services editor**.
5. Click the **Extensions** tab, which is located at the bottom of the Web Services Editor within the assembly tool.

6. Expand **Response sender service configuration details** > **Integrity**. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification while the data is transmitted across the Internet. For more information on digitally signing SOAP messages, see XML digital signature.
7. Indicate the parts of the message to sign by clicking **Add**, and selecting **Body**, **Timestamp**, or **SecurityToken**.

   The following list contains descriptions of the message parts:

   **Body** The body is the user data portion of the message.

   **Timestamp**
   The time stamp determines if the message is valid based on the time that the message is sent and then received. If this option if selected, proceed to the next step and click **Add Created Time Stamp**, which indicates that the time stamp is added to the message.

   **SecurityToken**
   The security token is used for authentication. If this option is selected, the authentication information is added to the message.
8. Optional: Expand the **Add created time stamp** section. Select this option if you want a time stamp added to the message. You can specify an expiration time for the time stamp, which helps defend against replay attacks. The lexical representation for duration is the ISO 8601 extended format, *PnYnMnDTnHnMnS*, where:
   - *nY* represents the number of years.
   - *nM* represents the number of months.
   - *nD* represents the number of days.
   - *T* is the date and time separator.
   - *nH* represents the number of hours.
   - *nM* represents the number of minutes.
   - *nS* represents the number of seconds. The number of seconds can include decimal digits to arbitrary precision.

   For example, to indicate a duration of 1 year, 2 months, 3 days, 10 hours, and 30 minutes, the format is: `P1Y2M3DT10H30M`. Typically, you configure a message time stamp for about 10 to 30 minutes. 10 minutes is represented as: `P0Y0M0DT0H10M0S`. The *P* character precedes time and date values.

## Results

**Important:** If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when running the client, you might need to configure the actor. You can configure the actor in the following locations:

- Click **Security extensions** > **Client service configuration details** and indicate the actor information in the **Actor URI** field.
- Click **Security extensions** > **Request sender configuration** > **Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the web service on the server, which processes the request and sends the response back. Configure the actor in the following locations:

- Click **Security extensions** > **Server service configuration**.
- Click **Security extensions** > **Response sender service configuration details** > **Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The actor fields might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure

that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which message parts to digitally sign when the server sends a response to the client.

### What to do next

After you specifying which message parts to digitally sign, you must specify which method is used to digitally sign the message. See "Configuring the server for response signing: choosing the digital signature method" for more information.

## Configuring the server for response signing: choosing the digital signature method

Use an assembly tool to specify which digital signature method to use when configuring the server for response signing.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the Extensions tab and the **Binding configurations** tab in the web services editor within the IBM assembly tools:

- "Configuring the server security bindings using an assembly tool" on page 2042
- Configuring the server security bindings using the administrative console

These two tabs are used to configure the Web Services Security extensions and the Web Services Security bindings, respectively.

### About this task

Complete the following steps to specify which digital signature method to use when configuring the server for response signing:

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application _name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file and click **Open with** > **Web services editor**.
5. Click the **Binding Configurations** tab.
6. Expand **Response sender binding configuration details** > **Signing information**.
7. Click **Edit** to choose a signing method. The signing info dialog is displayed and either select or enter the following information:
   - Canonicalization method algorithm
   - Digest method algorithm
   - Signature method algorithm

- Signing key name
- Signing key locator

The following table describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following address: http://www.w3.org/TR/xmldsig-core.

*Table 332. Digital signature methods. Use the methods to configure the server for response signing.*

| Name | Purpose |
|---|---|
| **Canonicalization method algorithm** | Canonicalizes the <SignedInfo> element before the information is digested as part of the signature operation. Use the same algorithm on the client response receiver. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration. |
| **Digest method algorithm** | Applies to the data after transforms are applied, if specified, to yield the <DigestValue> element. Signing the <DigestValue> element binds resource content to the signer key. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration. |
| **Signature method algorithm** | Converts the canonicalized <SignedInfo> element into the <SignatureValue> element. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration. |
| **Signing key name** | Represents the key entry associated with the signing key locator. The key entry refers to an alias of the key, which is found in the key store and is used to sign the request. |
| **Signing key locator** | Represents a reference to a key locator implementation class that locates the correct key store where the alias and certificate exists. For more information on configuring key locators, see the following file:<br>• "Configuring key locators using an assembly tool" on page 2021 |

8. Optional: Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Signature method algorithm and Digest method algorithm dropdown lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

### Results

You have specified which method is used to digitally sign a message when the server sends a message to a client.

### What to do next

After you configure the server to digitally sign the response message, you must configure the client to verify the digital signature contained in the response message. See "Configuring the client for response digital signature verification: verifying the message parts" for more information.

## Configuring the client for response digital signature verification: verifying the message parts

To configure the Web Services Security extensions and the Web Services Security bindings, use the **WS Extension** tab and the **WS Binding** tab in the Client Deployment Descriptor within an assembly tool.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to becomes familiar with the **WS Extension** tab and the **WS Binding** tab in the Client Deployment Descriptor within the assembly tool:

- "Configuring the client security bindings using an assembly tool" on page 2039
- Configuring the security bindings on a server acting as a client using the administrative console

You can use these two tabs to configure the Web Services Security extensions and the Web Services Security bindings, respectively.

## About this task

Complete the following steps to configure the client for response digital signature verification. The steps describe how to modify the extensions to indicate which parts of the response to verify.

## Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open perspective** > **Other** > **J2EE**.
3. Click **Application Client projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file and click **Open With** > **Deployment descriptor editor**.
5. Click the **WS extension** tab.
6. Expand the **Response receiver configuration** > **Required integrity** section. Required integrity refers to parts that require digital signature verification. Digital signature verification decreases the risk that the message parts have been modified while the message is transmitted across the Internet.
7. Indicate the parts of the message that must be verified. You can determine which parts of the message to verify by looking at the web service response sender configuration. Click **Add** and select one of the following parts:

   **Body** The body is the user data portion of the message.

   **Timestamp**
   The time stamp determines if the message is valid based on the time that the message is sent and then received. If the timestamp option is selected, proceed to the next step to add a received time stamp to the message.

   **Securitytoken**
   The security token authenticates the client. If the Securitytoken option is selected, the message is signed.
8. Optional: Expand the **Add received time stamp** section. Select **Add received time stamp** to add the received time stamp to the message.

## Results

**Important:** If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when running the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the web services client editor within an assembly tool:

- Click **Security extensions** > **Client service configuration details** and indicate the actor information in the Actor URI field.
- Click **Security extensions** > **Request sender configuration** > **Details** and indicate the actor information in the Actor field.

You must configure the same actor strings for the web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the web services editor within an assembly tool:

- Click **Security extensions** > **Server service configuration**.

- Click **Security extensions** > **Response sender service configuration details** > **Details** and indicate the actor information in the Actor field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The actor fields might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which message parts are digitally signed and must be verified by the client when the server sends a response message to the client.

### What to do next

After you specify which message parts contain a digital signature that must be verified by the client, you must configure the client to recognize the digital signature method used to digitally sign the message. See "Configuring the client for response digital signature verification: choosing the verification method" for more information.

## Configuring the client for response digital signature verification: choosing the verification method

You can configure the Web Services Security extensions and Web Services Security bindings using the **WS extension** tab and the **WS binding** tab in the web services editor within an assembly tool.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **WS extension** tab and the **WS binding** tab in the web services editor within the IBM assembly tools:

- "Configuring the server security bindings using an assembly tool" on page 2042
- Configuring the server security bindings using the administrative console

You can use these two tabs to configure the Web Services Security extensions and Web Services Security bindings, respectively. Also, you must specify which message parts contain digital signature information that must be verified by the client. See "Configuring the client for response digital signature verification: verifying the message parts" on page 2035 to specify which message parts are digitally signed by the server and must be verified by the client. The message parts specified for the server response sender must match the message parts specified for the client response receiver. Likewise, the digital signature method chosen for the server must match the digital signature method used by the client.

### About this task

Complete the following steps to configure the client for response digital signature verification. The steps describe how to modify the extensions to indicate which digital signature method the client will use during verification.

## Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open perspective** > **Other** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Binding** tab.
6. Expand the **Security response receiver binding configuration** > **Signing information** section.
7. Click **Edit** to select a digital signature method. The signing info dialog displays and either select or enter the following information:
   - **Canonicalization method algorithm**
   - **Digest method algorithm**
   - **Signature method algorithm**
   - **Signing key name**
   - **Signing key locator**

   For more conceptual information on digitally signing SOAP messages, see XML digital signature. The following table describes the purpose for each of these selections. Some of the following definitions are based on the XML-Signature specification, which can be found at: http://www.w3.org/TR/xmldsig-core.

*Table 333. Digital signature methods. Use the methods to configure the client for response digital signature verification.*

| Name | Purpose |
|---|---|
| **Canonicalization method algorithm** | The canonicalization method algorithm is used to canonicalize the `<SignedInfo>` element before it is digested as part of the signature operation. |
| **Digest method algorithm** | The digest method algorithm is the algorithm applied to the data after transforms are applied, if specified, to yield the `<DigestValue>`. The signing of the `<DigestValue>` binds resource content to the signer key. The algorithm selected for the client response receiver configuration must match the algorithm selected in the server response sender configuration. |
| **Signature method algorithm** | The signature method is the algorithm that is used to convert the canonicalized `<SignedInfo>` element into the `<SignatureValue>` element. The algorithm selected for the client response receiver configuration must match the algorithm selected in the server response sender configuration. |
| **Use certificate path reference** or **Trust any certificate** | When a message is signed, the public key used to sign it is transmitted with the message. To validate this public key at the receiving end, configure a certificate path reference. By selecting **User certificate path reference,** you must configure a trust anchor reference and certificate store reference to validate the certificate sent with the message. By selecting **Trust any certificate**, the signature is validated by the certificate sent with the message without the certificate itself being validated. |
| **Use certificate path reference: Trust anchor reference** | A trust anchor is a configuration that refers to a keystore that contains trusted, self-signed certificates and certificate authority (CA) certificates. These certificates are trusted certificates that you can use with any applications in your deployment. |
| **Use certificate path reference: Certificate store reference** | A certificate store is a configuration that has a collection of X.509 certificates. These certificates are not trusted for all applications in your deployment, but might be used as an intermediary to validate certificates for an application. |

8. Optional: Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Signature method algorithm and Digest method algorithm dropdown lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

### Results

**Important:** If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when running the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the web services client editor within an assembly tool:

- Click **Security extensions** > **Client service configuration details** and indicate the actor information in the Actor URI field.
- Click **Security extensions** > **Request sender configuration** > **Details** and indicate the actor information in the Actor field.

You must configure the same actor strings for the web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the web services editor within an assembly tool:

- Click **Security extensions** > **Server service configuration**.
- Click **Security extensions** > **Response sender service configuration details** > **Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The actor fields might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which method the client uses to verify the digital signature in the message parts.

### What to do next

After you configure the server for response signing and the client for request digital signature verification, verify that you have configured the client and the server to handle the message request.

## Configuring the client security bindings using an assembly tool

Use the web services client editor within an assembly tool to include the binding information, that describes how to run the security specifications found in the extensions, in the client enterprise archive (EAR) file.

### About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

When configuring a client for Web Services Security, the bindings describe how to run the security specifications found in the extensions. Use the web services client editor within an assembly tool to include the binding information in the client enterprise archive (EAR) file.

You can configure the client-side bindings from a pure client accessing a web service or from a web service accessing a downstream web service. This document focuses on the pure client situation. However, the concepts, and in most cases the steps, also apply when a web service is configured to

communicate downstream to another web service that has client bindings. Complete the following steps to edit the security bindings on a pure client (or server acting as a client) using an assembly tool:

## Procedure

1. Import the web services client EAR file into an assembly tool. When you edit the client bindings on a server acting as a client, the same basic steps apply. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**. The Client Deployment Descriptor is displayed.
5. Click the **WS Extension** tab and select the port QName bindings that you want to configure. The Web Services Security extensions are configured for outbound requests and inbound responses. You need to configure the following information for Web Services Security extensions. These topics are discussed in more detail in other sections of the documentation.

   **Request sender configuration details**

   **Details**
   "Configuring the client for request signing: digitally signing message parts" on page 2024

   **Integrity**
   "Configuring the client for request signing: digitally signing message parts" on page 2024

   **Confidentiality**
   "Configuring the client for request encryption: Encrypting the message parts" on page 2046

   **Login Config**

   **BasicAuth**
   "Configuring the client for basic authentication: specifying the method" on page 2057

   **IDAssertion**
   "Configuring the client for identity assertion: specifying the method" on page 2065

   **Signature**
   "Configuring the client for signature authentication: specifying the method" on page 2072

   **LTPA** "Configuring the client for LTPA token authentication: specifying LTPA token authentication" on page 2081

   **ID assertion**
   "Configuring the client for identity assertion: specifying the method" on page 2065

   **Add created time stamp**
   "Configuring the client for request signing: digitally signing message parts" on page 2024

   **Response receiver configuration details**

   **Required integrity**
   "Configuring the client for response digital signature verification: verifying the message parts" on page 2035

   **Required confidentiality**
   "Configuring the client for response decryption: decrypting the message parts" on page 2054

   **Add received time stamp**
   "Configuring the client for response digital signature verification: verifying the message parts" on page 2035

6. Click the **WS binding** tab and select the port qualified name binding that you want to configure. The Web Services Security bindings are configured for outbound requests and inbound responses. You need to configure the following information for Web Services Security bindings. These topics are discussed in more details in other sections of the documentation.

   **Security request sender binding configuration**

   **Signing information**
   "Configuring the client for request signing: choosing the digital signature method" on page 2026

   **Encryption information**
   "Configuring the client for request encryption: choosing the encryption method" on page 2047

   **Key locators**
   "Configuring key locators using an assembly tool" on page 2021

   **Login binding**

   **BasicAuth**
   "Configuring the client for basic authentication: collecting the authentication information" on page 2059

   **ID assertion**
   "Configuring the client for identity assertion: collecting the authentication method" on page 2066

   **Signing information**
   "Configuring the client for response digital signature verification: choosing the verification method" on page 2037

   **Encryption information**
   "Configuring the client for response decryption: choosing a decryption method" on page 2055

   **Trust anchor**
   "Configuring trust anchors using an assembly tool" on page 2018

   **Certificate store list**
   "Configuring the client-side collection certificate store using an assembly tool" on page 2020

   **Key locators**
   "Configuring key locators using an assembly tool" on page 2021

## What to do next

**Important:** When configuring the security request sender binding configuration, you must synchronize the information used to perform the specified security with the security request receiver binding configuration, which is configured in the server EAR file. These two configurations must be synchronized in all respects because there is no negotiation during run time to determine the requirements of the server.

For example, when configuring the encryption information in the security request sender binding Configuration, you must use the public key from the server for encryption. Therefore, the key locator that you choose must contain the public key from the server configuration. The server must contain the private key to decrypt the message. This example illustrates the important relationship between the client and

server configuration. Additionally, when configuring the security response receiver binding configuration, the server must send the response using security information known by this client security response receiver binding configuration.

The following table shows the related configurations between the client and the server. The client request sender and the server request receiver are relative configurations that must be synchronized with each other. The server response sender and the client response receiver are related configurations that must be synchronized with each other. Note that the related configurations are end points for any request or response. One end point must communicate its actions with the other end point because run time requirements are not negotiated.

*Table 334. Related configurations. The configurations must be synchronized with each other.*

| Client configuration | Server configuration |
|---|---|
| Request sender | Request receiver |
| Response receiver | Response sender |

## Configuring the server security bindings using an assembly tool

Use an assembly tool to edit bindings for a web service after these bindings are deployed on a server.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to importing the web services enterprise archive (EAR) file into the assembly tool, make sure that you have already run the WSDL2Java command on your web service to enable your Java Platform, Enterprise Edition (Java EE) application. You must import the Web services EAR file into the assembly tool.

### About this task

Create an Enterprise JavaBeans (EJB) file Java archive (JAR) file or a web application archive (WAR) file containing the security binding file (`ibm-webservices-bnd.xmi`) and the security extension file (`ibm-webservices-ext.xmi`). If this archive is acting as a client to a downstream service, you also need the client-side binding file (`ibm-webservicesclient-bnd.xmi`) and the client-side extension file (`ibm-webservicesclient-ext.xmi`). These files are generated using the WSDL2Java command. For more information, read about the WSDL2Java command for JAX-RPC applications. You can edit these files using the web services editor in the assembly tool.

When configuring server-side security for Web Services Security, the security extensions configuration specifies what security is performed, the security bindings configuration indicates how to perform what is specified in the security extensions configuration. You can use the defaults for some elements at the cell and server levels in the bindings configuration, including key locators, trust anchors, the collection certificate store, trusted ID evaluators, and login mappings and reference these elements from the WAR and JAR binding configurations.

Open the web services editor in an assembly tool to begin editing the server security extensions and bindings. The following steps can locate the server security extensions and bindings. Other tasks specify how to configure each section of the extensions and bindings in more detail.

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java EE perspective. Click **Window** > **Open Perspective** > **J2EE**.

3. Configure the server for inbound requests and outbound responses security configuration. To configure the server for inbound requests and outbound responses, complete the following steps:
   a. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
   b. Right-click the `webservices.xml` file and click **Open with** > **Web services editor**. The `webservices.xml` file represents the server-side (inbound) web services configuration. The `webservicesclient.xml` file represents the client-side (outbound) web services configuration.
4. In the web services editor (for the `webservices.xml` file and inbound requests and outbound responses web services configuration), there are several tabs at the bottom of the editor including Web Services, Port Components, Handlers, Security Extensions, Bindings, and Binding Configurations. The security extensions are edited using the **Security Extensions** tab. The security bindings are edited using the Security Bindings tab.
   a. Click the **WS Extensions** tab and select the port component binding to edit. The Web Services Security extensions are configured for inbound requests and outbound responses. You need to configure the following information for Web Services Security extensions. These topics are discussed in more detail in other topics in the documentation.

      **Request receiver service configuration details**

      **Required integrity**
      "Configuring the server for request digital signature verification: Verifying the message parts" on page 2028

      **Required confidentiality**
      "Configuring the server for request decryption: decrypting the message parts" on page 2048

      **Login config**

      **BasicAuth**
      "Configuring the server to handle basic authentication information" on page 2062

      **ID assertion**
      "Configuring the server to handle identity assertion authentication" on page 2067

      **Signature**
      "Configuring the server to support signature authentication" on page 2075

      **LTPA** "Configuring the server to handle LTPA token authentication information" on page 2083

      **Add received time stamp**
      "Configuring the server for request digital signature verification: Verifying the message parts" on page 2028

      **Response sender service configuration details**

      **Details**
      "Configuring the server for response signing: digitally signing message parts" on page 2032

      **Integrity**
      "Configuring the server for response signing: digitally signing message parts" on page 2032

      **Confidentiality**
      "Configuring the server for response encryption: encrypting the message parts" on page 2051

      **Add created time stamp**
      "Configuring the server for response signing: digitally signing message parts" on page 2032
   b. Click the **Binding Configurations** tab and select the port component binding to edit. The Web Services Security bindings are configured for inbound requests and outbound responses. You need to configure the following information for Web Services Security bindings. These topics are discussed in more details in other topics in the documentation.

**Response receiver binding configuration details**

**Signing Information**
"Configuring the server for request digital signature verification: choosing the verification method" on page 2030

**Encryption Information**
"Configuring the server for request decryption: choosing the decryption method" on page 2049

**Trust Anchor**
"Configuring trust anchors using an assembly tool" on page 2018

**Certificate Store List**
"Configuring the server-side collection certificate store using an assembly tool" on page 2021

**Key Locators**
"Configuring key locators using an assembly tool" on page 2021

**Login Mapping**

**Basic auth**
"Configuring the server to validate basic authentication information" on page 2063

**ID assertion**
"Configuring the server to validate identity assertion authentication information" on page 2069

**Signature**
"Configuring the server to validate signature authentication information" on page 2076

**LTPA** "Configuring the server to validate LTPA token authentication information" on page 2084

**Trusted ID evaluator**

**Trusted ID evaluator reference**

**Response sender binding configuration details**

**Signing information**
"Configuring the server for response signing: choosing the digital signature method" on page 2034

**Encryption information**
"Configuring the server for response encryption: choosing the encryption method" on page 2052

**Key locators**
"Configuring key locators using an assembly tool" on page 2021

## What to do next

Configure the client for outbound requests and inbound responses security configuration by right-clicking the `webservicesclient.xml` file and clicking **Open With** > **Deployment descriptor editor**. For more information, see "Configuring the client security bindings using an assembly tool" on page 2039.

# Configuring XML encryption for Version 5.x web services with an assembly tool

XML encryption is one method that WebSphere® Application Server provides to secure your web services. It enables you to encrypt an XML element, the content of an XML element, or arbitrary data such as an XML document.

## Securing web services for Version 5.x applications using XML encryption

XML encryption is one method that WebSphere Application Server provides to secure your web services. It enables you to encrypt an XML element, the content of an XML element, or arbitrary data such as an XML document.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

WebSphere Application Server provides several different methods to secure your web services. XML encryption is one of these methods. You can secure your web services using any of the following methods:

- XML digital signature
- XML encryption
- Basicauth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

### About this task

XML encryption enables you to encrypt an XML element, the content of an XML element, or arbitrary data such as an XML document. Like XML digital signature, a message is sent by the client as the request sender to the server as the request receiver. The response is sent by the server as the response sender to the client as the request receiver. Unlike XML digital signature, which verifies the authenticity of the sender, XML encryption scrambles the message content using a key, which can be unscrambled by a receiver that possesses the same key. You can use XML encryption in conjunction with XML digital signature to scramble the content while verifying the authenticity of the message sender.

To use XML encryption to secure web services, you must use an assembly tool. For more information, see the related information on Assembly Tools.

To securing web services for Version 5.*x* applications using XML encryption, complete the following steps:

### Procedure

1. Specify the encryption settings for the request sender. The message parts and the encryption method settings chosen for the request sender on the client must match the message parts and the method settings chosen for the request receiver on the server. To specify the encryption settings for the request sender:
   a. “Configuring the client for request encryption: Encrypting the message parts” on page 2046.
   b. “Configuring the client for request encryption: choosing the encryption method” on page 2047.
2. Specify the encryption settings for the request receiver. The decryption settings chosen for the request receiver must match the encryption settings chosen for the request sender.

   To specify the decryption settings for the request receiver:

a. “Configuring the server for request decryption: decrypting the message parts” on page 2048.
b. “Configuring the server for request decryption: choosing the decryption method” on page 2049.

3. Specify the encryption settings for the response sender. The message parts and the encryption method settings chosen for the response sender on the server must match the message parts and the method settings chosen for the response receiver on the client. To specify the encryption settings for the response sender:
   a. “Configuring the server for response encryption: encrypting the message parts” on page 2051.
   b. “Configuring the server for response encryption: choosing the encryption method” on page 2052.
4. Specify the encryption settings for the response receiver.

   **Remember:** The decryption settings chosen for the response receiver must match the encryption settings chosen for the response sender.

   To specify the decryption settings for the response receiver, complete the following steps:
   a. “Configuring the client for response decryption: decrypting the message parts” on page 2054.
   b. “Configuring the client for response decryption: choosing a decryption method” on page 2055.

### Results

After completing these steps, you have secured your web services using XML encryption.

## Configuring the client for request encryption: Encrypting the message parts

To configure the client for request encryption, specify which message parts to encrypt when configuring the client.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to familiarize yourself with the **WS Extensions** tab and the **WS Binding** tab in the Client Deployment Descriptor Editor within an assembly tool:

- “Configuring the client security bindings using an assembly tool” on page 2039
- Configuring the security bindings on a server acting as a client using the administrative console

These two tabs are used to configure the Web Services Security extensions and Web Services Security bindings, respectively.

### About this task

Complete the following steps to specify which message parts to encrypt when configuring the client for request encryption:

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS extensions** tab, which is located at the bottom of Client Deployment Descriptor Editor within the assembly tool.

6. Expand **Request sender configuration** > **Confidentiality**. Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone understanding the message flowing across the Internet. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the correct target. For more information on encrypting , see XML encryption.
7. Select the parts of the message that you want to encrypt by clicking **Add**. You can select one of the following parts:

   **Bodycontent**
   User data portion of the message

   **Usernametoken**
   Basic authentication information, if selected

### What to do next

After you specify which message parts to encrypt, you must specify which method to use to encrypt the request message. See "Configuring the client for request encryption: choosing the encryption method" for more information.

## Configuring the client for request encryption: choosing the encryption method

To configure the client for request encryption, specify which encryption method to use when configuring the client.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to familiarize yourself with the **WS Extensions** tab and the **WS Binding** tab in the Client Deployment Descriptor editor within an assembly tool:

- "Configuring the client security bindings using an assembly tool" on page 2039
- Configuring the security bindings on a server acting as a client using the administrative console

These two tabs are used to configure the Web Services Security extensions and Web Services Security bindings, respectively.

### About this task

Complete the following steps to specify which encryption method to use when configuring the client for request encryption:

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS binding** tab, which is located at the bottom of the Client Deployment Descriptor editor within the assembly tool.
6. Expand **Security request sender binding configuration** > **Encryption information**.

7. Select an encryption option and click **Edit** to view the encryption information or click **Add** to add another option. The following table describes the purpose of this information. Some of these definitions are based on the XML-Encryption specification, which is located at the following web address: http://www.w3.org/TR/xmlenc-core

   **Encryption name**
   Refers to the name of the encryption information entry.

   **Data encryption method algorithm**
   Encrypts and decrypts data in fixed size, multiple octet blocks.

   **Key encryption method algorithm**
   Represents public key encryption algorithms that are specified for encrypting and decrypting keys.

   **Encryption key name**
   Represents a Subject (**Owner** field of the certificate) from a public key certificate found by the encryption key locator, which is used by the key encryption method algorithm to encrypt the private key. The private key is used to encrypt the data.

   The key chosen must be a public key of the target. Encryption must be done using the public key and decryption must be done by the target using the private key (the personal certificate of the target).

   **Encryption key locator**
   Represents a reference to a key locator implementation class that locates the correct key store where the alias and the certificate exist. For more information on configuring key locators, see "Configuring key locators using an assembly tool" on page 2021 and Configuring key locators using the administrative console.

8. Optional: Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the **Data Encryption method algorithm** and **Key Encryption method algorithm** dropdown lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the WebSphere administrative console.

### Results

For more information, see "Configuring key locators using an assembly tool" on page 2021 and Configuring key locators using the administrative console.

### What to do next

You must specify which parts of the request message to encrypt. See "Configuring the client for request encryption: Encrypting the message parts" on page 2046 if you have not previously specified this information.

## Configuring the server for request decryption: decrypting the message parts

Use the **WS Extensions** tab and the **WS Binding** configurations tab to specify which parts of the request message must be decrypted by the server.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.x and later applications.

Complete this task to specify which parts of the request message must be decrypted by the server. You must know which parts of the request message the client encrypts because the server must decrypt the same message parts.

Prior to completing these steps, read either of the following topics to become familiar with the **WS Extensions** tab and the **WS Binding** configurations tab:

- "Configuring the server security bindings using an assembly tool" on page 2042
- Configuring the server security bindings using the administrative console

These two tabs are used to configure the Web Services Security extensions and Web Services Security bindings, respectively.

### About this task

Complete the following steps to configure the request receiver extensions:

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META_INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the **Extensions** tab, which is located at the bottom of the web services editor within the assembly tool.
6. Expand the **Request receiver service configuration details** > **Required confidentiality** section.
7. Select the parts of the message to decrypt. The message parts selected for the request decryption on the server must match the message parts selected for the message encryption on the client. Click **Add** and select either of the following message parts:

   **bodycontent**
   The user data section of the message.

   **usernametoken**
   This token is the basic authentication information.

### What to do next

After you specify which parts of the request message to decrypt, you must specify the method to use decrypt the message. See "Configuring the server for request decryption: choosing the decryption method" for more information.

## Configuring the server for request decryption: choosing the decryption method

You can use an assembly tool and the administrative console to configure the Web Services Security extensions and Web Services Security bindings.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **WS Extensions** tab and the **WS Bindings** tab:

- "Configuring the server security bindings using an assembly tool" on page 2042

- Configuring the server security bindings using the administrative console

These two tabs are used to configure the Web Services Security extensions and Web Services Security bindings, respectively.

## About this task

Complete this task to specify which decryption method is used by the server to decrypt the request message. You must know which decryption method the client uses because the server must use the same method.

## Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META_INF**.
4. Right-click the `webservices.xml` file, select **Open with** > **Web services editor**.
5. Click the **Binding Configurations** tab, which is located at the bottom of the web services editor within the assembly tool.
6. Expand the **Request receiver binding configuration details** > **Encryption information** section.
7. Click **Edit** to view the encryption information. The following table describes the purpose for each of these selections. Some definitions are taken from the XML-Encryption specification , which is located at the following web address: http://www.w3.org/TR/xmlenc-core

   **Encryption name**
   Represents the name of this encryption information entry; an alias for the entry.

   **Data encryption method algorithm**
   Encrypts and decrypts data in fixed size, multiple octet blocks. This algorithm must be the same as the algorithm selected in the client request sender configuration.

   **Key encryption method algorithm**
   Represents algorithms specified for encrypting and decrypting keys. This algorithm must be the same as the algorithm selected in the client request sender configuration.

   **Encryption key name**
   Represents a Subject from a personal certificate, which is typically a distinguished name (DN) that is found by the encryption key locator. The subject is used by the key encryption method algorithm to decrypt the secret key, and the secret key is used to decrypt the data.

   The key chosen must be a private key in the key store configured by the key locator. The key requires the same Subject used by the client to encrypt the data. Encryption must be done using the public key and decryption by using the private key (personal certificate). To ensure that the client encrypts the data with the correct public or private key, you must extract the public key from the server key store and add it to the key store specified in the encryption configuration information for the client request sender.

   For example, the personal certificate of a server is `CN=Bob, O=IBM, C=US`. Therefore the server contains the public and private key pair. The client sending the request should encrypt the data using the public key for `CN=Bob, O=IBM, C=US`. The server decrypts the data using the private key for `CN=Bob, O=IBM, C=US`.

   **Encryption key locator**
   Represents a reference to a key locator implementation class that finds the correct keystore where the alias and the certificate exist. For more information on configuring key locators, go to the following sections: “Configuring key locators using an assembly tool” on page 2021 and Configuring key locators using the administrative console.

8. Optional: Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Data Encryption method algorithm and Key Encryption method algorithm dropdown lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

### Results

It is important to note that for decryption, the encryption key name chosen must refer to a personal certificate that can be located by the key locator of the server referenced in the encryption information. Enter the Subject of the personal certificate here, which is typically a Distinguished Name (DN). The Subject uses the default key locator to find the key. If a custom key locator is written, the encryption key name can be anything used by the key locator to find the correct encryption key. The encryption key locator references the implementation class that finds the correct key store where this alias and certificate exist. Refer to "Configuring key locators using an assembly tool" on page 2021 and Configuring key locators using the administrative console for more information.

### What to do next

You must specify which parts of the request message to decrypt. See "Configuring the server for request decryption: decrypting the message parts" on page 2048 if you have not previously specified this information.

## Configuring the server for response encryption: encrypting the message parts

You can specify which parts of the response message to encrypt when configuring the server for response encryption.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **WS Extensions** tab and the **WS Bindings** tab in the Web services editor within an assembly tool:

- "Configuring the server security bindings using an assembly tool" on page 2042
- Configuring the server security bindings using the administrative console

These two tabs are used to configure the Web Services Security extensions and the Web Services Security bindings, respectively.

### About this task

Complete the following steps to specify which parts of the response message to encrypt when configuring the server for response encryption:

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule > META_INF**.
4. Right-click the `webservices.xml` file, select **Open with > Web services editor**.

5. Click the **Extensions** tab, which is located at the bottom of the Web Services Editor within the assembly tool.
6. Expand **Response sender service configuration details > Confidentiality**. Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone understanding the message flowing across the Internet. With confidentiality specifications, the response is encrypted before it is sent and decrypted when it is received at the correct target.
7. Select the parts of the response that you want to encrypt by clicking **Add** and selecting **Bodytoken** or **Usernametoken**. The following information describes the message parts:

   **Bodycontent**
   User data portion of the message.

   **Usernametoken**
   Basic authentication information, if selected.

   A user name token does not appear in the response so you do not need to select this option for the response. If you select this option, make sure that you also select it for the client response receiver. If you do not select this option, make sure that you do not select it for the client response receiver.

### What to do next

After you specify which message parts to encrypt, you must specify which method to use message encryption. See the task for choosing the encryption method when configuring the server for response encryption.

## Configuring the server for response encryption: choosing the encryption method

You can specify which method the server uses to encrypt the response message.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **Extensions** tab and the **Binding configurations** tab in the web services editor within an assembly tool:

- “Configuring the server security bindings using an assembly tool” on page 2042
- Configuring the server security bindings using the administrative console

These two tabs are used to configure the Web Services Security extensions and Web Services Security bindings, respectively.

### About this task

Complete the following steps to specify which method the server uses to encrypt the response message:

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META_INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.

5. Click the **Binding Configuration**s tab, which is located at the bottom of the Web Services Editor within the assembly tool.
6. Expand **Response sender binding configuration details** > **Encryption information**.
7. Click **Edit** to view the encryption information. The following table describes the purpose of this information. Some of these definitions are based on the XML-Encryption specification, which is located at the following web address: http://www.w3.org/TR/xmlenc-core

   **Encryption name**
   Refers to the name of the encryption information entry.

   **Data encryption method algorithm**
   Encrypts and decrypts data in fixed size, multiple octet blocks. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration.

   **Key encryption method algorithm**
   Represents public key encryption algorithms that are specified for encrypting and decrypting keys. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration.

   **Encryption key name**
   Represents a Subject from a public key certificate typically distinguished name (DN) that is found by the encryption key locator and used by the key encryption method algorithm to encrypt the private key. The private key is used to encrypt the data.

   The key name chosen in the server response sender encryption information must be the public key of the key configured in the client response receiver encryption information. Encryption by the response sender must be done using the public key and decryption must be done by the response receiver using the associated private key (the personal certificate of the response receiver).

   **Encryption key locator**
   The encryption key locator represents a reference to a key locator implementation class that finds the correct key store where the alias and the certificate exist. For more information, see the tasks for configuring key locators.
8. Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Data Encryption method algorithm and Key Encryption method algorithm drop-down lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

## Results

The encryption key name chosen must refer to a public key of the response receiver. For the encryption key name, use the Subject of the public key certificate, typically a Distinguished Name (DN). The name chosen is used by the default key locator to find the key. If you write a custom key locator , the encryption key name might be anything that is used by the key locator to find the correct encryption key (a public key). The encryption key locator references the implementation class that finds the correct key store where the alias and certificate exist.

## What to do next

You must specify which parts of the response message to encrypt. See the task for configuring the server for response encryption if you have not previously specified this information.

## Configuring the client for response decryption: decrypting the message parts

To configure the client for response decryption, specify which response message parts to decrypt when configuring the client. The server response encryption and client response decryption configurations must match.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **WS Extensions** tab and the **WS Binding** tab in the Client Deployment Descriptor Editor within an assembly tool:

- "Configuring the client security bindings using an assembly tool" on page 2039
- Configuring the security bindings on a server acting as a client using the administrative console

These two tabs are used to configure the Web Services Security extensions and the Web Services Security bindings, respectively.

### About this task

Complete the following steps to specify which response message parts to decrypt when configuring the client for response decryption. The server response encryption and client response decryption configurations must match.

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Extensions** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Response receiver configuration** > **Required confidentiality** section.
7. Select the parts of the message that you must decrypt by clicking **Add** and selecting either **Bodycontent** or **Usernametoken**. The following information describes these message parts:

   **Bodycontent**
   The user data portion of the message.

   **Usernametoken**
   The basic authentication information, if selected.

   The information selected in this step is encrypted by the server in the response sender.

   **Important:** A Username Token is typically not sent in the response. Thus, you usually do not need to select username token.

### What to do next

After you specify which message parts to decrypt, you must specify which method to use when decrypting the response message. See "Configuring the client for response decryption: choosing a decryption method" on page 2055 for more information.

## Configuring the client for response decryption: choosing a decryption method

To configure the client for response decryption, specify which decryption method to use when the client decrypts the response message. The server response encryption and client response decryption configurations must match.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **WS Extensions** tab and the **WS Bindings** tab in the Client Deployment Descriptor Editor within an assembly tool:

- "Configuring the client security bindings using an assembly tool" on page 2039
- Configuring the security bindings on a server acting as a client using the administrative console

These two tabs are used to configure the Web Services Security extensions and Web Services Security bindings, respectively.

### About this task

Complete the following steps to specify which decryption method to use when the client decrypts the response message. The server response encryption and client response decryption configurations must match.

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Binding** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Security response receiver binding configuration** > **Encryption information** section. For more information on encrypting and decrypting SOAP messages, see XML encryption.
7. Click **Edit** to view the encryption information. The following table describes the purpose for this information. Some of these definitions are based on the XML-Encryption specification, which is located at the following web address: http://www.w3.org/TR/xmlenc-core

   **Encryption name**
   Refers to the alias that is used for the encryption information entry.

   **Data encryption method algorithm**
   Encrypts and decrypts data in fixed size, multiple octet blocks.

   **Key encryption method algorithm**
   Represents public key encryption algorithms specified for encrypting and decrypting keys.

   **Encryption key name**
   Represents a Subject from a personal certificate, which is typically a distinguished name (DN) that is found by the encryption key locator. The Subject is used by the key encryption method algorithm to decrypt the secret key. The secret key is used to decrypt the data.

**Important:** The key chosen must be a private key of the client. Encryption must be done using the public key and decryption must be done by the private key (personal certificate). For example, the personal certificate of the client is: `CN=Alice, O=IBM, C=US`. Therefore, the client contains the public and private key pair. The target server that sends the response encrypts the secret key by using the public key for `CN=Alice, O=IBM, C=US`. The client decrypts the secret key by using the private key for `CN=Alice, O=IBM, C=US`.

**Encryption key locator**
Represents a reference to a key locator implementation class that finds the correct key store where the alias and the certificate exist. For more information on configuring key locators, see "Configuring key locators using an assembly tool" on page 2021 and Configuring key locators using the administrative console.

8. Optional: Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Data Encryption method algorithm and Key Encryption method algorithm dropdown lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

### Results

For decryption, the encryption key name chosen must refer to a personal certificate that can be located by the client key locator. The Subject (**owner** field of the certificate) of the personal certificate should be entered in the Encryption key name, this is typically a Distinguished Name (DN). The default key locator uses the Encryption key name to find the key within the keystore. If you write a custom key locator, the encryption key name can be anything used by the key locator to find the correct encryption key. The encryption key locator references the implementation class that locates the correct key store where this alias and certificate exists. For more information, see "Configuring key locators using an assembly tool" on page 2021 and Configuring key locators using the administrative console.

### What to do next

You must specify which parts of the request message to decrypt. See the topic"Configuring the client for response decryption: decrypting the message parts" on page 2054 if you have not previously specified this information.

# Configuring XML basic authentication for Version 5.x web services with an assembly tool

With the basic authentication (BasicAuth) authentication method, the request sender generates a BasicAuth security token using a callback handler. The request receiver retrieves the BasicAuth security token from the SOAP message and validates it using a Java™ Authentication and Authorization Service (JAAS) login module. Trust is established by using user name and password validation.

## Securing web services for Version 5.x applications using basic authentication

With the basic authentication (BasicAuth) authentication method, the request sender generates a BasicAuth security token using a callback handler. The request receiver retrieves the BasicAuth security token from the SOAP message and validates it using a Java Authentication and Authorization Service (JAAS) login module. Trust is established by using user name and password validation.

### About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

WebSphere Application Server provides several different methods to secure your web services. BasicAuth authentication is one of these methods. You might also secure your web services using any of the following methods:

- XML digital signature
- XML encryption
- BasicAuth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

To use BasicAuth authentication to secure web services, complete the following tasks:

### Procedure

1. Secure the client for BasicAuth authentication.
   a. Configure the client for basic authentication: specifying the method
   b. Configure the client for basic authentication: collecting the authentication information
2. Secure the server for BasicAuth authentication.
   a. Configure the server to handle basic authentication
   b. Configure the server to validate basic authentication information

### Results

After completing these steps, you have secured your web services using BasicAuth authentication.

## Configuring the client for basic authentication: specifying the method

Basic authentication (BasicAuth) refers to the user ID and password of a valid user in the registry of the target server. BasicAuth information can be collected in many ways, including through an administrative console prompt, a standard in (Stdin) prompt, or specified in the bindings that prevents user interaction.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

For more information on BasicAuth authentication, see: “BasicAuth authentication method” on page 2058.

### About this task

**Attention:** WebSphere Application Server supports nonce (randomly generated token) with BasicAuth authentication. For more information, see Nonce.

Complete the following steps to specify BasicAuth as the authentication method:

## Procedure

1. Launch an assembly tool. See more information on the assembly tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Extensions** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Request sender configuration** > **Login configuration** section. The only valid login configuration choices for a pure client are **BasicAuth** and **Signature**.
7. Select **BasicAuth** to authenticate the client using a user ID and a password. This user ID and password must be specified in the target user registry. The other choice, Signature, attempts to authenticate the client using the certificate used to digitally sign the message.

## What to do next

For more information on getting started with the web services client editor within the assembly tool, see either of the following topics:

- "Configuring the client security bindings using an assembly tool" on page 2039
- Configuring the security bindings on a server acting as a client using the administrative console

After you specify the BasicAuth authentication method, you must specify how to collect the authentication information. See "Configuring the client for basic authentication: collecting the authentication information" on page 2059.

***BasicAuth authentication method:***

When you use the BasicAuth authentication method, the security token that is generated is a <wsse:UsernameToken> element with <wsse:Username> and <wsse:Password> elements.

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6 and later applications.

WebSphere Application Server supports text passwords but not password digest because passwords are not stored and cannot be retrieved from the server. On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, a Java Authentication and Authorization Service (JAAS) login module is used to validate the security token. These two operations, token generation and token validation, are described in the following sections.

**BasicAuth token generation**

The request sender generates a BasicAuth security token using a callback handler. The security token returned by the callback handler is inserted in the SOAP message. The callback handler that is used is specified in the <LoginBinding> element of the bindings file, `ibm-webservicesclient-bnd.xmi`. The following callback handler implementations are provided with WebSphere Application Server and can be used with the BasicAuth authentication method:

- com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler
- com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler
- com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler

You can add your own callback handlers that implement the `javax.security.auth.callback.CallbackHandler` method.

**BasicAuth token validation**

The request receiver retrieves the BasicAuth security token from the SOAP message and validates it using a JAAS login module. The <wsse:Username> and <wsse:Password> elements in the security token are used to perform the validation. If the validation is successful, the login module returns a JAAS Subject. This Subject is set as the identity of the running thread. If the validation fails, the request is rejected with a SOAP fault exception.

The JAAS login configuration is specified in the <LoginMapping> element of the bindings file. Default bindings are specified in the `ws-security.xml` file. However, you can override these bindings using the application-specific `ibm-webservices-bnd.xmi` file. The configuration information consists of a CallbackHandlerFactory and a ConfigName value. The CallbackHandlerFactory option specifies the name of a class that is used for creating the JAAS CallbackHandler object. WebSphere Application Server provides the com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl CallbackHandlerFactory implementation. The ConfigName value specifies a JAAS configuration name entry. WebSphere Application Server searches the `security.xml` file for a matching configuration name entry. If a match is not found, it searches the `wsjaas.conf` file for a match. WebSphere Application Server provides the WSLogin default configuration entry, which is suitable for the BasicAuth authentication method.

## Configuring the client for basic authentication: collecting the authentication information

The basic authentication (BasicAuth) method refers to the user ID and the password of a valid user in the registry of the target server. Collection of BasicAuth information can occur in many ways including through a user interface prompt, a standard in (Stdin) prompt, or specified in the bindings, which prevents user interaction.

### About this task

**Note:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

For more information on BasicAuth authentication, see “BasicAuth authentication method” on page 2058.

Complete this task to specify the authentication information needed for BasicAuth authentication:

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Binding** tab, which is located at the bottom of deployment descriptor editor within the assembly tool.
6. Expand the **Security request sender binding configuration** > **Login binding** section.
7. Click **Edit** or **Enable** to view the login binding information. The login binding information displays and enter the following information:

   **Authentication method**

   Specifies the type of authentication. Select **BasicAuth** to use basic authentication.

**Token value type URI and Token value type local name**
When you select **BasicAuth**, you cannot edit the token value type URI and the local name values. Specifies values for custom authentication types. For BasicAuth authentication, leave these values blank.

**Callback handler**
Specifies the Java Authentication and Authorization Server (JAAS) callback handler implementation for collecting the BasicAuth information. You can use the following default implementations for the callback handler:

**com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler**
This implementation is used for non-user interface console prompts.

**Restriction:** This implementation prompts for the user name and password and reads them into the configuration from standard in. If you have a multi-threaded client and multiple threads attempt to read from standard in at the same time, all the threads will not successfully obtain the user name and password information. Therefore, you cannot use the `com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler` implementation with a multi-threaded client where multiple threads might attempt to obtain data from standard in concurrently.

**com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler**
This implementation is used for user interface panel prompts.

**com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler**
This implementation is used when you plan to always enter the user ID and password in the BasicAuth user ID and password section that follows.

**Basic Authentication user ID and Basic Authentication password**
Specifies values for the BasicAuth user ID and password, regardless of the default callback handler indicated previously, these user ID and password values are used to authenticate to the server for the Web Services Security authentication. If you leave these values blank, use either the `GUIPromptCallbackHandler` or the `StdinPromptCallbackHandler` implementation, but only on a pure client. Always fill-in these values for any web service that acts as a client to another web service that you want to specify for BasicAuth for authentication downstream. If you want the client identity of the originator to flow downstream, configure the web service client to use either ID assertion or Lightweight Third Party Authentication (LTPA).

**Property**
Specifies properties with name and value pairs for custom callback handlers to use. For BasicAuth authentication, you do not need to enter any information. To enter a new property, click **Add** and enter the new property and value.

## Results

**Other basic authentication entries**: There is a basic authentication entry in the Port Qualified Name Binding Details section. This entry is used for HTTP transport authentication, which might be required if the router servlet is protected.

Information specified in the Web Services Security basic authentication section overrides the basic authentication information specified in the Port Qualified Name Binding Details section for authorizing the web service.

For a server that acts as a client, do not specify a user interface or non-user interface prompt callback handler. To configure BasicAuth authentication from one web service to a downstream web service, select the `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHander` implementation and explicitly specify the BasicAuth user ID and password. If you want the client identity of the originator to flow downstream, configure the web service client to use ID assertion.

## What to do next

To use the BasicAuth authentication method, you must specify the method in the Login configuration section of the assembly tool . See “Configuring the client for basic authentication: specifying the method” on page 2057 if you have not previously specified this information.

***Identity assertion authentication method:***

When using the identity assertion (IDAssertion) authentication method, the security token generated is a <wsse:UsernameToken> element that contains a <wsse:Username> element.

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* applications.

On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, the security token is validated. These two operations, token generation and token validation operations, are described in the following sections.

**Identity assertion token validation**:

The request receiver retrieves the IDAssertion security token from the SOAP message and validates it using a Java Authentication and Authorization Service (JAAS) login module. With identity assertion, special processing is required to establish trust before asserting the identity as the established identity of the running thread. This special processing is defined by the <IDAssertion> element in the deployment descriptor file, `ibm-webservices-ext.xmi`. If all the validation checks are successful, the asserted identity is set as the identity of the running thread. If the validation fails, the request is rejected with a SOAP fault exception.

The JAAS login configuration is specified in the<LoginMapping> element of the bindings file. Default bindings are specified in the `ws-security.xml` file. However, you can override these bindings using the application specific `ibm-webservices-bnd.xmi` file. The configuration information consists of CallbackHandlerFactory and a ConfigName. CallbackHandlerFactory specifies the name of a class that is used for creating the JAAS CallbackHandler object. WebSphere Application Server provides the `com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl` CallbackHandlerFactory implementation. ConfigName specifies a JAAS configuration name entry.

WebSphere Application Server searches the `security.xml` file for a matching configuration name entry. If a match is not found it searches the `wsjaas.conf` file. WebSphere Application Server provides the system.wssecurity.IDAssertion default configuration entry, which is suitable for the identity assertion authentication method.

The <IDAssertion> element in the `ibm-webservices-ext.xmi` deployment descriptor file specifies the special processing required when using the identity assertion authentication method. The <IDAssertion> element is composed of two sub-elements: <IDType> and <TrustMode>.

The <IDType> element specifies the method for asserting the identity. The supported values for asserting the identity are:

- Username
- Distinguished name (DN)
- X.509 certificate

When <IDType> is *username*, a username token (for example, Bob) is provided. This user name is mapped to a user in the user registry and is the asserted identity after successful trust validation. When

the <IDType> value is *DN*, a user name token containing a distinguished name is provided (for example, `cn=Bob Smith, o=ibm, c=us`). This DN is mapped to a user in the user registry and this user is the asserted identity after successful trust validation. When the <IDType> is *X509Certificate*, a binary security token containing an X509 certificate is provided and the SubjectDN value from the certificate (for example, `cn=Bob Smith, o=ibm, c=us`) is extracted. This SubjectDN value is mapped to a user in the user registry and this user is the asserted identity after successful trust validation.

The `<TrustMode>` element specifies how the trust authority, or asserting authority, provides trust information. The supported values are:

- Signature
- BasicAuth
- No value specified

When the <TrustMode> value is `Signature`, the signature is validated. Then, the signer (for example, `cn=IBM Authority, o=ibm, c=us`) is mapped to an identity in the user registry (for example, IBMAuthority). To ensure that the asserting authority is trusted, the mapped identity (for example, IBMAuthority) is validated against a list of trusted identities. When the <TrustMode> element is `BasicAuth`, there is a user name token with a user name and password, which is the user name and password of the asserting authority.

The user name and password are validated. If they are successfully validated, that user name (for example, IBMAuthority) is validated against a list of trusted identities. If a value is not specified for `<TrustMode>`, trust is presumed and additional trust validation is not performed. This type of identity assertion is called *presumed trust mode*. Use the presumed trust mode only in an environment where the trust is established using some other mechanism.

If all the validations described previously succeed, the asserted identity (for example, Bob) is set as the identity of the running thread. If any of the validations fail, the request is rejected with a SOAP fault exception.

## Configuring the server to handle basic authentication information

Basic authentication (BasicAuth) refers to the user ID and the password of a valid user in the registry of the target server. After a request is received that contains basic authentication information, the server needs to log in to form a credential. The credential is used for authorization.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

### About this task

Complete the following steps to configure the server to handle BasicAuth authentication information:

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the **Extensions** tab, which is located at the bottom of the web services editor within an assembly tool.

6. Expand the **Request receiver service configuration details** > **Login configuration** section. You can select the following options:
   - **BasicAuth**
   - **Signature**
   - **ID assertion**
   - **Lightweight Third Party Authentication (LTPA)**
7. Select **BasicAuth** to authenticate the client with a user ID and a password. The client must specify a valid user ID and password in the server user registry. If the user ID and the password supplied are not valid, an exception is provided, and the request ends without invoking the resource.

   You can select multiple login configurations, which means that different types of security information might be received at the server. The order in which the login configurations are added decides the order in which they are processed when a request is received. Problems can occur if you have multiple login configurations added that have security tokens in common. For example, ID assertion contains a BasicAuth token. For ID assertion to work properly, list ID assertion ahead of BasicAuth in the processing list or the BasicAuth processing overrides the IDAssertion processing.

### What to do next

After you specify how the server handles BasicAuth authentication information, you must specify how the server validates the authentication information. See the task for configuring the server to validate BasicAuth authentication if you have not previously specified this information.

## Configuring the server to validate basic authentication information

Basic authentication (BasicAuth) refers to the user ID and the password of a valid user in the registry of the target server. You can specify how the server validates the BasicAuth information.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

After a request is received that contains basic authentication information, the server needs to log in to form a credential. The credential is used for authorization. If the user ID and the password supplied is invalid, an exception is thrown and the request ends without invoking the resource.

### About this task

Complete the following steps to specify how the server validates the BasicAuth authentication information:

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the **Binding Configurations** tab, which is located at the bottom of the web services editor within an assembly tool.
6. Expand the **Request receiver binding configuration details** > **Login mapping** section.
7. Click **Edit** to view the login mapping information or click **Add** to add new login mapping information. The login mapping dialog is displayed. Select or enter the following information:

**Authentication method**
Specifies the type of authentication that occurs. Select **BasicAuth** to use basic authentication.

**Configuration name**
Specifies the Java Authentication and Authorization Service (JAAS) login configuration name. For the BasicAuth authentication method, enter `WSLogin` for the JAAS login Configuration name.

**Use token valid type**
Determines if you want to specify a custom token type. For the default authentication method selections, you do not need to specify this option.

**Token value type URI and Token value type URI local name**
When you select BasicAuth, you cannot edit the token value type URI and local name values. Specifies custom authentication types. For BasicAuth authentication leave these fields blank.

**Callback handler factory class name**
Creates a JAAS CallbackHandler implementation that understands the following callbacks:

- javax.security.auth.callback.NameCallback
- javax.security.auth.callback.PasswordCallback
- com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback
- com.ibm.wsspi.wssecurity.auth.callback.XMLTokenReceiverCallback
- com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback

**Callback handler factory property name and Callback handler factory property value**
Specifies callback handler properties for custom callback handler factory implementations. You do not need to specify any properties for the default callback handler factory implementation. For BasicAuth, you do not need to enter any property values.

**Login mapping property name and Login mapping property value**
Specifies properties for a custom login mapping. For the default implementations including BasicAuth, leave these fields blank.

### What to do next

You must specify how the server handles the BasicAuth authentication method. See the task for configuring the server to handle basic authentication if you have not previously specified this information.

# Configuring identity assertion for Version 5.x web services with an assembly tool

With the identity assertion authentication method, the security token generates a <wsse:UsernameToken> element that contains a <wsse:Username> element. On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, the security token is validated. Trust is established through the use of a security token rather than through user name and password validation.

## Securing web services for Version 5.x applications using identity assertion authentication

With the identity assertion authentication method, the security token generates a <wsse:UsernameToken> element that contains a <wsse:Username> element. On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, the security token is validated. Unlike BasicAuth authentication, trust is established through the use of a security token rather than through user name and password validation.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

WebSphere Application Server provides several different methods to secure your web services. Identity assertion authentication is one of these methods. You might also secure your web services using any of the following methods:

- XML digital signature
- XML encryption
- BasicAuth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

### About this task

To use identity assertion authentication to secure web services, complete the following tasks:

### Procedure

1. Secure the client for identity assertion authentication.
   a. “Configuring the client for identity assertion: specifying the method”
   b. “Configuring the client for identity assertion: collecting the authentication method” on page 2066
2. Secure the server for identity assertion authentication.
   a. “Configuring the server to handle identity assertion authentication” on page 2067
   b. “Configuring the server to validate identity assertion authentication information” on page 2069

### Results

After completing these steps, you have secured your web services by using identity assertion authentication.

## Configuring the client for identity assertion: specifying the method

You can configure identity assertion authentication. The purpose of identity assertion is to assert the authenticated identity of the originating client from a web service to a downstream web service.

### About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

This task is used to configure identity assertion authentication. The purpose of identity assertion is to assert the authenticated identity of the originating client from a web service to a downstream web service. Do not attempt to configure identity assertion from a pure client. Identity assertion works only when you configure on the client-side of a web service acting as a client to a downstream web service.

In order for the downstream web service to accept the identity of the originating client (just the user name), you must supply a special trusted BasicAuth credential that the downstream web service trusts and can

authenticate successfully. You must specify the user ID of the special BasicAuth credential in a trusted ID evaluator on the downstream web service configuration. See topics about trusted ID evaluators.

Complete the following steps to specify identity assertion as the authentication method:

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Extension** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Request sender configuration** > **Login configuration** section.
7. Select **IDAssertion** as the authentication method. For more conceptual information on identity assertion authentication, see Identity assertion in a SOAP message.
8. Expand the **IDAssertion** section.
9. For the ID type, select **Username**. This value works with all registry types and originating authentication methods.
10. For the trust mode, select either **BasicAuth** or **Signature**.
    - By selecting **BasicAuth**, you must include basic authentication information (user ID and password), which the downstream web service has specified in the trusted ID evaluator as a trusted user ID. See “Configuring the client for signature authentication: collecting the authentication information” on page 2074 to specify the user ID and password information.
    - By selecting **Signature** the certificate configured in the signature information section used to sign the data also is that is used as the trusted subject. The Signature is used to create a credential and user ID, which the certificate mapped to the downstream registry, is used in the trusted ID evaluator as a trusted user ID.

### What to do next

See “Configuring the client security bindings using an assembly tool” on page 2039 for more information on the web services client editor within the assembly tool.

After you specify identity assertion as the authentication method used by the client, you must specify how to collect the authentication information. See “Configuring the client for identity assertion: collecting the authentication method” for more information.

## Configuring the client for identity assertion: collecting the authentication method

You can configure identity assertion authentication. The purpose of identity assertion is to assert the authenticated identity of the originating client from a web service to a downstream web service.

### About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

This task is used to configure identity assertion authentication. The purpose of identity assertion is to assert the authenticated identity of the originating client from a web service to a downstream web service. Do not attempt to configure identity assertion from a pure client. Identity assertion works only when you configure on the client-side of a web service acting as a client to a downstream web service.

In order for the downstream web service to accept the identity of the originating client (just the user name), you must supply a special trusted BasicAuth credential that the downstream web service trusts and can authenticate successfully. You must specify the user ID of the special BasicAuth credential in a trusted ID evaluator on the downstream web service configuration. See the information on trusted ID evaluators.

Complete the following steps to specify how the client collects the authentication information:

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Binding** tab, which is located at the bottom of the Deployment Descriptor Editor within an assembly tool.
6. Expand the **Security request sender binding configuration** > **Login binding** section.
7. Click **Edit** to view the login binding information and select **IDAssertion**. The login binding dialog is displayed. Select or enter the following information:

   **Authentication method**
   The authentication method specifies the type of authentication that occurs. Select **IDAssertion** to use identity assertion.

   **Token value type URI and Token value type Local name**
   When you select IDAssertion, you cannot edit the token value type Universal Resource Identifier (URI) and the local name. Specifies custom authentication types. For IDAssertion authentication, leave these values blank.

   **Callback handler**
   Specifies the Java Authentication and Authorization Service (JAAS) callback handler implementation for collecting the BasicAuth information. Specify the `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler` implementation for IDAssertion.

   **Basic authentication User ID and Basic authentication Password**
   In this field, the trust mode entered in the extensions is BasicAuth. Specifies the trusted user ID and password in these fields. The user ID specified must be an ID that is trusted by the downstream web service. The web service trusts the user ID if it is entered as a trusted ID in a trusted ID evaluator in the downstream web service bindings. If the trust mode entered in the extensions is `Signature`, you do not need to specify any information in this field.

   **Property name and Property value**
   Specifies properties with name and value pairs, for use by custom callback handlers. For IDAssertion, you do not need to specify any information in this field.

### What to do next

To use the identity assertion authentication method, you must specify the method in the Security extensions section of an assembly tool. See “Configuring the client for identity assertion: specifying the method” on page 2065 if you have not previously specified this information.

## Configuring the server to handle identity assertion authentication

The purpose of identity assertion is to assert the authenticated identity of the originating client from a web service to a downstream web service. You can configure identity assertion authentication for the server. Do not attempt to configure identity assertion from a pure client.

## About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

For the downstream web service to accept the identity of the originating client (user name only), you must supply a special trusted BasicAuth credential that the downstream web service trusts and can authenticate successfully. You must specify the user ID of the special BasicAuth credential in a trusted ID evaluator on the downstream web service configuration. For more information on trusted ID evaluators, see Trusted ID evaluator. The server side passes the special BasicAuth credential into the trusted ID evaluator, which returns `true` or `false` that this ID is trusted. After it is trusted, the user name of the client is mapped to the credential, which is used for authorization.

Complete the following steps to configure the server to handle identity assertion authentication information:

## Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the **Extensions** tab, which is located at the bottom of the web services editor within the assembly tool.
6. Expand the **Request receiver service configuration details** > **Login configuration** section. The options you can select are:
   - **BasicAuth**
   - **Signature**
   - **ID assertion**
   - **LTPA** (Lightweight Third Party Authentication)
7. Select **IDAssertion** to authenticate the client using the identity assertion data provided.

   The user ID of the client must be in the target user registry or repository, which is configured on the **Security** > **Global security** panel in the administrative console for WebSphere Application Server. You can select multiple login configurations, which means that different types of security information can be received at the server. The order in which the login configurations are added determines the processing order when a request is received. Problems can occur if you have multiple login configurations added that have common security tokens. For example, ID assertion contains a BasicAuth token, which is the trusted token. For ID assertion to work properly, you must list ID assertion ahead of BasicAuth in the list or BasicAuth processing overrides ID assertion processing.
8. Expand the **IDAssertion** section and select both the **ID Type** and the **Trust Mode**.
   a. For ID Type, the options are:
      - **Username**
      - **DN** (distinguished name)
      - **X509certificate**

      These choices are just preferences and are not guaranteed. Most of the time the Username option is used. You must choose the same ID Type as the client.
   b. For Trust Mode, the options are:
      - **BasicAuth**
      - **Signature**

The Trust Mode refers to the information sent by the client as the trusted ID.

1) If you select **BasicAuth**, the client sends basic authentication data (user ID and password). This BasicAuth data is authenticated to the configured user registry. When the authentication occurs successfully, the user ID must be part of the trusted ID evaluator trust list.
2) If you select **Signature**, the client signing certificate is sent. This certificate must be mappable to the configured user registry. For **Local OS**, the common name (CN) of the distinguished name (DN) is mapped to a user ID in the registry. For **Lightweight Directory Access Protocol (LDAP)**, the DN is mapped to the registry for the ExactDN mode. If it is in the CertificateFilter mode, attributes are mapped accordingly. In addition, the user name from the credential generated must be in the Trusted ID Evaluator trust list.

### What to do next

For more information on getting started with the Web Services Editor within an assembly tool, see "Configuring the server security bindings using an assembly tool" on page 2042.

After you specify how the server handles identity assertion authentication information, you must specify how the server validates the authentication information. See the task for configuring the server to validate identity assertion authentication information.

## Configuring the server to validate identity assertion authentication information

The purpose of identity assertion is to assert the authenticated identity of the originating client from a web service to a downstream Web service.

### About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6 and later applications.

Use this task to configure identity assertion authentication. Do not attempt to configure identity assertion from a pure client.

For the downstream web service to accept the identity of the originating client (user name only), you must supply a special trusted BasicAuth credential that the downstream web service trusts and can authenticate successfully. You must specify the user ID of the special BasicAuth credential in a trusted ID evaluator on the downstream web service configuration. For more information on trusted ID evaluators, see the topic about the trusted ID evaluator. The server side passes the special BasicAuth credential into the trusted ID evaluator, which returns a `true` or `false` response that this ID is trusted. After it is trusted, the user name of the client is mapped to the credential, which is used for authorization.

Complete the following steps to validate the identity assertion authentication information:

### Procedure

1. Launch an assembly tool. For more information, see the related information on assembly tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective > J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the Binding Configurations tab, which is located at the bottom of the web services editor within the assembly tool.
6. Expand the **Request receiver binding configuration details** > **Login mapping** section.

7. Click **Edit** to view the login mapping information. Click **Add** to add new login mapping information. The login mapping dialog is displayed. Select or enter the following information:

   **Authentication method**
   Specifies the type of authentication that occurs. Select **IDAssertion** to use basic authentication.

   **Configuration name**
   Specifies the Java Authentication and Authorization Service (JAAS) login configuration name. For the IDAssertion authentication method, enter `system.wssecurity.IDAssertion` for the Java Authentication and Authorization Service (JAAS) login configuration name.

   **Use token value type**
   Determines if you want to specify a custom token type. For the default authentication method selections, you do not need to specify this option.

   **Token value type URI and Token value type local name**
   When you select ID assertion, you cannot edit the token value type URI and local name values. Specifies custom authentication types. For the ID assertion authentication method, leave these values blank.

   **Callback handler factory class name**
   Ccreates a JAAS CallbackHandler implementation that understands the following callbacks:

   - javax.security.auth.callback.NameCallback
   - javax.security.auth.callback.PasswordCallback
   - com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback
   - com.ibm.wsspi.wssecurity.auth.callback.XMLTokenReceiverCallback
   - com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback

   For any of the default authentication methods (BasicAuth, IDAssertion, and Signature), use the callback handler factory default implementation. Enter the following class name for any of the default Authentication methods including IDAssertion:

```
com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl
```

   This implementation creates the correct callback handler for the default implementations.

   **Callback handler factory property name and Callback handler factory property value**
   Specifies callback handler properties for custom callback handler factory implementations. The default callback handler factory implementation does not need any specified properties. For ID assertion, leave these values blank.

   **Login mapping property name and Login mapping property value**
   Specifies properties for a custom login mapping. For the default implementations including IDAssertion, leave these values blank.

8. Expand the **Trusted ID evaluator** section.
9. Click **Edit** to see a dialog that displays all the trusted ID evaluator information. The following table describes the purpose of this information.

   **Class name**
   Refers to the implementation of the trusted ID evaluator that you want to use. Enter the default implementation as

```
com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl
```

   If you want to implement your own trusted ID evaluator, you must implement the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` interface.

   **Property name**
   Represents the name of this configuration. Enter `BasicIDEvaluator`.

**Property value**

Defines the name and value pairs that can be used by the trusted ID evaluator implementation. For the default implementation, the trusted list is defined here. When a request comes in and the trusted ID is verified, the user ID, as it appears in the user registry, must be listed in this property. Specify the property as a name and value pair where the name is *trustedId_n*. *n* is an integer starting from 0 and the value is the user ID associated with that name. An example list with the trusted names include two properties.

For example: `trustedId_0 = user1, trustedId_1 = user2`. The previous example means that both `user1` and `user2` are trusted. `user1` and `user2` must be listed in the configured user registry

10. Expand the **Trusted ID evaluator reference** section.
11. Click **Enable** to add a new entry. The text you enter for the **Trusted ID evaluator reference** must be the same as the name entered previously in the **Trusted ID evaluator**. Make sure that the name matches exactly because the information is case sensitive. If an entry is already specified, you can change it by clicking **Edit**.

### What to do next

You must specify how the server handles the identity assertion authentication method. See "Configuring the server to handle identity assertion authentication" on page 2067 if you have not previously specified this information.

# Configuring signature authentication for Version 5.x web services with an assembly tool

With the signature authentication method, the request sender generates a signature security token using a callback handler. The security token returned by the callback handler is inserted in the SOAP message. The request receiver retrieves the Signature security token from the SOAP message and validates it using a Java™ Authentication and Authorization Service (JAAS) login module.

## Securing web services for version 5.x applications using signature authentication

WebSphere Application Server provides several different methods to secure your web services. XML digital signature is one of these methods.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6 and later applications.

You can secure your web services by using any of the following methods:

- XML digital signature
- XML encryption
- BasicAuth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

### About this task

With the signature authentication method, the request sender generates a signature security token using a callback handler. The security token returned by the callback handler is inserted in the SOAP message. The request receiver retrieves the Signature security token from the SOAP message and validates it using

a Java Authentication and Authorization Service (JAAS) login module. To use signature authentication to secure Web services, complete the following tasks:

### Procedure

1. Secure the client for signature authentication.
   a. "Configuring the client for signature authentication: specifying the method."
   b. "Configuring the client for signature authentication: collecting the authentication information" on page 2074.
2. Secure the server for signature authentication.
   a. "Configuring the server to support signature authentication" on page 2075.
   b. "Configuring the server to validate signature authentication information" on page 2076.

### Results

After completing these steps, you have secured your web services using signature authentication.

## Configuring the client for signature authentication: specifying the method

Signature authentication, the use of an X.509 certificate to login on the target server, can be configured.

### About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

This task is used to configure signature authentication. A signature refers to the use of an X.509 certificate to login on the target server. For more information on signature authentication, see "Signature authentication method" on page 2073.

Complete the following steps to specify signature as the authentication method:

### Procedure

1. Launch an assembly tool. For more information, read about assembly tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF** .
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Extension** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Request sender configuration** > **Login configuration** section. The following login configuration options are valid for a managed client and Web services acting as a client are:

   **BasicAuth**
   Use this option for a managed client.

   **Signature**
   Use this option for a managed client.

   **IDAssertion**
   Use this option for web services acting as a client.
7. Select **Signature** to authenticate the client using the certificate used to digitally sign the request.

## Results

For more information on getting started with the web services client editor within the assembly tool, see “Configuring the client security bindings using an assembly tool” on page 2039.

After you specify signature as the authentication method, you must specify how to collect the authentication information. See “Configuring the client for signature authentication: collecting the authentication information” on page 2074 for more information.

***Signature authentication method:***

Signature authentication refers to an X.509 certificate that is sent by the client to the server. The certificate is used to authenticate to the user registry that is configured at the server. When using the signature authentication method, the security token is generated with a ds:Signature and a wsse:BinarySecurityToken element.

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, a Java Authentication and Authorization Service (JAAS) login module is used to validate the security token. These two operations, token generation and token validation, are described in the following sections.

**Signature token generation**

The request sender generates a Signature security token using a callback handler. The security token returned by the callback handler is inserted in the SOAP message. The callback handler is specified in the <LoginBinding> element of the bindings file, `ibm-webservicesclient-bnd.xmi`. WebSphere Application Server provides the following callback handler implementation that can be used with the Signature authentication method:
com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler

You can add your own callback handlers that implement the javax.security.auth.callback.CallbackHandler implementation.

**Security token validation**

The request receiver retrieves the Signature security token from the SOAP message and validates it using a JAAS login module. The <ds:Signature> and <wsse:BinarySecurityToken> elements in the security token are used to perform the validation. If the validation is successful, the login module returns a Java Authentication and Authorization Service (JAAS) Subject. This Subject then is set as the identity of the running thread. If the validation fails, the request is rejected with a SOAP fault exception.

The JAAS login configuration is specified in the `<LoginMapping>` element of the bindings file. Default bindings are specified in the `ws-security.xml` file. However, you can override these bindings using the application-specific `ibm-webservices-bnd.xmi` file. The configuration information consists of a CallbackHandlerFactory and a ConfigName. The CallbackHandlerFactory specifies the name of a class that is used for creating the JAAS CallbackHandler object. WebSphere Application Server provides the com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImp CallbackHandlerFactory implementation. The ConfigName specifies a JAAS configuration name entry. WebSphere Application Server searches in the `security.xml` file for a matching configuration name entry. If a match is not found, it searches the `wsjaas.conf` file. WebSphere Application Server provides the system.wssecurity.Signature default configuration entry, which is suitable for the signature authentication method.

## Configuring the client for signature authentication: collecting the authentication information

Signature authentication refers to an X.509 certificate that is sent by the client to the server. The certificate is used to authenticate to the user registry that is configured at the server. The client collects the authentication information for signature authentication.

### About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

You can configure signature authentication. A signature refers to the use of an X.509 certificate to login on the target server.

Complete the following steps to specify how the client collects the authentication information for signature authentication:

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the WS Binding tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Security request sender binding configuration** > **Signing information** and click **Edit** to modify the signing key name and signing key locator. To create new signing information, click **Enable**. The certificate that is sent to log in at the server is the one configured in the Signing Information section. Review the key locator information to understand how the signing key name maps to a key within the key locator entry.

   The following list describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following web address: http://www.w3.org/TR/xmldsig-core

   **Canonicalization method algorithm**
   Canonicalizes the <SignedInfo> element before it is digested as part of the signature operation.

   **Digest mehod algorithm**
   Represents the algorithm that is applied to the data after transforms are applied, if specified, to yield the <DigestValue> element. The signing of the <DigestValue> element binds the resource content to the signer key. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration.

   **Signature method algorithm**
   Represents the algorithm that is used to convert the canonicalized <SignedInfo> element value into the <SignatureValue> value. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration.

   **Signing key name**
   Represents the key entry that is associated with the signing key locator. The key entry refers to an alias of the key, which is used to sign the request.

   **Signing key locator**
   Represents a reference to a key locator implementation.

7. Expand the **Security request sender binding configuration** > **Login binding** section.
8. Click **Edit** to view the login binding information. Select or enter the following information:

   **Authentication method**
   Specifies the type of authentication that occurs. Select **Signature** to use signature authentication.

   **Token value type URI and Token value type URI local name**
   When you select **Signature**, you cannot edit token value type Uniform Resource Identifier (URI) and local name values. Specifies custom authentication types. For signature authentication, leave these fields blank.

   **Callback handler**
   Specifies the Java Authentication and Authorization Server (JAAS) callback handler implementation for collecting signature information. Enter the following callback handler for signature authentication:
   `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler`

   This callback handler is used because the signature method does not require user interaction.

   **Basic authentication user ID and Basic authentication password**
   Leave the BasicAuth fields blank when signature authentication is used.

   **Property name and property value**
   This field enables you to enter properties and name and value pairs for use by custom callback handlers. For signature authentication, do not enter any information.

### What to do next

**Other customization entries**: There is a basic authentication entry in the Port Qualified Name Binding Details section. This entry is used for HTTP transport authentication, which might be required if the router servlet is protected.

Information specified in the Web Services Security signature authentication section overrides the basic authentication information specified in the Port Qualified Name Binding Details section for authorizing the Web service.

To use the signature authentication method, you must specify the authentication method in the Login configuration section of an assembly tool.

## Configuring the server to support signature authentication

Signature authentication refers to an X.509 certificate sent by the client to the server. The certificate is used to authenticate to the user registry configured at the server. After a request is received by the server that contains the certificate, the server needs to log in to form a credential. The credential is used for authorization. You can configure signature authentication at the server.

### About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

If the certificate supplied cannot be mapped to an entry in the user registry, an exception is provided and the request ends without invoking the resource.

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.

2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective by clicking **Window** > **Open perspective** > **Other** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the **Extensions** tab, which is located at the bottom of the Web Services Editor within the assembly tool.
6. Expand the **Request receiver service configuration details** > **Login configuration** section. You can select from the following options:
   - BasicAuth
   - Signature
   - ID assertion
   - Lightweight Third Party Authentication (LTPA)
7. Select **Signature** to authenticate the client using an X509 certificate. The certificate that is sent from the client is the certificate that issued for signing the message. You must be able to map this certificate to the configured user registry. For Local operating system (OS) registries, the common name (cn) of the distinguished name (DN) is mapped to a user ID in the registry. For Lightweight Directory Access Protocol (LDAP), you can configure multiple mapping modes:
   - `EXACT_DN` is the default mode that directly maps the DN of the certificate to an entry in the LDAP server.
   - `CERTIFICATE_FILTER` is the mode that provides the LDAP advanced configuration with a place to specify a filter that maps specific attributes of the certificate to specific attributes of the LDAP server.

### What to do next

For more information on getting started with the web services editor within the assembly tool, see "Configuring the server security bindings using an assembly tool" on page 2042.

After you specify how the server handles signature authentication information, you must specify how the server validates the authentication information. See the task for configuring the server to validate signature authentication.

## Configuring the server to validate signature authentication information

Signature authentication refers to an X.509 certificate sent by the client to the server. The certificate is used to authenticate to the user registry configured at the server. After a request is received by the server that contains the certificate, the server needs to log in to form a credential. The credential is used for authorization. You can validate signature authentication at the server.

### About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

If the certificate supplied cannot be mapped to an entry in the user registry, an exception is thrown and the request ends without invoking the resource.

Complete the following steps to configure the server to validate signature authentication:

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective by clicking **Window** > **Open perspective** > **Other** > **J2EE**.

3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the **Binding Configurations** tab, which is located at the bottom of the web services editor within the assembly tool.
6. Expand the **Request receiver binding configuration details** > **Login mapping** section.
7. Click **Edit** to view the login mapping information or click **Add** to add new login mapping information. The login mapping dialog is displayed and you select (or enter) the following information:

   **Authentication method**
   Specifies the type of authentication. Select **Signature** to use signature authentication.

   **Configuration name**
   Specifies the Java Authentication and Authorization Service (JAAS) login configuration name. For the signature authentication method, enter `system.wssecurity.Signature` for the JAAS login configuration name. This specification logs in with the `com.ibm.wsspi.wssecurity.auth.module.SignatureLoginModule` JAAS login module.

   **Use token value type**
   Determines if you want to specify a custom token type. For the default authentication method selections, you can leave this field blank.

   **URI and local name**
   When you select Signature method, you cannot edit the token value type URI and local name values. Specifies custom authentication types. For signature authentication, you can leave this field blank.

   **Callback handler factory class name**
   Creates a JAAS CallbackHandler implementation that understands the following callback handlers:

   - javax.security.auth.callback.NameCallback
   - javax.security.auth.callback.PasswordCallback
   - com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback
   - com.ibm.wsspi.wssecurity.auth.callback.XMLTokenReceiverCallback
   - com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback

   For any of the default authentication methods (BasicAuth, IDAssertion, and Signature), use the callback handler factory default implementation. Enter the following class name for any of the default authentication methods including signature:

```
com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl
```

   This implementation creates the correct callback handler for the default implementations.

   **Callback handler factory property name and callback handler factory property value**
   Specifies callback handler properties for custom callback handler factory implementations. You do not need to specify any properties for the default callback handler factory implementation. For signature, you can leave this field blank.

   **Login mapping property name and login mapping property value**
   Specifies properties for a custom login mapping to use. For the default implementations including signature, you can leave this field blank.

## What to do next

Specify how the server handles the signature authentication method. See “Configuring the server to support signature authentication” on page 2075 if you have not previously specified this information.

# Configuring pluggable tokens for Version 5.x web services with an assembly tool

WebSphere Application Server provides several different methods to secure your web services, including the pluggable token method. To use pluggable tokens to secure your web services, you must configure both the client request sender and the server request receiver.

## Securing web services for version 5.x applications using a pluggable token

To use pluggable tokens to secure your web services, you must configure both the client request sender and the server request receiver. You can configure your pluggable tokens using the WebSphere Application Server administrative console.

### About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

WebSphere Application Server provides several different methods to secure your web services. A pluggable token is one of these methods. You might secure your Web services by using any of the following methods:

- XML digital signature
- XML encryption
- Basicauth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

Complete the following steps to secure your web services using a pluggable token:

### Procedure

1. Generate a security token using the Java Authentication and Authorization Service (JAAS) CallbackHandler interface. The Web Services Security runtime uses the JAAS CallbackHandler interface as a plug-in to generate security tokens on the client side or when web services are acting as a client.
2. Configure your pluggable token. For more information, see the following tasks:
   - “Configuring pluggable tokens using an assembly tool”
   - Configuring pluggable tokens using the administrative console

## Configuring pluggable tokens using an assembly tool

The following information describes how to configure a pluggable token using an assembly tool.

### Before you begin

**Important:** There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

This document describes how to configure a pluggable token in the request sender (`ibm-webservicesclient-ext.xmi` and `ibm-webservicesclient-bnd.xmi` file) and request receiver (`ibm-webservices-ext.xmi` and `ibm-webservices-bnd.xmi` file).

The pluggable token is required for the request sender and request receiver because they are a pair. The request sender and the request receiver must match for the receiver to accept a request.

Prior to completing these steps, it is assumed that you have already created a web service that is based on the Java Platform, Enterprise Edition (Java EE) specification. See either of the following topics for an introduction of how to manage Web Services Security binding information for the server:

- "Configuring the server security bindings using an assembly tool" on page 2042
- Configuring the server security bindings using the administrative console

## About this task

You must specify the security constraints in the `ibm-webservicesclient-ext.xmi` and the `ibm-webservices-ext.xmi` files for the required tokens using an IBM assembly tool.

Complete the following steps to configure the request sender using the `ibm-webservicesclient-ext.xmi` and `ibm-webservicesclient-bnd.xmi` files:

## Procedure

1. Launch an assembly tool. For more information, read about assembly tools.
2. Switch to the Java EE perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Extension** tab. The web service client security extensions editor is displayed.
   a. Under Service References, select an existing service reference or click **Add** to create a new reference.
   b. Under Port Qname Bindings, select an existing port qualified name for the selected service reference or click **Add** to create a new port name binding.
   c. Under Request Sender Configuration: Login Configuration, select an exiting authentication method or type in a new one in the editable list box (Lightweight Third Party Authorization (LTPA) is a supported token generation when web services are acting as client).
   d. Click **File** > **Save** to save the changes.
6. Click the **Web services client binding** tab. The web services client binding editor is displayed.
   a. Under Port qualified name binding, select an existing entry or click **Add** to add a new port name binding. The web services client binding editor displays for the selected port.
   b. Under Login binding, click **Edit** or **Enable**. The Login Binding dialog box is displayed.
      1) In the Authentication Method field, enter the authentication method. The authentication method that you enter in this field must match the authentication method defined on the **Security Extension** tab for the same web service port. This field is mandatory.
      2) (Optional) Enter the token value type information in the URI and Local name fields. These fields are ignored for the BasicAuth, Signature, and IDAssertion authentication methods, but required for other authentication methods. The token value type information is inserted into the <wsse:BinarySecurityToken>@ValueType element for binary security token and is used as the namespace for the XML-based token.
      3) Enter an implementation of the Java Authentication and Authorization Service (JAAS) `javax.security.auth.callback.CallbackHandler` interface. This field is mandatory.
      4) Enter the basic authentication information in the **User ID** and **Password** fields. The basic authentication information is passed to the construct of the `CallbackHandler` implementation. The use of the basic authentication information depends on the implementation of `CallbackHandler`.
      5) In the Property field, add name and value pairs. These pairs are passed to the construct of the `CallbackHandler` implementation as `java.util.Map` values.

6) Click **OK**.

Click **Disable** under Login binding on the **Web services client port binding** tab to remove the authentication method login binding.

c. Click **File** > **Save** to save the changes.

7. In the Package Explorer window, right-click the `webservices.xml` file and click **Open with** > **Web services editor**. The Web Services window displays.
   a. Click the **Security extensions** tab. The Web Service Security extensions editor is displayed.
      1) Under Web Services Description Extension, select an existing service reference or click **Add** to create a new extension.
      2) Under Port Component Binding, select an existing port qualified name for the selected service reference or click **Add** to create a new one.
      3) Under Request Receiver Service Configuration Details: Login Configuration, select an exiting authentication method or click **Add** and enter a new method in the **Add AuthMethod** field that displays. You can select multiple authentication methods for the request receiver. The security token of the incoming message is authenticated against the authentication methods in the order that they are specified in the list. Click **Remove** to remove the selected authentication method or methods.
   b. Click **File** > **Save** to save the changes.
   c. Click the **Bindings** tab. The web services bindings editor is displayed.
      1) Under web service description bindings, select an existing entry or click **Add** to add a new web services descriptor.
      2) Click the **Binding configurations** tab. The web services binding configurations editor is displayed for the selected web services descriptor.
      3) Under Request receiver binding configuration details: login mapping, click **Add** to create a new login mapping or click **Edit** to edit the selected login mapping. The Login mapping dialog is displayed.
         a) In the Authentication method field, enter the authentication method. The information entered in this field must match the authentication method defined on the **Security Extensions** tab for the same web service port. This field is mandatory.
         b) In the **Configuration name** field, enter a JAAS login configuration name. This field is mandatory. You must define the JAAS login configuration name in the WebSphere Application Server administrative console under **Security** > **Global security**. Under Authentication, click **Java Authentication and Authorization Service** > **Application logins**. For more information, read about configuring programmatic logins for Java Authentication and Authorization Service.
         c) (Optional) Select **Use Token value type** and enter the token value type information in the URI and Local name fields. This information is optional for BasicAuth, Signature and IDAssertion authentication methods, but required for any other authentication method. The token value type is used to validate the <wsse:BinarySecurityToken>@ValueType element for binary security tokens and to validate the namespace of the XML-based token.
         d) Under Callback Handler Factory, enter an implementation of the `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory` interface in the Class name field. This field is mandatory.
         e) Under Callback Handler Factory property, click **Add** and enter the name and value pairs for the Callback Handler Factory Property. These name and value pairs are passed as `java.util.Map` to the `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory.init()` method. The use of these name and value pairs is determined by the `CallbackHandlerFactory` implementation.
         f) Under Login Mapping Property, click **Add** and enter the name and value pairs for the Login mapping property. These name and value pairs are available to the JAAS Login Modules

through the `com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback` JAAS Callback interface. Click **Remove** to delete the selected login mapping.

g) Click **OK**.

d. Click **File** > **Save** to save the changes.

### Results

The previous steps define how to configure the request sender to create security tokens in the SOAP message and to configure the request receiver to validate the security tokens found in the incoming SOAP message. WebSphere Application Server supports pluggable security tokens.

You can use the authentication method defined in the login bindings and login mappings to generate security tokens in the request sender and validate security tokens in the request receiver.

### What to do next

After you configure pluggable tokens, you must configure both the client and the server to support pluggable tokens. See the following topics to configure the client and the server:

- Configuring the client for LTPA token authentication: Specifying LTPA token authentication
- Configuring the client for LTPA token authentication: Collecting the authentication information
- Configuring the server to handle LTPA token authentication
- Configuring the server to validate LTPA token authentication information

## Configuring the client for LTPA token authentication: specifying LTPA token authentication

To configure Lightweight Third-Party Authentication (LTPA) token authentication, specify LTPA token authentication. Only configure the client for LTPA token authentication if the authentication mechanism configured in WebSphere Application Server is LTPA.

### About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Use this task to configure Lightweight Third-Party Authentication (LTPA) token authentication. Only configure the client for LTPA token authentication if the authentication mechanism configured in WebSphere Application Server is LTPA. When a client authenticates to a WebSphere Application Server, the credential created contains an LTPA token. When a web service calls a downstream web service, you can configure the first web service to send the LTPA token from the originating client. Do not attempt to configure LTPA from a pure client. LTPA works only when you configure the client-side of a web service acting as a client to a downstream web service. For the downstream web service to validate the LTPA token, the LTPA keys on both servers must be the same.

Complete the following steps to specify LTPA token as the authentication method:

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.

5. Click the **Extensions** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Request sender configuration** > **Login configuration** section.
7. Select **LTPA** as the authentication method. For more conceptual information on LTPA authentication, see “Lightweight Third Party Authentication” on page 2085.

### What to do next

After you specify LTPA token as the authentication method, you must specify how to collect the LTPA token information. See “Configuring the client for LTPA token authentication: collecting the authentication method information” for more information.

## Configuring the client for LTPA token authentication: collecting the authentication method information

To configure Lightweight Third-Party Authentication (LTPA) token authentication, collect the LTPA token authentication information. Do not configure the client for LTPA token authentication unless the authentication mechanism configured in WebSphere Application Server is LTPA.

### About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Use this task to configure Lightweight Third-Party Authentication (LTPA) token authentication. Do not configure the client for LTPA token authentication unless the authentication mechanism configured in WebSphere Application Server is LTPA. When a client authenticates to a WebSphere Application Server, the credential created contains an LTPA token. When a web service calls a downstream web service, you can configure the first web service to send the LTPA token from the originating client. Do not attempt to configure LTPA from a pure client. LTPA works only when you configure the client-side of a web service acting as a client to a downstream web service. In order for the downstream web service to validate the LTPA token, the LTPA keys on both servers must be the same.

Complete the following steps to specify how to collect the LTPA token authentication information:

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Bindings** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Security request sender binding configuration** > **Login binding** section.
7. Click **Edit** to view the login binding information and select **LTPA**. If LTPA is not already there, enter it as an option. The login binding dialog is displayed. Select or enter the following information:

   **Authentication method**
   Specifies the type of authentication that occurs. Select **LTPA** to use identity assertion.

   **Token value type URI and token value type local name**
   When you select **LTPA**, you must edit the token value type **URI** (Uniform Resource Identifier) and the **local name** fields. Specifies values for custom authentication types, which are authentication methods not mentioned in the specification. For the token value type **URI** field,

enter the following string: `http://www.ibm.com/websphere/appserver/tokentype/5.0.2`. For the **local name** field, enter the following string: `LTPA`.

**Callback handler**
Specifies the Java Authentication and Authorization Service (JAAS) callback handler implementation for collecting the LTPA information. Specify the `com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler` implementation for LTPA.

**Basic authentication user ID and basic authentication password**
For LTPA, you can leave these fields empty. However, when you omit this information, the LTPA `CallbackHandler` implementation attempts to obtain the LTPA token from the invocation (RunAs) credential. If an invocation (RunAs) credential does not exist, then the LTPA token is not propagated.

**Property name and property value**
For LTPA, you can leave these fields blank.

### What to do next

See "Configuring the client for LTPA token authentication: specifying LTPA token authentication" on page 2081 if you have not previously specified this information.

## Configuring the server to handle LTPA token authentication information

Lightweight Third-Party Authentication (LTPA) is a type of authentication mechanism in WebSphere Application Server security that defines a particular token format. The purpose of the LTPA token authentication is to flow the LTPA token from the first web service, which authenticated the originating client, to the downstream web service. You can configure the server for LTPA token authentication.

### About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

This task is used to configure LTPA. Do not attempt to configure LTPA from a pure client. After the downstream web service receives the LTPA token, it validates the token to verify that the token has not been modified and has not expired. For validation to be successful, the LTPA keys that are used by both the sending and receiving servers must be the same.

Complete the following steps to specify that LTPA is the authentication method. The authentication method indicated in these steps must match the authentication method that is specified for the client.

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the Extensions tab, which is located at the bottom of the web services editor within the assembly tool.
6. Expand the **Request receiver service configuration details** > **Login configuration** section. You can select from the following options:
   - **BasicAuth**
   - **Signature**

- **ID assertion**
- **LTPA**

7. Select **LTPA** to authenticate the client using the LTPA token received from the request.

### What to do next

After you specify the authentication method, you must specify the information that the server must validate. See “Configuring the server to validate LTPA token authentication information” for more information.

## Configuring the server to validate LTPA token authentication information

Lightweight Third-Party Authentication (LTPA) is a type of authentication mechanism in WebSphere Application Server security that defines a particular token format. The purpose of the LTPA token authentication is to flow the LTPA token from the first web service, which authenticated the originating client, to the downstream web service. You can configure the server to validate LTPA token authentication.

### About this task

**Important:** There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

This task is used to configure LTPA. Do not attempt to configure LTPA from a pure client. After the downstream web service receives the LTPA token, it validates the token to verify that the token has not been modified and has not expired. For validation to be successful, the LTPA keys used by both the sending and receiving servers must be the same.

Complete the following steps to specify how the server must validate the LTPA token authentication information:

### Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the Binding Configurations tab, which is located at the bottom of the web services editor within the assembly tool.
6. Expand the **Request receiver binding configuration details** > **Login mapping** section.
7. Click **Edit** to view the login mapping information. The login mapping information is displayed. Select or enter the following information:

   **Authentication method**
   Specifies the type of authentication that occurs. Select `LTPA` to use LTPA token authentication.

   **Configuration name**
   Specifies the Java Authentication and Authorization Service (JAAS) login configuration name. For the LTPA authentication method, enter `WSLogin` for the JAAS login configuration name. This configuration understands how to validate an LTPA token.

   **Use token value type**
   Determines if you want to specify a custom token type. For LTPA authentication, you must select this option because LTPA is considered a custom type. LTPA is not in the Web Services Security Specification.

**Token value type URI and local name**
Specifies custom authentication types. If you select **Use Token value type** you must enter data into the Token value Type URI (Uniform Resource Identifier) and local name fields. For the token value type URI field, enter the following string: `http://www.ibm.com/websphere/appserver/tokentype/5.0.2`. For the local name, enter the following string: `LTPA`

**Callback handler factory class name**
Creates a JAAS CallbackHandler implementation that understands the following callback handlers:

- javax.security.auth.callback.NameCallback
- javax.security.auth.callback.PasswordCallback
- com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback
- com.ibm.wsspi.wssecurity.auth.callback.XMLTokenReceiverCallback
- com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback

For any of the default authentication methods (BasicAuth, IDAssertion, Signature, and LTPA), use the callback handler factory default implementation. Enter the following class name for any of the default authentication methods including LTPA:

```
com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl
```

This implementation creates the correct callback handler for the default implementations.

**Callback handler factory property**
Specifies callback handler properties for custom callback handler factory implementations. Default callback handler factory implementation does not any property specifications. For LTPA, leave this field blank.

**Login mapping property**
Specifies properties for a custom login mapping. For default implementations including LTPA, leave this field blank.

## What to do next

See the task for configuring the server to handle LTPA token authentication information if you have not previously specified this information.

***Lightweight Third Party Authentication:***

When you use the lightweight third party authentication (LTPA) method, the <wsse:BinarySecurityToken> security token is generated. On the request sender side, the security token is generated by invoking a callback handler. On the request receiver side, the security token is validated by a Java Authentication and Authorization Service (JAAS) login module.

**Important:** The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6 and later applications.

The following information describes token generation and token validation operations.

**LTPA token generation**
The request sender uses a callback handler to generate an LTPA security token. The callback handler returns a security token that is inserted in the SOAP message. Specify the appropriate callback handler in the <LoginBinding> element of the bindings file (`ibm-webservicesclient-bnd.xmi`). The following callback handler implementation can be used with the LTPA authentication method:

- `com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler`

You can add your own callback handlers that implement the `javax.security.auth.callback.CallbackHandler` property.

When using the LTPA authentication method (or any authentication method other than BasicAuth, Signature or IDAssertion), the TokenValueType attribute of the <LoginBinding> element in the bindings file (`ibm-webservicesclient-bnd.xmi`) must be specified. The values to use for the LTPA TokenValueType attribute are:

- `uri="http://www.ibm.com/websphere/appserver/tokentype/5.0.2"`
- `localName="LTPA"`

**LTPA token validation**

The request receiver retrieves the LTPA security token from the SOAP message and validates the message using a JAAS login module. The <wsse:BinarySecurityToken> security token is used to perform the validation. If the validation is successful, the login module returns a JAAS Subject. Subsequently, this Subject is set as the identity of the running thread. If the validation fails, the request is rejected with a SOAP fault.

The appropriate JAAS login configuration to use is specified in the bindings file <LoginMapping> element. Default bindings specified in the `ws-security.xml` file, but these can be overridden using the application-specific `ibm-webservices-bnd.xmi` file. The configuration information consists of a CallbackHandlerFactory, a ConfigName and a TokenValueType attribute. The CallbackHandlerFactory specifies the name of a class to use to create the JAAS CallbackHandler object. A CallbackHandlerFactory implementation is provided (com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl). The ConfigName attribute specifies a JAAS configuration name entry. The Web Services Security run time first searches the `security.xml` file for a matching entry and if a matching entry is not found, the run time searches the `wsjaas.conf` file. A default configuration entry suitable for the LTPA authentication method is provided (`WSLogin`). An appropriate TokenValueType element is located in the LTPA LoginMapping section of the default `ws-security.xml` file.

# Deploying applications that use SAML

After SAML policy sets and bindings have been configured, and SAML tokens created, the SAML token information can be sent from the original login server to other servers using the SAML propagation feature. You can also extract SAML attributes from an existing SAML token and then create additional tokens using the extracted attributes.

## About this task

Use the SAML propagation feature of WebSphere Application Server to send SAML token information based on the original login to other servers using a SAML token. Four propagation methods are provided. You can propagate the original SAML token, the SAML token identity and attributes, the WSCredential and WSPrincipal information, or a pre-existing SAML token inserted in the RequestContext.

When SAML is installed on a WebSphere server, you can create SAML attributes using the SAML runtime API. The SAML attributes are added to a CredentialConfig object, which is used to generate a SAML token. The API also provides a function that extracts SAML attributes from an existing SAML token and processes the attributes.

The following topics provide more information about deploying SAML applications.

# Propagating SAML tokens

You can use various SAML token propagation methods to include SAML tokens in outbound web services messages.

## About this task

A web services client can include two types of tokens in outbound web services messages:

- Original SAML tokens the client received from inbound web services messages.
- New self-issued SAML tokens.

New SAML tokens can be generated using attributes from the original SAML tokens, or using attributes from the WSPrincipal user name in the RunAs Subject. The web services policy configuration determines which SAML tokens will be propagated. You can override the policy configuration by programmatically inserting SAML tokens that you want to propagate into the Axis2 RequestContext object.

Four propagation methods are enabled. This table summarizes the propagation methods and the associated binding options:

*Table 335. Propagation methods and associated binding options. Use propagation to include SAML tokens in web services messages.*

| SAML token propagation method | Binding option | Implementation details |
|---|---|---|
| Propagate the original SAML token. | The tokenRequest binding option is set to the value, `propagation`. | Sends the original SAML token from the server where the token was received to other servers using WS-Security. |
| Propagate the user security name, unique security name, group IDs, and security realm name. | The tokenRequest binding option is set to the value, `issueByWSCredential`. | Overrides the default system implementation.<br><br>The self-issued SAML token contains user security name, user unique security name, group IDs, and security realm name that are specified by the WSCredential object in user security context. |
| Propagate the SAML token identity and attributes. | No binding option is set. | Default system implementation.<br><br>The server self-generates a new SAML token containing the original SAML attributes, Authentication method, and NameIdentifier or SAML NameID, and sends the new self-generated SAML token to downstream servers using WS-Security. The new SAML token issuer name, issuer signing certificate, and lifetime are determined by the SAML provider configuration properties. |
| Propagate the WSPrincipal. | The tokenRequest binding option is set to the value, `issueByWSPrincipal`. | Overrides the default system implementation.<br><br>The self-issued SAML token contains WSPrincipal information in the RunAs subject. The information is stored as NameIdentity or NameID without copying anything from the original SAML token, even if the token exists in the subject. |
| Programmatically propagate a pre-existing SAML token. | Insert the SAML token that you want to propagate into the RequestContext using the property, `com.ibm.wsspi.wssecurity.core.token.config.WSSConstants.`*`SAMLTOKEN_IN_MESSAGECONTEXT`*. | Overrides all other existing binding options. |

## Procedure

1. Propagate the original SAML token by setting the tokenRequest binding option to the value, `propagation`, in the bindings.xml file, as shown in the steps. This method sends the original SAML token to other servers using WS-Security. In order for the propagation to succeed, there must be a valid SAML token in the RunAs subject. The server extracts the SAML token from the RunAs subject in the current security context and validates the following conditions. If any of these conditions are invalid, the WS-Security runtime environment does not propagate the SAML token, and the propagation request fails.
   - The SAML token has not expired, and the expiration time is within the time window of the notOnOrAfter value.
   - The ConfirmationMethod setting in the SAML token is the same as the confirmationMethod binding option defined in the token generator configuration.
   - The token ValueType in the SAML token matches the ValueType in the token generator configuration.

Perform these steps to set the correct value for the tokenRequest binding option. This procedure assumes that a web services client application named JaxWSServicesSamples is deployed, and that the Saml Bearer Client sample binding is attached.

a. Click **Applications > Application types > WebSphere enterprise Applications > *JaxWSServicesSamples* > Service client policy sets and bindings > *Saml Bearer Client sample* > WS-Security > Authentication and protection**.

b. Click **gen_saml11token** in the Authentication tokens table.

c. Click **Callback handler**.

d. Add the custom property `tokenRequest` and set the property value to `propagation`.

2. To propagate the SAML token identity and attributes using a self-issuing SAML token, modify the outbound tokenGenerator in the bindings.xml file. This method sends the original SAML attributes, NameIdentifier or NameID, and authentication method from the original SAML token to other servers using WS-Security. If there is no SAML token in the subject, the server uses the WSPrincipal, stored as NameIdentifier or NameID, to create a self-issued SAML token. This propagation method is the default system implementation. In this method, the binding option is not set.

   The following limitations apply to the bindings.xml file when you are using this propagation method:

   - Do not set the tokenRequest binding option in the bindings.xml file.
   - Do not set the stsURI binding option in the bindings.xml file, or set the option to this value: `www.websphere.ibm.com/SAML/Issuer/Self`.

3. To propagate the WSPrincipal, modify the bindings.xml file as shown in the steps. Set the tokenRequest binding option to the value, `issueByPrincipal`, in the bindings.xml file. Using this method, the self-issued SAML token is always based on the WSPrincipal even if there is a SAML token in the subject. The new SAML token contains the WSPrincipal user name as the NameId or NameIdentifier. The token does not contain any other attributes in the WSPrincipal or WSCredential objects.

   The following limitation applies to the bindings.xml file when you are using this propagation method:

   - Do not set the stsURI binding option in the bindings.xml file, or set the option to the value, `www.websphere.ibm.com/SAML/Issuer/Self`.

   Perform these steps to set the correct value for the tokenRequest binding option. This procedure assumes that a web services client application named JaxWSServicesSamples is deployed, and that the Saml Bearer Client sample binding is attached.

   a. Click **Applications > Application types > WebSphere enterprise Applications > *JaxWSServicesSamples* > Service client policy sets and bindings > *Saml Bearer Client sample* > WS-Security > Authentication and protection**.

   b. Click **gen_saml11token** in the Authentication tokens table.

   c. Click **Callback handler**.

   d. Add the custom property `tokenRequest` and set the property value to `issueByPrincipal`.

4. To propagate a pre-existing SAML token by inserting SAMLToken in the RequestContext, follow these steps. Use this method to send a SAML token that you created to downstream servers using WS-Security. The propagation is automatically triggered if the WS-Security runtime detects a SAML token in the RequestContext. The pre-existing token overrides any other existing binding options. To use this propagation method, save the existing SAML token in the RequestContext by specifying `com.ibm.wsspi.wssecurity.core.token.config.WSSConstants.`*`SAMLTOKEN_IN_MESSAGECONTEXT`* as the key, as shown in the steps.

   a. Generate a SAML token using the method `SAMLToken samlToken = <token type>`, for example:

```
SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

   b. Save the SAMLToken to the RequestContext, for example:

```
Map requestContext = ((BindingProvider)port).getRequestContext();
   requestContext.put("com.ibm.wsspi.wssecurity.core.token.config.WSSConstants.SAMLTOKEN_IN_MESSAGECONTEXT", samlToken );
```

   This propagation option can co-exist with the other propagation methods, and overrides the other methods. If the SAML token in the RequestContext is expired, or the token expiration time is less than

current time plus the cache cushion, the WS-Security runtime environment ignores the SAML token, and uses one of the other three propagation methods that is configured in the bindings.xml file. To avoid using the other three propagation methods, add the following binding option to the custom properties under callback handler in the TokenGenerator configuration: `failOverToTokenRequest = false`.

5. To propagate a user's group memberships, unique security name, and realm name contained in the `com.ibm.websphere.security.cred.WSCredential` object, modify the `bindings.xml` file as shown in the steps. Set the `tokenRequest` binding option to the value, `issueByWSCredential`, in the `bindings.xml` file. Using this method, the self-issued SAML token is always based on the `WSCredential` even if there is a SAML token in the subject.

   The new SAML 1.1 token contains the following assertions:

   - The `NameIdentifier` element contains the `SecurityName` value from `WSCredential` with the `NameQualifier` element set to the realm name from `WSCredential`. The `SecurityName` is obtained by calling the `WSCredential.getSecurityName()` method. The realm name is obtained by calling the `WSCredential.getRealmName()` method.
   - All attributes have an `AttributeNamespace` set to `com.ibm.websphere.security.cred.WSCredential` as the value.
   - The `GroupIds` attribute contains all group names that a user belongs to. The group names are obtained by calling the `WSCredential.getGroupIds()` method.
   - The `UniqueSecurityName` attribute contains the unique security name, which is obtained by calling the `WSCredential.getUniqueSecurityName()` method.
   - Optionally, you can assert the realm name from `WSCredential` by adding the `includeRealmName=true` custom property in the callback handler.

   The new SAML 2.0 token contains the following assertions:

   - The `NameID` element contains the `SecurityName` value from `WSCredential` with the `NameQualifier` element set to the realm name from `WSCredential`. The `SecurityName` is obtained by calling the `WSCredential.getSecurityName()` method. The realm name is obtained by calling the `WSCredential.getRealmName()` method.
   - All attributes have a `NameFormat` set to `com.ibm.websphere.security.cred.WSCredential` as the value.
   - The `GroupIds` attribute contains all group names that a user belongs to. The group names are obtained by calling the `WSCredential.getGroupIds()` method.
   - The `UniqueSecurityName` attribute contains the unique security name, which is obtained by calling the `WSCredential.getUniqueSecurityName()` method.
   - Optionally, you can assert the realm name from `WSCredential` by adding the `includeRealmName=true` custom property in the callback handler.

   The following limitation applies to the `bindings.xml` file when you use the propagation method:

   - Do not set the `stsURI` binding option in the `bindings.xml` file.

   Perform these steps to set the correct value for the `tokenRequest` binding option. This procedure assumes that a Web services client application named `JaxWSServicesSamples` is deployed, and that the `Saml Bearer Client sample` binding is attached.

   a. Click **Applications > Application types > WebSphere enterprise Applications > *JaxWSServicesSamples* > Service client policy sets and bindings > *Saml Bearer Client sample* > WS-Security > Authentication and protection.**
   b. Click **gen_saml11token** in the Authentication tokens table.
   c. Click **Callback handler**.
   d. Add the `tokenRequest` custom property and set the property value to `issueByWSCredential`.

   The following example illustrates the `NameIdentifier` and `Attribute` statement from a self-issued SAML 1.1 assertion based on `WSCredential`.

```
<saml:AttributeStatement>
    <saml:Subject>
        <saml:NameIdentifier NameQualifier="ldap.acme.com:9080">uid=alice,dc=acme,dc=com</saml:NameIdentifier>
        <saml:SubjectConfirmation>
            <saml:ConfirmationMethod>urn:oasis:names:tc:SAML:1.0:cm:bearer</saml:ConfirmationMethod>
        </saml:SubjectConfirmation>
    </saml:Subject>
    <saml:Attribute AttributeName="UniqueSecurityName" AttributeNamespace="com.ibm.websphere.security.cred.WSCredential">
        <saml:AttributeValue>uid=alice,dc=acme,dc=com</saml:AttributeValue>
    </saml:Attribute>
    <saml:Attribute AttributeName="GroupIds" AttributeNamespace="com.ibm.websphere.security.cred.WSCredential">
        <saml:AttributeValue>cn=development,dc=acme,dc=com</saml:AttributeValue>
        <saml:AttributeValue>cn=deployment,dc=acme,dc=com</saml:AttributeValue>
        <saml:AttributeValue>cn=test,dc=acme,dc=com</saml:AttributeValue>
    </saml:Attribute>
</saml:AttributeStatement>
```

The following example illustrates the `NameID` and `Attribute` statement from a self-issued SAML 2.0 assertion based on `WSCredential`.

```
<saml2:AttributeStatement>
    <saml2:Attribute Name="UniqueSecurityName"
           NameFormat="com.ibm.websphere.security.cred.WSCredential">
        <saml2:AttributeValue>uid=alice,dc=acme,dc=com</saml2:AttributeValue>
    <saml2:Attribute>
    <saml2:Attribute AttributeName="GroupIds"
           NameFormat="com.ibm.websphere.security.cred.WSCredential">
        <saml2:AttributeValue>cn=development,dc=acme,dc=com</saml2:AttributeValue>
        <saml2:AttributeValue>cn=deployment,dc=acme,dc=com</saml2:AttributeValue>
        <saml2:AttributeValue>cn=test,dc=acme,dc=com</saml2:AttributeValue>
    </saml2:Attribute>
</saml2:AttributeStatement>

<saml2:NameID NameQualifier="ldap.acme.com:9060">alice</saml2:NameID>
```

# Creating SAML attributes in SAML tokens

Using the SAML runtime API, you can create SAML tokens containing SAML attributes. You can also extract the SAML attributes from an existing SAML token.

## About this task

When WebSphere Application Server Version 7.0.0.7 and later is installed, you can create SAML attributes using the SAML token library APIs. The SAML attributes are added to a CredentialConfig object, which is used to generate a SAML token. The API also provides a function that extracts SAML attributes from an existing SAML token and processes the attributes.

To create a SAML token containing SAML attributes, perform the following steps:

## Procedure

1. Initialize a com.ibm.wsspi.wssecurity.saml.data.SAMLAttribute object. This creates a SAML attribute based on an address, for example:

```
SAMLAttribute sattribute =
         new SAMLAttribute("urn:oid:2.5.4.20", //Name
       new String[] {" any address"}, //Attribute Values
       null,  /*XML Attributes empty on this example*/
       "urn:oasis:names:tc:SAML:2.0:profiles:attribute:X500", //NameSpace
       "urn:oasis:names:tc:SAML:2.0:attrname-format:uri",  //format
       "Address");
```

2. Use the SAMLTokenFactory to create a CredentialConfig object containing a SAML attribute. This method requires the Java security permisson wssapi.SAMLTokenFactory.newCredentialConfig.
   a. Create a com.ibm.wsspi.wssecurity.saml.config.CredentialConfig object and set a valid principal name.
   b. Create a SAML attribute.
   c. Create a list of SAML attributes and add the SAML attribute to the list.
   d. Add the SAML attribute list to the CredentialConfig object.

See the following example:

```
SAMLTokenFactory samlFactory =
  SAMLTokenFactory.getInstance("http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV2.0");//samlTokenType

CredentialConfig credentialConfig = samlFactory.newCredentialConfig();
credentialConfig.setRequesterNameID("any name");

SAMLAttribute sattribute =
         new SAMLAttribute("urn:oid:2.5.4.20", //Name
        new String[] {" any address"}, //Attribute Values
        null,  /*XML Attributes empty on this example*/
        "urn:oasis:names:tc:SAML:2.0:profiles:attribute:X500", //NameSpace
        "urn:oasis:names:tc:SAML:2.0:attrname-format:uri",  //format
        "Address");

ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
al.add(sattribute);
credentialConfig.setSAMLAttributes(al);
```

3. Specifying the CredentialConfig as a parameter, use the com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory newSAMLToken method to create a SAML token containing the attributes. This step assumes that a RequesterConfig `reqData` object and a ProviderConfig `samlIssuerCfg` object have already been created. For more information on these objects, read about RequesterConfig and ProviderConfig.
   a. Obtain an instance of the SAMLTokenFactory.
   b. Create a SAML token using the newSAMLToken method from the SAMLTokenFactory, for example:

```
SAMLTokenFactory samlFactory =
  SAMLTokenFactory.getInstance("http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV1.1");

SAMLToken aSamlToken = samlFactory.newSAMLToken(credentialConfig, reqData, samlIssuerCfg);
```

4. Optional: Extract SAML attributes from an existing SAML token. This step is useful to extract the SAML attributes from a received SAML token. You can use this step when a SAML assertion is received and the attributes contained in the assertion need to be processed.
   a. Invoke the getSAMLAttributes() method with the token as a parameter to obtain a list of the SAML attributes in the token. This method requires the Java security permission wssapi.SAMLToken.getSAMLAttributes.
   b. Apply an iterator to the list.
   c. Iterate through the list and perform any additional processing required for your application.

   See the following example:

```
List<SAMLAttribute> aList = aSAMLToken.getSAMLAttributes();
java.util.Iterator<SAMLAttribute> i = aList.iterator();

while(i.hasNext()){

   SAMLAttribute anAttribute = i.next();

   //do something with namespace
   String namespace = anAttribute.getAttributeNamespace();

   //do something with name
   String name = anAttribute.getName();

   //do something with friendly name
   String friendlyName = anAttribute.getFriendlyName();

   //process sring attribute values
   String[] stringAttributeValues = anAttribute.getStringAttributeValue();

   //process XML attribute values
   XMLStructure[] xmlAttributeValues = (XMLStructure[]) anAttribute.getXMLAttributeValue();

   }
```

## SAML user attributes

A SAML assertion can contain user attributes relating to the principal of the SAML token. A SAML assertion can contain multiple user attributes.

You can include user attributes in the token to communicate the address of the person who is the SAML assertion principal. This example shows a SAML assertion containing a user attribute:

```
<saml:AttributeStatement>
  <saml:Attribute  xmlns:x500=
      "urn:oasis:names:tc:SAML:2.0:profiles:attribute:X500"
    NameFormat=
      "urn:oasis:names:tc:SAML:2.0:attrname-format:uri"
    Name="urn:oid:2.5.4.20"
    FriendlyName="Address">
          <saml:AttributeValue xsi:type="xs:string">
                      11111 Parker Lane, Austin, Texas, 78758
          </saml:AttributeValue>
  </saml:Attribute>
</saml:AttributeStatement>
```

This table describes the parameters used in the assertion:

| Parameter | Description |
|---|---|
| NameFormat | Specifies how the attribute is interpreted. |
| Name | Indicates the formal name of the attribute. |
| FriendlyName | Provides a user-friendly name for an attribute when the Name parameter is cryptic. |
| AttributeValue | The value of the user attribute. The value can be a string, or a complex XML type. |

# Establishing security context for web services clients using SAML security tokens

WebSphere Application Server supports two policy set caller binding configuration options to establish client security context using SAML security tokens in web services SOAP request messages. The two configuration options are mapping SAML tokens to a user entry in a local user repository and, asserting SAML tokens based on a trust relationship.

## Before you begin

This task assumes that you are familiar with WebSphere Application Server SAML technology.

## About this task

This task describes setting the WebSphere Application Server policy set caller binding configuration option to establish client security context using SAML security tokens in web services SOAP request messages. You can either map SAML tokens to a user entry in a local user repository or assert SAML tokens based on a trust relationship. The second configuration option does not require accessing the local user repository. Instead, the WS-Security runtime environment populates the client security context entirely using the contents of SAML security tokens. This process is based on a trust relationship to the SAML token issuer. If a SAML tokens specifies the sender-vouches subject confirmation method. the process is based on a trust relationship to the message sender.

## Procedure

1. Configure a policy set caller binding and select the SAML token type to represent a web services client request.
   a. Click **WebSphere enterprise applications** > ***application_name*** > **Service provider policy sets and bindings** > ***binding_name*** > **WS-Security** > **Callers**.
   b. Click **New** to create the caller configuration.
   c. Specify a **Name**, such as `caller`.

d. Enter a value for the **Caller identity local part**. For example, `http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV2.0`, which must match the local part of the `CustomToken` element in the attached WS-Security policy.

e. Click **Apply** and **Save**.

2. Optional: Map SAML security tokens to a user entry in a local user repository. Mapping to a user entry is the default behavior when you configure a caller binding without specifying a configuration option. Alternatively and optionally, you can select this configuration option explicitly using the following steps:

   a. On the caller binding configuration page, add a Callback handler: `com.ibm.websphere.wssecurity.callbackhandler.SAMLIdAssertionCallbackHandler`.

   b. Add a Callback handler custom property, `crossDomainIdAssertion`, and set its value to `false`.

3. Optional: Assert SAML security tokens based on trust relationship.

   a. On the caller binding configuration page, add a Callback handler: `com.ibm.websphere.wssecurity.callbackhandler.SAMLIdAssertionCallbackHandler`.

   b. Add a Callback handler custom property, `crossDomainIdAssertion`, and set its value to `true`.

   **Note:** In WebSphere Application Server Version 7.0 Fix Pack 7 and later releases, the WS-Security runtime environment takes a SAML token Issuer name to represent the foreign security realm name. WS-Security takes the `NameID` element in the case of SAML 2.0 security tokens or the `NameIdentifier` element in the case of SAML 1.1 security tokens to represent user security name. Alternatively, you can explicitly specify which SAML token attribute to use to represent user security name. Moreover, you can also specify which SAML token attribute to use to represent user group membership. Read about SAML assertions across WebSphere Application Server security domains for a detailed discussion of the SAML token assertion trust model and binding configuration.

   Version 8 supports propagating select security context data in SAML tokens. You must set a `tokenRequest` custom property with an `issueByWSCredential` property value in the WS-Security binding configuration of the web services client. Read about propagating SAML tokens for a detailed description of this binding option. When the `crossDomainIdAssertion` property is set to `true` in Version 8, WS-Security checks whether a SAML token contains a SAML Attribute `UniqueSecurityName` with a `NameFormat` element with a value of `com.ibm.websphere.security.cred.WSCredential`. If found, WS-Security uses the `NameQualifier` attribute value of the `NameID` element or `NameIdentifier` element to represent the user security realm name. WS-Security also uses the `UniqueSecurityName` attribute value and the `GroupIds` attribute value to represent a unique user name and group membership. This default behavior is different between Version 7 and Version 8 of the product. You can add a `CallbackHandler` property, `IssuerNameForRealm`, and set its value to `true` to configure Version 8 to preserve the Version 7 behavior. Alternatively, you can add a `CallbackHandler` property, `NameQualifierForRealm`, and set its value to `true` to configure Version 8 to always use the `NameQualifier` attribute to represent the user security realm name.

## Results

You have configured a web service to establish a client security context using the SAML security token in the web services SOAP request messages.

## Example

The following example illustrates the `NameIdentifier` and `Attribute` elements from a self-issued SAML 1.1 assertion based on `WSCredential`:

```
<saml:AttributeStatement>
    <saml:Subject>
        <saml:NameIdentifier NameQualifier="ldap.example.com:9080">uid=alice,dc=example,dc=com</saml:NameIdentifier>
        <saml:SubjectConfirmation>
            <saml:ConfirmationMethod>urn:oasis:names:tc:SAML:1.0:cm:bearer</saml:ConfirmationMethod>
        </saml:SubjectConfirmation>
```

```
    </saml:Subject>
    <saml:Attribute AttributeName="UniqueSecurityName" AttributeNamespace="com.ibm.websphere.security.cred.WSCredential">
        <saml:AttributeValue>uid=alice,dc=example,dc=com</saml:AttributeValue>
    </saml:Attribute>
    <saml:Attribute AttributeName="GroupIds" AttributeNamespace="com.ibm.websphere.security.cred.WSCredential">
        <saml:AttributeValue>cn=development,dc=example,dc=com</saml:AttributeValue>
        <saml:AttributeValue>cn=deployment,dc=example,dc=com</saml:AttributeValue>
        <saml:AttributeValue>cn=test,dc=example,dc=com</saml:AttributeValue>
    </saml:Attribute>
</saml:AttributeStatement>
```

The following example illustrates the `NameID` and `Attribute` elements from a self-issued SAML 2.0 assertion based on `WSCredential`:

```
<saml2:AttributeStatement>
    <saml2:Attribute Name="UniqueSecurityName" NameFormat="com.ibm.websphere.security.cred.WSCredential" />
    <saml2:AttributeValue>uid=alice,dc=example,dc=com</saml2:AttributeValue>
    <saml2:Attribute>
        <saml2:Attribute AttributeName="GroupIds" NameFormat="com.ibm.websphere.security.cred.WSCredential" />
        <saml2:AttributeValue>cn=development,dc=example,dc=com</saml2:AttributeValue>
        <saml2:AttributeValue>cn=deployment,dc=example,dc=com</saml2:AttributeValue>
        <saml2:AttributeValue>cn=test,dc=example,dc=com</saml2:AttributeValue>
    </saml2:Attribute>
<saml2:AttributeStatement>

<saml2:NameID NameQualifier="ldap.example.com:9060">alice</saml2:NameID>
```

# Chapter 40. Developing web services - Transaction support (WS-Transaction)

WS-Transaction is an interoperability standard that includes the WS-AtomicTransaction, WS-BusinessActivity, and WS-Coordination specifications. The Web Services Atomic Transaction (WS-AT) support in the application server provides transactional quality of service to the web services environment. Distributed web services applications, and the resources they use, can take part in distributed global transactions. With Web Services Business Activity (WS-BA) support in the application server, web services on different systems can coordinate activities that are more loosely coupled than atomic transactions. Such activities can be difficult or impossible to roll back atomically, and therefore require a compensation process if an error occurs. Web Services Coordination (WS-COOR) specifies a CoordinationContext and a Registration service with which participant web services can enlist to take part in the protocols that are offered by specific coordination types.

## Creating an application that uses the Web Services Business Activity support

To create an application component that uses the business activity support, you must set **Run EJB methods under a Business Activity scope** in the deployment descriptor of the relevant application component, and if required, create and specify a compensation handler for the application to use if there is an error. You then build the component into the application and deploy the application onto a server that has the business activity support enabled. The application component can be either an enterprise bean or a web service that is implemented as an enterprise bean.

### Before you begin

For information about editing deployment descriptors by using Rational Application Developer, refer to the Rational Application Developer information.

### About this task

Complete this task for an application that runs on a business-activity-enabled sever to use the business activity support at run time, and to undertake work that might later be compensated by a compensation handler. If the application requires compensation when a business activity scope ends, the application passes the data that is required by the compensation process to a compensation handler indirectly, by using the business activity API. The data that is required by the compensation process can be in the form of either a serializable object or a Service Data Object (SDO).

### Procedure

1. Design the application component that requires the business activity support. In particular, define the application component requirements for compensation and close activities. If the application component requires compensation, define the nature of the data in the serializable object or the SDO that the application component passes to the compensation handler.
2. Using the information from your application design, create the compensation handler for the application component, if required. This handler defines the close and compensation logic that runs upon completion of a business activity scope that has the handler added to it through an application component.
   a. Open your chosen WebSphere Application Server assembly tool.
   b. Create a new Java class that implements the appropriate interface, depending on the format of the data that is required by the compensation process:
      - For a serializable object, implement the com.ibm.websphere.wsba.serializable.CompensationHandler interface.
      - For an SDO, implement the com.ibm.websphere.wsba.CompensationHandler interface.

© Copyright IBM Corp. 2011

c. Implement the close and compensate methods on the new compensation handler object, to take appropriate actions depending on the serializable or SDO data that passes to the handler when it is invoked.

The compensation handler class is now ready for the application component to reference, and for assembly into an application.

3. Open the application component in the assembly tool.
4. Open the deployment descriptor for the application component in the deployment descriptor viewer.
5. Scroll to the **Compensation** section and select the **Run EJB methods under a Business Activity scope** check box.
6. In the **Compensation handler class** text field, type the fully qualified class name of the compensation handler class that you created earlier.
7. Save the deployment descriptor.
8. Build the application, including both the application component and the compensation handler. If the application is a web service, the application must be compliant with the Java Specification Request (JSR) 109 standard.
9. Deploy the application onto an application server that is business-activity-enabled.

### Results

The application is now business-activity-enabled, and can use the business activity support at run time through the business activity API. The application component has a compensation handler associated with it, and can therefore call the setCompensationDataImmediate and setCompensationDataAtCommit methods at run time to add the compensation handler to the business activity scope. For more information about these methods, see the topics about the Business activity API. If the unit of work with which the business activity scope is associated fails, the compensation handler performs actions to compensate for the error.

### What to do next

Ensure that the compensation handler class is on the application class path for the WebSphere Application Server runtime environment.

## Business activity API

Use the business activity application programming interface (API) to create business activities and compensation handlers for an application component, and to log data that is required to compensate an activity if there is a failure in the overall business activity.

### Overview

The business activity support provides a UserBusinessActivity API and two interfaces: a serializable.CompensationHandler interface and a CompensationHandler interface. Each interface has two exceptions: RetryCompensationHandlerException and CompensationHandlerFailedException. You can look up the UserBusinessActivity interface from the application server Java Naming and Directory Interface (JNDI) at `java:comp/websphere/UserBusinessActivity`. For example:

```
InitialContext ctx = new InitialContext();
UserBusinessActivity uba = (UserBusinessActivity) ctx.lookup("java:comp/websphere/UserBusinessActivity");
```

You can use the getId method to access the unique identifier for the business activity that is currently associated with the calling thread. The identifier is the same as the one that is generated for the business activity scope at run time and that is used for information, warning, and error messages. For example, the application can use the identifier in audit or diagnostic messages, and it is possible to correlate between application-generated and runtime-generated messages.

```
InitialContext initialContext = new InitialContext();
UserBusinessActivity uba = initialContext.lookup("java:comp/websphere/UserBusinessActivity");
...
String activityId = uba.getId();
if (activityId == null)
// No activity on the thread
else
// Output audit message including activity id
```

If an application component runs work that might require compensating upon failure in the business activity, you must provide a compensation handler class that is assembled as part of the deployed application. This Java class must implement one of the following interfaces:

- com.ibm.websphere.wsba.serializable.CompensationHandler, which takes a takes a parameter of a serializable object
- com.ibm.websphere.wsba.CompensationHandler, which takes a parameter of a Service Data Object (SDO)

Typically, applications that already have their data available in DataObject format will use the CompensationHandler interface, and applications that do not will use the serializable.CompensationHandler interface. Both interfaces support the close and compensate methods.

An application must register a compensation handler implementation that works with the type of compensation data (serializable object or SDO) that the application uses. If there is a mismatch between the type of data that the application component uses and the compensation handler implementation, there is an error.

During normal application processing, the application can make one or more invocations to the `setCompensationDataImmediate` or `setCompensationDataAtCommit` methods, passing in either a serializable object or an SDO that represents the current state of the work performed.

When the underlying unit of work (UOW) that the root business activity is associated with completes, all registered compensators are coordinated to complete. During completion, either the compensate or the close method is called on the compensation handler, passing in the most recent compensation data logged by the application component as a parameter. Your compensation handler implementation must be able to understand the data that is stored in either the serializable object or the SDO DataObject; when using this data, the compensation handler must be able to determine the nature of the work performed by the enterprise bean and compensate or close in an appropriate way, for example by undoing changes made to database rows if there is a failure in the business activity. You associate the compensation handler with an application component by using the assembly tooling, such as Rational Application Developer.

## Active and inactive compensation handlers

You implement the serializable.CompensationHandler or CompensationHandler interface for any application component that executes code that might have to be compensated within a business activity scope. Compensation handler objects are registered implicitly with the business activity scope under which the application runs, whenever the application calls the UserBusinessActivity API to specify compensation data. Compensation handlers can be in one of two states, active or inactive, depending on any transactional UOW under which they are registered. A compensation handler that is registered within a transactional UOW might initially be inactive until the transaction commits, at which point the compensation handler becomes active (see the following section). A compensation handler that is registered outside a transactional UOW always becomes active immediately.

When a business activity completes, it drives only active compensation handlers. Any inactive compensation handlers that are associated with the business activity are discarded and never driven.

## Logging compensation data

The business activity API specifies two methods that allow the application to log compensation data. This data is made available to the compensation handlers during their processing when the business activity completes. The application calls one of these methods, depending on whether it expects transactions to be part of the business activity.

**setCompensationDataAtCommit()**

Call the setCompensationDataAtCommit method when the application expects a global transaction on the thread.

- If a global transaction is present on the thread, the CompensationHandler object is initially inactive. If the global transaction fails, it rolls back any transactional work done within its transaction context in an atomic manner, and drives the business activity to compensate other completed UOWs. The compensation handler does not have to be involved. If the global transaction commits successfully, the compensation handler becomes active because if the overall business activity fails, the compensation handler is required to compensate the durable work that is completed by the global transaction. The setCompensationDataAtCommit method configures the CompensationHandler instance to undertake this compensation function.
- If a global transaction is not present when the setCompensationDataAtCommit method is called, the compensation handler becomes active immediately.

For example, for an SDO, and using the same business activity instance as in the previous example:

```
DataObject compensationData = doWorkWhichWouldNeedCompensating();
uba.setCompensationDataAtCommit(compensationData);
```

**setCompensationDataImmediate()**

Call the setCompensationDataImmediate method when the application does not expect a global transaction on the thread.

The setCompensationDataImmediate method makes a CompensationHandler instance active immediately, regardless of the current UOW context at the time that the method is invoked. The compensation handler is always able to participate during completion of the business activity.

The role of the setCompensationDataImmediate method is to compensate any non-transactional work, in other words, work that can be performed either inside or outside a global transaction, but that is not governed by the transaction. An example of this type of work is sending an email. The compensation handler must be active immediately so that if a failure occurs in a business activity, this non-transactional work is always compensated.

For example, for a serializable object, and using the same business activity instance as in the previous example:

```
Serializable compensationData = new MyCompensationData();
uba.setCompensationDataImmediate(compensationData);
```

Although these two compensation data logging methods, if called in the same enterprise bean, use the same compensation handler class, they create two separate instances of the compensation handler class at run time. Therefore, the actions of the methods are mutually exclusive; calling one of the methods does not overwrite any work carried out by the other method.

If a compensation handler instance is already added to the Business Activity by using one of these methods, and then the same method is called, passing in `null` as a parameter, that compensation handler instance is removed from the business activity, and is not driven to close or compensate during completion of the business activity.

As described previously, the business activity support adds a compensation handler instance to the business activity when a compensation data logging method is called for the first time by the enterprise bean that uses that business activity. At the same time, a snapshot of the enterprise application context is

taken and logged with the compensation data. When the business activity competes, all the compensation handlers that were added to the business activity are driven to compensate or close. The code that you create in the CompensationHandler or serializable.CompensationHandler class is guaranteed to run in the same enterprise application context that was captured in the earlier snapshot.

For details about the methods available in the business activity API, see the topic about additional APIs.

# Chapter 41. Developing web services - Transports

Transport chains represent a network protocol stack that is used for I/O operations within an application server environment. Transport chains are part of the channel framework function that provides a common networking service for all components.

## Configuring the SOAP over JMS transport for JAX-WS web services

## SOAP over JMS protocol

The web services engine supports the use of an emerging industry standard SOAP over Java Message Service (JMS)-compliant messaging transport as an alternative to HTTP for communicating SOAP messages between clients and servers.

**Note:** This product supports an emerging industry standard SOAP over JMS protocol. The SOAP over JMS specification provides a standard set of interoperability guidelines for using a JMS-compliant transport with SOAP messages to enable interoperability between the implementations of different vendors. Using this standard, a mixture of client and server components from different vendors can interoperate when exchanging SOAP request and response messages over the JMS transport for both Java API for XML Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services. By using the JMS transport, your enterprise beans based web service clients and servers can communicate through JMS queues and topics instead of through HTTP connections.

IBM and other vendors have been working on the proposed SOAP over JMS specification since 2005. The specification has been submitted to W3C and a working group is established. The current member submission of this draft specification was jointly published in October, 2007. Refer to the SOAP over JMS specification for details of this industry standard.

This topic provides a summary of the emerging industry-standard SOAP over JMS protocol. Use this SOAP over JMS transport protocol if you need to provide implementations for the client or server components. Also, you need to make sure that the implementations are interoperable with the client and server components provided by the web services engine in WebSphere Application Server.

#### Client responsibilities

The client component is responsible for sending SOAP request messages and receiving SOAP response messages while adhering to the following protocol constraints:

- The client must use a javax.jms.BytesMessage object or a javax.jms.TextMessage object to transmit the SOAP request message to the server.
- The client must set the following properties on the JMS request message before sending the message to the destination queue or topic:
  - **SOAPJMS_contentType**: This property is similar to the Content-Type header found in an HTTP message and is used to describe the content type of the message. A text-only SOAP message, for example, a message with no attachments, has the following value set for this JMS message property:

```
text/xml; charset="UTF-8"
```

    For a SOAP message containing attachments, use the following code to set the SOAPJMS_contentType property on the JMS message:

```
multipart/related; type="text/xml"; start="<...content-id_of_first_ part...>"
```

    This example represents a multipart message, where the first part is of type `text/xml` and contains the SOAP envelope. The other parts of the multipart message contain various attachments. The HTTP 1.1 specification contains more information about the Content-Type header.

© IBM Corporation 2009

- **enableTransaction**: Set this optional property to true on an outbound JMS request message if you want the server component to process the web service request under the same transaction that was used to receive the message from the destination queue or topic. This property is an IBM extension to the SOAP over JMS specification.

  **Note:** For client components, only set this property to true for one-way or two-way asynchronous requests to avoid synchronization problems that can occur with two-way synchronous web service requests. If this property is not set or is set to the default value of false, the server suspends the transaction that was used to receive the request message from the destination queue or topic prior to invoking the web services engine to process the request.
- **SOAPJMS_requestURI**: You must set this property to the JMS endpoint URL associated with the request.
- **SOAPJMS_soapAction**: This optional property is set on an outbound JMS request message to indicate the soapAction value associated with the web services request. This property is similar to the SOAPAction HTTP header used when transporting web service requests over an HTTP transport. The value of the soapAction property is a URI identifying the intent of the SOAP request. If the SOAPJMS_soapAction property is specified, it is used by the server component to determine the target of the request. The SOAP specification places no restrictions on the format or specificity of the URI nor does the specification require that the URI is resolvable. Typically, this property is set to the soapAction value from the WSDL document.
- **SOAPJMS_targetService**: You must set this property on an outbound JMS request message, and the value must match the targetService property value that is found in the JMS endpoint URL for the request. This value is used by the server component to determine the port component to which the request is dispatched.
- **SOAPJMS_bindingVersion**: This property indicates the version number of the protocol used by the client and server. Set the value to 1.0.

- If the request message represents a two-way request, meaning that a reply is expected, the client component must set the JMS message JMSReplyTo property to specify the queue that is used for the reply message. The JMS message setJMSReplyTo method is used to specify the queue. You can benefit from configuring a permanent reply queue on the client to prevent the client from having to create a temporary queue each time a web service request is made. Read about configuring a permanent reply queue for web services using SOAP over JMS to learn more about creating this special queue.
- If the SOAP request message represents a one-way request, meaning that a reply message is not expected, the client component must not set the JMS message JMSReplyTo property.
- The client component can assume that a reply message is a JMS BytesMessage object.
- The client component can assume that the reply message correlation ID matches the message ID of the original request message.

**Server responsibilities**

The server component is responsible for receiving the SOAP request messages and sending the SOAP response messages, while adhering to the following protocol constraints:

- The server component can expect to receive a JMS BytesMessage. If something other than a BytesMessage is received by the server component, then a fault with the subcode, unsupportedJMSMessageFormat, is returned to the client if a reply is expected.
- The server component can expect to receive a javax.jms.BytesMessage object or a javax.jms.TextMessage object. If something other than a BytesMessage or TextMessage is received by the server component, then a fault with the subcode, unsupportedJMSMessageFormat, is returned to the client if a reply is expected.
- The server component must process the SOAP request properly to produce an appropriate SOAP reply message.

- The server component must send a reply message back to the client only if the JMS request message's JMSReplyTo property is set. The JMS message getJMSReplyTo method is used to retrieve the JMSReplyTo property value from the JMS message. This property value indicates the reply destination.
- When sending a reply message, the server component must use the same message type as the request. If the request was received as a BytesMessage, the reply must be sent as a BytesMessage. Similarly, if the request was received as a TextMessage, the reply must be sent as a TextMessage.
- The server component must set the following properties in the JMS reply message before sending the message to the reply queue:
  - **SOAPJMS_contentType**: This property is used to describe the content type of the message. See the description for this property in the client responsibilities section in this topic.
  - **correlation ID**: Set the correlation ID property of the JMS reply message to the message ID of the original JMS request message. This correlation is done by calling the JMS message setJMSCorrelationID method.
  - **SOAPJMS_bindingVersion**: This property indicates the version number of the protocol used by the client and server. Set the value to 1.0.

### Example: SOAP request without attachments

The following example displays the results from calling the JMS message toString method for a request message without attachments:

```
  JMSMessage class: jms_bytes
  JMSType:          null
  JMSDeliveryMode:  2
  JMSExpiration:    0
  JMSPriority:      4
  JMSMessageID:     null
  JMSTimestamp:     -1
  JMSCorrelationID: null
  JMSDestination:   null
  JMSReplyTo:       queue://_Q_7D6C2035383215AB00000000000F4241?busName=WsFvtBus
  JMSRedelivered:   false
    JMS_IBM_MsgType: 1
    SOAPJMS_contentType: text/xml; charset=UTF-8
    SOAPJMS_targetService: MaelstromWsEndpoint
    SOAPJMS_requestIRI: jms:jndi:jms/MyRequestQueue?jndiConnectionFactoryName=jms/MyConnFactory&targetService=MyPort1
    SOAPJMS_soapAction: "getQuote"
    SOAPJMS_bindingVersion: 1.0
3c3f786d6c2076657273696f6e3d22312e302220656e636f64696e673d227574662d38223f3e3c73

...
```

### Example: SOAP request with attachments

The following example displays the results from calling the JMS message toString method for a request message with attachments:

```
  JMSMessage class: jms_bytes
  JMSType:          null
  JMSDeliveryMode:  2
  JMSExpiration:    0
  JMSPriority:      4
  JMSMessageID:     null

```

## JMS endpoint URL syntax

As part of an emerging industry-standard SOAP over JMS protocol, a Java Message Service (JMS) endpoint URL syntax has been defined. A JMS endpoint URL is used to access Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) web services with the JMS transport. This URL specifies the JMS destination and connection factory, as well as the port component name for the Web service request. This endpoint URL is similar to the HTTP endpoint URL, which specifies the host and port as well as the context root and port component name.

**Note:** This product supports an emerging industry standard SOAP over JMS protocol. The SOAP over JMS specification provides a standard set of interoperability guidelines for using a JMS-compliant transport with SOAP messages to enable interoperability between the implementations of different vendors. Using this standard, a mixture of client and server components from different vendors can interoperate when exchanging SOAP request and response messages over the JMS transport for both Java API for XML Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services. By using the JMS transport, your enterprise beans based web service clients and servers can communicate through JMS queues and topics instead of through HTTP connections.

IBM and other vendors have been working on the W3C SOAP over JMS specification since 2005. The specification has been submitted to W3C and a working group is established. The current member submission of this document was jointly published in October, 2007. The application server supports the current draft specification from W3C.

**Note:** A JMS endpoint URL has the following general form:

```
jms:jndi:<destination-jndi-name>?<property>=<value>&<property>=<value>&...
```

The URL consists of the jms: transport type, followed by the jndi: variant type, followed by the JNDI name of the destination queue or topic, followed by the query string containing a list of property and value pairs that are used to specify various JMS endpoint information. The jndi: variant means that JNDI is used to locate object names in the endpoint URL string.

The properties supported in the URL string are described in the following tables:

*Table 336. Destination-related properties (required). Use these properties to specify destination-related properties for a JMS endpoint URL.*

| Property name | Description |
|---|---|
| jndiConnectionFactoryName | Specifies the JNDI name of the connection factory that is used by the client runtime to establish a connection to the JMS messaging engine. |
| targetService | Specifies the name of the port component to which the request is dispatched. |

*Table 337. JNDI-related properties (optional). Use these properties to specify JNDI-related properties for a JMS endpoint URL.*

| Property name | Description |
|---|---|
| jndiInitialContextFactory | Specifies the name of the initial context factory class to use. This value maps to the java.naming.factory.initial property. |
| jndiURL | Specifies the JNDI provider URL. This value maps to the java.naming.provider.url property. |

*Table 338. JMS-related properties (optional). Use these properties to specify JMS-related properties for a JMS endpoint URL.*

| Property name | Description |
|---|---|
| deliveryMode | Indicates whether the request message is persistent or not. The valid values are PERSISTENT and NON_PERSISTENT. The default value is NON_PERSISTENT. |
| timeToLive | Specifies the lifetime, in milliseconds, of the request message. A value of 0 indicates an infinite lifetime. If this parameter is not specified, then the JMS-defined default value is used. |
| priority | Specifies the JMS priority associated with the request message. Specify this value as a positive integer from 0, the lowest priority, to 9, the highest priority. If this parameter is not specified, then the JMS-defined default value is used. |
| replyToName | Specifies the JNDI name of the JMS destination to which the response message is sent. Using this optional property enables the client to use a previously defined, permanent queue rather than a temporary queue, for receiving replies. |
| messageType | Specifies the message type to use with the request message. A value of BYTES indicates the javax.jms.BytesMessage object is used. A value of TEXT indicates javax.jms.TextMessage object is used. The default value is BYTES. |

The required properties jndiConnectionFactoryName and targetService must be in the JMS endpoint URL string. The remaining properties are optional.

If you set values for the deliveryMode, timeToLive, and priority properties on the JMS request, these values are propagated from the JMS request message to the corresponding JMS reply message.

See the SOAP over Java Message Service specification in the web services specifications and APIs documentation to learn more about this industry standard.

## IBM proprietary SOAP over JMS protocol (deprecated)

You can use a SOAP over Java Message Service (JMS) transport as an alternative to HTTP for communicating SOAP messages between clients and servers. The web services engine supports the use of an IBM proprietary implementation as well as the industry standard implementation.

**Note:** In earlier versions of the application server, an IBM proprietary SOAP over JMS protocol was supported for Java API for XML-based RPC (JAX-RPC) applications. In WebSphere Application Server 7.0 and later, this proprietary SOAP over JMS protocol is now deprecated in favor of an emerging industry standard SOAP over JMS protocol. You can use the IBM proprietary SOAP over JMS protocol with your Java API for XML Web Services (JAX-WS) or JAX-RPC web services; however, take advantage of the emerging standard SOAP over JMS protocol. If your client

application invokes enterprise beans-based web services that are supported by an earlier version of the WebSphere Application Server, you must continue to use the IBM proprietary SOAP over JMS protocol to access those web services.

You can use a SOAP over JMS transport if you need to provide implementations for the client or server components, and you need to make sure that the implementations are interoperable with the client and server components provided by the web services engine in the application server. The IBM proprietary SOAP over JMS protocol describes specific message exchange requirements for client and server components so they can exchange SOAP request and response messages through the use of the JMS APIs supported by the application server.

**Client responsibilities**

The client component is responsible for sending SOAP request messages and receiving SOAP response messages while adhering to the following protocol constraints:

- The client must use either a JMS TextMessage object, for example, javax.jms.TextMessage, or a BytesMessage object, for example, javax.jms.BytesMessage, to transmit the SOAP request message to the server. If the request message contains attachments, a BytesMessage object must be used. If the request message does not contain attachments, the client can use a TextMessage or a BytesMessage object. The application server client implementation uses only a BytesMessage object for the request message due to the potential need to transmit attachments.
- The client must set the following properties on the JMS request message before sending the message to the destination queue or topic:
  - **contentType**: This property is similar to the Content-Type header found in an HTTP message and is used to describe the content type of the message. A text-only SOAP message, for example, a message with no attachments, is written as follows:

```
text/xml; charset="UTF-8"
```

    The **contentType** property in a SOAP request message that contains attachments must be set as follows:

```
multipart/related; type="text/xml"; start="<...content-id of first part...>"
```

    This example represents a multi-part message, where the first part is of type `text/xml` that contains the SOAP message. The other parts of the multi-part message contain various attachments. The HTTP 1.1 specification contains more information about the Content-Type header.
  - **enableTransaction**: Set this optional property to `true` on the outgoing SOAP over JMS request message if the server component should process the web service request under the same transaction that was used to receive the message from the destination queue or topic. The client component should only set this property to `true` for a one-way request to avoid synchronization problems that can occur with a two-way web service request. If this property is not set or is set to the default value of `false`, then the server will suspend the transaction that was used to receive the request message from the destination queue or topic prior to invoking the web services engine to process the request.

    **gotcha:** The client component should only set this property to `true` for a one-way request. Setting this property to `true` for a two-way web server request is not supported because of synchronization problems.
  - **endpointURL**: This property must be set to the JMS endpoint URL associated with the request.
  - **soapAction**: This optional property is set on an outgoing SOAP over JMS request message to indicate the soapAction value associated with the web services request. This property is similar to the SOAPAction HTTP header used when transporting web service requests over an HTTP transport. The value of the soapAction property is a URI identifying the intent of the SOAP request. If the soapAction property is specified, it is used by the server component to determine the target of the

request. The SOAP specification places no restrictions on the format or specificity of the URI or that it is resolvable. Typically, this property is set to the soapAction value from the WSDL document.
  - **targetService**: This property must be set to the targetService property value that is found in the JMS-style endpoint location URL for the request. This value is used by the server component to determine the port component in the target when dispatching the request.
  - **transportVersion**: This property indicates the version number of the protocol used by the client and server. Set the value to 1 (one).
- If the SOAP request message represents a two-way request, the client component must set the JMS message's replyTo property to specify the queue that is used for the reply message. The JMS message `setJMSReplyTo` method is used for this. It can be beneficial to configure a permanent **replyTo** queue on the client to prevent the client from having to set the JMS message's replyTo property each time a web service request is made.
- If the SOAP request message represents a one-way request, the client component must not set the JMS message's replyTo property.
- The client component must be prepared to handle a reply message that is a BytesMessage or a TextMessage object, regardless of the type of JMS message used to transmit the SOAP request. The application server component responds with the same type of JMS message that is received from the client, unless the response contains attachments and a BytesMessage object must be used.
- The client component can assume that the reply message correlation ID matches the original request message ID.

**Server responsibilities**

The server component is responsible for receiving the SOAP request messages and sending the SOAP response messages while adhering to the following protocol constraints:

- The server must be prepared to receive a TextMessage or a BytesMessage. If the request contains attachments, a ByteMessage must be used. The WebSphere product implementation of the server component responds in kind when sending the reply message back to the client, unless the response contains attachments and a BytesMessage is used.
- The server component must process the SOAP request properly to produce an appropriate SOAP reply message.
- The server component must send a reply message back to the client only if the JMS request message's replyTo property is set.
- The server component must set the following properties in the JMS reply message before sending the message to the replyTo queue:
  - **contentType**: See the description for this property in the client responsibilities section in this article.
  - Set the **correlation ID** of the JMS reply message to the message ID of the original JMS request message. This is done by calling the JMS message `setJMSCorrelationID` method.
  - **transportVersion**: This property indicates the version number of the protocol used by the client and server. Set the value to 1 (one).

**Example: SOAP request without attachments**

The following example displays the results from calling the JMS message `toString` method for a request message without attachments:

```
JMSMessage class: jms_bytes
JMSType:          null
JMSDeliveryMode:  2
JMSExpiration:    0
JMSPriority:      4
JMSMessageID:     ID:d438eebf04cb124aa25c5821110a134f0000000000000001
JMSTimestamp:     1092110476167
JMSCorrelationID: null
JMSDestination:   topic://NewsGroupTopic?topicSpace=FvtTopicSpace
JMSReplyTo:       null
```

```
JMSRedelivered:   false
JMS_IBM_System_MessageID: 6B6765B36943A18C_11000001
transportVersion: 1
JMSXUserID:
targetService: NGConsumerJMS
JMSXAppID: Service Integration Bus
endpointURL: jms:/topic?destination=jms/NewsGroupTopic&connectionFactory;
  =jms/NewsGroupTCF&targetService;=NGConsumerJMS

contentType: text/xml; charset=utf-8
3c736f6170656e763a456e76656c6f706520786d6c6e733a736f6170656e763d22687474703a2f2f
736368656d61732e786d6c736f61702e6f72672f736f61702f656e76656c6f70652f2220786d6c6e
...
```

The following SOAP Version 1.1 example displays the payload from the previous message example:

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
 xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<soapenv:Body soapenv:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
<postMessage><ngName xsi:type="xsd:string">news.current.events</ngName>
<msg xsi:type="xsd:string">This is a sample news item.</msg>
</postMessage>
</soapenv:Body>
</soapenv:Envelope>
```

For SOAP Version 1.2, the `encodingStyle` parameter is not supported, so the example looks similar to the following:

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
 xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<soapenv:Body>
<postMessage><ngName xsi:type="xsd:string">news.current.events</ngName>
<msg xsi:type="xsd:string">This is a sample news item.</msg>
</postMessage>
</soapenv:Body>
</soapenv:Envelope>
```

### Example: SOAP request with attachments

The following example displays the results from calling the JMS message `toString` method for a request message with attachments:

```
JMSMessage class: jms_bytes
JMSType:          null
JMSDeliveryMode:  1
JMSExpiration:    1092086312310
JMSPriority:      4
JMSMessageID:     ID:4bb64ed64e7d813d59ba5fec110a134f0000000000000001
JMSTimestamp:     1092086012310
JMSCorrelationID: null
JMSDestination:   queue://Logger_Q
JMSReplyTo:       queue://_Q_6B6765B36943A18C_00000385
JMSRedelivered:   false
JMS_IBM_System_MessageID: 6B6765B36943A18C_10000001
transportVersion: 1
JMSXUserID:
targetService: WSLoggerJMS
JMSXAppID: Service Integration Bus
endpointURL: jms:/queue?
destination=jms/Logger_Q&connectionFactory=jms/Logger_CF&targetService=WSLoggerJMS
contentType: multipart/related; type="text/xml";
start="<945414389.1092086011970.IBM.WEBSERVICES@myhost1>";
boundary="----=_Part_0_247953397.1092086011970"

...
```

## IBM proprietary JMS endpoint URL syntax (deprecated)

A Java Message Service (JMS) endpoint URL is used to access Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) web services with the JMS transport. This proprietary URL specifies the Java Message Service (JMS) destination and connection factory, as well as the port component name for the web service request. This endpoint URL is similar to the HTTP endpoint URL, which specifies the host and port as well as the context root and port component name.

**Note:** A JMS endpoint URL has the following general form:

`jms:/[`*queue*`|`*topic*`]?<`*property*`>=<`*value*`>&<`*property*`>=<`*value*`>&...`

The URL consists of the `jms:` transport type, followed by either `/queue` or `/topic` to indicate the JMS destination type, followed by the query string containing a list of property and value pairs that are used to specify the JMS endpoint information.

The properties supported in the URL string are described in the following tables:

*Table 339. Destination-related properties (required). Use these properties to specify destination-related properties for a JMS endpoint URL.*

| Property name | Description |
|---|---|
| destination | Specifies the Java Naming and Directory Interface (JNDI) name of the destination queue or topic. |
| connectionFactory | Specifies the JNDI name of the connection factory. |
| targetService | Specifies the name of the port component to which the request is dispatched. |

*Table 340. JNDI-related properties (optional). Use these properties to specify JNDI-related properties for a JMS endpoint URL.*

| Property name | Description |
|---|---|
| initialContextFactory | Specifies the name of the initial context factory to use which is mapped to the java.naming.factory.initial property. |
| jndiProviderURL | Specifies the JNDI provider URL, which is mapped to the java.naming.provider.url property. |

*Table 341. JMS-related properties (optional). Use these properties to specify JMS-related properties for a JMS endpoint URL.*

| Property name | Description |
|---|---|
| deliveryMode | Indicates whether the request message is persistent or not. The valid values are `1` for nonpersistent and `2` for persistent. The default value is `1`. |
| timeToLive | Specifies, in milliseconds, the lifetime of the JMS request message. The default value of `0` indicates an infinite lifetime. However, when you are using web services, this property is bounded by the value that is specified for the synchTimeout property. The setting for the synchTimeout property determines how long a client waits for a response from the server. This bounding prevents the JMS message from remaining active after the client has stopped waiting for a response from the server. |
| priority | Specifies the JMS priority associated with the request message. Valid values are between `0` to `9`. The default value is `4`. A value of `0` is the lowest priority and a value of `9` is the highest priority. |
| replyToDestination | Specifies the JNDI name of a queue to be used to receive reply messages. Using this optional property enables the client to use a permanent queue, rather than a temporary queue, for receiving replies. |

If you set values for the deliveryMode, timeToLive, and priority properties on the JMS request, these values are propagated from the JMS request message to the corresponding JMS reply message.

The required properties, destination, connectionFactory, and targetService must be contained in the JMS endpoint URL string. The rest of the properties are optional.

You can set any of the properties on the client Stub object. The various properties can be specified by including them as part of the endpoint URL or you can set these properties programmatically by the client on the Stub object. Properties specified on the client Stub object take precedence over properties that are specified as part of a JMS endpoint URL string.

## Invoking web service requests transactionally using SOAP over JMS transport

Use the `enableTransactionalOneWay` property to ensure that one-way and two-way asynchronous web service requests using the industry standard SOAP over JMS transport will be sent to the destination queue or topic transactionally.

## About this task

When using JMS to transport Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) web service requests, the default behavior is for the SOAP message to be added to the destination queue or topic non-transactionally or outside of the client application's transaction. Adding the SOAP message to the destination queue or topic is done outside of the transaction to avoid synchronization problems that can occur with two-way synchronous web service requests. However, you can choose to enable one-way and two-way asynchronous requests to be processed as part of a transaction. You can use the `enableTransactionalOneWay` property to ensure that one-way and two-way asynchronous web service requests that use the JMS transport are sent to the destination queue or topic transactionally. When the client application invokes the web service request, the resulting SOAP request message is added to the destination queue or topic as part of the client application's transaction.

Use one of the following ways to enable the `enableTransactionalOneWay` property.

## Procedure

- Set the `enableTransactionalOneWay` property programmatically. The value of the property is a Boolean.
  - For JAX-WS clients, set the property on the client JAX-WS `RequestContext` object. For example:

```
((BindingProvider) port).getRequestContext().put
(com.ibm.websphere.webservices.Constants.ENABLE_TRAN_ONEWAY,
new Boolean(true));
```

  - For JAX-RPC clients, set the property on the client JAX-RPC Stub or Call object. For example:

```
stub._setProperty(com.ibm.websphere.webservices.Constants.ENABLE_TRAN_ONEWAY,
new Boolean(true));
```

- For JAX-RPC clients, set the `enableTransactionalOneWay` property as a custom property in the `ibm-webservicesclient-bnd.xmi` deployment descriptor file by using the wsadmin command.

  For more information about the wsadmin tool options, see the options for the AdminApp object install, installInteractive, edit, editInteractive, update, and updateInteractive commands information..

  Use the `$AdminApp` object along with the `-WebServicesClientCustomProperty` option to set the value of the property within the client binding file, `ibm-webservicesclient-bnd.xmi`. The value of the custom property, `enableTransactionalOneWay`, is either `true` or `false`.
  - Using Jacl:

```
$AdminApp edit MyApplication {-WebServicesClientCustomProperty {{MyEJBJar.jar MyEJB
service/MyServiceRef MyPort enableTransactionalOneWay true}}}
```

  - Using Jython:

```
 AdminApp.edit('MyApplication', ['-WebServicesClientCustomProperty', [['MyEJBJar.jar',
'MyEJB', 'service/MyServiceRef ', 'MyPort', 'enableTransactionalOneWay', 'true']]])
```

## Results

You have a web services client application that is configured to invoke one-way and two-way asynchronous requests transactionally when using the JMS transport.

## What to do next

After you have enabled the `enableTransactionalOneWay` property, run the client application.

# Invoking one-way JAX-RPC web service requests transactionally using the JMS transport (deprecated)

Use the `enableTransactionalOneWay` property to ensure that one-way JAX-RPC web service requests using the IBM proprietary JMS transport will be sent to the destination queue or topic transactionally.

## About this task

**Note:** Beginning with WebSphere Application Server 7.0, the IBM proprietary SOAP over JMS protocol is deprecated in favor of the emerging industry standard protocol. You can use the IBM proprietary SOAP over JMS protocol with your Java API for XML Web Services (JAX-WS) or JAX-RPC web services, however, you are encouraged to take advantage of the SOAP over JMS protocol standard. This task describes configuring a permanent replyTo queue when using the IBM proprietary SOAP over JMS transport. To learn more about the SOAP over JMS standard, see the using SOAP over JMS to transport web services documentation.

When using JMS to transport web service requests, the default behavior is for the SOAP message to be added to the destination queue or topic non-transactionally or outside of the client application's transaction. Adding the SOAP message to the destination queue or topic is done outside of the transaction to avoid synchronization problems that can occur with two-way web service requests. However, you can choose to enable one-way requests to be processed as part of the transaction. The `enableTransactionalOneWay` property can be used to ensure that one-way web service requests that use the JMS transport will be sent to the destination queue or topic transactionally. When the client application invokes the one-way web service request, the resulting SOAP request message is added to the destination queue or topic as part of the client application's transaction.

Use one of the following ways to enable the `enableTransactionalOneWay` property.

## Procedure

- Set the `enableTransactionalOneWay` property programmatically on the client JAX-RPC Stub or Call object.

  When using a static Stub to invoke the web service operation, set the `enableTransactionalOneWay` property on the Stub object before invoking the web service method. When using a Call object to invoke the web service operation, set the `enableTransactionalOneWay` property on the Call object before invoking the `invokeOneWay()` method.

```
Service service = /* Obtain the desired service */
MyStub stub = service.getPort();

/* Set enableTransactionalOneWay property on Stub */
stub._setProperty(com.ibm.websphere.webservices.Constants.ENABLE_TRAN_ONEWAY, new Boolean(true));

/* Invoke the one-way operation */
stub.myOneWayOperation("Parm1");
```

  The value of the property is Boolean.

- Set the `enableTransactionalOneWay` property as a custom property in the `ibm-webservicesclient-bnd.xmi` deployment descriptor file by using the wsadmin command.

  For more information about the wsadmin tool options, see the options for the AdminApp object install, installInteractive, edit, editInteractive, update, and updateInteractive commands information.

  Use the `$AdminApp` object along with the `-WebServicesClientCustomProperty` option to set the value of the property within the client binding file, `ibm-webservicesclient-bnd.xmi`. The value of the custom property, `enableTransactionalOneWay`, is either `true` or `false`.

  – Using Jacl:

```
$AdminApp edit MyApplication {-WebServicesClientCustomProperty {{MyEJBJar.jar MyEJB
service/MyServiceRef MyPort enableTransactionalOneWay true}}}
```

  – Using Jython:

```
 AdminApp.edit('MyApplication', ['-WebServicesClientCustomProperty', [['MyEJBJar.jar',
'MyEJB', 'service/MyServiceRef ', 'MyPort', 'enableTransactionalOneWay', 'true']]])
```

## Results

You have a web service client application that is configured to invoke one-way requests transactionally while using the JMS transport.

### What to do next

After you have enabled the `enableTransactionalOneWay` property, run the client application.

## Configuring SOAP over JMS message types

You can configure your SOAP over Java Message Service (JMS) request or response messages to use either BytesMessage or TextMessage objects.

### Before you begin

A web service must be implemented as an enterprise bean for accessibility through the JMS transport.

### About this task

For your web services that use the emerging industry standard SOAP over JMS protocol, you can configure the SOAP over JMS requests and responses to specify whether the messages are transmitted within JMS BytesMessage (`javax.jms.BytesMessage`) or TextMessage (`javax.jms.TextMessage`) objects. The default message type is BytesMessage.

If the JMS message is a BytesMessage, the body of the JMS message is binary data.

If the JMS message is a TextMessage, the body of the JMS message is string data. For example, consider configuring text messages if you want to implement an audit or logging facility that requires JMS messages that are human readable.

When using SOAP over JMS as a transport for web services request and response messages, it is important to understand the following performance considerations when deciding whether to use BytesMessage or TextMessage objects:

- Memory usage -

  The payload within a TextMessage is string-based and because the individual characters are based on the UTF-16 character encoding, the payload within a TextMessage is likely to occupy twice as many bytes as an equivalent BytesMessage. For request and response messages with small payloads, this difference in memory usage between TextMessages and BytesMessages might not be important, but for large payloads, the difference in memory usage might become more important to consider for your business environment.
- Binary attachments -

  When a JMS TextMessage is used to transport request and response messages, any binary attachments that are included along with the SOAP message body must be base64-encoded because the underlying message payload is string-based. When binary attachments are base64-encoded, additional processing time and memory are required to perform the transformation on that data. As a result, it is possible that the base64-encoded binary attachment might be up to one-third larger than the original unencoded version of the attachment. In this case, if this larger encoded attachment part is then transported in a string-based message payload, the memory usage required to transport the binary attachment part might be almost three times the memory size of the original unencoded binary attachment within a BytesMessage.

### Procedure

- Specify the JMS message type for JAX-WS applications.

  You can configure the JMS message type to specify `BYTES` or `TEXT` in the following ways when using JAX-WS applications. The JAX-WS Web services engine searches for the messageType property in the order of this list and uses the first setting that it finds.

  – Set the messageType property in the JMS endpoint location URL string; for example:

```
jms:jndi:jms/MyQueue&....&messageType=TEXT
```

See the JMS endpoint URL syntax information for details on how to set this property using this method.

- Set the com.ibm.websphere.webservices.transport.jms.messageType custom property in the JMS transport policy binding in the administrative console. See the JMS transport bindings information for details on how to set this property using the administrative console.
- Set the com.ibm.websphere.webservices.transport.jms.messageType property programmatically on the RequestContext object of the JAX-WS BindingProvider.
- Set the com.ibm.websphere.webservices.transport.jms.messageType global system property in the JVM process under which the application server is running. See the Java virtual machine custom properties information for details on how to set this property using this method.

• Specify the JMS message type for JAX-RPC applications.

You can configure the JMS message type to specify `BYTES` or `TEXT` in the following ways when using JAX-RPC applications. The JAX-RPC Web services engine searches for the messageType property in the order of this list and uses the first setting that it finds.

- Set the messageType property in the JMS endpoint location URL string; for example:

```
jms:jndi:jms/MyQueue&....&messageType=TEXT
```

See the JMS endpoint URL syntax information for details on how to set this property using this method.

- Set the com.ibm.websphere.webservices.transport.jms.messageType property programmatically on the Stub or Call object of the client application..
- Set the com.ibm.websphere.webservices.transport.jms.messageType custom property in the client binding file, META-INF/ibm-webservicesclient-bnd.xmi.
- Set the com.ibm.websphere.webservices.transport.jms.messageType global system property in the JVM process under which the application server is running. See the Java virtual machine custom properties information for details on how to set this property using this method.

### Results

You have configured a web service client to use either TextMessage or BytesMessage objects when using the SOAP over JMS protocol to transmit request and response messages.

---

# Invoking JAX-WS web services asynchronously using the HTTP transport

## Using the JAX-WS asynchronous response servlet

Java API for XML-Based Web Services (JAX-WS) includes an asynchronous response servlet, which is used within the application server environment to receive responses for JAX-WS requests that are invoked asynchronously.

### Before you begin

JAX-WS provides support for invoking web services using an asynchronous client invocation by using either a callback or polling model. Both the callback model and the polling model are available on the Dispatch client and the dynamic proxy client. When a JAX-WS client that is running within the application server environment uses an asynchronous client invocation, the responses are received by the asynchronous response servlet. To learn how to use the asynchronous client invocation model, read about invoking JAX-WS web services asynchronously.

### About this task

The asynchronous response servlet is used within an application server to handle incoming asynchronous responses. The servlet uses the same secure and unsecure HTTP ports assigned to the application server. The servlet starts automatically when the application server starts. Because the asynchronous response servlet does not perform role-based authorization checks, only user authentication checks are performed.

The asynchronous response servlet supports both the HTTP and HTTPS protocols. Since the servlet inherits the SSL configuration of the application server, configuring the application server also configures the servlet. The asynchronous response servlet is not affected by the custom HTTP and SSL port properties used by the asynchronous response listener and only runs on the application ports for the application server.

### Procedure

1. Determine if you want the JAX-WS client to use the HTTP or HTTPS transport mechanism.
2. Configure the web container transport chains to modify the SSL configuration of the application server. The servlet inherits these settings. Read about configuring transport chains to learn how to configure the web container transport chains.

### Results

The asynchronous response servlet is configured to enable your JAX-WS clients to receive asynchronous responses on the HTTP or HTTPS transport protocol.

**Note:** When you add a new application server to your environment, the asynchronous response servlet is automatically restarted so the deployment.xml file can be updated for the new application server. If your application receives an incoming response when the asynchronous response servlet is restarting, the incoming response might fail with an HTTP 404 error.

**Note:** JAX-WS services do not successfully return asynchronous responses to clients that are installed in application security-enabled WebSphere Application Servers. Because the Asynchronous Response Servlet for WebSphere Application Server, which handles asynchronous web services responses, is protected when application security is enabled, you must supply a credential together with the JAX-WS service incoming response. Attach the HTTPTransport policy set binding to the JAX-WS service in the service attachment. Additionally, enter a valid basic authentication user ID and password, which are defined in the user registry of the client, into the Basic authentication for outbound asynchronous service responses field.

## Using the JAX-WS asynchronous response listener

Java API for XML-Based Web Services (JAX-WS) includes an asynchronous response listener, which is used within the Thin Client for JAX-WS and application client environments to receive responses for requests that are invoked asynchronously.

### Before you begin

JAX-WS provides support for invoking web services using an asynchronous client invocation by using either a callback or polling model. Both the callback model and the polling model are available on the Dispatch client and the dynamic proxy client. When the JAX-WS client uses an asynchronous client invocation, the responses are received by the asynchronous response listener. To learn how to use the asynchronous client invocation model, read about invoking JAX-WS web services asynchronously.

## About this task

The asynchronous response listener is used within a Web services client to handle incoming asynchronous responses. You can use the listener in Thin Client for JAX-WS environments and application client environments. By default, the listener opens a random port to listen for asynchronous responses or you can optionally configure a specific port for the listener to use. The listener starts automatically in the JAX-WS run time when the JAX-WS client is configured to expect an asynchronous response.

There are two versions of the asynchronous response listener. The unsecure version of the asynchronous response listener supports the HTTP protocol, and the secure version of the asynchronous response listener supports the HTTPS protocol. The correct asynchronous response listener is automatically started based on the particular transport used by the JAX-WS client. To ensure that the correct Secure Sockets Layer (SSL) handshaking occurs between the asynchronous response listener and the application server, configure the SSL properties using the SSL transport policy or the Java system properties.

For web services clients running in the application server environment, use the asynchronous response servlet for receiving asynchronous responses.

## Procedure

1. Determine if you want the JAX-WS client to use the HTTP or HTTPS transport mechanism.
2. Configure the asynchronous response listener for unsecure communication using HTTP.

   You can configure the HTTP port for the asynchronous response listener as a Java system property or as a custom property within the transport policy. Properties that are defined in the policy set binding files override any Java system property that might have been defined.

   a. Define the `com.ibm.websphere.webservices.http.listenerPort` property as a Java system property. If this property is set as a Java system property, then all asynchronous response listeners within that Java Virtual Machine (JVM) are affected.

   b. Define the `com.ibm.websphere.webservices.http.listenerPort` property within the `HTTPTransport` transport policy set bindings files. If this property is set as a custom property within a transport policy set binding, then only the services for which the policy set has been configured are affected.
3. Configure the asynchronous response listener for secure communication using HTTPS.

   You can configure the HTTPS port for the asynchronous response listener as a Java system property or as a custom property within the transport policy.

   a. Define the `com.ibm.websphere.webservices.https.listenerPort` property as a Java system property. If this property is set as a Java system property, thenall asynchronous response listeners within that JVM are affected.

   b. Define the `com.ibm.websphere.webservices.https.listenerPort` property within the `SSLTransport` transport policy set bindings files. If this property is set as a custom property within a transport policy set binding, then only the services for which the policy set has been configured are affected.

## Results

Your JAX-WS web services client is configured to use the asynchronous response listener to receive incoming asynchronous responses.

## Example

The following examples demonstrate how to enable the asynchronous response listener when defining the custom port of 9999:

Use the following Java command to configure the custom HTTP port for the asynchronous response listener in a thin client environment:

```
- java.exe -Dcom.ibm.websphere.webservices.http.listenerPort=9999 com.ibm.websphere.my_program
```

Use the following launchClient command to configure the custom HTTP port for the asynchronous response listener in an application client container:

```
- launchClient.bat MyClient.ear -CCDcom.ibm.websphere.webservices.http.listenerPort=9999
```

The following is an excerpt from an HTTPTransport policy binding.xml file that includes the asynchronous response listener properties:

```
</wsp:Policy>
   </wsp:ExactlyOne>
 </wsp:All>
    <wshttp:outAsyncResponseProxy>
     <wshttp:connectInfo host="" port=""></wshttp:connectInfo>
                  <wshttp:basicAuth userid="" password=""></wshttp:basicAuth>
    </wshttp:outAsyncResponseProxy>
    <wshttp:properties>
  <wshttp:customProperty name="com.ibm.websphere.webservices.http.listenerPort" value="9999" />
   </wshttp:properties>
 </wsp:All>
   </wsp:ExactlyOne>
</wsp:Policy>
```

### What to do next

Run the JAX-WS client with the specified asynchronous response listener options.

# Invoking JAX-WS web services asynchronously using the SOAP over JMS transport

## Using the JAX-WS JMS asynchronous response message listener

Java API for XML-Based Web Services (JAX-WS) includes a Java Message Service (JMS) asynchronous response message listener, which is used to receive responses to asynchronous JAX-WS requests that use the JMS transport. The JMS asynchronous response message listener is used in the application server and application client environments.

### Before you begin

JAX-WS provides support for invoking web service operations asynchronously by using either a callback or a polling model. When the JAX-WS client uses the JMS transport to invoke asynchronous operations, the responses are received by the asynchronous response message listener. To learn how to use the JAX-WS asynchronous client invocation model, read about invoking JAX-WS web services asynchronously.

### About this task

The JMS asynchronous response message listener is used within the web services client environment to receive incoming asynchronous responses when the client application is using the JMS Transport. The listener requires a connection factory and a queue to function correctly. Begin by configuring the connection factory and queue, and then specify the JNDI names of the connection factory and queue to the listener by setting Java system properties. The environment in which the client is running determines how the system properties are set.

The JMS asynchronous response message listener is started automatically by the web services client runtime environment when the client invokes the first asynchronous JAX-WS operation using the JMS transport.

The connection factory and the queue configured with the asynchronous response message listener is used for all requests that are invoked within a particular Java process such as for the application server or an application client container. You can share the connection factory among different Java processes. However, you cannot share a queue among Java processes.

## Procedure

1. Determine if you want the JAX-WS client to use the JMS transport mechanism.
2. For each Java process that will use JMS as a transport for asynchronous JAX-WS requests, configure the connection factory and queue that are used by the JMS asynchronous response listener for that process. You can share a connection factory among multiple Java processes, but you cannot share a queue among Java processes.
3. For each Java process, set the com.ibm.websphere.webservices.jms.AsyncReplyQueueName and com.ibm.websphere.webservices.jms.AsyncReplyCFName Java system properties to specify the JNDI names of the queue and connection factory that are used by the JMS asynchronous response message listener for that process.

   If the JNDI name of the queue is the default value, jms/DefaultAsyncReplyQueue, then you do not need to set the AsyncReplyQueueName property. Likewise, if the JNDI name of the connection factory is the default value, jms/DefaultAsyncReplyCF, then you do not need to set the AsyncReplyCFName property as well.

   If your client runs within the application server environment, then set the properties as application server system properties by using the administrative console or the wsadmin command.

   If your client runs within the application client container environment, then you should set the properties by using the –CCD option on the launchClient command line.

## Results

Your JAX-WS web services client is configured to use the JMS asynchronous response message listener to receive asynchronous response messages when using the JMS transport.

## Example

Suppose that you have a JAX-WS web services client that runs in the application client container environment and uses the JMS transport to communicate with the server. Suppose also that the client invokes asynchronous JAX-WS operations. You can create a connection factory with the JNDI name, jms/MyAppCF, and a queue with the JNDI name, jms/MyAppAsyncReplyQueue. When you invoke the client with the launchClient command, specify the JNDI names of the queue and connection factory as illustrated in the following command:

```
launchClient MyAppClient.ear \
   -CCDcom.ibm.websphere.webservices.jms.AsyncReplyQueueName=jms/MyAppReplyQueue \
   -CCDcom.ibm.websphere.webservices.jms.AsyncReplyCFName=jms/MyAppCF \
   <application arguments>
```

# Chapter 42. Developing web services - UDDI registry

The Universal Description, Discovery, and Integration (UDDI) specification defines a way to publish and discover information about web services. The UDDI specification defines a standard for the visibility, reusability, and manageability that are essential for a service-oriented architecture (SOA) registry service. The UDDI registry is a directory for web services that is implemented using the UDDI specification. It is a component of WebSphere® Application Server.

Web services are self-contained, modular applications that can be described, published, located, and invoked over a network. They implement a services oriented architecture (SOA), which supports the connecting or sharing of resources and data in a very flexible and standardized manner. Services are described and organized to support their dynamic, automated discovery and reuse.

## Developing with the UDDI registry

You can access the UDDI registry in several ways; the UDDI registry user interface, application programming interfaces (APIs), or the Java API for XML Registries (JAXR).

### About this task

You can access the UDDI registry programmatically by using several application programming interfaces (APIs).

You can also explore the UDDI registry by using the UDDI registry user interface (also referred to as the UDDI registry user console), which is a graphical interface.

You can access both UDDI (Version 2 only) and ebXML registries by using the Java API for XML Registries (JAXR). This Java client API is part of the Java EE specification.

### Procedure

- "UDDI registry client programming"
- "Using the UDDI registry user interface" on page 2134
- "Using the JAXR provider for UDDI" on page 2140

## UDDI registry client programming

The UDDI registry provides several application programming interfaces (APIs) that you can use to access the UDDI registry programmatically.

### About this task

The UDDI Version 3 registry supports multiple versions of UDDI. It supports UDDI Version 1, Version 2, and Version 3.

For details of the Version 1 and Version 2 API, refer to the UDDI Version 2 Specifications.

For details of the UDDI Version 3.0.2 API, refer to the UDDI Version 3.0.2 Specification.

The UDDI registry information in this information center defines the support that the UDDI registry provides for the UDDI Version 3.0.2 specification and associated addenda.

The following UDDI Version 3 API sets are supported:
- The UDDI V3 Inquiry API
- The UDDI V3 Publish API
- The UDDI V3 Custody and Ownership Transfer API

© Copyright IBM Corp. 2011

- The UDDI V3 Security API

**Restriction:** In DB2 for zSeries® Version 7, the length of publish and inquiry strings are limited to 255 characters. If this limit is exceeded, error 10500 (E_Fatal) is returned. If you use a character set that uses multiple byte characters, it is easy to exceed this limit. Therefore, use care if you use this type of character set.

## Procedure

1. Learn about the standard aspects of the UDDI APIs by using the following topics.
   - "UDDI registry Version 3 entity keys" on page 2126 explains UDDI entity keys, and the capability with UDDI Version 3 to save UDDI entities with publisher-assigned keys.
   - "Digital signatures and the UDDI registry" on page 2129 explains the support for digital signing of UDDI entities, and for validation of signatures.
2. Access the APIs programmatically. The recommended client API is the UDDI Version 3 Client, which allows access to the UDDI Version 3 APIs from Java client code.

   Other client APIs are provided for compatibility with previous versions of the UDDI registry:
   - The UDDI4J programming interface provides Java class libraries for accessing UDDI Version 1 and Version 2 APIs. These class libraries are both deprecated in this release, and are replaced by the UDDI Version 3 Client for Java.
   - The UDDI EJB Interface provides an Enterprise JavaBeans (EJB) interface to the UDDI Version 2 APIs. The UDDI EJB interface is deprecated in this release.

   Although the recommended programmatic access to the UDDI APIs is through the UDDI Version 3 Client for Java, it is also valid to use the UDDI APIs directly by using SOAP. To use the SOAP API, construct a properly-formed UDDI message in the body of a SOAP request, and send it by using HTTP POST to the appropriate SOAP endpoint for the UDDI service. The response is returned in the body of the HTTP reply.

   The UDDI registry samples include samples that demonstrate how to program directly to the SOAP API. The samples are written in Java code, but you can use other programming languages to create your SOAP client, provided that you still send requests that are compliant to the SOAP specification. Valid UDDI requests must conform to the UDDI schema, as detailed in the UDDI specification

   Support is also provided to use HTTP GET to return XML representations of UDDI entities: see "HTTP GET services for UDDI registry data structures" on page 2130 for details.

## Inquiry API for the UDDI Version 3 registry

The Inquiry API provides four forms of query that follow broadly used conventions that match the needs of software that is traditionally used in registries.

The four forms of query are:
- The browse pattern
- The drilldown pattern
- The invocation pattern
- Inquiry API functions

### Browse pattern for the UDDI registry

Software that is used to explore and examine data, especially hierarchical data, requires browse capabilities. The browse pattern characteristically involves starting with some broad information, performing a search, finding general result sets, then selecting more specific information for drill-down patterns.

The UDDI API specifications accommodate the browse pattern with the *find_xx* API calls. These calls form the search capabilities that the API provides. The calls are matched with summary return messages that return overview information about the registered information that is associated with the inquiry message type and the search criteria specified in the inquiry.

A typical browse sequence might involve finding whether there is any information registered for a business you know about. This sequence starts with a call to find_business, perhaps passing the first characters of the business name that you know. This action returns a businessList result. This result is overview information, including keys, names, and descriptions, that is derived from the registered businessEntity information, matching on the name fragment that you provide. If the business you are looking for is in this list, you can use the find_service API call to drill down into the corresponding businessService information, and look for specific technical models, such as purchasing or shipping. Similarly, if you know the technical *fingerprint*, that is, the tModel signature, of a particular software interface, and you want to see if the business you are looking for provides a web service that supports that interface, you can use the find_binding inquiry message.

## Drilldown pattern for the UDDI registry

When you have a key for one of the four main data types that a UDDI registry manages, you can use that key to access the full registered details of a specific data instance. The UDDI data types are businessEntity, businessService, bindingTemplate, and tModel. You can access the full registered information for any of these structures by passing a relevant key type to one of the *get_xx* API calls.

Continuing the example from the previous section, one data item that is returned by all of the *find_x* return sets is key information. For the business you are interested in, the businessKey value that is returned in the contents of a businessList structure can be passed as an argument to the get_businessDetail message. The successful return to this message is a businessDetail message that contains the full registered information for the entity with the key value that is passed. This information will be a full businessEntity structure.

## Invocation pattern for the UDDI registry

For an application to take advantage of a remote web service that is registered in the UDDI registry by other businesses or entities, you must prepare that application to use the information found in the registry for the specific service being invoked.

The *bindingTemplate* data that is obtained from the UDDI registry represents the specific details about an instance of a given interface type, including the location at which a program starts interacting with the service. The calling application or program caches this information and uses it to contact the service at the registered address whenever the calling application needs to communicate with the service instance.

In remote procedure technologies that were previously popular, tools automate the tasks that are associated with caching, or hard coding, location information. However, there are problems when a remote service moves and the callers do not know about the move. There are many reasons why a remote service might move, for example, a server upgrade, disaster recovery, service acquisition, or a change to the business name.

When a call fails using cached information previously obtained from a UDDI registry, the correct behavior is to query the UDDI registry for fresh bindingTemplate information. If the data that is returned is different from the cached information, the service invocation can automatically try the invocation again, using the fresh information. If the result of this retry is successful, the new information replaces the cached information.

By using this pattern with web services, a business that uses a UDDI registry can automate the recovery of a large number of partners without unneccessary communication and coordination costs. For example, if a business activates a disaster recovery site, most of the calls from partners fail when they try to invoke services at the failed site. By updating the UDDI information with the new address for the service, partners who use the invocation pattern automatically locate the new service information and recover without further administrative action.

***Inquiry API functions in the UDDI registry:***

You can use the Inquiry API set to locate and obtain details about entries in a UDDI registry.

The Inquiry API is split into a number of functions, where each function requires some mandatory and some optional arguments.

The find_*xx* API functions can accept an optional findQualifiers argument.

To access all API calls and arguments that are supported by the UDDI Version 3 registry programmatically, use the UDDI Version 3 Client for Java. To access the API functions graphically, you can use the UDDI user interface, but not all functions are available with this method.

The UDDI Version 3 registry supports the following Inquiry API calls:

**find_binding**
: Locates specific bindings in a registered businessService. Returns a bindingDetail message that contains zero or more bindingTemplate structures that match the criteria specified in the argument list.

**find_business**
: Locates information about one or more businesses. Returns a businessList message that matches the conditions specified in the arguments.

**find_relatedBusinesses**
: Locates information about businessEntity registrations that are related to a specific business entity whose key is passed in the inquiry. The related businesses feature is used to manage registration of business units and subsequently relate them based on organizational hierarchies or business partner relationships. Returns a relatedBusinessList message that contains results that match the conditions specified in the argument list.

**find_service**
: Locates specific services in a registered businessEntity. Returns a serviceList message that matches the conditions specified in the arguments.

**find_tModel**
: Locates a list of tModel entities that match a set of specified criteria. The response is a list of abbreviated information about registered tModel data that matches the specified criteria. The result is returned in a tModelList message.

**get_bindingDetail**
: Requests the runtime bindingTemplate information for the purpose of invoking a registered business API. Returns a bindingDetail message.

**get_businessDetail**
: Returns complete businessEntity information for one or more specified businessEntity registrations that match the specified businessKey values. Returns a businessDetail message.

**get_opertionalInfo**
: Gets full operational information pertaining to one or more entities in the registry. Returns an operationalInfos structure.

**get_serviceDetail**
: Requests full information about a known businessService structure. Returns a serviceDetail message.

**get_tModelDetail**
: Gets full details for a given set of registered tModel data. Returns a tModelDetail message.

For details of the query syntax, refer to the UDDI Version 3 API specification.

*FindQualifier values for API functions in the UDDI registry:*

The find_*xx* API functions (find_business, find_service, find_binding, find_tModel and find_relatedBusinesses) accept an optional findQualifiers argument, which can contain multiple findQualifier values.

The following list contains the findQualifier short names, a brief description, and the appropriate find function.

**andAllKeys**
Specifies that the identifierBag element uses AND behavior with keys, rather than OR behavior. This behavior is the default for the categoryBag and tModelBag elements. This value applies to the find_business, find_service, find_binding, and find_tModel functions. This value does not apply to the find_relatedBusinesses function.

**approximateMatch**
Specifies that wildcard search behavior is required. This is no longer the default behavior; the default behavior is specified by the exactMatch value. This value applies to the find_business, find_service, find_binding, find_tModel, and find_relatedBusiness functions.

**binarySort**
Specifies a faster sort by using a binary sort by name, as represented in Unicode codepoints. This value applies only to the find_business, find_service and find_tModel functions.

**bindingSubset**
This value is used only with a categoryBag element in the find_business or find_services functions.

**caseInsensitiveMatch**
Specifies that the matching behavior for name, keyValue, and keyName, where applicable, is not case-sensitive. By default, the matching behavior is case-sensitive. This value applies to the find_business, find_service, and find_tModel functions.

**caseInsensitiveSort**
Specifies that the sorting behavior for name, keyValue, and keyName, where applicable, is not case-sensitive. By default, the sorting behavior is case-sensitive.

**caseSensitiveMatch**
Specifies that the matching behavior for name, keyValue, and keyName, where applicable, is case-sensitive. This is the default behavior. This value applies to the find_business, find_service, find_binding, find_tModel, and find_relatedBusinesses functions.

**caseSensitiveSort**
Specifies that the sorting behavior for the result set is case-sensitive. This is the default behavior. This value applies to the find_business, find_service, and find_tModel functions.

**combineCategoryBags**
For a find_business function, specifies that the categoryBag entries for the full businessEntity element behave as though all categoryBag elements found at the businessEntity level and in all contained or referenced businessService elements and bindingTemplate elements are combined.

For a find_service function, specifies that the categoryBag entries for the full businessService element behave as though all categoryBag elements found at the businessService level and in all contained or referenced elements in the bindingTemplate elements are combined.

This value applies only to the find_business and find_service functions.

**diacriticInsensitiveMatch**
Specifies that the matching behavior for name, keyValue, and keyName, where applicable, is performed without regard to diacritics, for example accent marks. This is an optional value that applies to the find_business, find_service, find_binding, find_tModel, and find_relatedBusinesses functions.

**diacriticSensitiveMatch**
Specifies that the matching behavior for name, keyValue, and keyName, where applicable, is performed with regard to diacritics, for example accent marks. This is the default behavior. This value applies to the find_business, find_service, find_binding, find_tModel, and find_relatedBusinesses functions.

**exactMatch**
Specifies that only entries with names, keyValues, and keyNames, where applicable, that exactly match the name argument passed in, after normalization, are returned. The matching behavior is sensitive to case and diacritics, where applicable, and is the default behavior. This value applies to the find_business, find_service, find_binding, find_tModel, and find_relatedBusinesses functions.

**signaturePresent**
Specifies that the result set is restricted to either entities that contain an XML digital signature element, or entities that are contained in an entity that contains an XML digital signature element. This value applies to the find_business, find_service, find_binding, find_tModel, and find_relatedBusinesses functions.

**orAllKeys**
Specifies that the tModelBag and categoryBag elements use OR behavior with the keys in a bag, rather than AND behavior. It is not possible to use OR behavior with the categories and retain the default AND behavior of the tModel entities. For the find_business function, this is the default behavior for the identifierBag element. This value applies to the find_service, find_binding (for categoryBag and tModelBag) and find_tModel functions, where it is the default behavior for the identifierBag element and applies to the categoryBag element.

**orLikeKeys**
Specifies that when a categoryBag or identifierBag element contains multiple keyedReference elements, the elements use OR behavior with any keyedReference filters that come from the same namespace, that is, the filters have the same tModelKey value, rather than AND behavior. This value applies to the find_business, find_service, find_binding, and find_tModel functions.

**serviceSubset**
Specifies that the component of the search that involves categorization uses only the categoryBag elements from contained or referenced businessService elements in the registered data, and ignores any entries found in the categoryBag that are not direct descendent elements of registered businessEntity elements. This value applies only to the find_business function with the categoryBag element.

**sortByNameAsc**
Specifies that the result set that a find or get inquiry API returns is sorted on the name field in ascending order. This value takes precedence over sortByDateAsc and sortByDateDesc values, but if a sortByDate*Xxx* value is used without a sortByName*Xxx* value, the result set is sorted by date, regardless of the name field. This value applies to the find_business, find_service, find_tModel, and find_relatedBusinesses functions.

**sortByNameDesc**
Specifies that the result set that a find or get inquiry API returns is sorted on the name field in descending order. This value takes precedence over sortByDateAsc and sortByDateDesc values, but if a sortByDate*Xxx* value is used without a sortByName*Xxx* value, the result set is sorted by date, regardless of the name field. This value applies to the find_business, find_service, find_tModel, and find_relatedBusinesses functions.

**sortByDateAsc**
Specifies that the result set that a find or get inquiry API returns is sorted on the most recent date when each entity, or any entities that they contain, were last updated, in ascending chronological order, that is, the oldest entity is returned first. If this value is used with a sortByName*Xxx* value, the name-based sort takes precedence over the date-based sort, that is, the results are sorted by name, then within names by date, oldest to newest. This is the default behavior for the find_binding function. This value applies to the find_business, find_service, find_tModel, and find_relatedBusinesses functions.

**sortByDateDesc**
Specifies that the result set that a find or get inquiry API returns is sorted on the most recent date when each entity, or any entities that they contain, were last updated, in descending chronological order, that is, the most recently changed entity is returned first. If this value is used with a sortByName*Xxx* value, the name-based sort takes precedence over the date-based sort, that is, the results are sorted by name, then within names by date, newest to oldest. This value applies to the find_business, find_service, find_binding, find_tModel and find_relatedBusinesses functions.

**suppressProjectedServices**
Specifies that a find_service or find_business function must not return service projections. This value is enabled by default whenever the find_service function is used without a businessKey key. This value applies to the find_business and find_service functions.

For further details on the findQualifiers, refer to the UDDI Version 3 Specification documentation.

## Publish API for the UDDI Version 3 registry

Use the UDDI Publish API to publish, delete, and update information that is contained in a UDDI registry. The messages that are defined in this section all behave synchronously.

To access all API calls and arguments that are supported by the UDDI Version 3 registry programmatically, use the UDDI Version 3 Client for Java. To access the API functions graphically, you can use the UDDI user interface, but not all functions are available with this method.

The UDDI Version 3 registry supports the following Publish API calls:

**add_publisherAssertions**
: Adds one or more publisherAssertions to the assertion collection of an individual publisher.

**delete_binding**
: Deletes one or more instances of bindingTemplate data from the UDDI registry.

**delete_business**
: Removes one or more business registrations and all direct contents from a UDDI registry.

**delete_publisherAssertions**
: Removes one or more publisherAssertion elements from an assertion collection of a publisher.

**delete_service**
: Removes one or more businessService elements from the UDDI registry and from its containing businessEntity parent.

**delete_tModel**
: Logically deletes one or more tModel structures. Logical deletion hides the deleted tModel entities from find_tModel result sets, but does not physically delete them, so they are returned on a get_registeredInfo request.

**get_assertionStatusReport**
: Provides administrative support to determine the status of current and outstanding publisher assertions that involve any of the business registrations that the individual publisher account manages. A publisher can use this message to see the status of assertions that they have made, and to see assertions that others have made that involve businessEntity structures that the calling publisher account controls.

**get_publisherAssertions**
: Obtains the full set of publisher assertions that are associated with an individual publisher account. Publisher assertions are used to control publicly visible business relationships.

**get_registeredInfo**
: Obtains an abbreviated list of all businessEntity and tModel data that are controlled by the individual that is associated with the credentials that are passed.

**save_binding**
: Saves or updates a complete bindingTemplate element. This message can be used to add or update one or more bindingTemplate elements as well as the container or contained relationship that each bindingTemplate has with one or more existing businessService elements.

**save_business**
: Saves or updates information about a complete businessEntity element. This API has the broadest scope of all the save_*xx* API calls in the publisher API, and can be used to make comprehensive changes to the published information for one or more businessEntity elements that an individual controls.

**save_service**
: Adds or updates one or more businessService elements that a specified businessEntity exposes.

**save_tModel**
: Adds or updates one or more registered tModel entities.

**set_publisherAssertions**
: Manages all the tracked relationship assertions that are associated with an individual publisher account.

For full details of the Publish API syntax, refer to the UDDI Version 3 API specification.

## Custody and Ownership Transfer API for the UDDI Version 3 registry

Use the UDDI Custody and Ownership Transfer API to transfer custody or ownership of one or more entities that are contained in a UDDI Version 3 registry. The UDDI Version 3 registry supports only intra-node ownership transfer; it does not support inter-node custody transfer.

To access all API calls and arguments that are supported by the UDDI Version 3 registry programmatically, use the UDDI Version 3 Client for Java. To access the API functions graphically, you can use the UDDI user interface, but not all functions are available with this method.

The UDDI Version 3 registry supports the following Custody and Ownership Transfer API calls:

**discard_transferToken**
: Discards a transferToken that is obtained through the get_transferToken API.

**get_transferToken**
: Initiates the transfer of ownership of one or more businessEntity or tModel entities from one publisher to another. When the API is invoked, no transfer takes place. Instead, the relinquishing publisher uses this API to obtain permission from the custodial node, in the form of a transferToken, to undertake the transfer. The relinquishing publisher gives the transferToken to the recipient publisher, who must invoke the transfer_entities API to transfer the entities.

**transfer_entities**
: Performs the transfer of entities when called by the recipient publisher. The recipient publisher must specify an unexpired transferToken on the call.

For details of the query syntax, refer to the UDDI Version 3 API specification.

## Security API for the UDDI Version 3 registry

The UDDI Version 3 registry has an independent Security API, unlike UDDI Version 1 and Version 2, where the Security API is part of the Publish API.

To access all API calls and arguments that are supported by the UDDI Version 3 registry programmatically, use the UDDI Version 3 Client for Java. To access the API functions graphically, you can use the UDDI user interface, but not all functions are available with this method.

The UDDI Version 3 registry supports the following Security API calls:

**discard_authToken**
: Informs a node that a previously obtained authentication token is no longer required and is no longer valid if it is used after this message is received. The token is discarded and the session is effectively ended.

**get_authToken**
: Requests an authentication token in the form of an authInfo element from a UDDI node.

For full details of the Security API syntax, refer to the UDDI Version 3 API specification.

## UDDI registry Version 3 entity keys

The UDDI Version 3 specification expands the space available for keys. Entity keys can be any Universal Resource Identifier (URI) that follows the recommended UDDI scheme. Depending on registry policy, both the UDDI registry and the publisher of the entity can assign keys.

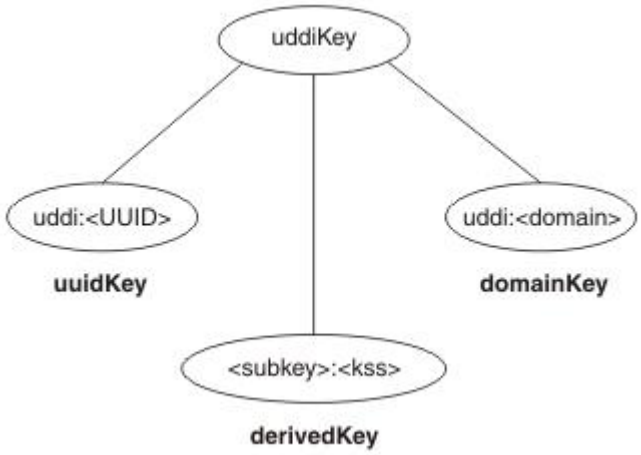
Entity keys are identifiers that are used to address entities in a UDDI registry. Each businessEntity, businessService, bindingTemplate, or tModel entity has a unique identifier that is generated or assigned when it is first published in the UDDI registry. In a particular registry, a key must be unique. For UDDI Version 1 and Version 2, the space is limited to a universal unique identifier (UUID). For UDDI Version 3, entity keys can be any URI that follows the recommended UDDI scheme.

For UDDI Version 3, depending on registry policy, not only can the UDDI registry assign keys, but also the publisher of the entity. These differences raise issues for maintaining key uniqueness and managing key space.

## UDDI Scheme

The UDDI Version 3 registry implements the recommended UDDI scheme, as detailed in Section 4.4 of the UDDI Version 3 Specification. (http://uddi.org/pubs/uddi_v3.htm). This scheme defines the format of the keys, the valid characters, and the concept of key space.

In the UDDI Version 3 registry, a key is any URI and is limited to 255 characters. The following diagram shows the different types of keys in the UDDI key scheme:



All keys are composed of a set of tokens that are separated by colons (:). The first token for all keys that follow the UDDI scheme is uddi. There are three types of keys:

- The uuidKey keys contain two tokens, the mandatory uddi and a <UUID>. These keys ensure uniqueness through the UUID algorithm.
- The domainKey keys contain two tokens, the mandatory uddi and a domain name. These keys are for creating additional mutually exclusive key spaces.
- The derivedKey keys are composite keys that are based on a subkey, which is any uddiKey, and an additional token, kss, which is a key-specific string that differentiates keys. A publisher can assign the kss token, or the kss token can be calculated algorithmically (UUID).

Another concept that is included in the UDDI key scheme is a *key generator*. A key generator represents a key space. A publisher can save entities by using keys from a certain key space only if that publisher owns the key generator that represents the key space. This feature helps to secure unique keys. The key generator is a tModel entity, with a key that is in the form <subkey>:keygenerator. By owning this tModel entity, a publisher can assign keys in the form <subkey>:<kss>. The publisher can also publish new key generator tModel entities in the form <subkey>:<kss>:keygenerator.

## Key uniqueness and registry root key space

You can configure instances of the UDDI registry as a root registry or as an affiliate registry.

Root registries define their own root key space by defining their own root key generator. This action defines the total key space that the registry manages. All keys that the registry generates are in this key space. If the policy allows, publishers can request subdivisions of this key space by publishing new key generator tModel entities in the form <rootkeygenerator>:<subdivisionIdentifier>:keygenerator. Publishers can then include publisher-supplied keys in subsequent publish requests that are in their allocated key space subdivision, <rootkeygenerator>:<subdivisionIdentifier>:<kss>.

To avoid key collisions, affiliate registries must establish their root key generator by first submitting a tModel:keygenerator request to the root registry they want to be an affiliate of, and then using this

subdivision of the key space of the root registry as their own root key generator. This process ensures that there are no collisions between keys that are generated or accepted by an affiliate registry, and other keys in the root registry key space.

To maintain key uniqueness, simple rules are applied. The registry generates new keys only in the key space that is defined by its own root key generator. The registry only accepts publisher-supplied keys that are in subdivisions of key space that the publisher owns, that is, as the result of a previous successful tModel tModel:keygenerator publish request.

### Simple example for a private root registry:

```
with a Root keygenerator:

uddi:aPrivateRegistryKeySpaceIdentifier:keygenerator

generates Entity Keys of format:

uddi:aPrivateRegistryKeySpaceIdentifier:<uuid>

depending on Policy, accepts tModel:keygenerator requests from Publishers for
'top-level' subdivisions of format:

uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:
keygenerator
```

### Publishing tModel:keygenerator requests for subdivisions of key space

Depending on policy, a publisher can submit a request for a top-level subdivision of the key space in the root registry for its own use. The policy can specify whether the registry supports publisher-supplied keys and whether the user entitlements of particular publisher allow the publisher to submit requests for key space.

As well as top-level subdivisions of the key space in the root registry, a publisher can also create additional subdivisions of key space.

The following simple example continues from the previous example and requests the subdivision `a`:

```
uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:
a:keygenerator
```

For a request for a further subdivision to be successful, the publisher that requested, and owns, the tModel entity for the subdivision above must make the request. In the previous example, this publisher is uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:keygenerator).

### Publishing with a publisher-supplied key

After a publisher successfully requests a subdivision of the key space in a root registry, that publisher must establish and maintain its own scheme to ensure that the keys that are generated for use as publisher-supplied keys in subsequent publish requests are unique in the subdivision.

Valid schemes need to generate keys that are unique derived keys in the allocated key space subdivision, for example by including a unique (incremented) numeric index.

The following simple example continues from the previous example. For a key space subdivision that results from the tModel:keygenerator request:

```
uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:
a:keygenerator

valid keys are:

uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:a:1

uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:a:2
```

## Digital signatures and the UDDI registry

In UDDI Version 3, publishers can digitally sign UDDI elements while they are publishing. The UDDI Version 3 schema supports the signing of businessEntity, businessServices, bindingTemplate, tModel, and publisherAssertion elements.

You can validate UDDI elements that are digitally signed to prove that they have not been modified or tampered with, and that their integrity is intact.

For full details about signing UDDI entities and verifying signatures, see *Appendix I: Support for XML Digital Signatures* in the UDDI Version 3.0.2. specification.

The UDDI registry does not validate signatures when signed elements are published. When the signed elements are retrieved, the retrieving client is responsible for validating the signature and providing a mechanism to ensure that the signer certificate is signed by a Certificate Authority (CA) that the client approves and trusts. If a signature is decrypted successfully by using the signer public key, it indicates that only the owner of the corresponding private key can have signed and published this element.

### Signature generation

The attributes of an element are included in the generation of an element signature. Therefore, all entity keys must be available when the signature is generated. Publishers can generate publisher-assigned keys for all the keys of an element before signing. Alternatively, if publishers publish the element without keys, the registry node generates the required entity keys and then retrieves, signs, and republishes the signed element.

### Signature validation

The signature element to validate is in the top-level element that a call to the getXXDetails method returns. The client is responsible for the validation. The client must have previously imported the X509.3 certificate of the publisher, and validated that certificate based on the CA it trusts. In this way, the client has access to the public validation key of the publisher that corresponds to the private signing key that the publisher used to sign the entity before publishing it.

You can use the UDDI Version 3 Client to construct Java API for XML-based RPC (JAX-RPC) objects and to invoke the UDDI Version 3 web service. As part of this client, you can use a helper class, com.ibm.uddi.v3.client.apilayer.xmldig.SignatureUtilities, to create and validate digital signatures on the UDDI Version 3 entities that support them. For details of application programming interfaces (APIs) in this helper class and the SignatureUtilitiesException exception, see the API information.

For UDDI, digital signatures are used to sign the data. They are not used to authenticate the SOAP message.

## UDDI Version 3 Client

You can use the UDDI Version 3 Client for Java to access the UDDI Version 3 application programming interfaces (APIs) from Java client code.

The UDDI Version 3 Client for Java is a Java API for XML-based RPC (JAX-RPC) class library that provides an API that client programs can use to interact with a Version 3 UDDI registry. This class library can be used to construct UDDI JAX-RPC objects and to invoke the UDDI Version 3 web service.

This client also contains an XML digital signature utility class called SignatureUtilities, which is provided to construct and validate digital signatures on UDDI elements.

### Multiple language encoding support

The UDDI Version 3 API supports both UTF-8 and UTF-16 encoding. Internally, UTF-16 characters are stored as UTF-8 characters. This behavior is not apparent to the user application.

### Client JAR file

WebSphere Application Server provides the class library `uddiv3client.jar`, which contains the JAX-RPC UDDI Version 3 types and UDDI WebService invocation classes. This Java archive (JAR) file is in *app_server_root*/UDDIReg/clients.

The UDDI Version 3 client provides port types that map onto the UDDI Version 3 SOAP Inquiry, Publish, Custody Transfer, and Security APIs. These APIs are protected by access control mechanisms, for example role mappings. A client program that uses the UDDI Version 3 client gets the appropriate port type for the request that is issued, for example, the UDDI_Publication_PortType for a save_business request. If the role mappings are such that the request requires a WebSphere Application Server authenticated user ID, the client program passes the user ID and password by setting the relevant properties on the JAX-RPC stub for that port.

### UDDI Version 3 Client samples

The following UDDI registry samples illustrate the use of the Version 3 Client. To access the samples, see the Samples for WebSphere Application Server and use the UDDI Registry link.

**UDDIv3ClientBindingSample.java**
An example of how to save and find binding templates.

**UDDIv3ClientBusinessSample.java**
An example of how to save and find business entities.

**UDDIv3ClientServiceSample.java**
An example of how to save and find business services.

**UDDIv3ClientSignedBusinessSample.java**
An example of how to sign and verify a business entity.

**UDDIv3ClientTModelSample.java**
An example of how to save and find TModel entities.

**UDDIv3ClientSignedTModelSample.java**
An example of how to sign and verify TModel entities.

These classes contain details on how to compile and run the samples.

## HTTP GET services for UDDI registry data structures

The UDDI registry offers an HTTP GET service for access to the XML representations of the businessEntity, businessService, bindingTemplate, and tModel UDDI data structures. The Uniform Resource Locators (URLs) at which these structures are accessible use the entity key as a URL parameter. The XML element that is returned is a businessDetail, serviceDetail, bindingDetail or tModelDetail element, according to the type of entity key that is supplied.

XML for both UDDI Version 2 and Version 3 can be retrieved, each at different URLs. The URLs to send the HTTP GET requests to are in the following formats:

**For UDDI Version 2:**
http://*server*:*port*/uddisoap/get?*entityKey_type=v2_entityKey*

**For UDDI Version 3:**
http://*server*:*port*/uddiv3soap/get?*entityKey_type=v3 entityKey*

For example, if the server is myserver.com and the port is 9080, you can access the uddi-org:types tModel entity at the following URLs:

**UDDI Version 2:**
http://myserver.com:9080/uddisoap/get?tModelKey=uuid:c1acf26d-9672-4404-9d70-39b756e62ab4

**UDDI Version 3:**
http://myserver.com:9080/uddiv3soap/get?tModelKey=uddi:uddi.org:categorization:types

A number of UDDI node property and policy settings relate to the HTTP GET services:

- Version 3 HTTP GET for UDDI entities
  - Node supports HTTP GET
  - URL prefix for Version 3 GET servlet
  - Node generates discovery URLs
- Version 2 HTTP GET for discovery URLs
  - Prefix for generated discovery URLs
  - Node generates discovery URLs

## UDDI registry SOAP service end points

UDDI Version 3 supports multiple versions of SOAP API services. Depending on the security settings for WebSphere Application Server and the user data constraint transport guarantee settings for the UDDI SOAP service, UDDI Version 3 supports different end points for different services.

The following list of default context root and Uniform Resource Locator (URL) values apply when WebSphere Application Server security is enabled and you and do not change the default supplied security settings. If you do not use the default security settings, the context root and URL values might differ.

In the following URLs, the variables have the following values:

- *host_name* is the name of the machine that is running the relevant profile.
- *http_port* is the internal HTTP port for the profile, for example 9080.
- *ssl_port* is the internal secure sockets layer (SSL) port for the profile, for example 9443.
- Version 1 and Version 2 SOAP API services

  **Inquiry service**
  Default (soap.war) context-root='/uddisoap' and url-pattern = 'inquiryAPI' or 'inquiryapi'.

  Default URL: http://*host_name*:*http_port*/uddisoap/inquiryapi

  **Publish service**
  Default (soap.war) context-root='/uddisoap' and url-pattern = 'publishAPI' or 'publishapi'.

  Default URL: https://*host_name*:*ssl_port*/uddisoap/publishapi or http://*host_name*:*http_port*/uddisoap/publishapi
- Version 3 SOAP API services

  **Inquiry service**
  Default (soap.war) context-root='/uddiv3soap' and url-pattern = '/services/UDDI_Inquiry_Port'

  Default URL: http://*host_name*:*http_port*/uddiv3soap/services/UDDI_Inquiry_Port

  **Publish service**
  Default (soap.war) context-root='/uddiv3soap' and url-pattern = '/services/UDDI_Publish_Port'

  Default URL: https://*host_name*:*ssl_port*/uddiv3soap/services/UDDI_Publish_Port or http://*host_name*:*http_port*/uddiv3soap/services/UDDI_Publish_Port

  **Custody transfer service**
  Default (soap.war) context-root='/uddiv3soap' and url-pattern = '/services/UDDI_Custody_Port'

Default URL: https://hostname:9443/uddiv3soap/services/UDDI_Custody_Port or
http://hostname:9080/uddiv3soap/services/UDDI_Custody_Port

**Security service**

Default (soap.war) context-root='/uddiv3soap' and url-pattern = '/services/UDDI_Security_Port'

Default URL: https://*host_name*:*ssl_port*/uddiv3soap/services/UDDI_Security_Port or
http://*host_name*:*http_port*/uddiv3soap/services/UDDI_Security_Port

An endpoint is available for using HTTP GET to return XML representations of UDDI entities. See the information about HTTP GET services for UDDI registry data structures.

If you configure the UDDI registry to use WebSphere Application Server security, and you do not change the default data confidentiality settings for the UDDI SOAP service, services with default end point URLs with HTTPS and a SSL port require that their data is transported confidentially. Requests that do not use HTTPS are rejected.

If you configure the UDDI registry to use WebSphere Application Server security and you change the data confidentiality setting for the UDDI SOAP service to NONE, or you disable WebSphere Application Server security, services with default end point URLs with HTTPS and a SSL port can also use HTTP and a HTTP port.

To understand how access to the SOAP APIs is protected, see the information about access control for UDDI registry interfaces.

## UDDI4J programming interface (Deprecated)

The UDDI4J Version 2 APIs are deprecated in this version of WebSphere Application Server. The UDDI Version 3 Client for Java is the preferred API for accessing UDDI through Java code.

WebSphere Application Server provides UDDI4J classes in the com.ibm.uddi.jar file. This file contains classes that support Version 1 and Version 2 of the UDDI specification, providing compatability with earlier versions of WebSphere Application Server. The UDDI4J classes in this file are deprecated.

The UDDI4J methods map onto the UDDI Version 1 and Version 2 SOAP Inquiry and Publish APIs. These APIs are protected by access control mechanisms, for example role mappings. If the role mappings for these APIs are such that requests to these interfaces require a WebSphere Application Server authenticated user ID, a client program that uses UDDI4J must pass the user name and password, by setting the system properties http.basicAuthUserName and http.basicAuthPassword. A UDDI4J client program can also specify details for a proxy server, including a user name and password, by using the following system properties:

- http.proxyHost
- http.proxyPort
- http.proxyUserName
- http.proxyPassword

## Using the UDDI EJB Interface (Deprecated)

Use the Enterprise JavaBeans (EJB) application programming interface (API) of the UDDI registry component to publish, find, and delete UDDI entries. However, the UDDI EJB interface is deprecated and supports UDDI version 2 API requests only.

### Before you begin

Both WebSphere Application Server and the UDDI registry must be installed, and must both be running. You cannot use the EJB client from a machine that does not have WebSphere Application Server installed.

## About this task

**Note:** The UDDI EJB interface is deprecated in WebSphere Application Server Version 6.0.

The client classes that are required for the EJB interface are contained in *app_server_root*/UDDIReg/clients/uddiejbclient.jar. For the Java documentation for these classes, see the information about additional APIs.

The EJB API is contained in two stateless session beans, one for the inquiry API (com.ibm.uddi.ejb.InquiryBean) and one for the publish API (com.ibm.uddi.ejb.PublishBean), whose public methods form an EJB interface for the UDDI registry. All the public methods on the InquiryBean class correspond to UDDI Version 2 inquiry API functions, and all the public methods on the PublishBean class correspond to UDDI Version 2 publish API functions. Not all UDDI Version 2 API functions are implemented, for example get_authToken, discard_authToken, and get_businessDetailExt.

In each interface, there are groups of overloaded methods that correspond to the operations in the UDDI 2.0 specification. There is a separate method for each major variation in function. For example, the single UDDI operation find_business is represented by ten variations of findBusiness methods, with different variations to find by arguments such as name or categoryBag.

The arguments for the EJB interface methods are Java objects in the com.ibm.uddi.datatypes package. Generally, there is a one-to-one correspondence between classes in this package and elements of the UDDI Version 2 XML schema. There are exceptions to this correspondence, for example, where UDDI XML elements can be represented by a single string. For more information, see the Java documentation for the package com.ibm.uddi.datatypes in the information about additional APIs.

The methods on the EJB InquiryBean class map to the EJB inquiry role, and those of the EJB PublishBean class map to the EJB publish role. The EJB inquiry and publish roles protect the EJB interface, as described in information about access control for UDDI registry interfaces. If the role mapping is such that a method requires a WebSphere Application Server authenticated user ID, a client program can supply the user ID and password, either when prompted by WebSphere Application Server, or by providing application code that logs in to the default realm using the user ID and password. Use the `sas.client.props` configuration file to determine how to specify the user ID and password when you configure security.

To use the EJB client, use the following steps.

## Procedure

1. Set up your environment to communicate with WebSphere Application Server: AIX HP-UX Linux Solaris

```
. app_server_root/bin/setupCmdLine.sh
```

   Windows

```
app_server_root/bin/setupCmdLine.bat
```

   AIX HP-UX Linux Solaris Notice that a single space character follows the period (.)
2. Ensure that your CLASSPATH includes the uddiejbclient.jar file (from the *app_server_root*/UDDIReg/clients directory), and the code for your client.
3. Compile your EJB client programs: AIX HP-UX Linux Solaris

```
$JAVA_HOME/bin/javac -extdirs $WAS_EXT_DIRS:$JAVA_HOME/jre/lib/ext
-classpath $WAS_CLASSPATH:$CLASSPATH yourcode.java
```

   Windows

```
%JAVA_HOME%/bin/javac -extdirs $WAS_EXT_DIRS:%JAVA_HOME%/jre/lib/ext
-classpath %WAS_CLASSPATH%:%CLASSPATH% yourcode.java
```

4. Run the compiled programs: AIX HP-UX Linux Solaris

```
$JAVA_HOME/bin/java -Djava.ext.dirs=$WAS_EXT_DIRS:$JAVA_HOME/jre/lib/ext
-Dwas.install.root=$WAS_HOME -Dserver.root=$WAS_HOME $CLIENTSAS $CLIENTSOAP
-cp $WAS_CLASSPATH:$WAS_HOME/UDDIReg/clients/uddiejbclient.jar:$CLASSPATH
<class name> <args>
```

Windows

```
%JAVA_HOME%\bin\java -Djava.ext.dirs=%WAS_EXT_DIRS%;%JAVA_HOME%\jre\lib\ext
-Dwas.install.root=%WAS_HOME% -Dserver.root=%WAS_HOME% %CLIENTSAS% %CLIENTSOAP%
-cp %WAS_CLASSPATH%;%WAS_HOME%\UDDIReg\clients\uddiejbclient.jar:%CLASSPATH%
<class name> <args>
```

Ensure that your PATH statement starts with *app_server_root*/java/bin.

# Using the UDDI registry user interface

The UDDI registry user interface (also referred to as the UDDI registry user console) is a graphical interface that you can use to issue inquiry requests and explore the UDDI registry.

## Before you begin

If you require multiple language encoding, the UDDI user console supports only Universal Transformation Format (UTF)-8 encoding. For UTF-8 encoding support, configure the application server that hosts the UDDI registry for UCS transformation format. The UDDI user console does not support UTF-16 encoding.

## About this task

The UDDI user console provides a graphical user interface to most of the UDDI Version 3 API. The user console does not support the full API set, but provides a way to issue inquiry requests and to familiarize yourself with general UDDI concepts. Explanatory text on the screens provides help. The following list describes areas that are not supported through the user console, and other known restrictions in the user console.

- You cannot specify maximum rows on find queries. You can set the “Single maximum rows” value for the registry by using the “Maximum inquiry result set size” general property on the administrative console.
- The identifier feature is not supported in the find business area or the find technical model (tModel) area.
- In the add business area, adding discovery URLs, identifiers or digital signatures is not supported.
- In the add technical model (tModel) area, adding identifiers or digital signatures is not supported.

The exact behavior of the user console depends on the following configurable factors:

- Whether WebSphere Application Server security is enabled.
- How the UDDI registry GUI role mappings are set. The UDDI registry supports two security roles for the user console:
  - GUI_Publish_User
  - GUI_Inquiry_User.
- How the UDDI registry GUI secure sockets layer (SSL) transport guarantee constraints are set. The UDDI registry supports the configuration of SSL settings, including two settings for the user console.

The following table summarizes the behavior of the UDDI registry user console.

*Table 342. Behavior of the UDDI user console. The table lists the URLs used for the different UDDI registry settings, along with a description of the behavior associated with each setting.*

| WebSphere Application Server security status | URL used to access the UDDI user console | Behavior of the UDDI user console |
|---|---|---|
| Enabled | http://*host_name*:*http_port*/uddigui | Inquiry requests do not require authentication; they use the HTTP URL and are not secure. Publish requests require WebSphere Application Server authentication. When you access the publish pane, you are dynamically redirected to use HTTPS, and are prompted for a user ID and password. For a successful request, the authenticated user must be registered as a UDDI publisher.<br><br>If the GUI_Inquiry_User role is mapped to all authenticated users, and the transport guarantee in the user data constraint section for that role is set to CONFIDENTIAL, all requests, including inquiry, require authentication and use of HTTPS. |
| | https://*host_name*:*ssl_port*/uddigui | Requests are secure; you are prompted to authenticate with a user ID and password. For a successful request, the authenticated user must be registered as a UDDI publisher. |
| Disabled | http://*host_name*:*http_port*/uddigui | No requests, either publish or inquire, are authenticated and the data flow is not secure (non- SSL). Even though SSL transport-guarantee settings are defined, they are not enforced if security is disabled. All publish operations are performed using a user ID of UNAUTHENTICATED, or a value that can be configured by using the administrative console or the Java Management Extensions (JMX) management interface (this applies to new requests only). |
| | https://*host_name*:*ssl_port*/uddigui | No requests, either publish or inquire, are authenticated, but the data flow is secure because the SSL URL and port are used explicitly. All publish operations are performed using a user ID of UNAUTHENTICATED, or a value that can be configured by using the administrative console or the JMX management interface (this applies to new requests only). |

The variables in the table have the following values:

- *host_name* is the name of the machine that is running the relevant profile.
- *http_port* is the internal HTTP port for the profile, for example 9080.
- *ssl_port* is the internal SSL port for the profile, for example 9443.

To display the UDDI registry user console, use the following procedure.

## Procedure

1. Start the UDDI application, if it is not already running.
2. Open a browser window and ensure that cookies are enabled.
3. Access the UDDI registry user console through one of the following default URLs.
   - http://*host_name*:*http_port*/uddigui
   - https://*host_name*:*ssl_port*/uddigui
4. Optional: To change the appearance and operation of the UDDI registry user console, modify the appropriate `.css` stylesheet files. You can edit style class definitions in the stylesheet files, including font attributes, layout, and colors. The stylesheet files are in the following directory:

```
profile_root/installedApps/cell_name/
UDDIRegistry.node_name.server_name.ear/v3gui.war/theme
```

   After you change a stylesheet file, refresh the browser window for the changes to take effect.

## Results

The user console displays the default frameset, which contains the following items:

- The header frame.
- The navigation frame, which shows find options.
- The details frame.

## What to do next

You can now use the UDDI user console to find, edit, or publish UDDI information.

## Finding an entity by using the UDDI registry user interface

You can use the UDDI registry user interface to find services, businesses, and technical models.

### Before you begin

Ensure that the UDDI registry application is started and the UDDI registry user console is displayed.

### About this task

To use the UDDI registry user interface (also referred to as the UDDI registry user console) to find services, businesses, and technical models, use the following procedure.

### Procedure

1. In the UDDI registry console, activate the Find pane. Either click the **Find** tab, or click the **Find** link at the top of the page or on the Welcome page.
2. For a simple search without any find qualifiers, use the following steps:
   a. In the **Quick Find** section of the **Find** tab, select the kind of entity that you want to find; service, business, or technical model.
   b. In the **Starting with** field, enter the name of the entity. Use the percent (%) wildcard character to search for a partial name.
   c. Click **Find**.

   The results are displayed.
3. For advanced search, use the following steps:
   a. In the **Advanced Find** section of the **Find** tab, click the appropriate link for the kind of entity that you want to find; service, business, or technical model. The advanced search form is displayed in the frame.
   b. Enter your search criteria in the advanced search form, and select any find qualifiers that you require.

      You must enter at least one name to search for, by using the **Add Name** link. You can use this link to enter multiple names.

      You can also add multiple categorizations. To add a categorization, use the **Show category tree** link in the **Categorizations** section to display, a tree of categories (or taxonomies) that define the types of item to find according to various classification systems. Expand the tree to find the category that you want, click the category to add the information to the advanced search form, then use the **Add Categorization** link to include the category in the search.
   c. Click **Find *entities***.

   The results are displayed in the detail frame.

## Publishing an entity by using the UDDI registry user interface

You can use the UDDI registry user interface to publish businesses and technical models.

### Before you begin

Ensure that the UDDI registry application is started and the UDDI registry user console is displayed.

### About this task

You can use the UDDI registry user interface (also referred to as the UDDI registry user console) to publish businesses and technical models.

To publish a service, publish a business, and then edit the entity to add a service to that business.

### Procedure

1. In the UDDI registry console, activate the Publish pane. Either click the **Publish** tab, or click the **Publish** link at the top of the page or on the Welcome page.
2. To publish an entity by name only, use the Quick publish section and the following steps:
   a. In the **Quick Publish** section of the **Publish** tab, select the kind of entity that you want to publish; business or technical model.
   b. In the **Name** field, enter the name of the entity.
   c. Click **Publish**.

   The details of the published entity are displayed.
3. To publish an entity with more information, use the following steps:
   a. In the **Advanced Publish** section of the **Publish** tab, click the appropriate link for the kind of entity you want to publish; business or technical model. The advanced publish form is displayed.
   a. Enter the details for the entity in the advanced publish form. You can enter multiple names, descriptions, contacts, or categorizations by using the relevant **Add** link.

      To add a categorization, use the **Show category tree** link in the **Categorizations** section to display a tree of categories (or taxonomies) that define the types of item to publish according to various classification systems. Expand the tree to find the category that you want, click the category to add the information to the advanced publish form, then click the **Add Categorization** link.
   b. Click **Publish *entity*** to publish the business or technical model to the UDDI registry.

## Editing or deleting an entity by using the UDDI registry user interface

You can use the UDDI registry user interface to edit or delete the businesses and technical models that you own, for example, to add services to businesses.

### Before you begin

Ensure that the UDDI registry application is started and the UDDI registry user console is displayed.

### About this task

To use the UDDI registry user interface (also referred to as the UDDI registry user console) to edit or delete the businesses and technical models that you own, or add services to businesses, use the following steps.

### Procedure

1. In the UDDI registry console, activate the Publish pane. Either click the **Publish** tab, or click the **Publish** link at the top of the page or on the Welcome page.
2. In the Registered Information section on the **Publish** tab, click **Show owned entities** to show the businesses and technical models that you registered in the UDDI registry.
3. Optional: To delete a business or a technical model, click **Delete** in the **Actions** column for that entity. When you delete a technical model, it is hidden, rather than physically deleted, as specified by the UDDI Version 3.0 specification. If you click **Shown owned entities**, the technical model is still displayed, but if you use the Find function, the technical model is not displayed. All other entities are deleted from the UDDI registry in the usual way.

4. Optional: To edit a business or technical model, click **Edit** in the **Actions** column for that entity, enter the required details, then click **Update *entity*** to save the changes in the UDDI registry.
5. Optional: To add a service to a business, click **Add service** in the **Actions** column for that business. Enter the details, then click **Add Service** to publish the service to the UDDI registry. The service details are displayed.

## Creating business relationships by using the UDDI registry user interface

If your business has an association with another business in the UDDI registry, for example a preferred supplier, you can describe this association in the UDDI registry by creating a *business relationship*.

### Before you begin

- The UDDI registry contains the following default relationship types:

  **Parent-child**
  A hierarchical relationship exists between the two business entities, which might represent, for example, a large organization and a subsidiary.

  **Peer-peer**
  The two business entities represent peer organizations, for example a company and its supplier.

  **Identity**
  The two business entities represent the same organization.

  If you require a different relationship type, create a user-defined value set to represent the relationship type that you require, as described in the topic about user-defined value set support in the UDDI registry.
- Each business that is involved in the relationship must already exist in the UDDI registry.
- Ensure that the UDDI registry application is started and the UDDI registry user console is displayed.

### About this task

Complete this task when you want to publicize an association between two businesses in the UDDI registry. For example, your organization, represented by a business entity in the UDDI registry, might have several departments, each one represented by a different business entity in the UDDI registry. You might want to declare these departments as being linked to the parent organization, by creating parent-child relationships between the appropriate business entities.

### Procedure

1. Activate the **Publish** tab by clicking it, or by clicking the **Publish** link at the top of the page or on the Welcome page.
2. Under **Registered Information**, click **Show owned entities**. The entities that you own are displayed in the detail frame on the right.
3. In the section for the businesses that you own, find the business that you want to link from, and click the **Add relationship** link for that business. The Add Business Relationship pane is displayed. The business key for the business that you selected is already listed in the From section.
4. Click **Add** to add the second business, the business that you want to link to. The advanced find pane is displayed.
5. Find the second business, as described in the advanced find step of “Finding an entity by using the UDDI registry user interface” on page 2136.
6. Click **Select** to add the second business to the relationship. If you want to change the positions of the businesses, click **Swap**.
7. Select the type of relationship from the **Type** list.
8. If required, type a description in the **Usage** field.

9. Click **Add relationship** to create the relationship. If you own both businesses, no further action is required. The relationship is displayed as a *publisher assertion* in the list of entities that you own. The status of the assertion is complete.
10. If you do not own the second business, the status of the assertion is pending. The owner of the second business must create a relationship from their business to yours, for the relationship to be complete and visible to other parties. The relationship type must match the type that you chose earlier.

### Results

The business relationship is published to the UDDI registry. The UDDI user interface only shows publisher assertions for entities that you own. To view other relationships, use the UDDI inquiry API provided.

### What to do next

For more information about publisher assertions, refer to the UDDI specification.

To remove an assertion that you own, display your owned entities and click the **Delete** link for the relevant publisher assertion. If the business in the To field is owned by someone else, the status of the assertion becomes pending, and the relationship is no longer visible to other parties.

## Example: Publishing a business, service, and technical model using the UDDI registry user interface

This example describes how to use the UDDI registry user interface to publish a used car business called Modern Cars to the UDDI registry, and how to publish a service and technical model for the business.

Before you begin, ensure that the UDDI registry application is started and the UDDI registry user console is displayed.

### Adding the business

1. Click the **Publish** tab to activate the Publish pane.
2. Under **Advanced Publish**, click **Add a business**. The advanced publish form is displayed.
3. Type `Modern Cars` in the **Name** field for the business. Select the language of the business name from the list, then click **Add Name** to add the name to the business.
4. Type a description for the business, for example `Used cars for sale` in the **Description** field. Select the language of the description from the list, then click **Add Description** to add the description to the business. You can add multiple descriptions in a variety of languages as required.
5. In the **Contact** section, type your name as a contact for customers of the business. Select the language as before, and click **Add Contact**. The business contact form is displayed. Enter the details, using the **Add *entity*** links to add the information as you reach the end of each subsection. All the text fields in the form are cleared when you click an **Add *entity*** link. Click **Add Contact** to save the contact information into the Modern Cars business.
6. Use the **Categorizations** section to describe the Modern Cars business according to the NAICS 2002 categorization system:
   a. Click **Show category tree** to display the various categorization systems.
   b. Expand the **NAICS 2002** tree, then expand **Retail Trade [44]** > **Motor Vehicle and Parts Dealers [441]** > **Automobile Dealers [4411]** > **Used Car Dealers [44112]**. Click the **Used Car Dealers [441120]** category to add the category type, key name, and key value to the advanced publish form.
   c. Click **Add Categorization** to add the information to the business.
   d. Close the category tree by clicking **Close** .
7. Click **Publish Business** to publish the Modern Cars business to the UDDI registry. The details of the business are displayed.

### Adding a service to the business

1. Click the **Publish** tab to activate the Publish pane.
2. Under **Registered Information**, click **Show owned entities** to display the Modern Cars business and any other entities that you own.
3. Click **Add service** in the **Actions** column of the Modern Cars business. The publish service page is displayed.
4. Add a name and description for the service, in the same way as for the business itself.
5. Click **Add a Service Binding** to display the service binding form.
   a. Enter an access point (the URL for the service on the network) and a description for the service binding.
   b. Click **Add Technical Model Instance Information** to display a page where you can describe and publish a technical model instance for the service binding.
   c. In the technical model information page, click **Add Technical Model**.
   d. Search for the technical model that the instance uses, select the technical model from the results, then click **Add**.
   e. Complete the other fields on the form and click **Add Technical Model Instance**.
   f. Click **Add Binding** to save the information into the service.

   Enter an access point (the URL for the service on the network) and a description for the service binding.
6. Add a categorization in the same way as for the business.
7. Click **Add Service** to publish the service to the UDDI registry.

### Adding a technical model

1. In the **Advanced Publish** section, click **Add a technical model** to display the publish technical model form.
2. Add a name and description for the technical model, in the same way as for the business and the service.
3. Click **Add an Overview Document** to display the overview document form. The overview document describes the technical model.
   a. Type the location of the overview document in the **Overview URL** field.
   b. Click **Add Overview Document URL**.
   c. Add a description and click **Add Overview Document** to save the information in the technical model.
4. Add a categorization in the same way as for the business.
5. Click **Publish Technical Model** to publish the technical model to the UDDI registry.

## Using the JAXR provider for UDDI

To get started with the Java API for XML Registries (JAXR) provider, you can use a sample program. You also need to consider class libraries, authentication and security, internal taxonomies, and logging and messages.

### About this task

**Note:** In WebSphere Application Server Version 8.0, Java API for XML Registries (JAX-R) APIs are deprecated. The Java Platform, Enterprise Edition (Java EE) 6 platform began the deprecation process for JAX-R because it is based on Universal Description, Discovery and Integration (UDDI) 2 technology, which is no longer relevant. If your applications use JAX-R, then you might consider using UDDI 3.

## Procedure

- To obtain the ConnectionFactory instance, create a connection to the registry, and save an organization in the registry, see the following sample program.

```
import java.net.PasswordAuthentication;
import java.util.ArrayList;
import java.util.Collection;
import java.util.HashSet;
import java.util.Properties;
import java.util.Set;

import javax.xml.registry.BulkResponse;
import javax.xml.registry.BusinessLifeCycleManager;
import javax.xml.registry.Connection;
import javax.xml.registry.ConnectionFactory;
import javax.xml.registry.JAXRException;
import javax.xml.registry.RegistryService;
import javax.xml.registry.infomodel.Key;
import javax.xml.registry.infomodel.Organization;

public class JAXRSample
{
    public static void main(String[] args) throws JAXRException
    {
        //Tell the ConnectionFactory to use the JAXR provider for UDDI
        System.setProperty("javax.xml.registry.ConnectionFactoryClass",
                           "com.ibm.xml.registry.uddi.ConnectionFactoryImpl");
        ConnectionFactory connectionFactory = ConnectionFactory.newInstance();

        //Set the URLs for the UDDI inquiry and publish APIs.
        //These must be the URLs of the UDDI version 2 APIs.
        Properties props = new Properties();
        props.setProperty("javax.xml.registry.queryManagerURL",
                          "http://localhost:9080/uddisoap/inquiryapi");
        props.setProperty("javax.xml.registry.lifeCycleManagerURL",
                          "http://localhost:9080/uddisoap/publishapi");
        connectionFactory.setProperties(props);

        //Create a Connection to the UDDI registry accessible at the above URLs.
        Connection connection = connectionFactory.createConnection();

        //Set the user ID and password used to access the UDDI registry.
        PasswordAuthentication pa = new PasswordAuthentication("Publisher1",
                        new char[] { 'p', 'a', 's', 's', 'w', 'o', 'r', 'd' });
        Set credentials = new HashSet();
        credentials.add(pa);
        connection.setCredentials(credentials);

        //Get the javax.xml.registry.BusinessLifeCycleManager interface,
        //which contains methods corresponding to UDDI publish API calls.
        RegistryService registryService = connection.getRegistryService();
        BusinessLifeCycleManager lifeCycleManager =
                                   registryService.getBusinessLifeCycleManager();

        //Create an Organization (UDDI businessEntity) with name
        //"Organization 1".
        Organization org =
                          lifeCycleManager.createOrganization("Organization 1");

        //Add the Organization to a Collection, ready to be saved in the UDDI
        //registry.
        Collection orgs = new ArrayList();
        orgs.add(org);

        //Save the Organization in the UDDI registry.
        BulkResponse bulkResponse = lifeCycleManager.saveOrganizations(orgs);

        //Obtain the Organization Key (the UDDI businessEntity
        //businessKey) from the response.
        if (bulkResponse.getExceptions() == null)
        {
        //1 Organization was saved, so 1 key will be returned in the
        //response collection
            Collection responses = bulkResponse.getCollection();
            Key organizationKey = (Key)responses.iterator().next();
            System.out.println("\nOrganization Key = " +
```

```
                                        organizationKey.getId());
        }
    }
}
```

- Ensure that the class path is set.

  The class libraries of the JAXR provider for UDDI are in the com.ibm.uddi_1.0.0.jar file, in the *app_server_root*/plugins directory. When you use the JAXR API from a Java EE application running under WebSphere Application Server, all required classes are automatically on the class path. When you use the JAXR API from outside this environment, the following .jar files must be on the Java class path:

  – *app_server_root*/lib/bootstrap.jar
  – *app_server_root*/plugins/com.ibm.uddi_1.0.0.jar
  – *app_server_root*/plugins/com.ibm.ws.runtime_6.1.0

- To use the JAXR provider for UDDI, first you must specify the name of the ConnectionFactory implementation class. Set the javax.xml.registry.ConnectionFactoryClass system property to com.ibm.xml.registry.uddi.ConnectionFactoryImpl.

  If you do not set this system property, the value defaults to com.sun.xml.registry,common.ConnectionFactoryImpl, which cannot be found and causes a JAXRException exception when the ConnectionFactory.newInstance() method is called.

  The JAXR provider for UDDI does not support lookup of the ConnectionFactory using Java Naming and Directory Interface (JNDI).

- To specify connection-specific properties, set a java.util.Properties object on the JAXR ConnectionFactory before you obtain a connection.

  The full list of these properties is in the JAXR specification. The following table lists the three most important properties, and what values they take to use the JAXR provider for UDDI to access the UDDI registry.

*Table 343. Connection-specific properties required to use the JAXR provider for UDDI to access the UDDI registry. The table lists the different properties along with a description for each one.*

| Property | Description |
|---|---|
| javax.xml.registry.queryManagerURL | The URL for the Inquiry API of the UDDI registry for UDDI Version 2. Typically, this property is in the form: `http://hostname:port/uddisoap/inquiryapi`. This property is required. |
| javax.xml.registry.lifeCycleManagerURL | The URL for the Publish API of the UDDI registry for UDDI Version 2. Typically, this property is in the form: `http://hostname:port/uddisoap/publishapi`.<br><br>If you do not specify this property, it defaults to the value of the javax.xml.registry.queryManagerURL property. However, the UDDI registry typically has different URLs for the Inquiry and Publish APIs, so it is advisable to specify both properties. |
| javax.xml.registry.authenticationMethod | The method of authentication to use when authenticating with the registry. This can take one of two values, UDDI_GET_AUTHTOKEN and HTTP_BASIC. If you do not specify a value, the default value is UDDI_GET_AUTHTOKEN. See the following step for more information. |

  The only required connection property is javax.xml.registry.queryManagerURL. However, it is advisable to set javax.xml.registry.lifeCycleManagerURL and understand the default value of javax.xml.registry.security.authenticationMethod. The other connection properties that are defined in the JAXR specification are optional, and their values are not specific to the UDDI registry. The JAXR provider for UDDI does not define any additional provider-specific properties.

- To determine which method the JAXR provider uses to authenticate with the UDDI registry, set the javax.xml.registry.authenticationMethod connection property.

  The javax.xml.registry.authenticationMethod connection property determines which method the JAXR provider uses to authenticate with the UDDI registry. Two values of this property are supported:

  – UDDI_GET_AUTHTOKEN

The JAXR provider uses the UDDI V2 get_authToken API to authenticate with the registry. The JAXR provider makes the get_authToken call automatically when the connection credentials are set. The JAXR provider saves the UDDI V2 authToken that the call returns to use on subsequent UDDI publish API calls.

– HTTP_BASIC

The JAXR provider uses HTTP basic authentication to authenticate with the registry. WebSphere Application Server supports HTTP basic authentication when security is enabled. The JAXR provider does not make a get_authToken call. Instead, whenever there is a UDDI API call (both Inquiry and Publish), the user name and password are sent in the HTTP headers, using HTTP basic authentication. If the UDDI registry does not require HTTP basic authentication, the credentials are ignored.

The JAXR provider for UDDI does not support the CLIENT_CERTIFICATE or MS_PASSPORT methods of authentication.

If you do not set this property, the default authentication method is UDDI_GET_AUTHTOKEN.

- To use Secure Sockets Layer (SSL) to encrypt HTTP traffic between the JAXR provider for UDDI and the UDDI registry, see “Using SSL with the UDDI JAXR provider” on page 2144.
- To supply a custom internal taxonomy, see “Creating a custom internal taxonomy for the JAXR provider” on page 2145.
- To switch on UDDI4J logging, set the org.uddi4j.logEnabled system property to `true`. The JAXR provider for UDDI uses UDDI4J Version 2 to communicate with the UDDI registry, and UDDI4J has its own logging.

## Java API for XML Registries (JAXR) provider for UDDI

The Java API for XML Registries (JAXR) is a Java client API for accessing both UDDI (Version 2 only) and ebXML registries. It is part of the Java Platform, Enterprise Edition (Java EE) specification.

**Note:** In WebSphere Application Server Version 8.0, Java API for XML Registries (JAX-R) APIs are deprecated. The Java Platform, Enterprise Edition (Java EE) 6 platform began the deprecation process for JAX-R because it is based on Universal Description, Discovery and Integration (UDDI) 2 technology, which is no longer relevant. If your applications use JAX-R, then you might consider using UDDI 3.

The JAXR API comprises the Java EE packages javax.xml.registry and javax.xml.registry.infomodel. Java EE API documentation is at Web Services Reference.

The preferred UDDI Java client APIs are:

- UDDI4J Version 2, for UDDI Version 2
- UDDI Version 3 Client for Java, for UDDI Version 3

### JAXR provider

The current JAXR specification (Version 1.0) defines a JAXR provider as an implementation of the JAXR API. Generally, a JAXR provider can be a JAXR provider for UDDI, a JAXR provider for ebXML, or a pluggable provider that supports both UDDI and ebXML. The JAXR provider for UDDI is a provider for UDDI only.

### UDDI versions

A JAXR provider for UDDI accesses a UDDI registry that uses the UDDI Version 2 SOAP APIs only. The UDDI registry for UDDI Version 3 in this version of WebSphere Application Server supports the UDDI Version 1, 2 and 3 SOAP APIs. Therefore you can use the JAXR provider for UDDI to access this registry. You can also use the JAXR provider to access the UDDI registry for UDDI Version 2 in WebSphere Application Server Version 5.x.

To work with the UDDI Version 3 SOAP APIs, use the UDDI Version 3 Client for Java; you cannot use JAXR.

### Capability level

The JAXR specification defines two capability profiles, capability level 0 and capability level 1. The JAXR API documentation categorizes each JAXR method as either level 0 or level 1. Generally, a JAXR provider for UDDI has capability level 0 and supports all level 0 methods, whereas a JAXR provider for ebXML has capability level 1 and supports all level 0 and level 1 methods. The JAXR provider for UDDI is a capability level 0 provider, and supports only level 0 methods.

### Authentication and security

The javax.xml.registry.authenticationMethod connection property determines which method the JAXR provider uses to authenticate with the UDDI registry.

The JAXR provider uses UDDI Version 2 SOAP Inquiry and Publish APIs. These APIs are protected, as described in the topic about access control for UDDI registry interfaces.

You can use Secure Sockets Layer (SSL) to encrypt HTTP traffic between the JAXR provider for UDDI and the UDDI registry.

## Using SSL with the UDDI JAXR provider

You can use Secure Sockets Layer (SSL) to encrypt HTTP traffic between the Java API for XML Registries (JAXR) provider for UDDI and the UDDI registry.

### About this task

**Note:** In WebSphere Application Server Version 8.0, Java API for XML Registries (JAX-R) APIs are deprecated. The Java Platform, Enterprise Edition (Java EE) 6 platform began the deprecation process for JAX-R because it is based on Universal Description, Discovery and Integration (UDDI) 2 technology, which is no longer relevant. If your applications use JAX-R, then you might consider using UDDI 3.

To use SSL, set the JAXR client program as follows.

### Procedure

1. For the javax.xml.registry.queryManagerURL and javax.xml.registry.lifeCycleManagerURL connection properties, specify a URL with the protocol https and the appropriate port to use SSL to access the UDDI registry. The default port of the UDDI registry for HTTPS is 9443. Often, only the lifeCycleManager URL, that is, the UDDI Publish API URL, requires SSL.
2. Add a new security provider to the java.security.Security object, according to the Java Secure Sockets Extension (JSSE) implementation that is used. If running under the JVM provided in WebSphere Application Server, the JSSE that is provided by IBM is on the classpath automatically. Use the following code to add the IBM security provider:

```
java.security.Security.addProvider(new com.ibm.jsse.JSSEProvider());
```

3. Set the javax.net.ssl.trustStore system property to the file name of the client trust store file. The client trust store file is a Java key store (.jks) file and must contain the server certificate of the UDDI registry. To manage key store files, you can use the iKeyman tool.
4. Set the javax.net.ssl.trustStorePassword system property. This property is the password used to open the client trust store file.
5. Optional: If you use a JVM version that is earlier than the version that is provided with WebSphere Application Server, you might need to set the java.protocol.handler.pkgs system property to com.ibm.net.ssl.internal.www.protocol.

### What to do next

For more information about SSL and the iKeyman tool, see the topic about secure communications using SSL.

## Creating a custom internal taxonomy for the JAXR provider

You can create a custom internal taxonomy and make it available to the Java API for XML Registries (JAXR) provider.

### About this task

**Note:** In WebSphere Application Server Version 8.0, Java API for XML Registries (JAX-R) APIs are deprecated. The Java Platform, Enterprise Edition (Java EE) 6 platform began the deprecation process for JAX-R because it is based on Universal Description, Discovery and Integration (UDDI) 2 technology, which is no longer relevant. If your applications use JAX-R, then you might consider using UDDI 3.

The JAXR provider for UDDI supplies a number of internal taxonomies. You can also supply a custom internal taxonomy. To create a new custom internal taxonomy and make it available to the JAXR provider, use the following procedure.

### Procedure

1. Create a text file that contains the taxonomy element data. You can use the `iso3166-2003-data.txt` file in `plugins/com.ibm.uddi_1.0.0` as an example. This file is the taxonomy data file for the supplied ISO 3166 taxonomy. The first few lines are:

```
iso3166#--#World#--
iso3166#AD#Andorra#--
iso3166#AE#United Arab Emirates#--
iso3166#AE-AJ#'Ajm?n#AE
iso3166#AE-AZ#Ab? Z?aby[Abu Dhabi]#AE
iso3166#AE-DU#Dubayy [Dubai]#AE
iso3166#AE-FU#Al Fujayrah#AE
iso3166#AE-RK#Ra's al Khaymah#AE
iso3166#AE-SH#Ash Sh?riqah [Sharjah]#AE
iso3166#AE-UQ#Umm al Qaywayn#AE
iso3166#AF#Afghanistan#--
iso3166#AF-BAL#Balkh#AF
iso3166#AF-BAM#B?m??n#AF
```

   Each line represents one element of the taxonomy, or one concept in the taxonomy concept tree. Each line has the following format:

```
<taxonomy ID>#<element value>#<element name>#<parent element value>
```

   The following table describes the tokens in the format.

*Table 344. Tokens in the format of the taxonomy element data file. The table lists the different tokens along with a description for each one.*

| Token | Description |
|---|---|
| <taxonomy ID> | The taxonomy ID is the same for every element of a taxonomy. |
| <element value> | The concept value (UDDI keyValue). |
| <element name> | The concept name (UDDI keyName). |
| <parent element value> | The value of the parent element of the current element in the taxonomy tree. Except for the root element, for every element in the data file, there must be another line that defines a parent element. The root element is denoted by defining itself as its own parent. There must be only one root element, and no elements without parents. |
| # | The delimiter character. You can define this character for each taxonomy in the `taxonomyConfig.properties` file; the delimiter does not have to be the number sign (#). |

2. Save a ClassificationScheme (UDDI tModel entity) in the UDDI registry to represent the new internal taxonomy. To do this, use the javax.xml.registry.BusinessLifeCycleManager.saveClassificationSchemes() method.

3. Add the new taxonomy to the taxonomyConfig.properties file
   a. Copy the supplied taxonomyConfig.properties file from the root of the com.ibm.uddi_1.0.0.jar file. The content of the supplied taxonomyConfig.properties file is:

```
naics-1997 = UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2, naics-1997-data.txt, #
naics-2002 = UUID:1FF729F2-1948-46CF-B660-31EC107F1663, naics-2002-data.txt, #
unspsc  = UUID:DB77450D-9FA8-45D4-A7BC-04411D14E384, unspsc-data.txt,     #
unspsc7_data = UUID:CD153257-086A-4237-B336-6BDCBDCC6634, unspsc7-data.txt,   #
iso3166-2003 = UUID:4E49A8D6-D5A2-4FC2-93A0-0411D8D19E88, iso3166-2003-data.txt,#
```

   This file has one line for each internal taxonomy that is supplied. Each line has the following format:

```
<taxonomy ID> = <tModelKey>,<data filename>,<data file delimiter>
```

   The following table describes the tokens in the format.

*Table 345. Tokens in the format of the taxonomyConfig.properties file. The table lists the different tokens along with a description for each one.*

| Token | Description |
|---|---|
| <taxonomy ID> | The JAXR provider uses this value internally to identify each taxonomy. This value does not have to be the same as the taxonomy ID in the corresponding taxonomy data file. |
| <tModelKey> | The tModelKey element of the corresponding UDDI tModel entity, which is the id of the corresponding JAXR ClassificationScheme. |
| <data filename> | The name of the corresponding taxonomy data file. |
| <data file delimiter> | The delimiter character used in the taxonomy data file. All internal taxonomies that are supplied use the number sign (#), but user-supplied internal taxonomies might use different delimiter characters. |

   b. Add a new line for the new taxonomy to the copy of the taxonomyConfig.properties file. Do not remove any existing taxonomies from the file, because this makes them unavailable to the JAXR provider.
4. Add the copied taxonomyConfig.properties file to the Java class path, ahead of the jaxruddi.jar file.
5. If there are any JAXR client programs still running that were started before you added the new taxonomy to the taxonomyConfig.properties file, create a new connection to pick up the new taxonomy.

## JAXR provider for UDDI internal taxonomies

The Java API for XML Registries (JAXR) provider for UDDI supplies a number of internal taxonomies.

**Note:** In WebSphere Application Server Version 8.0, Java API for XML Registries (JAX-R) APIs are deprecated. The Java Platform, Enterprise Edition (Java EE) 6 platform began the deprecation process for JAX-R because it is based on Universal Description, Discovery and Integration (UDDI) 2 technology, which is no longer relevant. If your applications use JAX-R, then you might consider using UDDI 3.

The following table shows the internal taxonomies that the JAXR provider for UDDI supplies.

*Table 346. JAXR provider for UDDI internal taxonomies. The table lists the different internal taxonomies as well as their ClassificationScheme name and ClassificationScheme identification numbers.*

| Taxonomy | ClassificationScheme name (UDDI tModel name) | ClassificationScheme id (UDDI Version 2 tModelKey) |
|---|---|---|
| NAICS 1997 | ntis-gov:naics:1997 | UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2 |
| NAICS 2002 | ntis-gov:naics:2002 | UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2 |
| UNSPSC 3.1 | unspsc-org:unspsc:3-1 | UUID:DB77450D-9FA8-45D4-A7BC-04411D14E384 |
| UNSPSC 7 | unspsc-org:unspsc | UUID:CD153257-086A-4237-B336-6BDCBDCC6634 |
| ISO3166 2003 | ubr-uddi-org:iso-ch:3166-2003 | UUID:4E49A8D6-D5A2-4FC2-93A0-0411D8D19E88 |

The tModel entities that correspond to all these taxonomies are available in the UDDI Version 3 registry. If you use the JAXR provider to access a UDDI Version 2 registry, only the tModel entities that correspond to the NAICS 1997, UNSPSC 3.1, and ISO3166 taxonomies are available.

Each internal taxonomy is loaded into memory once for each JAXR Connection. The classification scheme of the taxonomy is created when the connection is created. At this time, the associated UDDI tModel entity is obtained from the registry and used to populate the ClassificationScheme attributes. The concept object tree of the taxonomy is not created until the first time the user requests the ClassificationScheme object. All subsequent requests for the same internal taxonomy that use the same connection return the same object tree.

Do not modify any part of the concept object tree programmatically. There is only one classification scheme and concept object tree for each internal taxonomy for each connection, and if you modify the concept tree programmatically, all future requests for this taxonomy that use the same connection return the modified objects, which might not be valid. If you modify the concept tree programmatically, the associated taxonomy data file does not change. To change the values in a user-defined internal taxonomy, change the taxonomy data file, then create a new connection to pick up the changes in a new concept tree.

Similarly, do not modify an internal classification scheme programmatically, except to modify and then save a user-defined internal classification scheme. A new connection is not required to pick up programmatic changes.

## JAXR provider logging and messages

The Java API for XML Registries (JAXR) provider for UDDI uses UDDI4J logging, commons logging, and some standard messages.

**Note:** In WebSphere Application Server Version 8.0, Java API for XML Registries (JAX-R) APIs are deprecated. The Java Platform, Enterprise Edition (Java EE) 6 platform began the deprecation process for JAX-R because it is based on Universal Description, Discovery and Integration (UDDI) 2 technology, which is no longer relevant. If your applications use JAX-R, then you might consider using UDDI 3.

**UDDI4J Logging**

The JAXR provider for UDDI uses UDDI4J Version 2 to communicate with the UDDI registry. UDDI4J has its own logging. To switch on UDDI4J logging, set the org.uddi4j.logEnabled system property to `true`. The XML request and response bodies of every UDDI request are sent to the standard error log.

**Trace** Entry, exit, exception, warning, and debug trace is provided by Commons Logging (JCL). Trace is created only if the JAXR client configures it. Entry, exit, and debug trace uses the debug level of logging. Exception and warning trace uses the information level of logging. Additionally, information-level logging is provided before each UDDI4J request is made.

**Standard error log messages**

The InternalTaxonomyManager, EnumerationManager, and PostalSchemeManager objects send warning messages to the System.err log if there is an error condition that does not justify an exception, but does require an information message. For example, warning messages are sent if a file contains a line that is not valid, or if a tModel entity that corresponds to an internal taxonomy cannot be found in the registry.

# Chapter 43. Developing Work area

This page provides a starting point for finding information about work areas, a WebSphere extension for improving developer productivity.

Work areas provide a capability much like that of global variables. They enable efficient sharing of information across a distributed application.

For example, you might want to add profile information as each customer enters your application. By placing this information in a work area, it is available throughout your application, eliminating the need to hand-code a solution or to read and write information to a database.

## Developing applications that use work areas

## Developing applications that use work areas

Applications interact with the work area service by implementing the UserWorkArea interface. This interface defines all of the methods used to create, manipulate, and terminate work areas.

### About this task

```
package com.ibm.websphere.workarea;

public interface UserWorkArea {
   void begin(String name);
   void complete() throws NoWorkArea, NotOriginator;

   String getName();
   String[] retrieveAllKeys();
   void set(String key, java.io.Serializable value)
      throws NoWorkArea, NotOriginator, PropertyReadOnly;
   void set(String key, java.io.Serializable value, PropertyModeType mode)
      throws NoWorkArea, NotOriginator, PropertyReadOnly;
   java.io.Serializable get(String key);
   PropertyModeType getMode(String key);
   void remove(String key)
      throws NoWorkArea, NotOriginator, PropertyFixed;
}
```

**Attention:** Enterprise JavaBeans (EJB) applications can use the UserWorkArea interface only within the implementation of methods in either the remote or local interface, or both; likewise, servlets can use the interface only within the service method of the HTTPServlet class. Use of work areas within any life cycle method of a servlet or enterprise bean is considered a deviation from the work area programming model and is not supported.

The work area service defines the following exceptions for use with the UserWorkArea interface:

**NoWorkArea**
Raised when a request requires an associated work area but none is present.

**NotOriginator**
Raised when a request attempts to manipulate the contents of an imported work area.

**PropertyReadOnly**
Raised when a request attempts to modify a read-only or fixed read-only property.

**PropertyFixed**
Raised by the remove method when the designated property has one of the fixed modes.

### Procedure

1. Access a partition by either:
   - Accessing the UserWorkArea partition, to access the UserWorkArea partition.

© Copyright IBM Corp. 2011

- Accessing a user-defined work area partition, to access a user-defined work area.

The following steps use the UserWorkArea partition as an example; however, you can use a user-defined partition in the same way.

2. Begin a new work area. Use the begin method to create a new work area and associate it with the calling thread. A work area is scoped to the thread that began the work area and is not accessible by multiple threads. The begin method takes a string as an argument; the string is used to name the work area. The argument must not be null, which causes the java.lang.NullPointer exception to be raised. In the following code example, the application begins a new work area with the name SimpleSampleServlet:

```
public class SimpleSampleServlet {
...
   try {
      ...
      userWorkArea = (UserWorkArea)jndi.lookup(
         "java:comp/websphere/UserWorkArea");
   }
   ...

   userWorkArea.begin("SimpleSampleServlet");
   ...
}
```

   The begin method is also used to create nested work areas; if a work area is associated with a thread when the begin method is called, the method creates a new work area nested within the existing work area.

   The work area service makes no use of the names associated with work areas; You can name work areas in any way that you choose. Names are not required to be unique, but the usefulness of the names for debugging is enhanced if the names are distinct and meaningful within the application. Applications can use the getName method to return the name associated with a work area by the begin method.

3. Set properties in the work area. An application with a current work area can insert properties into the work area and retrieve the properties from the work area. The UserWorkArea interface provides two set methods for setting properties and a get method for retrieving properties. The two-argument set method inserts the property with the property mode of normal. The three-argument set method takes a property mode as the third argument. Both set methods take the key and the value as arguments. The key is a String; the value is an object of the type java.io.Serializable. None of the arguments can be null, which causes the java.lang.NullPointer exception to be raised. The SimpleSample application below uses objects of two classes, the SimpleSampleCompany class and the SimpleSampleProperty class, as values for properties. The SimpleSampleCompany class is used for the site identifier, and the SimpleSamplePriority class is used for the priority. These classes are shown in following code example:

```
public class SimpleSampleServlet {
   ...
   userWorkArea.begin("SimpleSampleServlet");

   try {
      // Set the site-identifier (default is Main).
      userWorkArea.set("company",
         SimpleSampleCompany.Main, PropertyModeType.read_only);

      // Set the priority.
      userWorkArea.set("priority", SimpleSamplePriority.Silver);
   }

   catch (PropertyReadOnly e) {
     // The company was previously set with the read-only or
     // fixed read-only mode.
     ...
   }
```

```
    catch (NotOriginator e) {
     // The work area originated in another process,
     // so it can't be modified here.
     ...
   }

   catch (NoWorkArea e) {
      // There is no work area begun on this thread.
      ...
   }

   // Do application work.
   ...
}
```

The get method takes the key as an argument and returns a Java Serializable object as the value associated with the key. For example, to retrieve the value of the company key from the work area, the code example above uses the get method on the work area to retrieve the value.

**Setting property modes**. The two-argument set method on the UserWorkArea interface takes a key and a value as arguments and inserts the property with the default property mode of normal. To set a property with a different mode, applications must use the three-argument set method, which takes a property mode as the third argument. The values used to request the property modes are as follows:

- **Normal**: PropertyModeType.normal
- **Fixed normal**: PropertyModeType.fixed_normal
- **Read-only**: PropertyModeType.read_only
- **Fixed read-only**: PropertyModeType.fixed_readonly

4. Manage local work with a work area.
5. Complete the work area. After an application has finished using a work area, it must complete the work area by calling the complete method on the UserWorkArea interface. This terminates the association with the calling thread and destroys the work area. If the complete method is called on a nested work area, the nested work area is terminated and the parent work area becomes the current work area. If there is no work area associated with the calling thread, a NoWorkArea exception is created. Every work area must be completed, and work areas can be completed only by the originating process. For example, if a server attempts to call the complete method on a work area that originated in a client, a NotOriginator exception is created. Work areas created in a server process are never propagated back to an invoking client process.

   **Attention:** The work area service claims full local-remote transparency. Even if two beans happen to be deployed in the same server, and therefore the same JVM and process, a work area begun on an invocation from another is completed and the bean in which the request originated is always in the same state after any remote call.

   The following code example shows the completion of the work area created in the client application.

```
public class SimpleSampleServlet {
   ...
   userWorkArea.begin("SimpleSampleServlet");
   userWorkArea.set("company",
       SimpleSampleCompany.Main, PropertyModeType.read_only);
   userWorkArea.set("priority", SimpleSamplePriority.Silver);
   ...

   // Do application work.
   ...

   // Terminate the work area.
   try {
      userWorkArea.complete();
   }

   catch (NoWorkArea e) {
      // There is no work area associated with this thread.
      ...
   }
```

```
      catch (NotOriginator e) {
         // The work area was imported into this process.
         ...
      }
     ...
  }
```

The following code example shows the sample application completing the nested work area that it created earlier in the remote invocation.

```
public class SimpleSampleBeanImpl implements SessionBean {

    public String [] test() {
      ...

      // Begin a nested work area.
      userWorkArea.begin("SimpleSampleBean");
      try {
        userWorkArea.set("company",
                         SimpleSampleCompany.London_Development);
      }
      catch (NotOriginator e) {
      }

      SimpleSampleCompany company =
         (SimpleSampleCompany) userWorkArea.get("company");
      SimpleSamplePriority priority =
         (SimpleSamplePriority) userWorkArea.get("priority");

      // Complete all nested work areas before returning.
      try {
        userWorkArea.complete();
      }
      catch (NoWorkArea e) {
      }
      catch (NotOriginator e) {
      }
    }
  }
```

## Example

- Work area object types
- Using the work area partition manager

**Work area object types.** In the following example, the client creates a work area and inserts two properties into the work area: a site identifier and a priority. The site-identifier is set as a read-only property; the client does not allow recipients of the work area to override the site identifier. This property consists of the key company and a static instance of a SimpleSampleCompany object. The priority property consists of the key priority and a static instance of a SimpleSamplePriority object. The object types are defined as shown in the following code example:

```
public static final class SimpleSampleCompany {
   public static final SimpleSampleCompany Main;
   public static final SimpleSampleCompany NewYork_Sales;
   public static final SimpleSampleCompany NewYork_Development;
   public static final SimpleSampleCompany London_Sales;
   public static final SimpleSampleCompany London_Development;
}

public static final class SimpleSamplePriority {
   public static final SimpleSamplePriority Platinum;
   public static final SimpleSamplePriority Gold;
```

```
   public static final SimpleSamplePriority Silver;
   public static final SimpleSamplePriority Bronze;
   public static final SimpleSamplePriority Tin;
}
```

The client then makes an invocation on a remote object. The work area is automatically propagated; none of the methods on the remote object take a work area argument. On the remote side, the request is first handled by the SimpleSampleBean; the bean first reads the site identifier and priority properties from the work area. The bean then intentionally attempts, and fails, both to write directly into the imported work area and to override the read-only site-identifier property.

The SimpleSampleBean successfully begins a nested work area, in which it overrides the client's priority, then calls another bean, the SimpleSampleBackendBean. The SimpleSampleBackendBean reads the properties from the work area, which contains the site identifier set in the client and priority set in the SimpleSampleBean. Finally, the SimpleSampleBean completes its nested work area, writes out a message based on the site-identifier property, and returns.

**Using the work area partition manager.** The following code example illustrates the use of the work area partition manager interface. The sample illustrates how to create and retrieve a work area partition programmatically`. Please note that programmatically creating a work area partition is only available on the Java Platform, Enterprise Edition (Java EE) client. To create a work area partition on the server one must use the administrative console. Refer to the Work area partition service article for configuration parameters available to configure a partition.

```
import com.ibm.websphere.workarea.WorkAreaPartitionManager;
import com.ibm.websphere.workarea.UserWorkArea;
import com.ibm.websphere.workarea.PartitionAlreadyExistsException;
import com.ibm.websphere.workarea.NoSuchPartitionException;
import java.lang.IllegalAccessError;
import java.util.Properties;
import javax.naming.InitialContext;

//This sample demonstrates how to retrieve an instance of the
//WorkAreaPartitionManager implementation and how to use that
//instance to create a WorkArea partition and retrieve a partition.
//NOTE: Creating a partition in the way listed below is only available
//on a J2EE client.  To create a partition on the server use the
//WebSphere administrative console.  Retrieving a WorkArea
//partition is performed in the same way on both client and server.

public class Example {

     //The name of the partition to create/retrieve
     String partitionName = "myPartitionName";
     //The name in java naming the WorkAreaPartitionManager instance is bound to
     String jndiName = "java:comp/websphere/WorkAreaPartitionManager";

     //On a J2EE client a user would create a partition as follows:
     public UserWorkArea myCreate(){
         //Variable to hold our WorkAreaPartitionManager reference
         WorkAreaPartitionManager partitionManager = null;
         //Get an instance of the WorkAreaPartitionManager implementation
         try {
             InitialContext initialContext = new InitialContext();
             partitionManager = (WorkAreaPartitionManager) initialContext.lookup(jndiName);
         } catch (Exception e) {  }

         //Set the properties to configure our WorkArea partition
         Properties props = new Properties();
         props.put("maxSendSize","12345");
         props.put("maxReceiveSize","54321");
         props.put("Bidirectional","true");
      props.put("DeferredAttributeSerialization","true");
```

```
        //Variable used to hold the newly created WorkArea Partition
        UserWorkArea myPartition = null;

        try{
            //This is the way to create a partition on the J2EE client.  Use the
            //WebSphere Administrative Console to create a WorkArea Partition
            //on the server.
            myPartition = partitionManager.createWorkAreaPartition(partitionName,props);
        }
        catch (PartitionAlreadyExistsException e){  }
        catch (IllegalAccessException e){  }

        return myPartition;
    }

    //. . . .

    //In order to retrieve a WorkArea partition at some time later or
    //from some other class, do the following (from client or server):
    public UserWorkArea myGet(){
        //Variable to hold our WorkAreaPartitionManager reference
        WorkAreaPartitionManager partitionManager = null;
        //Get an instance of the WorkAreaPartitionManager implementation
        try {
            InitialContext initialContext = new InitialContext();
            partitionManager = (WorkAreaPartitionManager) initialContext.lookup(jndiName);
        } catch (Exception e) {  }

        //Variable used to hold the retrieved WorkArea partition
        UserWorkArea myPartition = null;
        try{
            myPartition = partitionManager.getWorkAreaPartition(partitionName);
        }catch(NoSuchPartitionException e){  }

        return myPartition;
    }
}
```

### What to do next

For additional information about work area, see the com.ibm.websphere.workarea package in the API. The generated API documentation is available in the information center table of contents from the path **Reference** > **APIs - Application programming interfaces**.

# Configuring work area partitions

# Configuring work area partitions

## About this task

The work area partition service extends the work area service by allowing the creation of multiple work areas with more configuration options than what is available to the UserWorkArea partition. Follow these steps to create and configure a work area partition:

## Procedure

1. Create a user defined partition on the server.
   a. Start the administrative console.
   b. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Business process services** > **Work area partition service**.
   c. Click **New**.

d. On the settings page for work area partitions, specify values such as the partition name, maxSendSize and maxReceiveSize, then click OK.
e. Save the new configuration.
f. Restart the server to apply the new configuration.

2. Create a user defined partition on the client. Use the createWorkAreaPartition method described in the The Work area partition manager interface article to programmatically create a partition. Refer to the Example: Using the work area partition manager article for an example of using this method.

### Results

You have created a work area partition.

### What to do next

Retrieve the partition through the work area partition manager interface and use it as defined by the work area service and the UserWorkArea interface. Refer to the Example: Using the work area partition manager article for an example.

## Work area partition service

The work area partition service is an extension of the work area service that allows the creation of multiple custom work areas. The work area partition service is an optional service to users. Any user that currently uses the work area service and the UserWorkArea partition can continue using it in the same manner. The UserWorkArea partition is created automatically (if it has not been disabled) by the work area partition service. By allowing a user the option to create their own work area partition through the work area partition service, they can have more control over configuration and access to their partition.

The work area partition service is essentially a "factory" for creating instances of the UserWorkArea interface. Applications interact with work areas by using the UserWorkArea interface and its implementation. This interface defines all of the methods used to create, manipulate, and complete work areas. The work area partition service allows users to create their own named instance of the UserWorkArea interface, each named instance is called a user defined work area partition, or partition for short. Each instance of the UserWorkArea interface (partition) is separate from other user defined partitions. Furthermore, a partition can be configured with various configuration options to provide qualities of service unique to an individual user's use case. Any configuration option made within the work area partition service panel will not effect the work area service.

Unlike the UserWorkArea partition, which is publicly known, work areas created by the work area partition service are accessible to, and known only by the creator. However, the work area partition service does not strictly enforce that a partition is accessed and/or operated on exclusively by the partition creator. There are no limitations should the creator want to publish their work area partition and make it publicly available by binding their partition reference in java naming or by other means. However, the work area partition service does try to hide a partition as much as possible should a user not want others to know about a certain partition. The work area partition service does not allow a person to determine, or query the names of all the partitions that have been created; however, it does not restrict the partitions from being accessed by users other than the creator of that partition. The context of a partition, such as the UserWorkArea partition or a user defined partition, is scoped to a single thread and is not accessible by multiple threads.

The work area partition reference that is returned to a user implements javax.naming. Referenceable, as well as com.ibm.websphere.UserWorkArea, therefore a user can bind their partition into a name to make their partition publicly available. An alternative to using Java naming to bind and access the partition is to use the work area partition manager interface. Anyone can access the work area partition manager

interface; therefore, if a user wants to make their partition publicly available, they simply need to publish their partition name. Other users can then call the getWorkAreaPartition method on the work area partition manager interface with the published name.

The WorkAreaPartitionManager.createWorkAreaPartition method can only be used from a Java Platform, Enterprise Edition (Java EE) client. To create a work area partition on the server side, one must use the administrative console. On the server side a work area partition must be created during server startup because each partition needs to be register with the appropriate Web and Enterprise JavaBeans (EJB) collaborators before the server has started. Custom work area partitions are created by the work area partition service and defined by the UserWorkArea interface.

The work area partition service also allows a user to configure partitions with additional properties that are not available on the UserWorkArea partition, such as bidirectional propagation of work area partition context and deferred attribute serialization. These properties are available as configuration properties when creating a partition. For a complete list of the configuration properties that are available when creating a partition, refer to the "Configurable Work Area Partition Properties" section in the The Work area partition manager interface article. The properties are defined as follows:

## Bidirectional propagation of work area context

If a remote invocation is issued from a thread associated with a work area, a copy of the work area is automatically propagated to the target object, which can use or ignore the information in the work area as necessary. If the calling application has a nested work area associated with it, a copy of the nested work area and all its ancestors are propagated to the target application. The target application can locally modify the information, as allowed by the property modes, by creating additional nested work areas; this information is propagated to any remote objects that it invokes.

Whether context changes propagate back to a calling application from a remote application depends on the configuration of the work area partition. If a user creates a partition to be bidirectional (selects the Bidirectional property during creation), changes made by a remote application propagates back to the calling application, meaning that changes made to the work area context by a downstream process will propagate back up stream. The UserWorkArea partition is not configured (and can never be configured) to be bidirectional; therefore context changes only flow to downstream processes and do not propagate back upstream.

## Example: Bidirectional propagation of work area context

Whether context changes propagate back to a calling application from a remote application depends on the configuration of the work area partition. If a user creates a bidirectional partition, changes made by a remote application propagate back to the calling application. Changes made to the work area context by a downstream process propagate back up stream. Figure 1 illustrates distribution of work area context on a remote call when the partition containing the given work area is configured for bidirectional propagation of its work area context. For this illustration, the client and server must have created a partition with the same name.

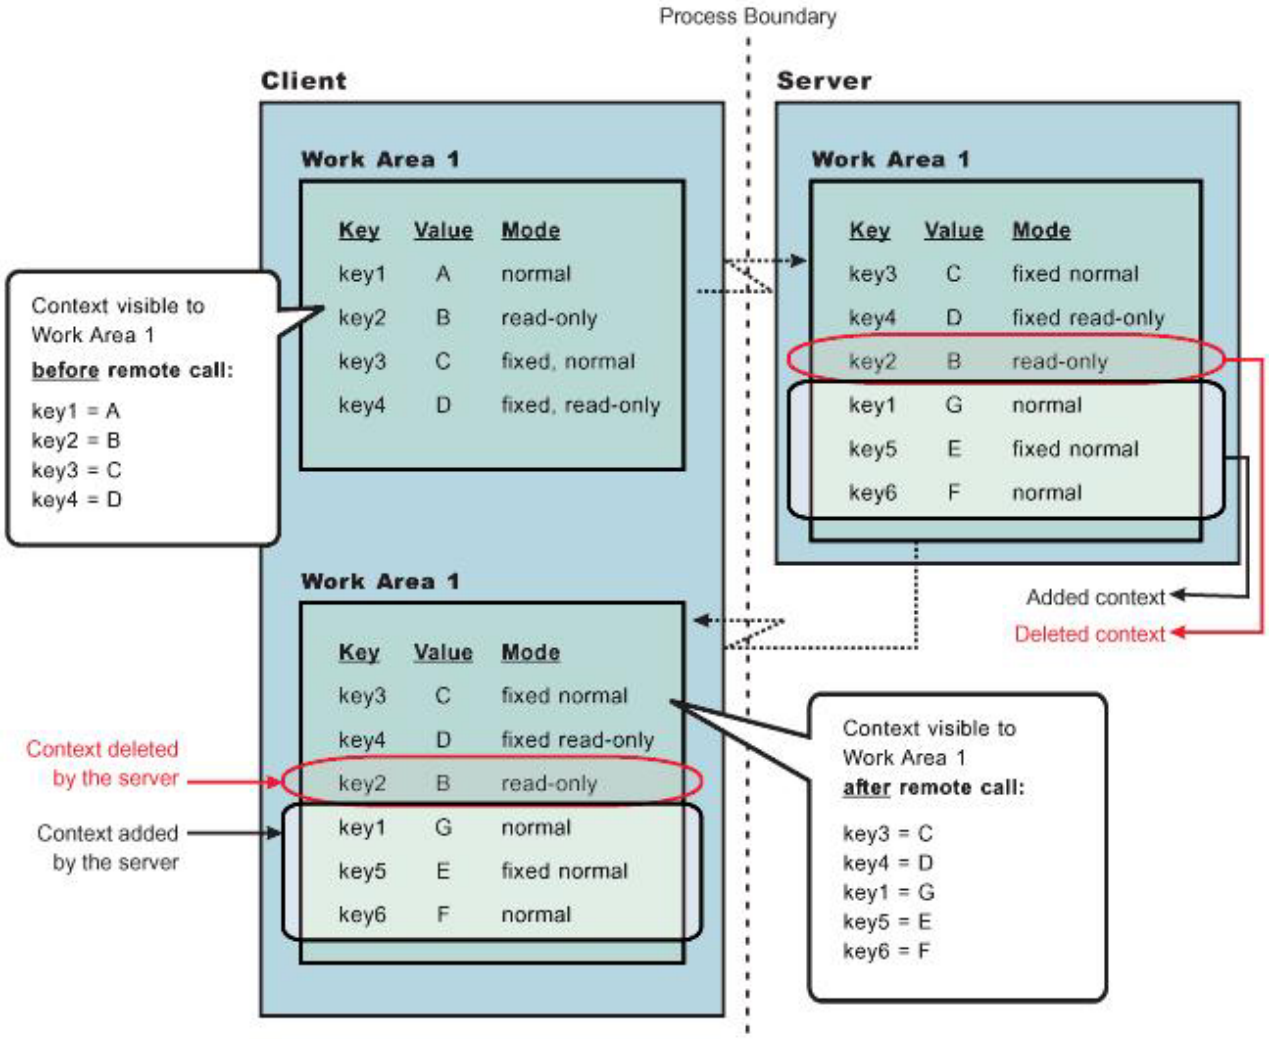


*Figure 7. Figure 1*

As Figure 1 shows, when the client makes a remote call to the server, the server receives the context set by the client process. The server then can make changes to this context or add to it. In this illustration, the server overwrites the value at **key1**, removes the property at **key2**, and adds two new properties at **key5** and **key6**. When the server application returns to the client, the work area context is propagated back to the client and demarshalled. The current work area is then updated with the new context. Note, that if the partition is not configured as bidirectional, and the server tries to change or remove context in work area, "Work Area 1", it receives a com.ibm.websphere.workarea.NotOriginator exception because the client was the originator of the work area. The server can retrieve the context in "Work Area 1". This is the main distinction between bidirectional propagation of context and non-bidirectional propagation.

## Example: Bidirectional propagation of nested work area context

If a remote application needs to add context to a work area that is only used by itself or any other remote objects, the remote application must begin another work area. By beginning a new work area, the new context added is scoped to that application and does not flow back to the calling application. The major benefit of nesting work areas is that nesting work areas allows an application to scope work area context to a given application. Taking the above illustration one step further, if the server has begun a work area before overwriting the value at **key1**, removing the property at **key2**, or adding new properties at **key5** and **key6**; those changes would not have propagated back to the client. This is shown in Figure 2. You can

also see from this figure that the client does not receive the context from the nested work area started by the server.

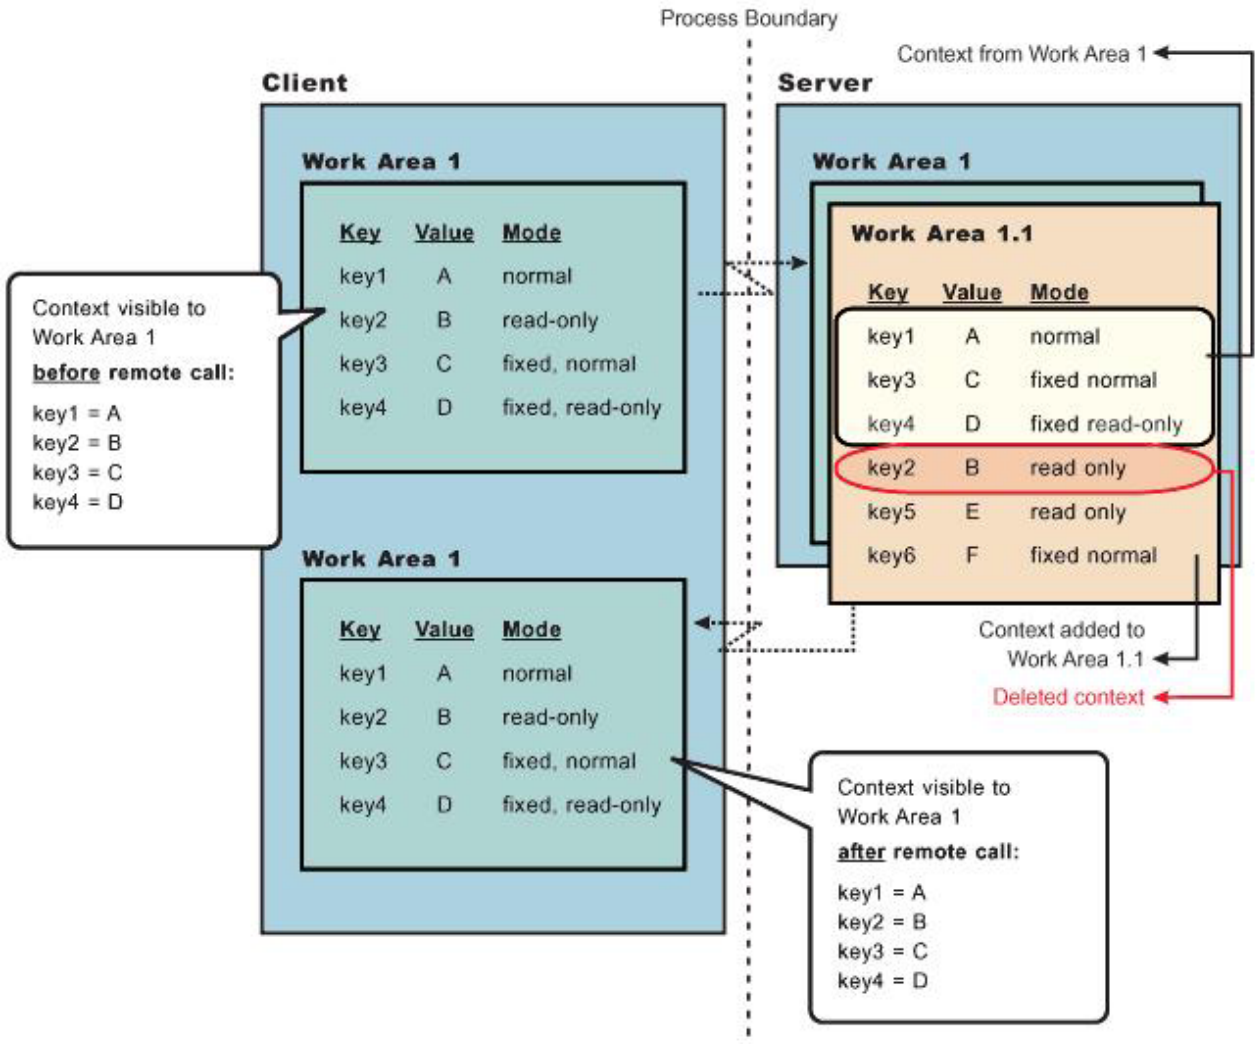

*Figure 8. Figure 2*

## Deferred attribute serialization of work area context

By default, on each set operation the attribute set into a work area is automatically serialized by the work area service. On each subsequent get operation on that same attribute it is deserialized and returned to the requester. This gives the work area service complete control of the attribute such that any changes to a mutable object are not reflected in the work area's copy of the attribute unless a user specifically resets the attribute into the work area. However, this can potentially lead to excessive serialization and deserialization.

Excessive serialization and deserialization can result in observable performance degradation under heavy load. The deferred attribute serialization configuration property is a caching feature that reduces serialization and deserialization operations. When deferred attribute serialization is enabled in a client or server process, by selecting the Deferred Attribute Serialization field during the creation of the work area, attributes set into the work area service are not automatically serialized during the set operation. Rather, a reference to the attribute is stored in the work area. If the attribute is mutable, then changes to the object

are reflected in the work area's reference to that attribute. When a get operation is performed on that attribute, the reference to that object is returned and no deserialization is performed.

Attributes are not actually serialized until the thread with which the attribute is associated makes a remote IIOP invocation. At that point the attribute is serialized and the serialized form of the attribute is cached. If the attribute is not reset into the work area, changes to the original attribute are still reflected within the attribute contained within the work area because the work area still holds a cached reference to the original object. However, if the work area has not been told that the attribute has changed by resetting the attribute into the work area, subsequent remote requests continues to use the cached serialized version of the attribute and direct changes to the mutable attribute are not propagated. This is an important distinction between enabling and not enabling the deferred attribute serialization configuration property and a user must pay close attention to this difference and how mutable objects are handled when enabling deferred attribute serialization. The work area service releases cached references and cached serialized versions of attributes when any of the following occur:

- An attribute is reset or removed.
- The work area is explicitly completed by the application.
- Server component ends execution of the request during which the work area was begun.
- Client process which began the work area terminates.

### Partition context propagation across process boundaries

Work area context automatically propagates from client to server when a client makes a remote call to a server. If a client is configured with, for example, three different work area partitions when it makes a remote call to a server, server1; the context associated with each partition on the client thread propagates to server1. If the same three partitions reside (have been created) on server1, the context is demarshalled to the appropriate partition. However, if none or only a few of the three partitions have been created on server1, only the context associated with a partition that is resident on both the client and server is demarshalled. The context associated with a partition that is not resident on server1 is still resident on server1 but will not be accessible. The context associated with partitions that are not resident on server1 must remain resident on server1 in case another remote call is made to a different server. Going one step further, if server1 makes a call to yet another server, server2 and assume server2 has created all the same partitions that the client has, server2 receives the context for the partitions that were not resident on server1. Any partitions that reside on server1 that did not reside on the client, now have its context propagated to server2.

For additional information about work area, see the com.ibm.websphere.workarea package in the Application Programming Interface (API). The generated API documentation is available in the information center table of contents from the path **Reference** > **APIs - Application Programming Interfaces**.

## The Work area partition manager interface

Applications interact with the work area partition service by using the work area partition manager interface. A user can retrieve an instance of the work area partition manager interface out of naming and use the methods that are defined in the following section.

An implementation of the work area partition manager interface is bound in Java naming at `java:comp/websphere/WorkAreaPartitionManager`. This interface is responsible for creating, retrieving, and manipulating work area partitions:

```
package com.ibm.websphere.workarea;

import com.ibm.websphere.workarea.UserWorkArea;
import com.ibm.websphere.workarea.PartitionAlreadyExistsException;
import com.ibm.websphere.workarea.NoSuchPartitionException;
import java.util.Properties;

public interface WorkAreaPartitionManager {
```

```
  //Returns an instance of a work area partition for the given name, or throws an exception if the
  //partition name doesn't exists.
  public UserWorkArea getWorkAreaPartition(String partitionName) throws NoSuchPartitionException;

  //Returns a new instance of a work area partition (an implementation of the UserWorkArea interface)
  //or throws an exception if the partition name already exists.  The createWorkAreaPartition should
  //only be used within a Java EE platform client and NOT on the
  //server.  To create a work area partition on the server, use the WebSphere administrative
  //console.
  public UserWorkArea createWorkAreaPartition(String partitionName, Properties props) throws
     PartitionAlreadyExistsException, java.lang.IllegalAccessException;
  }
}
```

EJB applications can use the work area partition manager interface only within the implementation of methods in either the remote or local interface, or both; likewise, servlets can use the interface only within the service method of the HTTPServlet class. Use of work areas within any life cycle method of a servlet or enterprise bean is considered a deviation from the work area programming model and is not supported.

Programmatically creating a work area partition through the createWorkAreaPartition method is only available on the Java EE client. To create a work area partition on the server, use the WebSphere administrative console as described in the Configuring work area partitions article. All partitions in a server process must be created before server startup is complete so that the work area service can register with the appropriate container collaborators. Therefore, calling the createWorkAreaPartition method in a server process after the server starts results in a java.lang.IllegalAccessException exception. The createWorkAreaPartition method can be called in a Java EE application client at any time.

## Configurable Work Area Partition Properties

This section applies to the use of the createWorkAreaPartition method on the WorkAreaPartitionManager interface. As is described above, this method should only be used on a Java EE client. To create a partition on the server, please see Configuring work area partitions.

The "createWorkAreaPartition" method on the WorkAreaPartitionManager interface takes a java.util.Properties objects. This Properties object, and the properties it contains, is used to define the work area partition. Below is an example of creating a Properties object and setting a property:

**Attention:** A more detailed example of the usage of the WorkAreaPartitionManager can be found in the Example: Using the work area partition manager article.

```
java.util.Properties props = new java.util.Properties():
props.put("maxSendSize","12345");
```

**Acceptable key/values pairs (properties) for defining a partition are as follows:**

- *maxSendSize* - Indicates the maximum size (bytes) of a work area that can be sent on a remote call. Acceptable values are:
  - "-1" = Uses the default size of 32767.
  - "0" = Unlimited size, this value will not be policed which might help performance a bit depending on the number of work area an application has.
  - "1" = Integer.MAX_VALUE
- *maxReceiveSize* - Indicates the maximum size (bytes) of a work area that can be received. Acceptable values are:
  - "-1" = Uses the default size of 32767.
  - "0" = Unlimited size, this value will not be policed which might help performance a bit depending on the number of work area an application has.
  - "1" = Integer.MAX_VALUE

- *Bidirectional* - Indicates if work area context that is changed by a downstream process should be propagated back upstream to the originator of that context. For a more complete description of this property, refer to the "Bidirectional propagation of work area context" in the Work area partition service article. Acceptable values are:
  - "true" = Context changes will be returned from a remote call.
  - "false" = Context changes will not be returned from a remote call.

  **Attention:** The default setting is "false."
- *DeferredAttributeSerialization* - Indicates if the serialization of attribute should be optimized to occur exactly once per process. For a more complete description of this property, refer to the "Deferred attribute serialization of work area context" section in the Work area partition service article. Acceptable values are:
  - "true"
    - When an attribute is set into the work area, it will not be serialized until a remote request is made.
    - If the value is unchanged by response, the serialized form will be used for subsequent requests; the live object will be retrieved via getters.
    - When requests are made during a remote request, a value is deserialized on demand exactly once. The serialized form is used for subsequent requests from this remote process on this distributed thread; subsequent requests in process for the same attribute returns the already deserialized value. There are risks with concurrency with DeferredAttributeSerialization. After serialization in a client process, updates to the attribute are no longer reflected in the work area's copy until the value is explicitly reset through the UserWorkArea interface. Changes made to a retrieved reference in a downstream process are not propagated to subsequent downstream requests (or returned on the reply as a changed value) unless explicitly reset through the UserWorkArea interface.
  - "false"
    - When an attribute is set into the work area, it is immediately serialized and the bytes are stored.
    - When an attribute is retrieved from the work area, it is always deserialized from stored bytes.

  **Attention:** The default value is "false."
- *EnableWebServicePropagation* - Indicates if work area context must propagate on a WebService call. Acceptable values are:
  - "true" = Context propagates on a WebService call.
  - "false" = Context does not propagate on a WebService call.

  **Attention:** The default value is "false."

## Exceptions

The work area partition service defines the following exceptions for use with the work area partition manager interface:

**PartitionAlreadyExistsException**
This exception is raised by the createWorkAreaPartition method on the WorkAreaPartitionManager implementation if a user tries to create a work area partition with a partition name that already exists. Partition names must be unique.

**NoSuchPartitionException**
This exception is raised by the getWorkAreaPartition method on the WorkAreaPartitionManager implementation if a user requests a work area partition with a partition name that does not exist.

**java.lang.IllegalAccessException**
This exception is raised by the createWorkAreaPartition method on the WorkAreaPartitionManager implementation if a user tries to create a work area partition during run time on a server process. This method can only be used on a Java EE client process. In the server process, a partition must be created using the administrative console.

For additional information about work area, see the com.ibm.websphere.workarea package in the application programming interface (API). The generated API documentation is available in the information center table of contents from the path **Reference** > **APIs - Application Programming Interfaces**.

## Example: Using the work area partition manager

The example below demonstrates the use of the work area partition manager interface. The sample illustrates how to create and retrieve a work area partition programmatically`. Please note that programmatically creating a work area partition is only available on the Java Platform, Enterprise Edition (Java EE) client. To create a work area partition on the server one must use the administrative console. Refer to the Work area partition service article for configuration parameters available to configure a partition.

```
import com.ibm.websphere.workarea.WorkAreaPartitionManager;
import com.ibm.websphere.workarea.UserWorkArea;
import com.ibm.websphere.workarea.PartitionAlreadyExistsException;
import com.ibm.websphere.workarea.NoSuchPartitionException;
import java.lang.IllegalAccessError;
import java.util.Properties;
import javax.naming.InitialContext;

//This sample demonstrates how to retrieve an instance of the
//WorkAreaPartitionManager implementation and how to use that
//instance to create a WorkArea partition and retrieve a partition.
//NOTE: Creating a partition in the way listed below is only available
//on a J2EE client.  To create a partition on the server use the
//WebSphere administrative console.  Retrieving a WorkArea
//partition is performed in the same way on both client and server.

public class Example {

     //The name of the partition to create/retrieve
     String partitionName = "myPartitionName";
     //The name in java naming the WorkAreaPartitionManager instance is bound to
     String jndiName = "java:comp/websphere/WorkAreaPartitionManager";

     //On a J2EE client a user would create a partition as follows:
     public UserWorkArea myCreate(){
         //Variable to hold our WorkAreaPartitionManager reference
         WorkAreaPartitionManager partitionManager = null;
         //Get an instance of the WorkAreaPartitionManager implementation
         try {
             InitialContext initialContext = new InitialContext();
             partitionManager = (WorkAreaPartitionManager) initialContext.lookup(jndiName);
         } catch (Exception e) {  }

         //Set the properties to configure our WorkArea partition
         Properties props = new Properties();
         props.put("maxSendSize","12345");
         props.put("maxReceiveSize","54321");
         props.put("Bidirectional","true");
      props.put("DeferredAttributeSerialization","true");

         //Variable used to hold the newly created WorkArea Partition
         UserWorkArea myPartition = null;

         try{
             //This is the way to create a partition on the J2EE client.  Use the
             //WebSphere Administrative Console to create a WorkArea Partition
             //on the server.
             myPartition = partitionManager.createWorkAreaPartition(partitionName,props);
         }
         catch (PartitionAlreadyExistsException e){  }
         catch (IllegalAccessException e){  }
```

```
        return myPartition;
    }

    //. . . .

    //In order to retrieve a WorkArea partition at some time later or
    //from some other class, do the following (from client or server):
    public UserWorkArea myGet(){
        //Variable to hold our WorkAreaPartitionManager reference
        WorkAreaPartitionManager partitionManager = null;
        //Get an instance of the WorkAreaPartitionManager implementation
        try {
            InitialContext initialContext = new InitialContext();
            partitionManager = (WorkAreaPartitionManager) initialContext.lookup(jndiName);
        } catch (Exception e) {  }

        //Variable used to hold the retrieved WorkArea partition
        UserWorkArea myPartition = null;
        try{
            myPartition = partitionManager.getWorkAreaPartition(partitionName);
        }catch(NoSuchPartitionException e){  }

        return myPartition;
    }
}
```

## Work area partition collection

Use this page to manage the work area service.

The work area partition service supports the definition of custom work area partitions.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Business Process Services** > **Work area partition service**.

## Name

Specifies the name of the work area partition that is used to retrieve the partition. This name must be unique.

## Description

Specifies the description of the work area partition.

## Enable service at server startup

Specifies whether the server attempts to start the specified service when the server starts.

## Bidirectional

Permits applications to modify the context of a work area that is imported by a Java EE request; modified properties are propagated back to the requestor environment. This option is disabled by default.

## Maximum send size

Specifies the maximum size of data that can be sent within a single work area. (0 = no limit; -1 = default)

A value of 0 means there is no limit to the data sent. The default value of -1 represents 32768 bytes of data sent.

## Maximum receive size
Specifies the maximum size of data that can be received within a single work area. (0 = no limit; -1 = default)

A value of 0 means there is no limit to the data received. The default value of -1 represents 32768 bytes of data received.

## Deferred attribute serialization
Specifies whether attribute serialization is deferred until the work area is propagated on a remote invocation.

## Enable Web service propagation
Specifies whether the work area partition is propagated on Web service requests. This option is disabled by default.

## Work area partition settings
Use this page to modify the work area partition settings.

The work area partition service supports the definition of custom work area partitions.

To view this administrative console page, click **Servers > Server types > WebSphere application servers >** *server_name*. Under **Container Settings**, expand **Business Process Services** then click **Work area partition service**. Click on a *work_area_partition_name*.

### Name
Specifies the name of the work area partition that is used to retrieve the partition. This name must be unique.

### Description
Specifies the description of the work area partition.

### Enable service at server startup
Specifies whether the server attempts to start the specified service when the server starts.

### Bidirectional
Permits applications to modify the context of a work area that is imported by a Java EE request; modified properties are propagated back to the requestor environment. This option is disabled by default.

### Maximum send size
Specifies the maximum size of data that can be sent within a single work area. (0 = no limit; -1 = default)

| | |
|---|---|
| **Data type** | Integer |
| **Units** | Bytes |
| **Default** | 32768 |
| **Range** | -1, 0 (no limit) and 1 to 2147483647 |

### Maximum receive size
Specifies the maximum size of data that can be received within a single work area. (0 = no limit; -1 = default)

| | |
|---|---|
| **Data type** | Integer |
| **Units** | Bytes |
| **Default** | 32768 |
| **Range** | -1, 0 (no limit) and 1 to 2147483647 |

### Deferred attribute serialization
Specifies whether attribute serialization is deferred until the work area is propagated on a remote invocation. This option is disabled by default.

### Enable Web service propagation
Specifies whether the work area partition is propagated on Web service requests. This option is disabled by default.

## Accessing a user defined work area partition

### About this task

The work area partition service provides a Java Naming and Directory Interface (JNDI) binding to an implementation of the work area partition manager interface under the name java:comp/websphere/WorkAreaPartitionManager. Applications that need to access their partition can perform a lookup on that JNDI name and then use the getWorkAreaPartition method on the work area partition manager, as shown in the following code example:

### Example

```
import com.ibm.websphere.workarea.*;
import javax.naming.*;

public class SimpleSampleServlet {
  ...

         //Variable to hold our WorkAreaPartitionManager implementation
         WorkAreaPartitionManager partitionManager = null;
         try {
             InitialContext initialContext = new InitialContext();
             partitionManager = (WorkAreaPartitionManager)
            initialContext.lookup("java:comp/websphere/WorkAreaPartitionManager");
         } catch (Exception e) {...}

         //Variable used to hold the retrieved WorkArea Partition
         UserWorkArea myPartition = null;
         try{
             myPartition = partitionManager.getWorkAreaPartition(partitionName);
         }catch(NoSuchPartitionException e){...}
}
```

### What to do next

The next step is to use the begin method to create a new work area and associate it with the calling thread, as described in the Beginning a new work area topic.

## Propagating work area context over Web services

WebSphere Application Server Version 6.1 introduces the option to propagate work area context on a Web service call. Prior to WebSphere Application Server Version 6.1, work area context was only propagated over RMI/IIOP calls. The work area application programming interfaces (APIs) have not changed to implement this propagation. You can use the work area APIs as they have in the past and as outlined in the work area documentation. However, by default, work area context is not propagated on a Web service call, you must enable this option.

### Procedure

1. Enable a server to propagate work area context on a Web service call.
   a. Start the administrative console.

b. Select **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Business Process Services** .
   - To enable the work area service, (the UserWorkArea partition) to propagate its context on a Web service call:
     – Select **Work area service**.
   - To enable an individual partition to propagate its context on a Web service call:
     – Select **Work area partition service**.
     – Select a partition.

c. Check the EnableWebServicePropagation field to enable Web service propagation.

d. Save the new configuration and restart the server to apply the new configuration.

2. Enable a client to propagate work area context on a Web service call:

   **Note:** The steps below are for the work area service (the UserWorkArea partition). For user defined partitions the EnableWebServicePropagation property must be set when creating a partition on the client, refer to the The Work area partition manager interface article.

   a. Set the property com.ibm.websphere.workarea.EnableWebServicePropagation to true when invoking the launchClient script found in the $WAS_HOME/bin directory. For example, to set this property to true, add the following system properties to the launchClient invocation as needed: -CCDcom.ibm.websphere.workarea.EnableWebServicePropagation=true

   b. Set the property com.ibm.websphere.workarea.EnableWebServicePropagation in a property file that is used by the launchClient script. Refer to the Running a Java EE client application with launchClient for additional information.

# Chapter 44. XML applications

This page provides a starting point for finding information about XML applications.

## Overview of XML support

You can use the XML support provided with this product to work with web applications that process data using standard XML technologies like Extensible Stylesheet Language Transformations (XSLT), XML Path Language (XPath), and XML Query Language (XQuery).

XML-structured data has become the predominant format for data interchange. XML data is navigated, queried, or transformed in almost every existing WebSphere application.

Since first being standardized, XML usage in application-development environments has grown significantly to include many scenarios. WebSphere Application Server is a leading platform for the latest application development standards, including XML.

**Note:** IBM WebSphere Application Server Version 8.0 delivers critical technology that provides application developers with support for the following key World Wide Web Consortium (W3C) XML standards:

- Extensible Stylesheet Language Transformations (XSLT) 2.0
- XML Path Language (XPath) 2.0
- XML Query Language (XQuery) 1.0

These new and updated W3C XML standards offer application developers numerous advanced capabilities for building XML applications. Specific benefits delivered in the XPath 2.0, XSLT 2.0, and XQuery 1.0 standards include the following:

- Simpler XML application development and improved developer productivity
- Improved ability to query large amounts of data stored in XML outside of a database with XQuery 1.0
- Improved XML-application performance through new features introduced in the W3C specifications to address previous shortcomings
- Improved XML-application reliability with new support for XML schema-aware processing and validation

**Note:** If you want to use XPath 1.0 or XSLT 1.0 (not in backwards-compatibility mode), continue to use Java API for XML Processing (JAXP) in Java 2 Platform, Standard Edition (J2SE) 1.6.

For more information about these W3C XML standards, go to W3C XQuery 1.0 and XSLT 2.0 Become Standards: Tools to Query, Transform, and Access XML and Relational Data.

The product provides the IBM XML Application Programming Interface in support of these standards. This application programming interface invokes a runtime engine that is capable of executing XPath 2.0, XSLT 2.0, and XQuery 1.0 as well as manipulating the returned XML data.

The product also includes the IBM Thin Client for XML with WebSphere Application Server. The thin client allows access to the same XML API and runtime functionality (XPath 2.0, XSLT 2.0, and XQuery 1.0) available in the full product. The thin client can be copied to multiple clients running Java SE in support of a WebSphere Application Server Version 8.0 installation.

## XSLT 2.0, XPath 2.0, and XQuery 1.0 major new functions

Valuable features have been added to XPath 2.0, XSLT 2.0, and XQuery 1.0 reflecting productivity and feature improvements beyond the XPath 1.0 and XSLT 1.0 standards.

© Copyright IBM Corp. 2011

## XPath 2.0

- XPath 2.0 has been improved to support the XPath 2.0 and XQuery 1.0 Data Model (XDM), which is based on sequences of heterogeneous items including nodes and primitive types. This replaces and improves on the XPath 1.0 node-set support and becomes the foundation of XSLT 2.0 and XQuery 1.0 data navigation.
- XPath 2.0 adds an extensive collection of functions and operators to allow for an easier programming experience, replacing the XPath 1.0 requirement for proprietary extension mechanisms. These functions and operators help with date and time handling, enhance the string manipulation, support regular expression matching and tokenization, extend the number handling, and add functions for sequence manipulation.
- XPath 2.0 supports schema-aware processing, which allows for data navigation based on XML schema information for not only built-in schema types, but also user-defined schema types.
- XPath 2.0 adds condition (if/then/else branches), iterative (for loops), and quantified expressions (some and every tests) typical of other languages.
- XPath 2.0 adds named collations across multiple functions allowing for locale-specific operation.
- XPath 2.0 provides a backwards-compatibility mode to run most XPath 1.0 expressions unchanged.

## XSLT 2.0

- XSLT 2.0 is based on XPath 2.0, allowing XSLT 2.0 to take advantage of all new XPath 2.0 features. Temporary trees have been added to allow navigation of constructed trees during transformation. User-defined functions can be defined in the XSLT language and are callable using XPath 2.0.
- XSLT 2.0 can write to multiple result documents in a single stylesheet execution.
- XSLT 2.0 supports regular expressions to analyze and separate strings.
- XSLT 2.0 allows variables and parameters to be typed, therefore improving the reliability of stylesheets and functions.
- XSLT 2.0 supports schema-aware processing, which allows XSLT 2.0 to check for valid input, temporary trees, and output documents.
- XSLT 2.0 supports initial named templates, which allows the processor to start with a defined template instead of having to match the input document, a feature commonly used with loading documents programmatically using the XPath 2.0 collection and document functions.
- Comparisons in sorting, grouping, and keys are supported with any data type and can use locale-specific named collations.
- XHTML has been added to XSLT 2.0 as a valid output format.
- The next-match instruction allows the same node to be processed with multiple templates.
- The character-map instruction allows fine grained control of serialization of characters.
- XSLT 2.0 added addition instructions for transforming and formatting dates and times.
- XSLT 2.0 added support for tunnel parameters, which allows parameters to be passed through multiple template calls without having to declare the parameter in each template call.
- XSLT 2.0 added multiple mode support to allow templates to apply to specific modes of processing within a stylesheet.
- Unparsed text can be incorporated into the data processed by a stylesheet, which then can be tokenized with the new regular expression support.
- XSLT 2.0 provides a backwards-compatibility mode to run most XSLT 1.0 stylesheets unchanged.

## XQuery 1.0

- XQuery 1.0 is based on XPath 2.0, allowing XQuery 1.0 to take advantage of all new XPath 2.0 features. XQuery 1.0 builds on XPath 2.0 to provide full XML Query capability.

- XQuery's FLOWR (For, Let, Order by, Where, Return) expression allows for complicated joins across XML datasets. FLOWR allows for query of large documents or collections of documents. XQuery allows for the mixture of direct XML construction along with computed content returned from FLOWR expressions.
- XQuery has the ability to define functions and variables with syntax that is familiar to users of other languages, allowing larger programs to be defined around the data-query operations.
- XQuery 1.0 supports schema-aware processing, which allows input and constructed documents and elements to be validated.

## Overview of the XML Samples application

The XML Samples application is written to be used with the XML specifications and other documents. However, the most important function that these samples provide is a place to begin experimenting with the XML API and the supported specifications.

### Limitations

The XML Samples application is not intended for deployment to production servers. It is for development and educational purposes only. All source code is provided as is for you to use, copy, and modify without royalty payment when you develop applications that run with WebSphere software. You can use the sample code either for your own internal use, for redistribution as part of an application, or in your products.

### Content

- The simple API invocation examples included in the samples are intended as simple examples of using the major new features of XPath 2.0, XSLT 2.0, and XQuery 1.0.
  - XPath 2.0 examples
    - Sample 1: Simple XPath invocation

      Shows how to invoke XPath
    - Sample 2: Invoking XPath 1.0 under an XPath 2.0 run time in backwards compatibility mode

      Shows an example that demonstrates differences between XPath 1.0 and XPath 2.0 as well as how to run existing XPath 1.0 statements under XPath 2.0 in backwards-compatibility mode
    - Sample 3: Invoking schema aware XPath 2.0 expressions

      Shows how to run schema-aware expressions; shows how to load schema documents, how to validate input documents, and how to declare namespace prefixes
    - Sample 4: XPath 2.0 - document function (relative URIs) with input and output documents

      Shows how to invoke XPath using the document function with relative URIs
    - Sample 5: XPath running in compiled mode

      Shows how to invoke XPath in compiled mode
    - Sample 6: XPath running in pre-compiled mode

      Shows how to invoke XPath in pre-compiled mode
    - Sample 7: XPath 2.0 collation support

      Shows how to invoke XPath with collation support
  - XSLT 2.0 examples
    - Sample 1: Simple XSLT invocation

      Shows how to invoke XSLT
    - Sample 2: Invoking XSLT 1.0 under an XSLT 2.0 run time in backwards compatibility mode

      Shows differences between XPath 1.0 and XPath 2.0 and how to run existing XSLT 1.0 stylesheets under a XSLT 2.0 processor in backwards-compatibility mode
    - Sample 3: XSLT 2.0 updated for-each support

Shows how to use the XSLT 2.0 for-each functionality

- Sample 4: XSLT 2.0 grouping support

  Shows how to use the capability offered by xsl:for-each-group

- Sample 5: XSLT 2.0 regular expression support

  Shows how to use XSLT 2.0 regular-expression support to work with data in structured legacy formats within XML strings

- Sample 6: XSLT 2.0 date formatting

  Shows how to use XSLT 2.0 date formatting with internationalization

- Sample 7: XSLT 2.0 multiple results

  Shows how to use an XSLT 2.0 result-document instruction to write to multiple outputs simultaneously

- Sample 8: XSLT 2.0 tunnel parameters

  Shows how to use XSLT 2.0 tunnel parameters to allow values to be set and accessible during stylesheet processing

- Sample 9: XSLT 2.0 stylesheet functions

  Shows how to use the XSLT 2.0 stylesheet functions

- Sample 10: XSLT 2.0 initial template

  Shows how to use the XSLT 2.0 initial-template functionality

- Sample 11: XSLT 2.0 template with multiple modes

  Shows how to use the XSLT 2.0 template with multiple modes functionality

- Sample 12: XSLT 2.0 XHTML support - no output method specified

  Shows how to use XSLT 2.0 XHTML support with the XHTML output method

- Sample 13: XSLT 2.0 XHTML support - output method specified

  Shows how to use XSLT 2.0 XHTML support with the XHTML output method

- Sample 14: XSLT 2.0 character maps

  Shows how to use XSLT 2.0 character maps functionality

- Sample 15: XSLT 2.0 "as" attribute

  Shows how to use the XSLT 2.0 "as" attribute functionality

- Sample 16: XSLT 2.0 embedded stylesheets

  Shows how to use the XSLT 2.0 embedded stylesheets functionality

- Sample 17: XSLT 2.0 running in compiled mode

  Shows how to run XSLT in compiled mode

- Sample 18: XSLT 2.0 running in pre-compiled mode

  Shows how to run XSLT in pre-compiled mode

- Sample 19: XSLT 2.0 undeclare-prefixes serialization parameter

  Shows how to use the XSLT undeclare-prefix parameter when producing XML output that is Version 1.1 or higher

- Sample 20: XSLT 2.0 next-match

  Shows how to use the XSLT next-match functionality

- Sample 21: XSLT 2.0 usage of XPath 2.0 collection function

  Shows how to use the collection function

- Sample 22: XSLT 2.0 schema awareness - input validation (valid)

  Shows how to use the stylesheets and schemas to validate input documents

- Sample 23: XSLT 2.0 schema awareness - input validation (invalid)

  Shows how to use the stylesheets and schemas to validate input documents

- Sample 24: XSLT 2.0 schema awareness - temporary tree (valid)

Shows how to use the validation attribute to validate temporary trees
- Sample 25: XSLT 2.0 schema awareness - temporary tree (invalid)
  Shows how to use the validation attribute to validate temporary trees
- Sample 26: XSLT 2.0 schema awareness - output document (valid)
  Shows how to use the validation attribute to validate the main output document
- Sample 27: XSLT 2.0 schema awareness - output document (invalid)
  Shows how to use the validation attribute to validate the main output document
- Sample 28: XSLT 2.0 schema awareness - element(*, T) function
  Shows how to use the stylesheets and schemas to match on element types instead of names
- Sample 29: XSLT 2.0 use-when
  Shows how to use the use-when functionality
- Sample 30: XSLT 2.0 collation support
  Shows how to use the for-each-group functionality with collations

– XQuery 1.0 examples
  - Sample 1: Simple XQuery invocation
    Shows how to invoke simple XQuery FLOWR expressions
  - Sample 2: XQuery FLWOR support - using doc function and cross document joins
    Shows how to invoke an XQuery that joins data from multiple documents
  - Sample 3: XQuery declare functions and variables
    Shows how to define and use XQuery functions and variables
  - Sample 4: XQuery TypeDeclaration support
    Shows how to use the TypeDeclaration functionality
  - Sample 5: XQuery running in compiled mode
    Shows how to run XQuery functions in compiled mode
  - Sample 6: XQuery running in pre-compiled mode
    Shows how to invoke XQuery in pre-compiled mode
  - Sample 7: XQuery operations on types (typeswitch, cast as)
    Shows how to use operations on types
  - Sample 8: XQuery schema awareness - input validation (valid)
    Shows how to validate the input document passed to the query
  - Sample 9: XQuery schema awareness - input validation (invalid)
    Shows how to validate the input document passed to the query
  - Sample 10: XQuery schema awareness - node validation (valid)
    Shows how to validate an element using the validate expression
  - Sample 11: XQuery schema awareness - node validation (invalid)
    Shows how to validate an element using the validate expression
  - Sample 12: XQuery schema awareness - element(*, T) function
    Shows how to use schema awareness to match on element types instead of names

• The Blog Comment Checker examples show how you can search all or your Blogger™ web publishing service blogs for questionable comments. They are examples of high-level applications that use XPath 2.0, XSLT 2.0, and XQuery 1.0.
  – XPath Blog Checker
  – XSLT Blog Checker
  – XQuery Blog Checker
  – Database Integration Checker

## Using the XML API to perform operations

You can use the IBM XML Application Programming Interface (API) to perform operations that use the new and updated W3C XML standards.

### Before you begin

**Limitations of the processor:**

- When using the namespace axis, only the namespaces declared on the current node are accessible through the namespace axis (rather than all of the namespaces that are in scope for the current node) if the input document supplied is a StreamSource, SAXSource, or StAXSource.
- When evaluating some string functions and operations, the processor might not handle Unicode characters with code points above #xFFFF correctly; it might incorrectly treat the surrogate pair in the UTF-16 encoding of the character as two separate characters.

### Procedure

- Perform basic operations.
- Precompile.
- Use resolvers.
- Use external variables and functions.
- Create items and sequences.
- Work with collations.
- Execute using the command-line tools.
- Use a message handler and manage exceptions.

## Building and running a sample XML application

You can use the IBM WebSphere Application Server XML thin client, the `com.ibm.xml.thinclient_8.0.0.jar` file, to build a sample XML application. You can also use the API documentation to improve your understanding of the XML API.

### Before you begin

1. Install the product.
2. Locate the `com.ibm.xml.thinclient_8.0.0.jar` file.

   You can find the `com.ibm.xml.thinclient_8.0.0.jar` file in your installation tree; for example:

   - Windows *app_server_root*`\runtimes\com.ibm.xml.thinclient_8.0.0.jar`
   - AIX HP-UX Linux Solaris *app_server_root*`/runtimes/com.ibm.xml.thinclient_8.0.0.jar`

To see how to build and use an application, refer to the sample application that is packaged with the product.

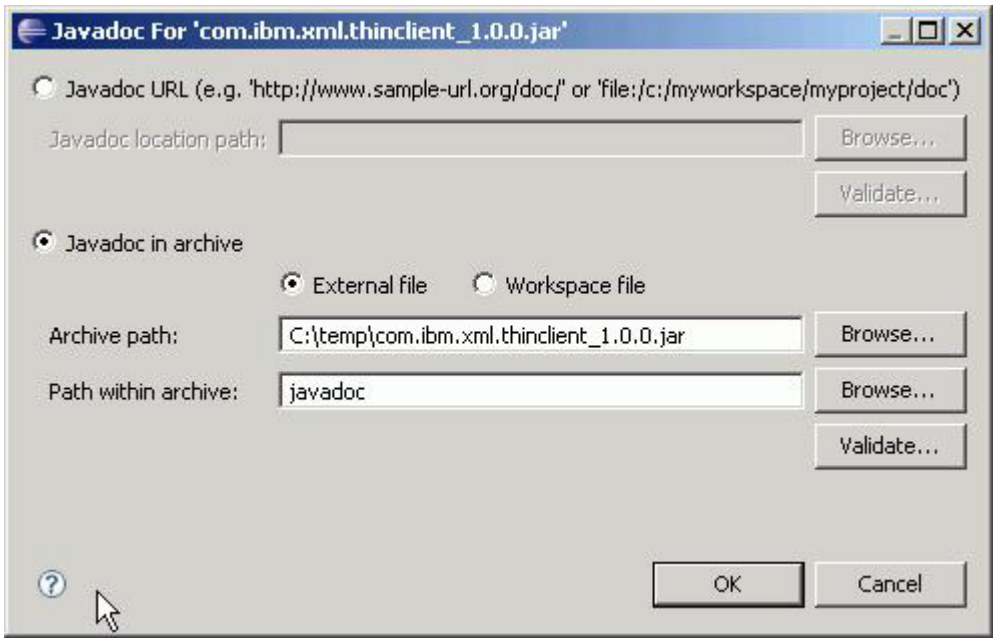
### About this task

Follow this procedure when you build and run a sample XML application.

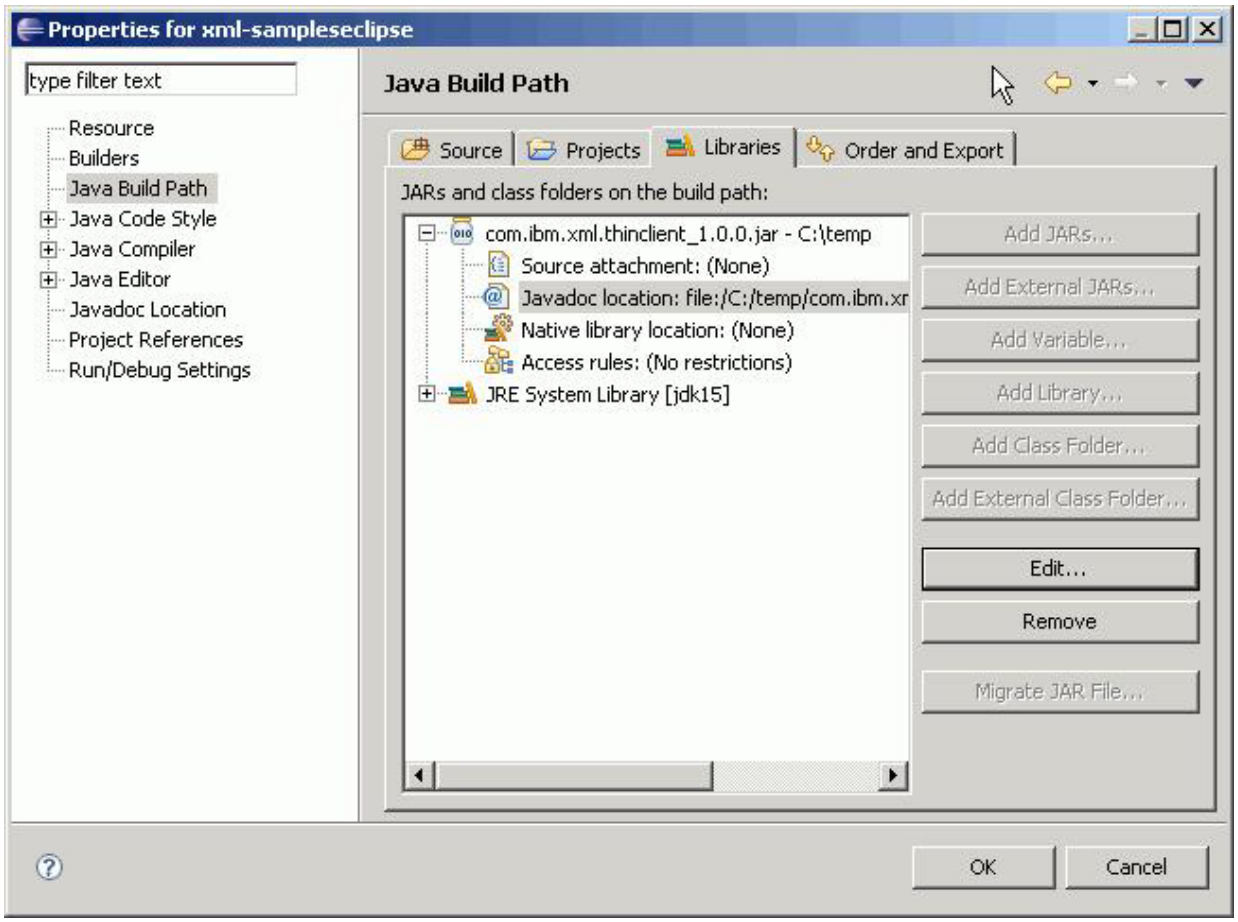
### Procedure

1. For build time, include the `com.ibm.xml.thinclient_8.0.0.jar` file in the build-time class path while developing your sample XML application.

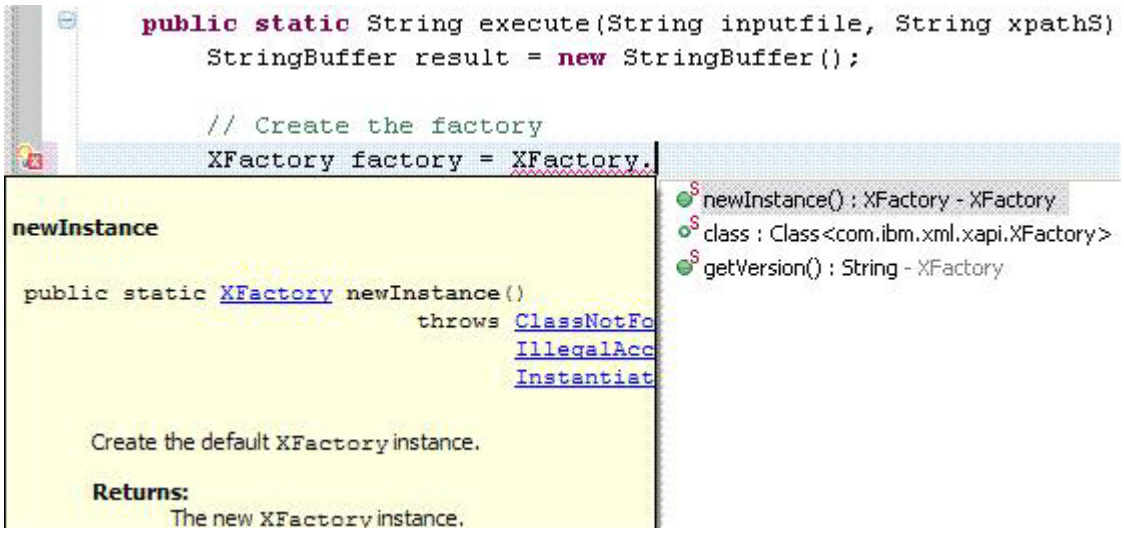
Also, attach the API documentation from the `javadoc` directory that is inside the `com.ibm.xml.thinclient_8.0.0.jar` file.



The results of these actions are shown in the following image:



When complete, your application should compile; and when using context completion, you should have access to the API documentation as shown here:



2. Deploy your application.

## Running the IBM Thin Client for XML

The IBM Thin Client for XML with WebSphere Application Server allows applications to take advantage of IBM XML technology components in a simple Java environment. Such applications can directly access the XML API to process XPath, XQuery, and XSL in a Java SE runtime environment. You can bundle the Thin Client for XML library with your application by using the WebSphere Application Server installation. The Thin Client for XML also extends the choice of Java SE runtime environment. It can be run in IBM Java Runtime Environments (JREs) packaged with WebSphere Application Server as well as in the Windows and Linux JREs from Sun Microsystems., the Sun Microsystems JREs that are downloaded from the Sun Microsystems website, or the JRE that is downloaded from the HP website.

### Before you begin

Before you can use the API provided by the Thin Client for XML you must obtain the Thin Client for XML Java archive (JAR) file. This can be accomplished by installing WebSphere Application Server. The Thin Client for XML JAR file, `com.ibm.xml.thinclient_8.0.0.jar`, is located in the *app_server_root*`\runtimes` directory.

Copy the JAR file, `com.ibm.xml.thinclient_8.0.0.jar`, to other machines to enable access to the XML API. Copies of the Thin Client for XML are subject to the terms and conditions of the license agreement for the WebSphere Application Server Version 8.0 product from which you obtained the Thin Client for XML. Refer to the license agreements for correct usage and other limitations.

The Thin Client for XML with WebSphere Application Server runs on distributed operating systems with Java SE Development Kit (JDK) support, including Version 1.5 and Version 1.6.

### About this task

Run the Thin Client for XML by completing this procedure.

### Procedure

Invoke the client application.
Run the following Java command:

Windows

```
java_install_root\bin\java
-classpath com.ibm.xml.thinclient_8.0.0.jar;list_of_your_application_jars_and_classes
fully_qualified_class_name_to_run
```

AIX HP-UX Solaris Linux

```
java_install_root/bin/java
-classpath com.ibm.xml.thinclient_8.0.0.jar:list_of_your_application_jars_and_classes
fully_qualified_class_name_to_run
```

# Performing basic operations

You can use this information to help you to perform basic XPath, XSLT, and XQuery operations.

## Procedure

- Perform basic XPath operations.
- Perform basic XSLT operations.
- Perform basic XQuery operations.
- View the results.
- Serialize the results.
- Navigate with XSequenceCursor.
- Navigate with XTreeCursor.

## Overview of the XML API

The product provides the IBM XML Application Programming Interface in support of the XML standards. This application programming interface invokes a runtime engine that is capable of executing XPath 2.0, XSLT 2.0, and XQuery 1.0 as well as manipulating the returned XML data.

***Supported input and result types:***

The API supports standard implementations of Java API for XML Processing (JAXP) input and result types.

The following standard implementations of the JAXP Source interface are supported as the input to the execute methods of an executable object (XPathExecutable, XQueryExecutable, and XSLTExecutable) as well as to other methods that take a Source object such as XItemFactory.item(Source), XDynamicContext.bind(QName, Source), and so on. They are also accepted for the stylesheet parameter to the XFactory.prepareXSLT methods. These classes are all included in the 1.6 version of the JRE. Refer to the Java API documentation for more information.

- javax.xml.transform.stream.StreamSource
- javax.xml.transform.dom.DOMSource
- javax.xml.transform.sax.SAXSource
- javax.xml.transform.stax.StAXSource

The XSourceResolver.getSource method can return any of the above implementations of source as well as a further implementation, XItemSource, provided by the API. This allows results from a previous query or transformation to be used as input to a new query or transformation without first serializing to a DOM or stream. The XItemSource can simply be initialized with the XItemView instance and returned by the XSourceResolver implementation.

The following standard implementations of the JAXP Result interface are supported for those execute methods that take a result as well as other methods that take a result object such as the export methods on XItemView and XSequenceCursor. These classes are included in the 1.6 version of the JRE. Refer to the Java API documentation for more information.

- javax.xml.transform.stream.StreamResult
- javax.xml.transform.dom.DOMResult

- javax.xml.transform.sax.SAXResult
- javax.xml.transform.stax.StAXResult

A further implementation of the Result interface, XSequenceCursorResult, is provided by the API to allow a result to be returned as an XSequenceCursor. The execute methods on the executable objects that do not take a result object return the result as an XSequenceCursor already; therefore, this is primarily for use with XSLT multiple result documents. An implementation of XResultResolver can return an XSequenceCursorResult to the processor and the processor will populate the XSequenceCursorResult with the XSequenceCursor and the associated output parameters during processing. After the transformation is complete the XSequenceCursor can be retrieved by the application by calling the getSequenceCursor method on the XSequenceCursorResult object. The output parameters can be retrieved by calling the getOutputParameters method. The output parameters then can be used on a call to the XSequenceCursor exportSequence method.

***The XFactory class:***

This is a quick overview of the methods that the XFactory class provides. The individual methods are discussed in detail in other articles in the information center.

The XFactory class is the main factory class for creating executables for XPath, XQuery, and XSLT. It is also the means for creating instances of other classes and factories such as the XStaticContext, XDynamicContext, XItemFactory, and XSequenceTypeFactory classes. An instance of XFactory maintains a set of registered schemas as well and can be validating or non-validating. A validating factory produces schema-aware executables and ensures that source documents get validated against the set of registered schemas before they are processed. If different sets of stylesheets or expressions need different sets of schemas, these can be kept separate by using more than one XFactory instance. An XFactory instance can be created by calling the static newInstance() method on the XFactory class. The instance is thread safe as long as the settings remain stable.

Here is an example of using the XFactory class.

```
// Create a new XFactory
XFactory factory = XFactory.newInstance();

// Create an XPath executable
XPathExecutable executable = factory.prepareXPath("/something/bar[2]");

// Create a new XStaticContext
XStaticContext staticContext = factory.newStaticContext();

// Create an XPath executable that is compiled in backwards
// compatibility mode
staticContext.setXPathCompatibilityMode(XStaticContext.XPATH1_0_BC_COMPATIBILITY);
XPathExecutable bcExecutable = factory.prepareXPath("/something/bar[2]", staticContext);

// Set validating
factory.setValidating(true);

// Register a schema
factory.registerSchema(new StreamSource("myschema.xsd"));

// Create a schema aware XPath executable
staticContext = factory.newStaticContext();
staticContext.declareNamespace("something", "http://myschema/something");
XPathExecutable schemaExecutable =
   factory.prepareXPath("/something:something/bar[2] instance of element(bar, something:barType)", staticContext);

// Get the item factory for this XFactory (the two are related
// since the item factory depends on the schemas that are
// registered with XFactory).
XItemFactory itemFactory = factory.getItemFactory();
```

***Relationship of the processor to the Java API for XML Processing (JAXP):***

In most cases, you will need to migrate any of your applications that used the Java API for XML Processing (JAXP) to use the current API.

The XSLT and XPath processing portions of JAXP are defined with reference to XSLT 1.0 and XPath 1.0. JAXP does not have provisions for XSLT 2.0 and XPath 2.0 processing. In particular, there are situations in which an XSLT 2.0 or an XPath 2.0 processor must produce a result that is different from that produced by an XSLT 1.0 or an XPath 1.0 processor given identical input and an identical stylesheet or expression. Therefore, it is not possible to instantiate the current processor using JAXP.

JAXP also does not have support for sequences, XQuery 1.0, or the many current data types that are available in XSLT 2.0, XPath 2.0, and XQuery 1.0. JAXP also is limited in the forms that input and output can take. All these things make it a poor fit for processing XSLT 2.0 stylesheets as well as XPath 2.0 and XQuery 1.0 expressions.

The following examples demonstrate common migration scenarios and how to write code using the current API that is equivalent to code that you might have written using JAXP.

### Processing an XSLT stylesheet using the API

The following example demonstrates how to process an XSLT stylesheet and apply it to some input to produce an instance of the javax.xml.transform.Result interface.

```
XFactory factory = XFactory.newInstance();
XSLTExecutable style = factory.prepareXSLT(new StreamSource("style.xsl"));
style.execute(new StreamSource("input.xml"), new StreamResult(System.out));
```

### Processing an XPath expression using the API

The following example demonstrates how to process an XPath expression and apply it to some input.

```
XFactory factory = XFactory.newInstance();
XPathExecutable pathExpr = factory.prepareXPath("/doc/child[@id='N1378']");

// Process input from a StreamSource
XSequenceCursor result1 = pathExpr.execute(new StreamSource("input.xml"));

// Process input from a DOM node
XSequenceCursor result2 = pathExpr.execute(new DOMSource(node));
```

### Resolving URI references

If you used instances of the JAXP URIResolver interface to resolve references to the XSLT document() function, you can now use the XSourceResolver interface to accomplish the same thing. To resolve references to the document() function or the fn:doc() function, you can set an instance of the XSourceResolver interface on an instance of the XDynamicContext interface; to resolve references to stylesheets imported through xsl:import and xsl:include declarations, you can set an instance of the XSourceResolver interface on an instance of the XStaticContext interface.

The following example shows how you might set up an instance of the XSourceResolver interface that treats input documents as XSLT stylesheets and uses them to generate the input data for reference to the doc or document functions in another XSLT stylesheet.

```
final XFactory factory = XFactory.newInstance();
XSLTExecutable style = factory.prepareXSLT(new StreamSource("style.xsl"));
XDynamicContext dContext = factory.newDynamicContext();

// Create and set an instance of an anonymous inner class as the
// XSourceResolver
dContext.setSourceResolver(new XSourceResolver() {
    // Create an item to use as the initial context node for
    // transformations in the getSource method
    private XItemView fDummyNode =
        factory.getItemFactory()
            .item(new StreamSource(
                new StringReader("<doc/>")));

    // Resolve URIs by loading the resource as an XSLT stylesheet
    // and evaluating it - return the result as the Source to use
    public Source getSource(String href, String base) {
        java.net.URI baseURI;
        try {
            // Get base URI object
            baseURI = new java.net.URI(base);
```

```
        } catch (java.net.URISyntaxException use) {
            throw new RuntimeException(use);
        }
        // Resolved relative reference against base URI
        String resolvedURI = baseURI.resolve(href).toString();

        // Prepare and execute the stylesheet
        XItemView transformResult =
            factory.prepareXSLT(new StreamSource(resolvedURI))
                .execute(fDummyNode);
        return new XItemSource(transformResult);
    }
});

XSequenceCursor result = style.execute(new StreamSource("input.xml"), dContext);
```

### Defining extension functions and external functions

Using JAXP for XPath expression evaluation, you could register an instance of the XPathFunctionResolver interface to supply the implementations of extension functions that your XPath expressions might call. The XSLT portion of JAXP does not have an equivalent mechanism.

With the current API, you can declare extension functions on an instance of the XStaticContext interface, specifying the expected types of the arguments and the expected type of the result of calling the function, and you can register the implementations of extension functions on an instance of the XDynamicContext interface. Your XSLT stylesheet and XPath and XQuery expressions can call any extension functions that you register.

### Setting the values of stylesheet parameters and external variables

Using JAXP, you could supply the initial values of stylesheet parameters by calling the Transformer.setParameter method and you could supply the values of variables for XPath expressions by supplying an instance of the XPathVariableResolver interface. Using the API, you can declare variables using the declareVariable() methods of the XStaticContext interface, specifying a variable name and the expected type of the variable. You can supply the values of stylesheet parameters, XPath variables, and XQuery external variables through one of the bind() methods of the XDynamicContext interface.

The following example shows how you might use a variable in an XPath expression to look up product entries in a catalog based on the product identifier.

```
XFactory factory = XFactory.newInstance();
XStaticContext sContext = factory.newStaticContext();

// Declare the XPath variable "query-id" in the static context
QName queryIdVar = new QName("query-id");
sContext.declareVariable(queryIdVar, XTypeConstants.STRING_QNAME);

// Prepare the XPath expression
XItemFactory itemFactory = factory.getItemFactory();
XPathExecutable expr =
    factory.prepareXPath("/catalog/product[id eq $query-id]", sContext);

XItemView catalog = itemFactory.item(new StreamSource("catalog.xml"));
XDynamicContext dContext = factory.newDynamicContext();

// Set the value of the "query-id" variable, and evaluate the
// expression with that variable value
dContext.bind(queryIdVar, "ID43785");
XSequenceCursor product1 = expr.execute(catalog, dContext);

// Set the value of the "query-id" variable, and evaluate the
// expression with the new variable value
dContext.bind(queryIdVar, "ID18574");
XSequenceCursor product2 = expr.execute(catalog, dContext);
```

### Identity transformation

Another operation that is frequently used in JAXP is the identity transformation. This is a convenient way of transforming data from one form to another—for example, serializing a DOM tree, or producing a DOM tree from SAX events. It is possible to perform identity transformations using the API. See “Performing basic XSLT operations” on page 2204 for an example.

### Prepare-time and execution-time configuration

In JAXP you supply much of the runtime configuration information for XSLT stylesheets – the values of stylesheet parameters, URIResolvers, and so on—directly on the objects that are used to perform transformations – instances of the Transformer interface and the TransformerHandler interface. Similarly, you supply configuration information for the preparation of stylesheets and XPath expressions directly on instances of the TransformerFactory and XPathFactory classes in JAXP.

With the API, you can supply configuration information that is needed at the time a stylesheet or an expression is prepared—namespace bindings, the types of external functions or variables, and so on—using an instance of the XStaticContext interface. Similarly, you can provide any configuration information that is needed to evaluate a stylesheet or expression—the values of variables, settings of output parameters, and so on—on an instance of the XDynamicContext interface, which you can pass as an argument to the execute methods of the XExecutable interface and its subinterfaces.

This separation of the configuration information into a separate object makes the API more thread safe. Your application can use the same instance of the XExecutable interface on different threads without any synchronization. This stands in contrast to JAXP, where instances of the Transformer, TransformerHandler and XPathExpression interfaces are not thread safe; every thread that uses them has to synchronize access to shared instances of those objects or create distinct copies that are specific to each thread.

### Handling errors

In JAXP, you could supply an instance of the ErrorHandler interface to control how the processor should respond to errors. In the API, you can achieve this by supplying an instance of the XMessageHandler interface on an instance of the XStaticContext interface for preparation-time errors or the XDynamicContext interface for execution-time errors.

### *Performance tips:*

Follow these tips to improve performance when using XPath, XQuery, and XSLT.

*Table 347. Performance tips.*

*Follow these tips to improve performance.*

| Language | Tip |
|---|---|
| XPath | Using // can be an expensive operation. Making the path more explicit (a/b/c rather than a//c) can improve performance. This is especially important when the path starts at or near the root of a large document. |
| | The last() function, because it requires fully evaluating the sequence to count the items, can be an expensive operation. |
| | Positional predicates with constant values, such as [3], are usually more efficient than those with values that are computed or that are retrieved from variables. |
| XQuery | Consider calling the registerImportedSchemas method on the XQueryExecutable instance if the query imports one or more schemas and the same query will be executed more than once. If registerImportedSchemas is not called, the imported schemas will be loaded every time one of the execute methods is called. By default, imported schemas can only be used to validate result trees; but calling this method has the same effect as registering the schemas with the XFactory, which means that they will be used to validate input documents. |

*Table 347. Performance tips (continued).*

*Follow these tips to improve performance.*

| Language | Tip |
|---|---|
| XSLT | Parameters are slower to access than variables. If you do not need to supply the value of the parameter externally, use a variable. |
| | Using xsl:key elements and the key() function can be an efficient way to retrieve node sets. |
| | Pattern matching and apply-templates dispatch are usually faster than the xsl:if or xsl:when statements. |
| | Positional predicates in match patterns are usually expensive. |
| | In general, simpler match patterns such as "address" are less expensive to process than complicated ones such as "/purchaseorder/shipping/customer/postal/address". Take advantage of your knowledge of the document's structure and your stylesheet's behavior to avoid unnecessarily overspecifying. |
| | For some data models, the xsl:skip-space operation must be applied during document navigation rather than during document load. This can add some execution-time overhead. |
| | Consider calling the registerImportedSchemas method on the XSLTExecutable instance if the stylesheet imports one or more schemas and the same stylesheet will be executed more than once. If registerImportedSchemas is not called, the imported schemas will be loaded every time one of the execute methods is called. By default, imported schemas can only be used to validate result trees; but calling this method has the same effect as registering the schemas with the XFactory, which means that they will be used to validate input documents. |
| XPath, XQuery, and XSLT | Decoding and encoding is expensive. Generally, UTF-8 and UTF-16 can be read and written more quickly than other encodings. |

## *XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-specific behaviors:*

*Table 348. Implementation-defined behaviors.*

*This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.*

| Feature | Description | Specification | Error Code | Documented Behavior |
|---|---|---|---|---|
| multi preserve-strip-space matched | It is a recoverable dynamic error if an element in the source document matches both an xsl:strip-space and an xsl:preserve-space declaration. | XSLT 2.0<br><br>Section 4.4 | XTRE0270 | The processor does not raise an error and recovers by selecting the xsl:strip-space or xsl:preserve-space declaration that occurs last in declaration order. |
| pattern evaluation | Any dynamic error or type error that occurs during the evaluation of a pattern against a particular node is treated as a recoverable error even if the error would not be recoverable under other circumstances. The optional recovery action is to treat the pattern as not matching that node. | XSLT 2.0<br><br>Section 5.5.4 | | The processor does not raise an error and recovers by treating the pattern as not matching that node. |
| multiple templates matched | It is a recoverable dynamic error if the conflict resolution algorithm for template rules leaves more than one matching template rule. The optional recovery action is to select, from the matching template rules that are left, the one that occurs last in declaration order. | XSLT 2.0<br><br>Section 6.4 | XTRE0540 | The processor does not raise an error and recovers by selecting the template that occurs last in declaration order. |

*Table 348. Implementation-defined behaviors (continued).*

*This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.*

| Feature | Description | Specification | Error Code | Documented Behavior |
|---|---|---|---|---|
| invalid value-xml space | It is a recoverable dynamic error if the name of a constructed attribute is xml:space and the value is not either default or preserve. The optional recovery action is to construct the attribute with the value as requested. This applies whether the attribute is constructed using a literal result element or by using the xsl:attribute, xsl:copy, or xsl:copy-of instructions. | XSLT 2.0<br><br>Section 11.1.2 | XTRE0795 | The processor does not raise an error and constructs the attribute with the value as requested. |
| invalid fragment in document uri | When a URI reference supplied to the document function contains a fragment identifier, it is a recoverable dynamic error if one of the following is true:<br>• the media type is not one that is recognized by the processor<br>• the fragment identifier does not conform to the rules for fragment identifiers for that media type<br>• if the fragment identifier selects something other than a sequence of nodes (if it selects a range of characters within a text node, for example)<br><br>The optional recovery action is to ignore the fragment identifier and return the document node. (Note that the recovery option is different from that in XSLT 1.0) | XSLT 2.0<br><br>Section 16.1 | XTRE1160 | The processor ignores the fragment identifier and returns the document node. No warning is raised. |
| same resource for multiple results | It is a recoverable dynamic error for a transformation to generate two or more final result trees with URIs that identify the same physical resource. The optional recovery action is implementation-dependent because it may be impossible for the processor to detect the error. | XSLT 2.0<br><br>Section 19.1 | XTRE1495 | The processor raises an error. |
| read and write to same resource | It is a recoverable dynamic error for a stylesheet to write to an external resource and read from the same resource during a single transformation, whether or not the same URI is used to access the resource in both cases. The optional recovery action is implementation-dependent; implementations are not required to detect the error condition. | XSLT 2.0<br><br>Section 19.1 | XTRE1500 | The processor does not attempt to detect this error condition. |
| disable output escaping not supported | It is a recoverable dynamic error if an xsl:value-of or xsl:text instruction specifies that output escaping is to be disabled and the implementation does not support this. The optional recovery action is to ignore the disable-output-escaping attribute. | XSLT 2.0<br><br>Section 20.2 | XTRE1620 | The processor does not provide the ability to disable output escaping and ignores the disable-output-escaping attribute without warning. |

*Table 348. Implementation-defined behaviors (continued).*

*This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.*

| Feature | Description | Specification | Error Code | Documented Behavior |
|---|---|---|---|---|
| disable output escaping for not serialized | It is a recoverable dynamic error if an xsl:value-of or xsl:text instruction specifies that output escaping is to be disabled when writing to a final result tree that is not being serialized. The optional recovery action is to ignore the disable-output-escaping attribute. | XSLT 2.0<br><br>Section 20.2 | XTRE1630 | The processor does not provide the ability to disable output escaping and ignores the disable-output-escaping attribute without warning. |
| integer overflow | On overflow and underflow situations during xs:integer arithmetic operations, implementations that support limited-precision integer operations must select from the following options:<br>• Always raising an error (FOAR0002)<br>• Providing an implementation-defined mechanism that allows users to choose between raising an error and returning a result that is modulo the largest representable integer value | XQuery 1.0 and XPath 2.0 Functions and Operators<br><br>Section 6.2 | FOAR0002 | The processor provides a mechanism to enable overflow detection for integer operations through the `com.ibm.xml.xapi.XStaticContext.setIntegerMathMode(int)` method, which can be called with the constants `INTEGER_MATH_MODE_OVERFLOW_DETECTION` or `INTEGER_MATH_MODE_LIMITED_PRECISION` (defined on the XStaticContext interface) to choose between the two options. A third option, `INTEGER_MATH_MODE_ARBITRARY_PRECISION`, is provided to allow arbitrary precision integers. |
| double float overflow | For xs:float and xs:double arithmetic operations, overflow behavior must conform to IEEE 754-1985, which allows the following options:<br>• Raising an error (FOAR0002) using an overflow trap<br>• Returning INF or -INF<br>• Returning the largest (positive or negative) non-infinite number | XQuery 1.0 and XPath 2.0 Functions and Operators<br><br>Section 6.2 | | The processor returns INF or -INF. |
| double float underflow | For xs:float and xs:double arithmetic operations, underflow behavior must conform to IEEE 754-1985, which allows the following options:<br>• Raising an error (FOAR0002) using an underflow trap<br>• Returning INF or -INF<br>• Returning 0.0E0, +/- 2**Emin, or a denormalized value where Emin is the smallest possible xs:float or xs:double exponent | XQuery 1.0 and XPath 2.0 Functions and Operators<br><br>Section 6.2 | | The processor returns 0.0E0. |
| invalid use of doctype-system or standalone attr | It is a serialization error to specify the doctype-system parameter or to specify the standalone parameter with a value other than omit if the instance of the data model contains text nodes or multiple element nodes as children of the root node. The serializer must either signal the error or recover by ignoring the request to output a document type declaration or standalone parameter. | SR<br><br>Section 5 | SEPM0004 | The processor raises a serialization error. |

*Table 348. Implementation-defined behaviors (continued).*

*This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.*

| Feature | Description | Specification | Error Code | Documented Behavior |
|---|---|---|---|---|
| invalid xml output encoding | A serialization error occurs if the output method is XML and an output encoding other than UTF-8 or UTF-16 is requested and the serializer does not support that encoding. The serializer must raise the error (SESU0007) or recover by using UTF-8 or UTF-16 instead. | SR<br><br>Section 5.1.2 | SESU0007 | The processor raises a serialization error. |
| error or recovery | Some dynamic errors are classed as recoverable errors. When a recoverable error occurs, the processor may signal the error (by reporting the error condition and terminating execution) or take a defined recovery action and continue processing. | XSLT 2.0<br><br>Section 2.9 | | The processor recovers from many of the recoverable errors but signals an error in some cases. Consult this table to determine the implementation-defined behavior of each type of recoverable error. |
| signal type errors statically | Whether or not type errors are signaled statically is implementation defined. | XSLT 2.0<br><br>Section 2.9 | | The processor detects type errors statically whenever possible; but there are cases where the error cannot be detected at compile time. In these cases, the error is detected at run time. |
| handling serialization errors | The handling of serialization errors is implementation defined. | XSLT 2.0<br><br>Section 20 | | Error messages are sent to a `com.ibm.xml.xapi.XMessageHandler` implementation that has been registered using the `setXMessageHandler` method on the `com.ibm.xml.xapi.XDynamicContext` interface. |
| base output URI | The way in which a base output URI is established is implementation defined. | XSLT 2.0<br><br>Section 2.3⌂ | | Users can set the base output URI using the `setBaseOutputURI` method on the `com.ibm.xml.xapi.XDynamicContext` interface. |
| extension attributes | Implementations may allow extension attributes to modify the behavior of extension functions and extension instructions or to influence the behavior of the serialization methods xml, xhtml, html, or text to the extent that the behavior of the serialization method is implementation defined or implementation-dependent. | XSLT 2.0<br><br>Section 3.3 | | The processor recognizes the indent-amount attribute on xsl:output declarations to specify how many spaces are used for each indentation level when indentation is enabled. The attribute must be from one of the following namespaces:<br>• http://www.ibm.com/xmlns/prod/xltxe-j<br>• http://xml.apache.org/xalan<br>• http://xml.apache.org/xslt<br>See also the additional serialization params item in this table. |
| user-defined data elements | An implementation may attach an implementation-defined meaning to user-defined data elements that appear in particular namespaces. The set of namespaces that are recognized for such data elements is implementation defined. | XSLT 2.0<br><br>Section 3.6.2 | | The processor does not recognize any user-defined data elements. |
| user-defined types | Support for additional user-defined or implementation-defined types is implementation defined. | XPath 2.0 Data Model<br><br>Section 2.6 | | A schema-aware processor is supported. |
| undefined type behavior | Some typed values in the data model are undefined. Attempting to access an undefined property is always an error. Behavior in these cases is implementation defined and the host language is responsible for determining the result. | XPath 2.0 Data Model<br><br>Section 2.5.2, Bullet 4.d | FOTY0012 | The processor raises an error. Error messages are sent to a `com.ibm.xml.xapi.XMessageHandler` implementation that has been registered using the `setXMessageHandler` method on the `com.ibm.xml.xapi.XDynamicContext` interface. |
| namespace node representation | Representation of namespaces, that is whether or not they are represented as nodes, is implementation dependent. | XPath 2.0 Data Model<br><br>Section 6.4 | | The namespace axis is supported. |

*Table 348. Implementation-defined behaviors (continued).*

*This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.*

| Feature | Description | Specification | Error Code | Documented Behavior |
|---|---|---|---|---|
| locate stylesheet module | After resolving against the base URI, the way in which the URI reference from the href attribute of an xsl:include or xsl:import declaration is used to locate a representation of a stylesheet module and the way in which the stylesheet module is constructed from that representation are implementation defined. In particular, which URI schemes are supported, whether fragment identifiers are supported, and what media types are supported are implementation defined. | XSLT 2.0<br><br>Section 3.10.1 | | Users may provide an `com.ibm.xml.xapi.XSourceResolver` implementation through the `com.ibm.xml.xapi.XStaticContext.setSourceResolver(XSourceResolver)` method. The `XSourceResolver` is used by the processor to resolve URIs from xsl:include and xsl:import declarations (therefore, the user may decide which URIs to support), and its `getSource(String, String)` method must return a JAXP Source object.<br><br>If no `XSourceResolver` is given, the processor handles the file URI scheme and those supported by the `java.net.URL.openConnection()` method. A URI fragment may be used to select an embedded stylesheet module within a source XML document. The fragment must identify an xsl:stylesheet element in the document by using the value of one of its attributes that is an xml:id attribute or is defined in a DTD as being of type ID or is defined in a schema as being of type xs:ID. There is no built-in support for non-XML media types, but users may use an `XSourceResolver` implementation to provide the processor with an XML representation of non-XML data. |
| extension functions | Extension functions<br><br>The XSLT 2.0 specification defines how extension instructions and extension functions are invoked, but the facilities for creating new extension instructions and extension functions are implementation defined. | XSLT 2.0<br><br>Section 18.1 | | Extension functions are supported through the processor's `XStaticContext.declareFunction` and `XDynamicContext.bindFunction` methods. Alternatively, it is also possible to declare extension functions directly within a stylesheet or query. The old style of extension functions supported in the parser and the processor are also supported for backwards compatibility; however, only 1.0 types are supported with the old style. See the API documentation for more information. It is recommended that you declare extension functions directly in your stylesheet or through the API for extension functions whenever possible rather than use the old style. |
| extension instructions | Extension instructions<br><br>The XSLT 2.0 specification defines how extension instructions and extension functions are invoked, but the facilities for creating new extension instructions and extension functions are implementation defined. | XSLT 2.0<br><br>Section 18.2 | XTDE1450 | User-defined extension instructions are not supported. Extension instructions must be protected with a fallback instruction; otherwise, the stylesheet will fail to compile. The redirect extension is supported for backwards compatibility; however, it is recommended that you use the XSLT 2.0 xsl:result-document instruction because this is more portable. |
| backwards-compatiblility | Whether a particular XSLT 2.0 implementation supports backwards-compatible behavior is implementation defined. | XSLT 2.0<br><br>Section 3.8 | | The backwards-compatibility feature as described in the XSLT 2.0 specification is supported. |
| in-scope collations for use-when | In-scope collations for use-when expressions | XSLT 2.0<br><br>Section 3.12 | | The only collation available during the evaluation of a use-when is the Unicode code-point collation. |
| current date time for use-when | Current date and time for use-when expressions | XSLT 2.0<br><br>Section 3.12 | | The current date time is the current date time of the system as retrieved by calling the `java.util.GregorianCalendar getInstance()` method. |
| implicit timezone for use-when | Implicit time zone for use-when expressions | XSLT 2.0<br><br>Section 3.12 | | The implicit time zone is the time zone of the system as retrieved by calling the `java.util.TimeZone getDefault()` method. |
| maximum number of decimal digits | Maximum number of total digits in decimal digits is implementation defined , but they must be at least 18 digits. | XSLT 2.0<br><br>Section 4.6 | | The implementation uses the `java.math.BigDecimal` class, which supports nearly unlimited precision, except that the number of digits to the right of the decimal place is limited to Integer.MAX_VALUE. Truncation is only required in the case of division, where there is the possibility of non-terminating decimals. The precision of the fractional part of the result is limited to 18 digits. The rounding mode in this case is ROUND_HALF_UP, where discarded fractions of 0.5 or higher are rounded up (away from zero) and lesser fractions are rounded down. |
| year component values | For the xs:date, xs:time, xs:dateTime, xs:gYear, and xs:gYearMonth types: the range of values of the year component (which must be at least +0001 to +9999), and the maximum number of fractional second digits (which must be at least 3) | XSLT 2.0<br><br>Section 4.6 | | The year component of the xs:date, xs:dateTime, xs:gYear, and xs:gYearMonth types has the range -(10^9-1) to (10^9)-1. The maximum number of fractional seconds digits supported for the xs:time and xs:dateTime types is three. |

*Table 348. Implementation-defined behaviors (continued).*

*This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.*

| Feature | Description | Specification | Error Code | Documented Behavior |
|---|---|---|---|---|
| duration | For the xs:duration type: the maximum absolute values of the years, months, days, hours, minutes, and seconds components | XSLT 2.0<br><br>Section 4.6 | | The maximum absolute values for the duration components are:<br>• year: 178956970<br>• month: 2147483647<br>• day: 106751991167<br>• hour: 2562047788015<br>• minute: 153722867280912<br>• second: 9223372036854775<br><br>Three digits of precision are supported for milliseconds. |
| year month duration | For the xdt:yearMonthDuration type: the maximum absolute value expressed as an integer number of months | XSLT 2.0<br><br>Section 4.6 | | The maximum absolute value for the xs:yearMonthDuration type is 2147483647 months. |
| day time duration | For the xdt:dayTimeDuration type: the maximum absolute value expressed as a decimal number of seconds | XSLT 2.0<br><br>Section 4.6 | | The maximum absolute value for the xs:dayTimeDuration type is 9223372036854775 seconds. |
| value maximum length | For the xs:string, xs:hexBinary, xs:base64Binary, xs:QName, xs:anyURI, xs:NOTATION types and types derived from them: the maximum length of the value | XSLT 2.0<br><br>Section 4.6 | | The theoretical maximum length is 2^31 - 1; however, the system is likely to run out of memory long before that limit is reached. |
| sequence length | Maximum number of items in a sequence | XSLT 2.0<br><br>Section 4.6 | | The theoretical maximum number of items is 2^31 - 1; however, the system is likely to run out of memory long before that limit is reached. |
| statically known collations | Set of in-scope collations | XSLT 2.0<br><br>Section 5.4.1<br><br>XPath 2.0<br><br>Section 2.1.1<br><br>XQuery 1.0<br><br>Section 2.1.1 | | Any URI is considered to be in the set of in-scope collations. Every URI that is used as a collation URI must be associated with a Java Collator at execution time. |
| implicit timezone | Implicit time zone | XSLT 2.0<br><br>Section 5.4.3.2<br><br>XPath 2.0<br><br>Section 2.1.2<br><br>XQuery 1.0<br><br>Section 2.1.2 | | The implicit time zone can be set using the `XDynamicContext.setImplicitTimeZone(Duration)` method in the processor. If the implicit time zone is not set, the system time zone is used as retrieved through the `java.util.TimeZone.getDefault()` method. |
| default collection | Default collection<br><br>This is the sequence of nodes that would result from calling the fn:collection function with no arguments. The value of the default collection may be initialized by the implementation. | XSLT 2.0<br><br>XPath 2.0<br><br>Section 2.1.2 | FODC0004 | The default collection is determined by the XCollectionResolver registered with the XDynamicContext. If no XCollectionResolver is registered an error is raised and the empty sequence is used. For more information about the XCollectionResolver interface, refer to the API documentation. |
| stylesheet parameter | Supply stylesheet parameter value when executing a transformation<br><br>A top-level xsl:param element declares a stylesheet parameter. A stylesheet parameter is a global variable with the additional property that its value can be supplied by the caller when a transformation is initiated. | XSLT 2.0<br><br>Section 9.5 | | If a value for a parameter is bound in the XDynamicContext, that value is used; otherwise, the default value specified in the stylesheet for the parameter is used.<br><br>To bind values to parameters, use the `XDynamicContext.bind()` methods. |

*Table 348. Implementation-defined behaviors (continued).*

*This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.*

| Feature | Description | Specification | Error Code | Documented Behavior |
|---|---|---|---|---|
| stylesheet function override mechanism | Override a stylesheet function to a function provided by the implementer; pertains to the xsl:function element<br><br>The optional override attribute defines what happens if this function has the same name and arity as a function provided by the implementer or made available in the static context using an implementation-defined mechanism. If the override attribute has the value yes, this function is used in preference; if it has the value no, the other function is used in preference. The default value is yes. Specifying override="yes" ensures interoperable behavior—the same code will execute with all processors. Specifying override="no" is useful when writing a fallback implementation of a function that is available with some processors but not others—it allows the vendor's implementation of the function (or a user's implementation written as an extension function) to be used in preference to the stylesheet implementation. | XSLT 2.0<br><br>Section 10.3 | | If the override attribute had the value of yes, stylesheet functions can override the following:<br>• extension functions declared in the `XStaticContext` using the `XStaticContext.declareFunction()` methods and bound in the `XDynamicContext` using the `XDynamicContext.bindFunction()` methods<br>• old style extension functions supported in XSLT4J and XL TXE-J 1.0<br>See Using extension functions.<br>• EXSLT extension functions implemented by the processor<br><br>Stylesheet functions cannot be made to override any of the core functions defined in the XSLT 2.0 specification or the XQuery 1.0 and XPath 2.0 Functions and Operators specification. |
| normalize copied xml id | When an xml:id attribute is copied using either the xsl:copy or xsl:copy-of instruction, it is implementation defined whether the value of the attribute is subjected to attribute value normalization—that is, effectively applying the normalize-space XQuery 1.0 and XPath 2.0 Functions and Operators function. | XSLT 2.0<br><br>Section 11.9 | | Neither the xsl:copy and xsl:copy-of instructions apply the normalize-space function on xml:id attributes; so all white spaces are preserved. |
| numbering sequences supported | Numbering sequences supported<br><br>Which numbering sequences, additional to those listed above, are supported is implementation defined. If an implementation does not support a numbering sequence represented by the given token, it must use a format token of 1. | XSLT 2.0<br><br>Section 12.3 | | The processor only supports the standard sets of numbering sequences. |
| bounds on range of numbers | Lower and upper bounds on the range of numbers<br><br>For the standard numbering sequences, any upper bound imposed by the implementation must not be less than 1000 (one thousand) and any lower bound must not be greater than 1. Numbers that fall outside this range must be formatted using the format token 1. The numbering sequence associated with the format token 1 has a lower bound of 0 (zero). | XSLT 2.0<br><br>Section 12.3 | | • Alphabet values: arbitrary precision when in integer arbitrary precision mode, otherwise 0 to 2^63 - 1<br>• Digit values: arbitrary precision when in integer arbitrary precision mode, otherwise 0 to 2^63 - 1<br>• Roman values: 0 - 9999<br>• Word number: 0 - 19999 |

*Table 348. Implementation-defined behaviors (continued).*

*This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.*

| Feature | Description | Specification | Error Code | Documented Behavior |
|---|---|---|---|---|
| default language for numbering | Default language for numbering<br><br>The lang attribute specifies which language's conventions are to be used; it has the same range of values as xml:lang (see the XML 1.0 specification). If no lang value is specified, the language that is used is implementation defined.<br><br>The set of languages for which numbering is supported is implementation defined. If a language is requested that is not supported, the processor uses the language that it would use if the lang attribute were omitted. | XSLT 2.0<br><br>Section 12.3 | | The default language for number formatting is always set to en-US. |
| languages for numbering | Set of languages for numbering<br><br>Many numbering sequences are language sensitive. | XSLT 2.0<br><br>Section 12.3 | | The languages supported are based on International Component Unicode (ICU) and languages supported by the JVM. |
| combinations for numbering | Combinations of values of the format token, the language, and the ordinal attribute for numbering | XSLT 2.0<br><br>Section 12.3 | | The processor only supports the ordinal value of yes. Any other values for the ordinal attribute are ignored as if the ordinal attribute was not specified. |
| data-type for sort | Effect of the data-type attribute for xsl:sort<br><br>If this has the effective value text, the atomized sort key values are converted to strings before being compared. If it has the effective value number, the atomized sort key values are converted to doubles before being compared. The conversion is done by using the string-FO or number-FO function as appropriate. If the data-type attribute has any other effective value, the value must be a lexical QName with a non-empty prefix and the effect of the attribute is implementation defined. | XSLT 2.0<br><br>Section 13.1.2 | | The supported values for the data-type attribute are 'text' and 'number'. For any other valid values, a warning message is issued and the data-type attribute is ignored. |
| collation uri | Manner in which the URI is associated with an actual collation rule or algorithm<br><br>The lang and case-order attributes are ignored if a collation attribute is present. But in the absence of a collation attribute, these attributes provide input to an implementation-defined algorithm to locate a suitable collation.<br><br>Facilities in XSLT 2.0 and XPath 2.0 that require strings to be ordered rely on the concept of a named collation. A collation is a set of rules that determine whether two strings are equal and, if not, which of them is to be sorted before the other. A collation is identified by a URI, but the manner in which this URI is associated with an actual rule or algorithm is implementation defined | XSLT 2.0<br><br>Section 13.1.3 | | Collation URIs are associated with a Java Collator through the API using one of the `XDynamicContext.bindCollation` methods. |

*Table 348. Implementation-defined behaviors (continued).*

*This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.*

| Feature | Description | Specification | Error Code | Documented Behavior |
|---|---|---|---|---|
| lang case-order determine collation | Which lang and case-order attributes determine a collation algorithm for sort | XSLT 2.0<br><br>Section 13.1.3 | | The processor retrieves a locale based on the value of the lang attribute. It then creates a Java collator using the `java.text.Collator.getInstance(Locale)` method. The compare method of the collator is overridden to handle the case-order attribute if specified. If the lang attribute was not specified, the processor proceeds as above using the default locale returned by the Java method `Locale.getDefault()`. |
| default collation for sort | Default collation for sort<br><br>If none of the collation, lang or case-order attributes is present in xsl:sort, the collation is chosen in an implementation-defined way. It is not required that the default collation for sorting should be the same as the default collation used when evaluating XPath expressions. (Section 5.4.1: Initializing the Static Context and Section 3.6.1: The default-collation attribute) | XSLT 2.0<br><br>Section 13.1.3 | | The processor uses the default locale returned by the Java method `Locale.getDefault()` to create a Java collator using the `java.text.Collator.getInstance(Locale)` method. |
| recognized media types | Set of media types recognized by a processor | XSLT 2.0<br><br>Section 16.1 | | The processor only supports XML files. |
| picture fallback in date formatting | Fallback representation for picture string in the date formatting functions; the format token n, N, or Nn, that indicates that the value of the component is to be output by name, in lowercase, uppercase, or title-case respectively<br><br>Components that can be output by name include (but are not limited to) months, days of the week, time zones, and eras. If the processor cannot output these components by name for the chosen calendar and language, it must use an implementation-defined fallback representation. | XSLT 2.0<br><br>Section 16.5.1 | | The processor will output [Calendar: AD] as the fallback. |
| set supported in date formatting functions | Languages, calendars, and countries that are supported in the date-formatting functions | XSLT 2.0<br><br>Section 16.5.2, first paragraph | | • Supported calendars: AD, ISO, BE<br>• Supported languages and locales: those returned by `java.util.Locale.getAvailableLocales()` |
| defaults in date formatting functions | Default language, calendar, and country in the date-formatting functions if arguments are omitted or empty | XSLT 2.0<br><br>Section 16.5.2, first paragraph | | • Default calendar: AD<br>• Default language and locale: those specified by `java.util.Locale.getDefault()` |
| default language in date formatting functions | Default language in the date-formatting functions<br><br>If the language argument is omitted, set to an empty sequence, or set to an invalid value or a value that the implementation does not recognize, the processor uses an implementation-defined language. | XSLT 2.0<br><br>Section 16.5.2, fourth paragraph | | See defaults in date formatting functions. |
| names abbrev in language in date formatting functions | Names and abbreviations in the date-formatting functions | XSLT 2.0<br><br>Section 16.5.2, seventh paragraph | | The International Components for Unicode (ICU) website has a Locale Explorer that contains links to tables for each supported locale. The processor uses the short names for the names of the days of the week and the months specified in those tables as the abbreviated forms, and it uses the long names as the unabbreviated forms. |
| calendar behavior in date formatting functions | Behavior of calendar in date-formatting functions | XSLT 2.0<br><br>Section 16.5.2, tenth paragraph | | The processor does not support any calendars with a non-null namespace URI. If the QName supplied has a prefix, the AD calendar will be used. |

*Table 348. Implementation-defined behaviors (continued).*

*This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.*

| Feature | Description | Specification | Error Code | Documented Behavior |
|---|---|---|---|---|
| default calendar in date formatting functions | Default calendar in date-formatting functions | XSLT 2.0<br><br>Section 16.5.2, eleventh paragraph | | See defaults in date formatting functions. |
| supported calendars in date formatting functions | Set of calendars supported in date-formatting functions | XSLT 2.0<br><br>Section 16.5.2, first paragraph following table of calendars | | See set supported in date formatting functions. |
| system property values | Actual values returned from system properties | XSLT 2.0<br><br>Section 16.5.5, second paragraph following the bulleted list | | The value of the system property:<br>• xsl:version is 2.0<br>• xsl:vendor is IBM Corporation<br>• xsl:vendor-url is http://www.ibm.com/<br>• xsl:product-name is XL Transform and Query Engine for Java<br>• xsl:product-version is 2.0<br>• xsl:is-schema-aware is yes<br>• xsl:supports-serialization is yes<br>• xsl:supports-backwards-compatibility is yes<br>• xsl:supports-namespace-axis is yes |
| set of system properties | Set of system properties | XSLT 2.0<br><br>Section 16.6.5 and Erratum XT.E14 | | The processor supports the following:<br>• All the system properties defined in Section 16.6.5 of the XSLT 2.0 specification<br>• New optional xsl:supports-namespace-axis property defined by XSLT Erratum XT.E14 |
| xslmessage | Way in which an xsl:message instruction sends a message | XSLT 2.0<br><br>Section 17, first paragraph | | According to Section 17 of the XSLT 2.0 specification, xsl:message sends a message in an implementation-defined way to an implementation-defined destination. The processor uses the string value of the document node created by the xsl:message instruction as the message.<br><br>If the user did not supply an instance of `com.ibm.xml.xapi.XMessageHandler` on the `com.ibm.xml.xapi.XDynamicContext` for the transformation, the message is written to the System.err output stream; and if the effective value of the terminate attribute was yes, the transformation throws an exception. If the user supplied an instance of `com.ibm.xml.xapi.XMessageHandler`, the message is passed on that object's `report()` method. See the API documentation for more information. |
| xslmessage destination | Output destination for document created by an xsl:message instruction | XSLT 2.0<br><br>Section 17, first paragraph | | See xslmessage. |
| error handling in ext functions | Consequences of an error for an extension function to return a string containing characters that are not XML | XSLT 2.0<br><br>Section 18.1.2, paragraph following the third note | | Section 18.1.2 of the XSLT 2.0 specification⌂ permits several behaviors when an extension function returns a string containing characters that are not permitted in XML, including treating them as if they were permitted. That is the behavior that the processor implements. |
| external objects | Way in which external objects are represented in the type system | XSLT 2.0<br><br>Section 18.1.3, second paragraph | | Data objects whose values are of types that do not map to built-in types as described in “Mapping XML types to Java types” on page 2199 are not supported. |

*Table 348. Implementation-defined behaviors (continued).*

*This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.*

| Feature | Description | Specification | Error Code | Documented Behavior |
|---|---|---|---|---|
| final result tree delivery | Way in which a final result tree is delivered to an application | XSLT 2.0<br><br>Section 19, third paragraph | | As described in Section 19.1 of the XSLT 2.0 specification, an implementation may allow a final result tree to be serialized or provide additional mechanisms through which they may be processed.<br><br>In the processor, a final result tree may be serialized or it may delivered to an application in the form of a `java.xml.transform.Result` object or a `com.ibm.xml.xapi.XSequenceCursor` object. If the URI of the final result tree is not equal to the base output URI, and:<br>• the user supplied a `com.ibm.xml.xapi.XResultResolver` on the `com.ibm.xml.xapi.XDynamicContext`, the result tree will be delivered to the application in the form of the `javax.xml.transform.Result` object returned by `com.ibm.xml.xapi.XResultResolver.getResult()`;<br>• otherwise, the result tree is serialized to the location specified by the URI using `java.net.URL.openConnection()`.<br>A final result tree whose URI is equal to the base output URI is delivered to the application using any `javax.xml.transform.Result` object specified on the `com.ibm.xml.xapi.XExecutable.execute` method used to invoke the transformation, or as the `com.ibm.xml.xapi.XSequenceCursor` returned from the `com.ibm.xml.xapi.XExecutable.execute()` method if that method's signature contains no `javax.xml.transform.Result` argument.<br>If the result tree is delivered in the form of a `javax.xml.transform.stream.StreamResult`, it is serialized to the location specified by the `StreamResult`; if it is delivered as an instance of any other subclass of `Result` or as an `XSequenceCursor`, the result tree is delivered in the form appropriate for that API.<br>Refer to the API documentation for additional information. |
| URI restriction | Restrictions on form of absolute URI used in an href | XSLT 2.0<br><br>Section 19.1, third paragraph following the second note | | As described in Section 19.1 of the XSLT 2.0 specification, an implementation may place implementation-defined limitations on an absolute URI that is the value of an href attribute on an xsl:result-document instruction. With the processor,<br>• If the user supplies an `com.ibm.xml.xapi.XResultResolver on the com.ibm.xml.xapi.XDynamicContext` in which the stylesheet is evaluated, there are no limitations on the form of such an absolute URI.<br>• If there is no user-supplied `XResultResolver`, the only restrictions are that if the href attribute is an absolute URI that:<br>– uses the file protocol, the user must have permission to open an output stream to that file<br>– uses some other protocol, the user must have permission to create an output stream to the URI, using the Java equivalent new `java.net.URL(href).openConnection().getOutputStream()` |
| final result tree location | Location to which final result trees are serialized | XSLT 2.0<br><br>Section 2.3 see base output URI | | By default, final result tree URIs will be interpreted relative to the base URI of the main output document. If another location is desired, an `XResultResolver` implementation can be registered with the dynamic context to implement user-defined behaviors. Use the `XDynamicContext.setResultResolver()` method to register the `XResultResolver` implementation. The base URI that is used can also be changed by calling the `XDynamicContext.setBaseOutputURI()` method. |
| default output encoding | Default value of the encoding attribute in xsl:output | XSLT 2.0<br><br>Section 20 | | The default output encoding is UTF-8. |
| byte-order-mark for UTF-8 | Byte-order-mark for UTF-8 | XSLT 2.0<br><br>Section 20 | | The default value is no, meaning that no BOM is produced at the start of UTF-8 files. |
| additional normalization form | Additional normalization form for serialization | XSLT 2.0 and XQuery 1.0 Serialization<br><br>Section 19.1<br><br>Section 20<br><br>Section 5.1.8 | | No implementation-defined normalization forms are provided. |

*Table 348. Implementation-defined behaviors (continued).*

*This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.*

| Feature | Description | Specification | Error Code | Documented Behavior |
|---|---|---|---|---|
| output version | Permitted and default value of the version attribute in xsl:output | XSLT 2.0<br><br>Section 20 | | The default for XML or XHTML is 1.0; users may explicitly specify 1.0 or 1.1. For HTML, the default is 4.0. |
| static-typing in stylesheet | Interaction of XSLT 2.0 stylesheets with the static typing feature of XPath 2.0 | XSLT 2.0 and XPath 2.0<br><br>XSLT 2.0 Section 21<br><br>XPath 2.0 Section F.1 | | This XSLT processor does not currently have a mechanism for requesting that its XPaths perform static typing. |
| built in types | Type definitions available within a stylesheet | XSLT 2.0<br><br>Section 3.13 | | The processor is schema aware as defined in Section 3.13 of the XSLT 2.0 specification. |
| namespace for additional error codes | Namespace that is used if additional error QNames are defined by the implementation | XSLT 2.0<br><br>Section 2.9 | | When appropriate, the processor does include the specified error code or code(s) in the text of its messages within square brackets. Additional errors are generally expressed similarly but without a specification prefix on the error identifier.<br><br>Error conditions are not presented as QNames; applications that wish to respond to errors programmatically must parse these error identifiers off the front of the error-message strings. |
| unparsed text encoding | Mechanism for determining encoding of an external source | XSLT 2.0<br><br>Section 16.2 | | The processor does not implement any additional heuristics. Encoding resolution proceeds immediately to step 5, and UTF-8 is assumed. |
| available documents | Mechanism for obtaining a document node and a media type given an absolute URI | XSLT 2.0<br><br>Section 2.3<br><br>Section 16.1 | | The default source resolution behavior for documents loaded using the XPath fn:doc function is to resolve relative URIs based on the base URI from the static context. If the base URI is not available, the current working directory is used. Absolute URIs are used unchanged. The default source resolution behavior for documents loaded using the XSLT document function is described in the XSLT 2.0 specification Multiple Source Documents. If no base URI is available, the current working directory is used. If the application needs to either constrain or extend these behaviors, it is possible to plug in an implementation of `XSourceResolver` to the `XDynamicContext` through the `setSourceResolver()` method. |
| additional output methods | Support for implementation-defined output method | XSLT 2.0 and XQuery 1.0 Serialization<br><br>Section 3 | | The processor does not implement any additional output methods. |
| additional serialization params | Effect of additional serialization parameters on the output of the serializer | XSLT 2.0 and XQuery 1.0 Serialization<br><br>Section 3<br><br>XSLT 2.0 Section 20 | | The processor implements the following additional serialization parameters:<br>• INDENT AMOUNT:<br>Specifies the number of spaces to use when the indent serialization parameter is enabled. Use the `XOutputParameters.setIndentAmount()` method or the xalan:indent-amount can be specified in the xsl:output element of an XSL stylesheet using the indent-amount attribute.<br>• BC MODE:<br>Enables backwards-compatibility mode for the serializer. If enabled and no output method is specified, XML will be used as a default. If disabled, the rules of XSLT 2.0 will be followed when no output method is specified. Use the `XOutputParameters.setBackwardsCompatible()` method to enable. For XSL stylesheets where the version is less than 2.0, backwards-compatibility mode is enabled by default. |
| additional normalization-form | Support for additional Unicode Normalization form | XSLT 2.0 and XQuery 1.0 Serialization<br><br>Section 5.1.8 | | No implementation-defined normalization forms are provided. |
| option in encoding phase | Effect of an option that allows the encoding phase to be skipped so that the result of serialization is a stream of Unicode characters | XSLT 2.0 and XQuery 1.0 Serialization<br><br>Section 4 | | No such option is provided by the processor. |

*Table 348. Implementation-defined behaviors (continued).*

*This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.*

| Feature | Description | Specification | Error Code | Documented Behavior |
|---|---|---|---|---|
| cdata sec mechanism | Alternative mechanism requested by the user to create CDATA sections | SR<br><br>Section 5.1.4 of XSLT 2.0 and XQuery 1.0 Serialization | | The processor does not provide an alternative mechanism for creating CDATA sections. |
| unicode version | Supported version of Unicode | XPath 2.0<br><br>Appendix D<br><br>XQuery 1.0<br><br>Appendix D | | The processor supports the version of Unicode supported by the host JRE—namely, Unicode Standard Version 4.0 for Java 5 and Java 6. |
| trace function | Trace function<br><br>The destination of the trace output is implementation defined. | XQuery 1.0 and XPath 2.0 Functions and Operators<br><br>Section 4 | | When using the fn:trace() function, the result will be passed to the `com.ibm.xml.xapi.XMessageHandler` (formerly `com.ibm.xml.xapi.XErrorHandler`). It is up to the user to specify their own `XMessageHandler` to handle the trace results reported by the processor. Trace-message type is indicated by `XMessageHandler.TRACE`. |
| recovery for under overflow integer operations | Mechanism that allows users to choose between raising an error and returning a result that is modulo the largest representable integer value during overflow or underflow arithmetic operations | XQuery 1.0 and XPath 2.0 Functions and Operators<br><br>Section 6.2 | | The processor provides a mechanism to enable overflow detection for integer operations through the `com.ibm.xml.xapi.XStaticContext.setIntegerMathMode(int)` method, which can be called with the constants INTEGER_MATH_MODE_OVERFLOW_DETECTION or INTEGER_MATH_MODE_LIMITED_PRECISION to choose between the two options. A third option is provided to allow arbitrary precision integers. |
| digits truncation | If the number of digits in the result of a numeric operation exceeds the number of digits that the implementation supports, the result is truncated or rounded in an implementation-defined manner. | XQuery 1.0 and XPath 2.0 Functions and Operators<br><br>Section 6.2<br><br>Section 3.2.3 of XML Schema Part 2: Datatypes Second Edition | | The implementation uses the java.math.BigDecimal class, which supports nearly unlimited precision except that the number of digits to the right of the decimal place is limited to Integer.MAX_VALUE. Truncation is only required in the case of division, where there is the possibility of non-terminating decimals. The precision of the fractional part of the result is limited to 18 digits. The rounding mode in this case is ROUND_HALF_UP, where discarded fractions of 0.5 or higher are rounded up (away from zero) and lesser fractions are rounded down. |
| collation abilities | Ability of specified collation to decompose strings into collation units suitable for substring matching is an-implementation-defined-property of a collation. | XQuery 1.0 and XPath 2.0 Functions and Operators<br><br>Section 7.5 | | If the Java Collator specified in a call to the `bindCollation` method of the `XDynamicContext` interface is an instance of the `RuleBasedCollator` class, the associated collation URI can be used with one of the functions that performs collation-based substring matching. |
| year value limits | Maximum number of digits for year values.<br><br>All minimally conforming processors must support year values with a minimum of 4 digits (YYYY) and a minimum fractional second precision of 1 millisecond or three digits (s.sss); however, conforming processors may set larger implementation-defined-limits on the maximum number of digits that they support in these two situations. | XQuery 1.0 and XPath 2.0 Functions and Operators<br><br>Section 10.1.1 | | The year component of the types xs:date, xs:dateTime, xs:gYear, and xs:gYearMonth has the range -(10^9-1) to (10^9)-1. |
| fractional second precision | Maximum number of digits for fractional second values | XQuery 1.0 and XPath 2.0 Functions and Operators<br><br>Section 10.1.1 | | The maximum number of fractional seconds digits supported for the xs:time and xs:dateTime types is 3. |

*Table 348. Implementation-defined behaviors (continued).*

*This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.*

| Feature | Description | Specification | Error Code | Documented Behavior |
|---|---|---|---|---|
| doc function | Various aspects of the processing provided by fn:doc are implementation defined. Implementations may provide external configuration options that allow any aspect of the processing to be controlled by the user. | XQuery 1.0 and XPath 2.0 Functions and Operators<br><br>Section 15.5.4 | | Users may provide an `com.ibm.xml.xapi.XSourceResolver` implementation through the `com.ibm.xml.xapi.XDynamicContext.setSourceResolver(XSourceResolver)` method. The `XSourceResolver` is used by the fn:doc implementation to resolve URIs (thus the user may decide which URIs to support), and its `getSource(String, String)` method must return a JAXP Source object. If no `XSourceResolver` is given, the processor handles the file URI scheme and those supported by the `java.net.URL.openConnection()` method. It does not process URI fragments. There is no built-in support for non-XML media types, but users may use an `XSourceResolver` implementation to provide the processor with an XML representation of non-XML data.<br><br>DTD validation and schema validation may be applied to the source document depending on the validation setting. The validation setting may be set on `com.ibm.xml.xapi.XFactory` instances using the `setValidating` method, and this setting is inherited by objects created by the `XFactory`. If a `com.ibm.xml.xapi.XDynamicContext` instance is provided to the execute or `executeToList` method of a `com.ibm.xml.xapi.XExecutable` instance, its validation setting is used; otherwise, the setting of the `XExecutable` instance itself is used. The processor does not provide a recovery mechanism for errors in retrieving the resource or parsing or validating its content.<br><br>The processor does not provide an option to relax the requirement for the fn:doc function to return stable results. |
| decimal operator precision | For xs:decimal values, the number of digits of precision returned by the numeric operators is implementation defined. | XQuery 1.0 and XPath 2.0 Functions and Operators<br><br>Section 6.2, last paragraph | | The number of digits of precision is the minimum required to represent the exact result without rounding, except in the case of division, where the number of digits of precision for the fractional part of the result is limited to 18. |
| collection doc stability | User option to evaluate the function without a guarantee of stability in addition to the manner in which such user options are provided | XQuery 1.0 and XPath 2.0 Functions and Operators<br><br>Sections 15.5.4 and 15.5.6 | | The processor does not provide an option to relax the requirement for the fn:doc or fn:collection functions to return stable results. |
| decimal precision | Number of decimal digits supported in xs:decimal<br><br>The result of casting a string to xs:decimal when the resulting value is not too large or too small but nevertheless has too many decimal digits to be accurately represented, is implementation defined. | XQuery 1.0 and XPath 2.0 Functions and Operators<br><br>Section 17.1.1 | | The implementation uses the `java.math.BigDecimal` class, which supports nearly unlimited precision, except that the number of digits to the right of the decimal place is limited to Integer.MAX_VALUE. Memory would be exhausted before this limit is reached. |
| raise warning | Circumstances in which warnings are raised, and the ways in which warnings are handled | XQuery 1.0 and XPath 2.0 Functions and Operators<br><br>Section 2.3<br><br>XPath 2.0<br><br>Section 2.3.1<br><br>XQuery 1.0<br><br>Section 2.3.1 | | The user can provide an implementation of `com.ibm.xml.xapi.XMessageHandler` using the `setMessageHandler()(XMessageHandler)` method on either `com.ibm.xml.xapi.XStaticContext` or `com.ibm.xml.xapi.XDynamicContext` for static and dynamic warnings respectively. The `report(int, String, XSourceLocation, Exception)` method of XMessageHandler will be called for each warning, with the first argument equal to `XMessageHandler.WARNING`.<br><br>If no `XMessageHandler` is provided, warnings are printed to the standard error output stream.<br><br>Warnings are raised in situations where the processor takes some action to avoid an error condition, such as substituting a default value for an invalid value, that the user might want to correct in the future. |

*Table 348. Implementation-defined behaviors (continued).*

*This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.*

| Feature | Description | Specification | Error Code | Documented Behavior |
|---|---|---|---|---|
| report error | Method by which errors are reported to the external processing environment | XQuery 1.0 and XPath 2.0 Functions and Operators<br><br>Section 2.3<br><br>XPath 2.0<br><br>Section 2.3.2<br><br>XQuery 1.0<br><br>Section 2.3.2 | | The user can provide an implementation of `com.ibm.xml.xapi.XMessageHandler` using the `setMessageHandler()(XMessageHandler)` method on either `com.ibm.xml.xapi.XStaticContext` or `com.ibm.xml.xapi.XDynamicContext` for static and dynamic errors respectively. The `report(int, String, XSourceLocation, Exception)` method of `XMessageHandler` will be called for each error, with the first argument equal to either `XMessageHandler.ERROR` or `XMessageHandler.FATAL_ERROR`.<br><br>If no `XMessageHandler` is provided, errors are printed to the standard error output stream. |
| XML 1.0 or XML 1.1 rules | Whether the processor is based on XML 1.0 or XML 1.1 rules for names and supported characters | XPath 2.0<br><br>Appendix D XQuery 1.0<br><br>Appendix D | | The processor follows XML 1.1 rules for the definitions of NCName and supported characters as well as for end-of-line handling and attribute value normalization. |
| default order of empty sequences | Whether the default handling of empty sequences in "order by" is "empty least" or "empty greatest" | XQuery 1.0<br><br>Section 3.8.3 | | The processor uses the default set by a call to the `XStaticContext` method `setDefaultOrderForEmptySequences`. Otherwise, the default setting is "empty greatest". |
| pragmas supported | The names and semantics of any XQuery extension expressions (pragmas) supported | XQuery 1.0<br><br>Section 3.14 | XQST0079 | The processor does not recognize or support any extension expressions. |
| options supported | The names and semantics of any XQuery option declarations supported | XQuery 1.0<br><br>Section 4.16 | | The processor currently supports the java-extension option for declaring extension functions within a query. See the API documentation for more information. |
| external function parameter passing | Protocols supported for passing parameters to external functions from XQuery and for returning a result | XQuery 1.0<br><br>Section 4.15 | | Extension functions are supported through the processor's `XStaticContext.declareFunction` and `XDynamicContext.bindFunction` methods. See the API documentation for more information. |
| invoking serialization | The means by which serialization is invoked for the result of evaluating an XQuery query | XQuery 1.0<br><br>Section 2.2.4 | | If an instance of the `javax.xml.transform.stream.StreamResult` interface is supplied on an evaluate method of an `XQueryExecutable` instance, the processor will serialize the result of the query. You can also serialize an `XSequenceCursor` that results from evaluating a query by calling one of the `exportSequence` methods. |
| default serialization parameters | The default values of the byte-order-mark, encoding, media-type, normalization-form, omit-xml-declaration, standalone, and version serialization parameters | XQuery 1.0<br><br>Section 2.2.4<br><br>Appendix C.3 | | The settings of the serialization parameters can be specified on an instance of the XOutputParameters interface.<br>• The default setting of the byte-order-mark serialization parameter is yes for the UTF-16 encoding, and it is no otherwise.<br>• The default setting of the encoding serialization parameter is UTF-8.<br>• The default setting of the media-type serialization parameter is text/xml in the case of the xml output method, text/html in the case of the html and xhtml output methods, and text/plain in the case of the text output method.<br>• The default setting of the normalization-form serialization parameter is none.<br>• The default setting of the omit-xml-declaration serialization parameter is no.<br>• The default setting of the standalone serialization parameter is no.<br>• The default setting of the version serialization parameter is 1.0 for the xml and xhtml output methods and 4.01 for the html output method. |
| unsuccessful external function call | The effect of an unsuccessful call to an external function | XQuery 1.0<br><br>Appendix D | | The processor will first report an error to any instance of the `XMessage` handler interface that is supplied and will then throw an exception if a call from XQuery to an external function is unsuccessful for any of (but not limited to) the following reasons:<br>• because the function name is not bound to a function definition using the `XDynamicContext.bindFunction` method<br>• the number or types of arguments supplied does not match the number or types expected by the implementation of the function<br>• some error or exception is thrown by the implementation of the function |

The following is implementation-specific information related to XSLT 1.0 support:

- The system-property function does not support Java system properties
- If the value of an attribute contains a tab, carriage return or line-feed character with the HTML output method, the processor will serialize the actual character rather than a character reference as part of the attribute value. Either is permitted by the XSLT 2.0 and XQuery 1.0 Serialization Recommendation and by the HTML 4.01 Recommendation, but previous versions of IBM XSLT processors would serialize the character as a character reference in such a context.

***Conformance statements:***

The processor is an implementation of the XSL Transformations (XSLT) Version 2.0 and the XQuery 1.0 W3C recommendations. See section 21 of the XSLT 2.0 recommendation and section 5 of the XQuery 1.0 recommendation for more information about conformance criteria for processors.

It implements the first editions of the XSLT 2.0, XQuery 1.0, and XPath 2.0 recommendations, with the levels of conformance described in this article, as well as all errata published in the proposed edited recommendations of the second editions of the XSLT 2.0, XQuery 1.0, XPath 2.0 and ancillary recommendations.

- XSL Transformations (XSLT) Version 2.0 (Second Edition)
- XQuery 1.0: An XML Query Language (Second Edition)
- XML Path Language (XPath) 2.0 (Second Edition)
- XQuery 1.0 and XPath 2.0 Functions and Operators (Second Edition)
- XQuery 1.0 and XPath 2.0 Data Model (XDM) (Second Edition)
- XSLT 2.0 and XQuery 1.0 Serialization (Second Edition)

This includes support for the fn:element-with-id function and the XSLT xsl:supports-namespace-axis system property.

**XSLT 2.0 conformance**

The processor conforms to XSLT 2.0 as a schema-aware XSLT processor. It also supports the following optional features of XSLT 2.0:

- serialization feature
- backwards-compatibility feature

For a complete list of implementation-defined features, read “XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-specific behaviors” on page 2180.

**XQuery 1.0 conformance**

The processor has minimal conformance to XQuery 1.0. It also supports the following optional features of XQuery 1.0:

- full axis feature
- serialization feature
- schema-import feature
- schema-validation feature

For a complete list of implementation-defined features, read “XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-specific behaviors” on page 2180.

**Data Model conformance**

The processor supports normative construction of an instance of the XQuery/XPath Data Model from an Infoset or from a PSVI. By default, construction of the instance of the Data Model will be from an Infoset. If the setValidating method of an XFactory instance is called with a value of true, any instance of the Data Model that the processor creates will be constructed from PSVI.

For more information, “Performing basic XQuery operations” on page 2208.

The processor supports both XML 1.0 and XML 1.1.

### Extension support

The processor supports the following additional extensions:

- indent-amount extension attribute of xsl:output
- selection of EXSLT extension functions
- redirect extension element

**xalan:indent-amount extension attribute of xsl:output**

If the value of the indent serialization parameter is yes for an explicit or an implicit xsl:result-document instruction in an XSLT stylesheet, the processor will use the value of any indent-amount extension attribute on the associated xsl:output declaration to determine the amount by which indentation should be increased for every level of element nesting in the serialized result.

The indent-amount extension attribute is in the http://xml.apache.org/xalan namespace.

**EXSLT extension functions**

In order to facilitate migration of XSLT 1.0 stylesheets, the processor supports many extension functions defined by the EXSLT community initiative. In many cases, these functions duplicate functions that have been included in XSLT 2.0, XPath 2.0 and XQuery 1.0.

For more information about EXSLT, see the EXSLT website.

**EXSLT common functions**

The processor supports only the node-set common extension function. This function is made redundant by the fact that XSLT 2.0 does not restrict the operations that can be performed on temporary trees.

The EXSLT common functions are in the namespace http://exslt.org/common.

**EXSLT dates-and-times functions**

The EXSLT dates-and-times functions provide facilities for manipulating date and time values. Most of these functions are redundant with the inclusion of the new date and time data types from XML Schema in XSLT 2.0, XQuery 1.0, and XPath 2.0.

The EXSLT dates-and-times functions are in the namespace http://exslt.org/dates-and-times.

**EXSLT dynamic functions**

The processor supports only the evaluate dynamic extension function.

The EXSLT dynamic functions are in the namespace http://exslt.org/dynamic.

**EXSLT math functions**

The EXSLT math functions provide facilities for several commonly used mathematical operations. Only the math:abs, math:max, math:min, and math:highest functions have been made redundant in XSLT 2.0, XQuery 1.0, and XPath 2.0.

The EXSLT math functions are in the namespace http://exslt.org/math.

**EXSLT set functions**

The EXSLT set functions define facilities for performing set operations on sequences of nodes. These have been made redundant by the new intersect and except set operations and the << and >> node comparison operations introduced in XSLT 2.0, XQuery 1.0, and XPath 2.0.

The EXSLT set functions are in the namespace http://exslt.org/sets.

**EXSLT string functions**

The EXSLT string functions provide facilities for string manipulation. The tokenize and split

functions have been made redundant by the new operations for string manipulation in XSLT 2.0, XQuery 1.0, and XPath 2.0, including the fn:tokenize function and the xsl:analyze-string instruction.

The EXSLT string functions are in the namespace http://exslt.org/strings.

**xalan:redirect extension element**

The redirect extension element provides a means of directing output from an XSLT stylesheet to more than one output destination. This extension element is made redundant by the new xsl:result-document instruction of XSLT 2.0.

The redirect extension element is in the http://xml.apache.org/xalan namespace.

## Choosing between the compiler and the interpreter

You can use either the compiler and the interpreter for preparing and executing an XQuery expression, XPath expression, or XSLT stylesheet. Choosing which one to use is very application specific and depends on several factors.

### About this task

This article is about choosing between the compiler and interpreter when you are preparing the expression, query, or stylesheet during the application run time.

Expressions, queries, and stylesheets can also be prepared ahead of time (precompiled). This is the most efficient option because the preparation is done ahead of time instead of during the application run time, but precompiling might not be applicable to all applications. See the articles related to precompiling for more details.

### Procedure

Use the setUseCompiler(true) method on the XStaticContext to use the compiler, and use the setUseCompiler(false) method to use the interpreter.
The default is to use the interpreter for preparing an XQuery expression, XPath expression, or XSLT stylesheet.
It takes longer to prepare a compiled executable than an interpreted executable, but a compiled executable generally runs faster; therefore, there is a trade off between the cost of preparing a compiled executable and the improved execution-time efficiency.

*Table 349. Differences between using the compiler and the interpreter.*

*Consider these factors when choosing between compiling and interpreting.*

| Factor | Description |
|---|---|
| Number of input documents that the executable will be used to process | If the executable will be used only to process a few input documents, it might not be worth the extra time needed to create a compiled executable because the improved efficiency of the executable might not make up for the extra prepare time. If the executable will be used to process many input documents, it might be worth the extra prepare time. |
| Size of the input documents | Larger input documents take longer to process; therefore, it might be worth the extra prepare time to create a compiled executable in order to get a more efficient executable object to handle the larger documents. |
| Size of the expression, query, or stylesheet | It takes longer to prepare a larger expression, query, or stylesheet; therefore, this affects the preparation time and execution time trade off. |

### Example

```
// Create a new XFactory
XFactory factory = XFactory.newInstance();

// Create a new XStaticContext
XStaticContext staticContext = factory.newStaticContext();

//Use the compiler
```

```
sc.setUseCompiler(true);

//Use the interpreter
sc.setUseCompiler(false);
```

## Using static and dynamic contexts

You can use the two context interfaces that the XML API provides—XStaticContext and XDynamicContext.

### About this task

**Static context**

The static context is used to configure prepare-time characteristics.

**Note:** Prepare-time refers to the execution of one of the prepare methods on XFactory or the execution of one of the compile methods on XCompilationFactory.

Static context defines items that are needed to prepare executables, items such as the names and types of external variables and functions that will be available at run time as well as compilation modes like backwards compatibility, math mode, and so on. These items do not change across invocations.

**Dynamic context**

The dynamic context is used to configure execution-time characteristics.

Dynamic context defines items that are unique to each invocation of an executable, items such as the values for external variables, external function implementations, and resolvers to external inputs or results. These items might change across invocations.

Prepare-time characteristics are not set directly on the XFactory instance so that it can be thread safe. The same is true for execution-time characteristics; they are kept in a separate object from the XExecutable instance so that the executable object itself is thread safe.

The prepare and execute steps themselves are separate because preparation takes time and it would be inefficient to prepare for every execution. Having separate steps allows an expression, query, or stylesheet to be prepared once and the resulting executable object then can be used to process any number of input documents.

### Procedure

- Use the static context, XStaticContext, to configure prepare-time characteristics.

  Prepare-time characteristics are built directly into the executable object; therefore, after an executable object has been created with a certain set of characteristics, they are fixed and cannot be changed. If an executable object for the same expression, query, or stylesheet is required that has different characteristics, a new one must be generated.

  Examples of methods on XStaticContext used for setting prepare-time characteristics:

  **setUseCompiler**

  The executable object that is generated is very different for compiled and interpreted; therefore, this is a prepare-time characteristic.

  **declareVariable**

  The type of a variable affects how the expression, query, or stylesheet gets compiled and therefore is a prepare-time characteristic.

  On the other hand, binding the value of a variable is an execution-time characteristic, and the value can be different for each execution.

  **setSourceResolver**

  A source resolver registered at prepare time is used to resolve includes and imports.

  A source resolver can also be registered at execution time, but it is used for a different purpose.

- Use the dynamic context, XDynamicContext, to configure execution-time characteristics.

Execution-time characteristics can be different on each call to the execute method of an executable object.

Examples of methods on XDynamicContext used for setting execution-time characteristics:

**bind methods**
The bind methods on XDynamicContext interface are used to supply a value for a variable. The value can be different for each execution.

**setSourceResolver**
A source resolver registered at execution time is used to resolve input documents loaded with the XPath fn:doc function or the XSLT fn:document function.

**setXSLTInitialTemplate**
Identify the initial template to invoke for an XSL transformation.

### What to do next

The XPath, XQuery, and XSLT specifications also have the concepts of static and dynamic context. For more information, see the following web pages:

- XPath Static Context
- XPath Dynamic Context
- XQuery Static Context
- XQuery Dynamic Context
- XSLT Static Context
- XSLT Dynamic Context

The XStaticContext and XDynamicContext interfaces merge settings from all three languages (XPath, XQuery, and XSLT). To find out which settings apply to which language refer to the "Performing Basic Operations" article for that language in the related tasks listed below.

## Mapping XML types to Java types

You can use this mapping between XML types and Java types when using external functions and variables. They are recommended mappings only; other types might work subject to type promotion, casting rules, and the range of values representable by the target type.

### Procedure

- Use this table to map between built-in types and Java types when using external functions and variables.

*Table 350. Built-in and Java types.*

*This table maps built-in types to Java types.*

| Built-in Types | Java Types |
|---|---|
| xs:anyURI | java.lang.String |
| xs:boolean | boolean, java.lang.Boolean |
| xs:base64Binary | byte[] |
| xs:hexBinary | byte[] |
| xs:date | javax.xml.datatype.XMLGregorianCalendar |
| xs:dateTime | javax.xml.datatype.XMLGregorianCalendar |
| xs:time | javax.xml.datatype.XMLGregorianCalendar |
| xs:duration | javax.xml.datatype.Duration |
| xs:dayTimeDuration | javax.xml.datatype.Duration |
| xs:yearMonthDuration | javax.xml.datatype.Duration |
| xs:gDay | javax.xml.datatype.XMLGregorianCalendar |
| xs:gMonth | javax.xml.datatype.XMLGregorianCalendar |

*Table 350. Built-in and Java types (continued).*

*This table maps built-in types to Java types.*

| Built-in Types | Java Types |
|---|---|
| xs:gMonthDay | javax.xml.datatype.XMLGregorianCalendar |
| xs:gYear | javax.xml.datatype.XMLGregorianCalendar |
| xs:gYearMonth | javax.xml.datatype.XMLGregorianCalendar |
| xs:decimal | java.math.BigDecimal |
| xs:integer | java.math.BigInteger |
| xs:nonPositiveInteger | java.math.BigInteger |
| xs:negativeInteger | java.math.BigInteger |
| xs:long | long, java.lang.Long |
| xs:int | int, java.lang.Integer |
| xs:short | short, java.lang.Short |
| xs:byte | byte, java.lang.Byte |
| xs:nonNegativeInteger | java.math.BigInteger |
| xs:unsignedLong | java.math.BigInteger |
| xs:unsignedInt | long |
| xs:unsignedShort | int |
| xs:unsignedByte | short |
| xs:positiveInteger | java.math.BigInteger |
| xs:double | double, java.lang.Double |
| xs:float | float, java.lang.Float |
| xs:QName | javax.xml.namespace.QName |
| xs:NOTATION | javax.xml.namespace.QName |
| xs:string | java.lang.String |
| xs:normalizedString | java.lang.String |
| xs:token | java.lang.String |
| xs:language | java.lang.String |
| xs:NMTOKEN | java.lang.String |
| xs:Name | java.lang.String |
| xs:NCName | java.lang.String |
| xs:ID | java.lang.String |
| xs:IDREF | java.lang.String |
| xs:ENTITY | java.lang.String |
| xs:untypedAtomic | java.lang.String |
| List | com.ibm.xml.xapi.XItemView[] |
| Union | com.ibm.xml.xapi.XItemView |
| All of the above-listed built-in types | com.ibm.xml.xapi.XItemView |
| | com.ibm.xml.xapi.XSequenceCursor |
| Complex types (types that represent nodes in the XML document) | com.ibm.xml.xapi.XItemView |
| | com.ibm.xml.xapi.XSequenceCursor |
| | org.w3c.dom.Node |

The mapping also applies to retrieving values from an XItemView. The XItemView getDoubleValue method returns Java primitive double; the getDateValue, getTimeValue, and getDateTimeValue methods all return an XMLGregorianCalendar; and so on.

If you want to use an external function in your XPath or XQuery expressions and it takes a built-in type as the argument, the actual Java method signature can specify any of the indicated Java types. If you want to use an external function, my:power(arg1 as xs:int, arg2 as xs:int) for example, to calculate the value of the first argument raised to the power of the second argument, you could write a Java method taking two Java primitive int arguments that performs the calculation.

- Use this table to map between sequence types and Java types when using external functions and variables.

*Table 351. Sequence and Java types.*

*This table maps sequence types to Java types.*

| Sequence Types | Java Types |
|---|---|
| All sequence types | com.ibm.xml.xapi.XSequenceCursor |
| Sequence type known to be a singleton (a sequence containing only one item) | com.ibm.xml.xapi.XItemView |
| | One of the types listed in the built-in types to Java types mapping table |
| Sequence type known to contain only nodes and no atomic items | org.w3c.dom.NodeList |
| | org.w3c.dom.traversal.NodeIterator |

## Performing basic XPath operations

You can use the XPathExecutable instances that are created using XFactory.prepareXPath methods to evaluate XPath expressions.

### About this task

XPath expressions can be passed to the XFactory.prepareXPath method using a JAXP StreamSource object or using a plain Java string object. The resulting XPathExecutable instance is thread safe and can be reused to evaluate an XPath expression on multiple XML input documents.

### Procedure

- Use the XStaticContext object with the prepareXPath method to pass in settings that affect how the XPath expression is prepared.

  If no XStaticContext object is provided, the default setting is used.

  **XStaticContext settings relevant to XPath:**

  **declareFunction**
  Declare a Java extension function

  **declareNamespace**
  Declare a namespace prefix and associate it with a namespace URI to be used as part of an XPath expression

  **declareVariable**
  Declare a variable externally to be used as part of an XPath expression

  **setBaseURI**
  Set the base URI used in the resolution of relative URIs (such as by the fn:resolve-uri function)

  The default is the base URI of the expression, query, or stylesheet if the base URI is available. If the base URI is not available, the current working directory is used.

  **setDefaultCollation**
  Set the default collation URI for string comparison operations

  The default is the Unicode code point collation URI.

  **setDefaultElementTypeNamespace**
  Specify the URI of the default element or type namespace

  Use an empty string to make it unspecified.

  The default is an empty string.

  **setDefaultFunctionNamespace**
  Specify the URI of the default function namespace

  Use an empty string to make it unspecified.

The default is "http://www.w3.org/2005/xpath-functions".

**setIntegerMathMode**
Set the integer math mode to one of the following:

**INTEGER_MATH_MODE_LIMITED_PRECISION**
Limit to 18-digit precision for xs:integer (default)

**INTEGER_MATH_MODE_ARBITRARY_PRECISION**
Allow users to have arbitrary precision for xs:integer

**INTEGER_MATH_MODE_OVERFLOW_DETECTION**
Generate an error if an overflow is detected

**setMessageHandler()**
Set the message handler for prepare-time errors

The default behavior is to print errors, warnings, and informational messages to System.err and to generate an XProcessException in the case of an unrecoverable error when compilation cannot continue. If the message handler that is registered does not generate its own exception in the case of an unrecoverable error, an XProcessException occurs.

**setUseCompiler**
Indicate whether to generate a compiled executable or an interpreted executable

A compiled executable takes longer to generate but runs faster than an interpreted executable. The default is interpreted.

**setXPathCompatibilityMode**
Sets the compatibility mode to be used when evaluating XPath expressions

The options are as follows:

**XPATH2_0_PURE_COMPATIBILITY (default)**
Use the default behavior defined by XPath 2.0 in evaluating expressions.

**XPATH1_0_BC_COMPATIBILITY**
Use the backwards-compatibility behavior defined by XPath 2.0 that yields results that are most consistent with those that would be produced by an XPath 1.0 processor.

**XPATH_LATEST_VERSION**
Use the default behavior defined by the most recent version of XPath supported by the processor.

- Provide an XDynamicContext object that can be used to pass settings to the XPathExecutable.execute method.

  These settings affect the behavior during the execution when the processor is evaluating an XPath expression.

  If no XDynamicContext object is provided, the default setting is used.

  **XDynamicContext settings relevant to XPath:**

  **bind** Bind a value to an external variable

  **bindCollation**
  Binds an instance of the java.text.Collator class to a particular collation URI for use in string comparisons that use that collation URI

  **bindFunction**
  Bind an external function so that it can be used as part of an XPath expression

  **bindSequence**
  Bind a sequence value to an external variable

**setCollectionResolver**
Set the collection resolver used to resolve documents loaded with the XPath fn:collection function

The default behavior is for references to the fn:collection function to return an empty sequence.

**setImplicitTimeZone**
Set the implicit time zone

The default is to use the system time zone as retrieved through the Java method java.util.TimeZone.getDefault().

**setMessageHandler()**
Set the message handler for excution-time errors

The default behavior is to print errors, warnings and informational messages to System.err and to generate an XProcessException in the case of an unrecoverable error. If the message handler that is registered does not generate its own exception in the case of an unrecoverable error, an XProcessException occurs.

**setSourceResolver**
Set the source resolver used to resolve documents loaded with the XPath fn:doc function

The default behavior is to resolve documents based on the base URI from the static context. If the base URI is not available, the current working directory is used.

- Use schemas with XPath expression evaluation.

  For schema-aware XPath evaluation and validating the input XML file, schema files can be registered using the XFactory.registerSchema() method or you can declare the xsi:schemaLocation directive in their input XML files. In either case, validation needs to be enabled using the XFactory.setValidating() method.

## Example

The following is a basic example of preparing and executing an interpreted XPath expression.

```
// Create a string for the XPath expression
String expression = "/doc/something";

// Create the factory
XFactory factory = XFactory.newInstance();

// Create an XPath executable for the expression
XPathExecutable xPathExecutable = factory.prepareXPath(expression);

// Create the input XML source
String xml = "<doc><something>something is selected</something></doc>";

// Execute the expression and store the results in an XSequenceCursor
XSequenceCursor xSequenceCursor = xPathExecutable.execute(new StreamSource(new ByteArrayInputStream(xml.getBytes())));
```

The following is a basic example of preparing and executing a compiled XPath expression.

```
// Create a string for the XPath expression
String expression = "/doc/something";

// Create the factory
XFactory factory = XFactory.newInstance();

// Create a new static context from the factory
XStaticContext xStaticContext = factory.newStaticContext();

// Set the mode to compile for the processor
xStaticContext.setUseCompiler(true);

// Create an XPath executable for the expression
XPathExecutable xPathExecutable = factory.prepareXPath(expression, xStaticContext);

// Create the input XML source
String xml = "<doc><something>something is selected</something></doc>";

// Execute the expression and store the results in an XSequenceCursor
XSequenceCursor xSequenceCursor = xPathExecutable.execute(new StreamSource(new ByteArrayInputStream(xml.getBytes())));
```

The following is a basic example of preparing and executing interpreted XPath expressions with schema validation.

```
// Create a string for the XPath expression
String expression = "/doc/byte cast as my:derived1-byte-enumeration-Type";

// Create the factory
XFactory factory = XFactory.newInstance();

// Create the schema source
String schema = "<xsd:schema xmlns:xsd='http://www.w3.org/2001/XMLSchema'" +
          " targetNamespace='http://www.schematype.ibm.com/UDSimple'" +
          " xmlns:my='http://www.schematype.ibm.com/UDSimple'" +
          " xmlns:smokey='http://www.schematype.ibm.com/UDSimple'>"
          + "  <xsd:simpleType name='derived1-byte-enumeration-Type'>"
          + "   <xsd:restriction base='xsd:byte'>"
          + "     <xsd:enumeration value='1' />"
          + "     <xsd:enumeration value='-1' />"
          + "     <xsd:enumeration value='0' />"
          + "     <xsd:enumeration value='127' />"
          + "     <xsd:enumeration value='-128' />"
          + "     <xsd:enumeration value='32' />"
          + "     <xsd:enumeration value='-32' />"
          + "     <xsd:enumeration value='8' />"
          + "     <xsd:enumeration value='-8' />"
          + "     <xsd:enumeration value='2' />"
          + "     <xsd:enumeration value='-2' />"
          + "   </xsd:restriction>"
          + "  </xsd:simpleType>"
          + "</xsd:schema>";
// Load schema
factory.registerSchema(new StreamSource(new ByteArrayInputStream(schema.getBytes())));

// Turn on validation
factory.setValidating(true);

// Create a new static context from the factory
XStaticContext xStaticContext = factory.newStaticContext();

// Add new namespace
xStaticContext.declareNamespace("my", "http://www.schematype.ibm.com/UDSimple");

// Create an XPath executable for the expression
XPathExecutable xPathExecutable = factory.prepareXPath(expression, xStaticContext);

// Create the input XML source
String xml = "<doc>" +
             "    <byte>1</byte>" +
             "</doc>";

// Execute the expression and store the results in an XSequenceCursor
XSequenceCursor xSequenceCursor = xPathExecutable.execute(new StreamSource(new ByteArrayInputStream(xml.getBytes())));
```

## Performing basic XSLT operations

You can use the XSLTExecutable instances that are created using XFactory.prepareXSLT methods to perform XSLT transformations.

### About this task

XSLT stylesheets can be passed to the XFactory.prepareXSLT method using a JAXP Source object. The resulting XSLTExecutable instance is thread safe and can be reused to transform multiple input documents.

### Procedure

- Use the XStaticContext object with the prepareXSLT method to pass in settings that affect how the XSLT stylesheet is prepared.

  If no XStaticContext object is provided, the default settings are used.

  **XStaticContext methods for changing settings relevant to XSLT:**

  **declareFunction**
  Declare a Java extension function

  **setBaseURI**
  Set the base URI used in the resolution of relative URIs (such as by the fn:resolve-uri function)

The default is the base URI of the expression, query, or stylesheet if the base URI is available. If the base URI is not available, the current working directory is used.

**setSourceResolver**
Set the source resolver used for includes and imports

The default source resolution behavior is to use the base URI of the expression, query, or stylesheet if available to resolve imports and includes. If the base URI is not available, the current working directory is used.

**setMessageHandler**
Set the message handler for prepare-time errors and other messages

The default behavior is to print errors, warnings, and informational messages to System.err and to generate an XProcessException in the case of an unrecoverable error when preparation cannot continue. If the message handler that is registered does not generate its own exception in the case of an unrecoverable error, an XProcessException occurs.

**setIntegerMathMode**
Set the integer math mode to one of the following:

**INTEGER_MATH_MODE_LIMITED_PRECISION (default)**
Use Java long to represent an integer value

**INTEGER_MATH_MODE_ARBITRARY_PRECISION**
Use Java BigInteger to represent an integer value

**INTEGER_MATH_MODE_OVERFLOW_DETECTION**
Use limited precision and generate execution-time errors when overflow is detected

See the XML API documentation for long and BigInteger for more information about the range of values supported for these types.

**setUseCompiler**
Indicate whether to generate a compiled executable or an interpreted executable

A compiled executable takes longer to generate but runs faster than an interpreted executable.

The default is interpreted.

**setDefaultCollation**
Set the default collation used for string comparison operations when the comparison operation does not specify a collation URI explicitly and there is no default collation URI declared within the stylesheet that is in scope for the operation

The default is the Unicode code-point collation URI.

- Provide an XDynamicContext object that can be used to pass settings to the XSLTExecutable.execute method.

  The XDynamicContext object passed in to the XSLTExecutable.execute command defines the settings for that execution.

  If no XDynamicContext object is provided, the default settings are used.

  **XDynamicContext methods for changing settings relevant to XSLT:**

  **bind** Bind a value to an XSLT parameter

  If no value is bound, the default value in the stylesheet is used.

  **bindSequence**
  Bind a sequence of values to an XSLT parameter

  If no value is bound, the default value in the stylesheet is used.

  **bindFunction**
  Bind a Java method object to an extension function name as declared in the XStaticContext

**setBaseOutputURI**
Set the base output URI to be used when resolving result documents

The default is to use the base URI of the main result document if available. If the base URI is not available, the current working directory is used.

**setMessageHandler**
Set the message handler for execution-time errors and other messages

The default behavior is to print errors, warnings and informational messages to System.err and to generate an XProcessException in the case of an unrecoverable error. If the message handler that is registered does not generate its own exception in the case of an unrecoverable error, an XProcessException occurs.

The message handler registered with the dynamic context is also used for calls to XPath fn:trace and fn:error functions as well as the XSLT xsl:message instruction.

**setImplicitTimeZone**
Set the implicit time zone

The default is to use the system time zone as retrieved through the Java method java.util.TimeZone.getDefault().

**setResultResolver**
Set the result resolver used to resolve the href specified in xsl:result-document instructions

The default behavior is to use the base output URI to resolve result documents.

**setSourceResolver**
Set the source resolver used to resolve documents loaded with the XPath fn:doc function and the XSLT fn:document function

The default behavior is to resolve documents based on the base URI from the static context for fn:doc and for fn:document if no base node is supplied. If the base URI is not available, the current working directory is used.

**setXSLTInitialMode**
Set the initial mode

If no initial mode is specified, the unnamed default mode is used.

**setXSLTInitialTemplate**
Set the initial template rule

If no initial template rule is specified, the initial template is chosen according to the rules of the xsl:apply-templates instruction for processing the initial context node in the initial mode.

**bindCollation**
Bind a Java Collator object or a Locale to a collation URI

If the collation URI is referenced in the stylesheet but no Collator or Locale is bound to it (with the exception of the Unicode code-point collation URI, which is bound by default), an error is raised.

**setCollectionResolver**
Set the collection resolver used to resolve URIs specified in calls to the XPath fn:collection function to a collection of nodes

If the fn:collection function is invoked and no collection resolver is registered an error is raised.

- Achieve an identity transformation by calling the exportItem method on an XItemView object created from a source using the XItemFactory.

  An identity XSLTExecutable cannot be created by preparing a null stylesheet.
- Achieve schema-aware transformations.

For schema-aware transformations, the processor picks up schemas registered with the XFactory instance through the registerSchema method or through the registerImportedSchemas method of the XSLTExecutable instance. But you should use the xsl:import-schema declaration to import them into the stylesheet as well, because this makes the stylesheet more portable.

For validating input documents, the schemas can be registered with the XFactory instance or declared in the XML file using the xsi:schemaLocation directive. In either case, validation needs to be enabled using the XFactory class setValidating method

## Example

The following is a basic example of preparing and executing an interpreted transformation.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create a StreamSource for the stylesheet
StreamSource stylesheet = new StreamSource("simple.xsl");

// Create an XSLT executable for the stylesheet
XSLTExecutable executable = factory.prepareXSLT(stylesheet);

// Create the input source
Source input = new StreamSource("simple.xml");

// Create the result
Result result = new StreamResult(System.out);

// Execute the transformation
executable.execute(input, result);
```

The following is a basic example of preparing and executing a compiled transformation.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create a StreamSource for the stylesheet
StreamSource stylesheet = new StreamSource("simple.xsl");

// Create a new static context
XStaticContext staticContext = factory.newStaticContext();

// Enable the compiler
staticContext.setUseCompiler(true);

// Create an XSLT executable for the stylesheet
XSLTExecutable executable = factory.prepareXSLT(stylesheet, staticContext);

// Create the input source
Source input = new StreamSource("simple.xml");

// Create the result
Result result = new StreamResult(System.out);

// Execute the transformation
executable.execute(input, result);
```

The following is a basic example of creating an identity transformation.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create the item factory
XItemFactory itemFactory = factory.getItemFactory();

// Create the input source
Source input = new StreamSource("simple.xml");

// Create the XItemView object from the input source
XItemView item = itemFactory.item(input);

// Create an XOutputParameters object
XOutputParameters params = factory.newOutputParameters();

// Set parameters
params.setMethod("xml");
params.setEncoding("UTF-8");
params.setIndent(true);

// Create the result
```

```
Result result = new StreamResult(System.out);

// Serialize to the result
item.exportItem(result, params);
```

The following is a basic example of creating a schema-aware transformation.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Enable validation
factory.setValidating(true);

// Create the schema source
StreamSource schema = new StreamSource("schema.xsd");

// Register the schema
factory.registerSchema(schema);

// Create the stylesheet source
StreamSource stylesheet = new StreamSource("schema.xsl");

// Create an XSLT executable for the stylesheet
XSLTExecutable executable = factory.prepareXSLT(stylesheet);

// Create the input source
StreamSource input = new StreamSource("schema.xml");

// Create the result
StreamResult result = new StreamResult(System.out);

// Execute the transformation
executable.execute(input, result);
```

## Performing basic XQuery operations

You can use the XQueryExecutable instances that are created using XFactory.prepareXQuery methods to evaluate XQuery expressions.

### About this task

XQuery expressions can be passed to the XFactory.prepareXQuery method using a JAXP StreamSource object or using a plain Java string object. The resulting XQueryExecutable instance is thread safe and can be reused to evaluate an XQuery expression on multiple XML input documents.

### Procedure

- Use the XStaticContext object with the prepareXQuery method to pass in settings that affect how the XQuery expression is prepared.

  If no XStaticContext object is provided, the default setting is used.

  **XStaticContext settings relevant to XQuery:**

  **declareFunction**
  Declare a Java extension function

  **declareNamespace**
  Declare a namespace prefix and associate it with a namespace URI to be used as part of an XQuery expression

  **declareVariable**
  Declare a variable externally to be used as part of an XQuery expression

  **setBaseURI**
  Set the base URI used in the resolution of relative URIs (such as by the fn:resolve-uri function)

  The default is the base URI of the expression, query, or stylesheet if the base URI is available. If the base URI is not available, the current working directory is used.

  **setBoundarySpacePolicy**
  Specify whether to preserve or strip white space

  The options are as follows:

**BOUNDARY_SPACE_STRIP (default)**

**BOUNDARY_SPACE_PRESERVE**

**setConstructionMode**
Specify whether to preserve the type of element and attribute nodes or strip them

The options are as follows:

**CONSTRUCTION_MODE_PRESERVE (default)**

**CONSTRUCTION_MODE_STRIP**

**setCopyNamespacesModeInherit**
Specify whether to inherit or ignore the namespace when copying element nodes

The options are as follows:

**COPY_NAMESPACES_MODE_INHERIT (default)**

**COPY_NAMESPACES_MODE_NO_INHERIT**

**setCopyNamespacesModePreserve**
Specify whether to preserve or strip the namespace when copying element nodes

The options are as follows:

**COPY_NAMESPACES_MODE_PRESERVE (default)**

**COPY_NAMESPACES_MODE_NO_PRESERVE**

**setDefaultCollation**
Set the default collation URI for string comparison operations

The default is the Unicode code point collation URI.

**setDefaultElementTypeNamespace**
Specify the URI of the default element or type namespace

Use an empty string to make it unspecified.

The default is an empty string.

**setDefaultFunctionNamespace**
Specify the URI of the default function namespace

Use an empty string to make it unspecified.

The default is "http://www.w3.org/2005/xpath-functions".

**setDefaultOrderForEmptySequences**
Set the behavior for default order on empty sequences to greatest or least

The options are as follows:

**DEFAULT_ORDER_FOR_EMPTY_SEQUENCES_LEAST (default)**

**DEFAULT_ORDER_FOR_EMPTY_SEQUENCES_GREATEST**

**setIntegerMathMode**
Set the integer math mode to one of the following:

**INTEGER_MATH_MODE_LIMITED_PRECISION**
Limit to 18-digit precision for xs:integer (default)

**INTEGER_MATH_MODE_ARBITRARY_PRECISION**
Allow users to have arbitrary precision for xs:integer

**INTEGER_MATH_MODE_OVERFLOW_DETECTION**
Generate an error if an overflow is detected

**setMessageHandler()**
Set the message handler for prepare-time errors

The default behavior is to print errors, warnings, and informational messages to System.err and to generate an XProcessException in the case of an unrecoverable error when compilation cannot continue. If the message handler that is registered does not generate its own exception in the case of an unrecoverable error, an XProcessException occurs.

**setOrderingMode**
Specify whether the results returned by certain path expressions, union, intersect, and except expressions as well as FLWOR expressions that have no order by clause are ordered or unordered

The options are as follows:

**ORDERING_MODE_ORDERED (default)**

**ORDERING_MODE_UNORDERED**

**setUseCompiler**
Indicate whether to generate a compiled executable or an interpreted executable

A compiled executable takes longer to generate but runs faster than an interpreted executable.

The default is interpreted.

- Provide an XDynamicContext object that can be used to pass settings to the XQueryExecutable.execute method.

  These settings affect the behavior during the execution when the processor is evaluating an XQuery expression.

  If no XDynamicContext object is provided, the default setting is used.

  **XDynamicContext settings relevant to XQuery:**

  **bind** Bind a value to an external variable

  **bindCollation**
  Binds an instance of the java.text.Collator class to a particular collation URI for use in string comparisons that use that collation URI

  **bindFunction**
  Bind an external function so that it can be used as part of an XQuery expression

  **bindSequence**
  Bind a sequence value to an external variable

  **setCollectionResolver**
  Set the collection resolver used to resolve documents loaded with the XPath fn:collection function

  The default behavior is for references to the fn:collection function to return an empty sequence.

  **setImplicitTimeZone**
  Set the implicit time zone

  The default is to use the system time zone as retrieved through the Java method java.util.TimeZone.getDefault().

  **setMessageHandler()**
  Set the message handler for execution-time errors

  The default behavior is to print errors, warnings and informational messages to System.err and to generate an XProcessException in the case of an unrecoverable error. If the message handler that is registered does not generate its own exception in the case of an unrecoverable error, an XProcessException occurs.

**setSourceResolver**
Set the source resolver used to resolve documents loaded with the XPath fn:doc function

The default behavior is to resolve documents based on the base URI from the static context. If the base URI is not available, the current working directory is used.

- Execute XQuery expressions with schema awareness.

  To validate the input XML files with XQuery, schema files can be registered using the XFactory.registerSchema() method or users can declare the xsi:schemaLocation directive in their input XML files. In either case validation needs to be enabled using the XFactory.setValidating() method. XQuery only supports validating the input XML file for now.

## Example

The following is a basic example of preparing and executing an interpreted XQuery expression.

```
// Create a string for the XQuery expression
String expression = "/doc/name[@first='David']";

// Create the factory
XFactory factory = XFactory.newInstance();

// Create the XQueryExecutable
XQueryExecutable xQueryExecutable = factory.prepareXQuery(expression);

// Create the input XML source
String xml = "<doc<name first='John'>Wrong</name><name first='David'>Correct</name></doc>";

// Execute the expression and store the results in an XSequenceCursor
XSequenceCursor xSequenceCursor = xQueryExecutable.execute(new StreamSource(new ByteArrayInputStream(xml.getBytes())));
```

The following is a basic example of preparing and executing a compiled XQuery expression.

```
// Create a string for the XQuery expression
String expression = "/doc/name[@first='David']";

// Create the factory
XFactory factory = XFactory.newInstance();

// Create a new static context from the factory
XStaticContext xStaticContext = factory.newStaticContext();

// Set the mode to compile for the processor
xStaticContext.setUseCompiler(true);

// Create the XQueryExecutable
XQueryExecutable xQueryExecutable = factory.prepareXQuery(expression, xStaticContext);

// Create the input XML source
String xml = "<doc><name first='John'>Wrong</name><name first='David'>Correct</name></doc>";

// Execute the expression and store the results in an XSequenceCursor
XSequenceCursor xSequenceCursor = xQueryExecutable.execute(new StreamSource(new ByteArrayInputStream(xml.getBytes())));
```

The following is a basic example of preparing and executing interpreted XQuery expressions with schema awareness.

```
// Create a string for the XQuery expression
String expression = "/my:doc/name[@first='David']/@first";

// Create the factory
XFactory factory = XFactory.newInstance();

// Create the schema source
String schema = "<xsd:schema xmlns:xsd='http://www.w3.org/2001/XMLSchema'" +
            " targetNamespace='http://www.schematype.ibm.com/UDSimple'" +
            " xmlns:my='http://www.schematype.ibm.com/UDSimple'" +
            " xmlns:smokey='http://www.schematype.ibm.com/UDSimple'>"
                   +" <xsd:element name='doc'>"
                   +   "<xsd:complexType> "
                   +   "<xsd:sequence>"
                   +   "<xsd:element name='name' minOccurs='0' maxOccurs='unbounded'>"
                   +  "<xsd:complexType>"
                   +   "<xsd:attribute name='first' type='xsd:string' use='optional'/>"
                   +  "</xsd:complexType>"
                   +   "</xsd:element>"
                   +  "</xsd:sequence>"
                   +  "</xsd:complexType>"
                   + "</xsd:element>"
                   + "</xsd:schema>";
```

```
// Load the schema
factory.registerSchema(new StreamSource(new ByteArrayInputStream(schema.getBytes())));

// Turn on validation
factory.setValidating(true);

// Create a new static context from the factory
XStaticContext xStaticContext = factory.newStaticContext();

// Add a new namespace
xStaticContext.declareNamespace("my", "http://www.schematype.ibm.com/UDSimple");

// Create the XQueryExecutable
XQueryExecutable xQueryExecutable = factory.prepareXQuery(expression, xStaticContext);

// Create the input XML source
String xml = "<my:doc xmlns:my='http://www.schematype.ibm.com/UDSimple'>" +
             "<name first='John'/><name first='David'/></my:doc>";

// Execute the expression and store the results in an XSequenceCursor
XSequenceCursor xSequenceCursor = xQueryExecutable.execute(new StreamSource(new ByteArrayInputStream(xml.getBytes())));
```

## Viewing the results

After your application has prepared or loaded the XExecutable object for an XPath expression (an XPathExecutable object), an XSLT stylesheet (an XSLTExecutable object), or an XQuery expression (an XQueryExecutable object), you apply the XExecutable object to some input and then do something with the result. The source of the input that you provide and what you would like to do with the result determine which of the execute methods you use.

### Procedure

- View XPath results.

  In the case of an XPath expression, the execute methods on the XPathExecutable interface return an instance of the XSequenceCursor class that contains the sequence that results from evaluating the expression with the given context item and dynamic context, if any.

  There is also a set of executeToList methods on the XPathExecutable interface. These methods return the sequence as an instance of the java.util.List<XItemView> interface, where each item in the sequence that results from evaluating the XPath expression is represented in the list as an instance of the XItemView interface. The entries in that list are in the same order as in the sequence that resulted from evaluating the XPath expression.

  The following example shows how to get the cost of each item on a purchase order as an XSequenceCursor.

```
XFactory factory = XFactory.newInstance();
XPathExecutable expr =
    factory.prepareXPath(
        "/purchaseOrder/item/(@unit-price * @quantity)");
XSequenceCursor exprResult = expr.execute(new StreamSource("input.xml"));
```

  The following example shows how to get the cost of each item on a purchase order in an instance of the java.util.List interface.

```
XFactory factory = XFactory.newInstance();
XPathExecutable expr =
    factory.prepareXPath(
        "/purchaseOrder/item/(@unit-price * @quantity)");
List<XItemView> exprResult =
   expr.executeToList(new StreamSource("input.xml"));
```

- Use the XItemView interface.

  You can access each item in a sequence using the methods on the XItemView interface. You can use the XItemView.isAtomic() method to determine whether the item is an atomic value or a node. If the item is an atomic value, you can use the getValueType() method on the XItemView interface. This method returns an instance of the enumerated type XTypeConstants.Type. If the atomic value is an instance of a built-in atomic type or a user-defined type derived from a built-in atomic type, the result of the getValueType() method is the enumerated value corresponding to that type. For an atomic value that could be of a user-defined derived type, you also might find it handy to use the XItemView.getValueTypeName() method to determine the precise type of the value.

  Given the type of an atomic value, you then can use the appropriate method to get the value.

```
XFactory factory = XFactory.newInstance();
XPathExecutable expr =
    factory.prepareXPath(
        "sum(/purchaseOrder/item/(@unit-price * @quantity))");
XItemView exprResult =
   expr.execute(new StreamSource(purchaseOrder));
double totalCost = 0.0;

// Decide how to get result based on the type of the value
switch (exprResult.getValueType()) {
case DOUBLE: {
    totalCost = exprResult.getDoubleValue();
    break;
}
case FLOAT: {
    totalCost = exprResult.getFloatValue();
    break;
}
case INTEGER: {
    totalCost = exprResult.getLongValue();
    break;
}
case DECIMAL: {
    totalCost = exprResult.getDecimalValue().doubleValue();
    break;
}
default: {
    System.err.println("Unexpected type for result");
}
}
```

The XItemView interface also extends the XNodeView interface, so if the result of calling the XItemView.isAtomic() method is false – that is, the item is a node – you can use the methods inherited from the XNodeView interface to access information about the node. The XNodeView.getNodeQName() method will return the name of the node and the XNodeView.getKind() method will return a value of the enumerated type XNodeView.Kind indicating what sort of node the item is: XNodeView.DOCUMENT, XNodeView.ELEMENT, and so on.

```
XFactory factory = XFactory.newInstance();

// Prepare an expression to get the first node whose string value matches a given query string
XPathExecutable expr =
    factory.prepareXPath(
        "(/descendant-or-self::node()/(self::node()|@*)[. = 'search'])[1]");
XItemView exprResult =
   expr.execute(new StreamSource(inputFile));

// Print the kind of node found and its name, if appropriate
switch (exprResult.getKind()) {
case ELEMENT: {
    System.out.print("Element " + exprResult.getNodeQName().toString());
    break;
}
case ATTRIBUTE: {
    System.out.print("Attribute " + exprResult.getNodeQName().toString());
    break;
}
case COMMENT: {
    System.out.print("Comment ");
    break;
}
case PROCESSING_INSTRUCTION: {
    System.out.print("PI " + exprResult.getNodeQName().toString());
}
}
```

You can also explore the tree that contains a node using the XTreeCursor interface.

- View XSLT and XQuery results.

  All the execute and executeToList methods available from the XPathExecutable interface are actually inherited from the XExecutable interface, so they are available for use on instances of the XSLTExecutable interface or the XQueryExecutable interface as well. In the case of an instance of the XQueryExecutable interface, the object the method returns contains the sequence that resulted from evaluating the query. In the case of the XSLTExecutable interface, the sequence contains the document node of the primary result of evaluating the stylesheet, if there is any.

  The XSLTExecutable and XQueryExecutable interfaces also define execute methods that accept an instance of the javax.xml.transform.Result interface. The result object that your application supplies will contain the primary result of evaluating the stylesheet, in the case of the XSLTExecutable interface, or the result of evaluating your query, in the case of XQueryExecutable.

The following example produces a DOM tree as the result of a transformation, and stores the tree in the instance of the DOMResult class that is passed as an argument to the XSLTExecutable.execute method.

```
XFactory factory = XFactory.newInstance();
XSLTExecutable style = factory.prepareXSLT(new StreamSource("style.xsl"));
DOMResult res = new DOMResult();
style.execute(new StreamSource("purchase.xml"), res);
Node node = res.getNode();
```

The following example produces an instance of the XSequenceCursor interface as the result of transformation.

```
XFactory factory = XFactory.newInstance();
XSLTExecutable style = factory.prepareXSLT(new StreamSource("style.xsl"));
XSequenceCursor xformResult =
        style.execute(new StreamSource("purchase.xml"));
```

- Use the XResultResolver and XSLT.

  An XSLT 2.0 stylesheet can produce more than one result document by using the xsl:result-document instruction. The primary result of the transformation is produced for any result tree that the stylesheet constructs that is not contained in an xsl:result-document instruction or that is contained in an xsl:result-document instruction that has an href attribute whose effective value is a zero-length string. The primary result is returned to your application using the various means described above.

  If your stylesheet evaluates an xsl:result-document instruction that has an href attribute whose effective value is not a zero-length string, by default that result is written to an output stream. The URI of the output stream is determined by resolving the effective value of the href attribute against the setting of the base output URI in the dynamic context.

  You can override this default behavior by supplying an instance of the XResultResolver interface on the XDynamicContext you use for the transformation. The getResult method on the XResultResolver interface is called if any xsl:result-document instructions are invoked; the result of the getResult method is an instance of the Result interface where the result of the xsl:result-document instruction is directed. Using the XResultResolver interface allows your application to decide on a case by case basis where to direct the result of all the xsl:result-document instructions in your stylesheets. If your application did not supply an instance of the Result interface for the primary result on the execute method of the XSLTExecutable interface, the getResult method of XResultResolver is called for the primary result as well.

  If the getResult method of XResultResolver returns a null reference, the default behavior is restored for that particular result—that is, the result is written to an output stream, in the case of a secondary result, or returned from as the result of the execute method as an instance of the XSequenceCursor interface, in the case of the primary result.

  The following example uses an instance of the XResultResolver interface to capture all the results produced by a stylesheet as instances of the XSequenceCursorResult class in the variable allResults. The application then could extract the instance of the XSequenceCursor interface that each instance of the XSequenceCursorResult class contains using the XSequenceCursorResult.getSequenceCursor() method.

```
final ArrayList<XSequenceCursorResult> allResults =
            new ArrayList<XSequenceCursorResult>();
XFactory factory = XFactory.newInstance();
XDynamicContext context = factory.newDynamicContext();

// Create XResultResolver that saves XSequenceCursorResult
// instances in allResults
context.setResultResolver(new XResultResolver() {
        public Result getResult(String href, String base) {
            XSequenceCursorResult result =
                    new XSequenceCursorResult();
            allResults.add(result);
            return result;
        }
    });

XSLTExecutable style = factory.prepareXSLT(new StreamSource("style.xsl"));
style.execute(new StreamSource("purchase.xml"), context);

// All results, including the primary, are now available from the allResults variable.
```

## Serializing the results

After your application has evaluated an XPath or XQuery expression or performed a transformation with an XSLT stylesheet, you might want to write the output as an actual XML document represented as a file or as a Java string. The process of rendering results as an XML document is known as serialization.

### Procedure

- Serialize an XSequenceCursor.

  Your application can call the XSequenceCursor.exportSequence method to serialize a sequence that is represented by an instance of the XSequenceCursor interface. The arguments on this method are an instance of the javax.xml.transform.Result interface and optionally an instance of the XOutputParameters interface.

  If the instance of the Result interface is also an instance of the javax.xml.transform.stream.StreamResult class, the sequence is serialized as described in the XSLT 2.0 and XQuery 1.0 Serialization Recommendation. The StreamResult object can contain an instance of the java.io.Writer class or the java.io.OutputStream class, where the processor will write the serialized sequence.

  You can create an instance of the XOutputParameters interface by calling XFactory.newOutputParameters() and call the methods on that object to override the default serialization parameter settings.

```
XFactory factory = XFactory.newInstance();
XPathExecutable expr = factory.prepareXPath("/purchaseOrder/item[@price > 1000]");
XSequenceCursor exprResult = expr.execute(new StreamSource(inputFile));

System.out.println("Items purchased costing more than $1000");
if (exprResult != null) {
    // Set indenting in order to pretty-print result
    XOutputParameters params = factory.newOutputParameters();
    params.setIndent(true);
    exprResult.exportSequence(new StreamResult(System.out), params);
} else {
    System.out.println("None found");
}
```

  You can also call one of the getOutputParameters() methods on an instance of the XSLTExecutable interface to get the serialization parameters that are associated with a particular output definition in an XSLT stylesheet. Use the XSLTExecutable.getOutputParameters(javax.xml.namespace.QName) method to get the serialization parameters for a named output definition or the no-argument XSLTExecutable.getOutputParameters() method to get those of the unnamed output definition. You might want do this to perform some post-processing on the result of the transformation using the instance of the XSequenceCursor interface that the transformation produces before serializing the result. If you change the settings of the serialization parameters in the instance of the XOutputParameters interface returned by one of the XSLTExecutable.getOutputParameters() methods, it will not affect the output definition in the stylesheet.

```
XFactory factory = XFactory.newInstance();
XSLTExecutable style = factory.prepareXSLT(new StreamSource("style.xsl"));
XSequenceCursor xformResult = style.execute(new StreamSource("purchase.xml");

XOutputParameters params = style.getOutputParameters(new QName("my-output-definition"));
params.setMethod(XOutputParameters.METHOD_XHTML);
xformResult.exportSequence(new StreamResult("output.html"), params);
```

  Note that according to the XSLT 2.0 and XQuery 1.0 Serialization Recommendation, a serialization error results if the sequence that is to be serialized contains attribute nodes or namespace nodes. If the sequence that you need to serialize might contain attribute or namespace nodes, get the values of those nodes as strings or some other appropriate type and serialize those values instead.

- Serialize a single item.

  You can also serialize just the current item in an instance of the XSequenceCursor interface by using one of the exportItem methods. The exportItem methods are inherited from the XItemView interface, so they can be called on an instance of that interface as well.

  As with the exportSequence method described above, the arguments of the exportItem method are an instance of the javax.xml.transform.Result interface and optionally an instance of the XOutputParameters interface. The effect of calling exportItem is identical to the effect of calling exportSequence with a sequence that consists of just the current item.

- Serialize the result of a transformation or query directly.

  Your application can also serialize the result of an XSLT transformation or XQuery expression directly by supplying an instance of the javax.xml.transform.Result interface on the XSLTExecutable.execute method or XQueryExecutable.execute method. The serialization parameter settings are determined by the attributes of any applicable xsl:output declaration or xsl:result-document instruction in the case of an XSLT stylesheet, and are always the default values in the case of the result of an XQuery expression.

```
XFactory factory = XFactory.newInstance();
XSLTExecutable style = factory.prepareXSLT(new StreamSource("style.xsl"));
style.execute(new StreamSource("purchase.xml"),
              new StreamResult("output.xml"));
```

  If your application supplies an instance of the XResultResolver interface on a transformation, your application can direct each final result tree to a different destination.

- Use identity transformation.

  You can use the XML API to transform XML data contained in an instance of javax.xml.transform.Source directly to an instance of a javax.xml.transform.Result. This is often referred to as an identity transformation. See “Performing basic XSLT operations” on page 2204 for an example.

## Navigating with XSequenceCursor

The XSequenceCursor interface gives you a view of your sequence data.

### About this task

A sequence in the XPath and XQuery Data Model contains zero or more atomic values, nodes, or a mixture of both. An instance of the XSequenceCursor interface always contains at least one item. If a sequence is empty, it is always represented by a null reference.

### Procedure

- At any given time, an instance of the XSequenceCursor interface is positioned to give you access to one of the items in a sequence. It is positioned initially at the first item in the sequence; and you can move forward or backward in the sequence, one item at a time, using the toNext() or toPrevious() methods, respectively.

  If the toNext() method or toPrevious() method is able to position the XSequenceCursor instance to the next or previous item in the sequence—that is, if there actually is a next or previous item—the method returns true. If the XSequenceCursor instance is already positioned at the last item in the case of the toNext() method or the first item in the case of the toPrevious() method, the method returns false and the instance of the XSequenceCursor interface remains positioned at the same item as before the call.

  The typical way of processing a sequence that is contained in an instance of the XSequenceCursor interface is as shown in the following example:

```
XFactory factory = XFactory.newInstance();
XPathExecutable expr = factory.prepareXPath("1 to 10");
XSequenceCursor exprResult = expr.execute();
long sum = 0;

// If exprResult is null, it means the result sequence is empty
if (exprResult != null) {
    do {
        // Get each value as a primitive Java long value, and accumulate
        sum = sum + exprResult.getLongValue();

        // Advance exprResult to the next item in the sequence
    } while (exprResult.toNext());
}

System.out.println("Sum is " + sum);
```

  The XSequenceCursor interface extends the XItemView interface. You can use the methods inherited from the XItemView interface to access the value and the type of the item in the sequence at which the XSequenceCursor is currently positioned.

- If your application needs to refer to more than one item in the sequence at the same time, you can call the method XSequenceCursor.getSingletonItem() to get an instance of the XItemView interface containing the data associated with the current item in the instance of the XSequenceCursor interface.

If you change the position of that instance of the XSequenceCursor interface through a call to the toNext() method or the toPrevious() method, the instance of the XItemView interface that was returned by an earlier call to the XSequenceCursor.getSingletonItem() method will still refer to that earlier item.

Consider the following example, which counts the number of items in a sequence that have the same type and value as the first item.

```
XFactory factory = XFactory.newInstance();

// Make a path expression whose result contains ordered part number as first item
// and all part numbers used by products in the catalog as the subsequent items
XPathExecutable expr =
    factory.prepareXPath(
        "string(/order/item/@part-num),doc('catalog.xml')/catalog/product/part/string(@part-num)");

// Read the invoice file
XSequenceCursor exprResult = expr.execute(new StreamSource(invoiceFile));

int sameAsFirstCount = 0;

// If exprResult is null, it means the result sequence is empty
if (exprResult != null) {
    // Get the first item in the result sequence
    XItemView firstItem = exprResult.getSingletonItem();

    // currentItem always refers to the current item in the result sequence
    XItemView currentItem = exprResult;
    do {
        // Get the type of the first item
        XTypeConstants.Type itemType = firstItem.getValueType();

        // Ensure the type of the first item is the same as the type of
        // the current item, and compare their values as Java objects
        if (itemType == currentItem.getValueType()
                && firstItem.getObjectValue(itemType)
                      .equals(currentItem.getObjectValue(itemType))) {
            sameAsFirstCount++;
        }

        //Advance exprResult (and currentItem) to the next item in the sequence
    } while (exprResult.toNext());
}

System.out.println("Number of items same as the first == "+(sameAsFirstCount-1));
```

The variable firstItem is created by the XSequenceCursor.getSingletonItem() method, so it always refers to the first item in the sequence. The variable currentItem contains a reference to the XSequenceCursor object, however, so it is always positioned at the current item in the sequence.

- If you ever need to access the items in the sequence non-sequentially, you might find it convenient to use the exportAsList method on the XSequenceCursor interface.

  This method returns an instance of the java.util.List<XItemView> interface that contains the items in your sequence in sequence order.

## Navigating with XTreeCursor

You can use the XTreeCursor interface to view your data.

### About this task

Suppose the sequence that results from evaluating an XPath or XQuery expression or an XSLT stylesheet contains nodes. You will find it very convenient to access the contents of those nodes by applying further XPath or XQuery expressions to those nodes. However, you might also choose to navigate through the tree structure associated with a node directly through the XML API.

### Procedure

- If the result of calling the XItemView.isAtomic() method is false—that is, the context item is a node—your application can call the XItemView.getXTreeCursor() method to gain direct access to the tree that contains the node.

  The XSequenceCursor interface extends XItemView, so calling the XSequenceCursor.getXTreeCursor() method returns an instance of the XTreeCursor interface that you can use to access the node on which the instance of the XSequenceCursor interface is positioned.

- The XTreeCursor interface also extends the XItemView interface; therefore, you can use the methods inherited from the XItemView interface to access information about the node on which your instance of the XTreeCursor interface is currently positioned.

  In particular, you can use the XTreeCursor.getXTreeCursor() method to create another instance of the XTreeCursor interface that you can use to navigate through the tree independently of the instance of the XTreeCursor interface from which it was created.

## Example

The following example shows how you can use the methods on the XTreeCursor interface to navigate through the tree containing your XML data.

```
/* Contents of library.xml

<library>
  <book title='Ulysses'><author><first>James</first><last>Joyce</last></author></book>
  <book title='Ada'><author><first>Vladimir</first><last>Nabokov</last></author></book>
</library>
*/

XItemFactory factory = XFactory.newInstance().getItemFactory();
XItemView item = factory.item(new StreamSource("library.xml"));

// 'tree' is initially positioned at the same node as
// 'item' - that is, the document node of the input
XTreeCursor tree = item.getTreeCursor();

// Position tree cursor to "library" element
tree.toFirstChild();

// Position tree cursor to white-space text node
tree.toFirstChild();

// Position to first "book" element
tree.toNextSibling();

// Position to white-space text node
tree.toNextSibling();

// Position to second "book" element
tree.toNextSibling();

// Create a second instance of XTreeCursor that is initially
// positioned at the same node as 'tree' - that is, the
// second "book" element
XTreeCursor secondBook = tree.getTreeCursor();

// Position 'tree' to "library" element
tree.toParent();

// Position 'secondBook' to "title" attribute
secondBook.toFirstAttribute();
```

The following example navigates through all the nodes in a tree in a depth-first fashion.

```
XItemFactory factory = XFactory.newInstance().getItemFactory();
XItemView item = factory.item(new StreamSource("library.xml"));

XTreeCursor tree = item.getTreeCursor();
boolean hasMoreNodes = true;

do {
    // Process current node

    if (tree.toFirstAttribute()) {
        do {
            // Process attributes
        } while (tree.toNextAttribute());
        tree.toParent();
    }

    if (tree.toFirstNamespace()) {
        do {
            // Process namespaces
        } while (tree.toFirstNamespace());
        tree.toParent();
    }

    boolean foundNext = false;

    // If the current node has a child, visit it next
    // If there's no child, go to the next sibling
    if (tree.toFirstChild() || tree.toNextSibling()) {
```

```
        foundNext = true;

    // If there's no child and no sibling, find an
    // ancestor's sibling instead.
    } else {
        do {
            hasMoreNodes = tree.toParent();
            if (hasMoreNodes) {
                foundNext = tree.toNextSibling();
            }
        } while (hasMoreNodes && !foundNext);
    }
} while (hasMoreNodes);
```

# Precompiling

You can use this information to help you to precompile an expression, query, or stylesheet.

## Procedure

- Precompile using the command-line tool.
- Precompile in Java.
- Load a precompiled executable.

## Precompiling using the command-line tools

You can use the CompileXSLT tool to precompile one or more stylesheets, use the CompileXPath tool to precompile one or more XPath expressions, and use the CompileXQuery tool to precompile one or more XQuery expressions.

### About this task

**Note:** See “Precompiling using ANT tasks” on page 2227 for information about using the TaskCompileXPath, TaskCompileXQuery, and TaskCompileXSLT ANT tasks as alternatives to using the CompileXPath, CompileXQuery, and CompileXSLT commands.

### Procedure

- **Compile XSLT**

  **Location**

  The product includes the following script that sets up the environment and invokes the tool.

  – Windows *app_server_root*\bin\compileXSLT.bat

  – AIX HP-UX Linux Solaris *app_server_root*/bin/compileXSLT.sh

  **Syntax**

  Windows

```
compileXSLT.bat
      -out output
      -dir directory
      -pkg package
      [-func name=funcName type=funcType argtype=argType...] ...
      -baseURI URI
      -imm int
      -v
      -h
      { stylesheet... | -i }
```

  AIX HP-UX Linux Solaris

```
./compileXSLT.sh
      -out output
      -dir directory
      -pkg package
      [-func name=funcName type=funcType argtype=argType...] ...
      -baseURI URI
      -imm int
      -v
      -h
      { stylesheet... | -i }
```

**Parameters**

**-out** *output*
Uses the name *output* as the base name for the generated classes

By default, the base name is XSLTModule.

This option is ignored if compiling multiple stylesheets.

**-dir** *directory*
Specifies a destination directory for the generated classes

The default is the current working directory.

**-pkg** *package*
Specifies a package name prefix for all generated classes

The default is the Java default package.

**-func name=***funcName* **type=***funcType* **argtype=***argType*
Adds a function binding to the static context for a single item

This simply declares the function, and a method object for the function also must be bound to the dynamic context at execution time.

*funcName*
Specifies the name of the function (expressed localPart,namespaceURI)

*funcType*
Specifies the return type of the function (expressed localPart,namespaceURI)

*argType*
Specifies the types of the function arguments (expressed localPart,namespaceURI) and is optional

This option can be used multiple times.

If the value of any option contains a blank space, enclose it in quotation marks.

This option can be used multiple times.

For example:

```
-func name=getId,http://example.org type=integer,http://www.w3.org/2001/XMLSchema argtype=string,http://www.w3.org/2001/XMLSchema
```

**-baseURI** *URI*
Specifies the base URI of the containing element

**-imm** *int*
Sets the integer math mode, which is a constant representing the level of precision required and whether overflow detection is required when working with xs:integer values

Valid values include:

**1** Values need only support the minimum precision required for a minimally conforming processor (18 digits).

**2** Values should support an arbitrary number of digits of precision; no overflow should occur.

**3** Values need only support the minimum precision required for a minimally conforming processor (18 digits); but any overflow condition should be detected and error FOAR0002 should be raised.

**-i** Forces the compiler to read the stylesheet from standard in

**-v** Prints the version of the compiler

**-h** Prints the usage statement

*stylesheet*

Full path to a file containing an XSL stylesheet to be compiled

The following is a basic example of compiling a stylesheet using the CompileXSLT tool:

– Windows `compileXSLT.bat -pkg com.examples -dir C:\stylesheets\output C:\stylesheets\simple.xml`

This compiles the `C:\stylesheets\simple.xml` stylesheet and places the resulting files in `C:\stylesheets\output\com\examples`.

– AIX HP-UX Linux Solaris `./compileXSLT.sh -pkg com.examples -dir /var/stylesheets/output /var/stylesheets/simple.xml`

This compiles the `/var/stylesheets/simple.xml` stylesheet and places the resulting files in `/var/stylesheets/output/com/examples`.

- **Compile an XPath expression**

**Location**

The product includes the following script that sets up the environment and invokes the tool.

– Windows *app_server_root*\bin\compileXPath.bat

– AIX HP-UX Linux Solaris *app_server_root*/bin/compileXPath.sh

**Syntax**

Windows

```
compileXPath.bat
      -out output
      -dir directory
      -pkg package
      -cpm mode
      -ns prefix=URI
      -schema URI
      [-func name=funcName type=funcType argtype=argType...] ...
      [-var name=varName type=varType] ...
      -baseURI URI
      -dnet URI
      -dnf URI
      -imm int
      -v
      -h
      { xpathfile... | -i }
```

AIX HP-UX Linux Solaris

```
./compileXPath.sh
      -out output
      -dir directory
      -pkg package
      -cpm mode
      -ns prefix=URI
      -schema URI
      [-func name=funcName type=funcType argtype=argType...] ...
      [-var name=varName type=varType] ...
      -baseURI URI
      -dnet URI
      -dnf URI
      -imm int
      -v
      -h
      { xpathfile... | -i }
```

**Parameters**

**-out** *output*

Uses the name *output* as the base name for the generated classes

By default, the base is XPathModule.

This option is ignored if compiling multiple expressions.

**-dir** *directory*
Specifies a destination directory for the generated executable

The default is the current working directory.

**-pkg** *package*
Specifies a package name prefix for all generated classes

The default is the Java default package.

**-cpm** *mode*
Specifies an alternate XPath compatibility mode.

For example, use 1.0 for compatibility with XPath Version 1.0.

**-ns** *prefix*=*URI*
Specifies a namespace for use during static processing

If the value of any option contains a blank space, enclose it in quotation marks.

This option can be used multiple times. In the case of multiple -ns arguments with the same prefix, the last one prevails.

**-schema** *URI*
Specifies any schema document that is used to populate the in-scope schema definitions

This option can be used multiple times.

**-func name=***funcName* **type=***funcType* **argtype=***argType*
Adds a function binding to the static context for a single item

This simply declares the function, and a method object for the function also must be bound to the dynamic context at execution time.

*funcName*
Specifies the name of the function (expressed localPart,namespaceURI)

*funcType*
Specifies the return type of the function (expressed localPart,namespaceURI)

*argType*
Specifies the types of the function arguments (expressed localPart,namespaceURI) and is optional

This option can be used multiple times.

If the value of any option contains a blank space, enclose it in quotation marks.

This option can be used multiple times.

For example:

```
-func name=getId,http://example.org type=integer,http://www.w3.org/2001/XMLSchema argtype=string,http://www.w3.org/2001/XMLSchema
```

**-var name=***varName* **type=***varType*
Adds a variable binding to the static context for a single item

This simply declares the variable, and a value also must be bound to the XDynamicContext at execution time.

*varName*
Specifies the name of the variable (expressed localPart[, namespaceURI])

If the variable is in no namespace, the namespace URI should be omitted.

Localpart is a required value.

*varType*
Specifies the type of the variable (expressed localPart,namespaceURI)

If the value of any option contains a blank space, enclose it in quotation marks.

This option can be used multiple times.

For example:

```
-var name=la,"http://www.ibm.com/Los Angeles" type=boolean,http://www.w3.org/2001/XMLSchema
```

**-baseURI** *URI*
Specifies the base URI of the containing element

**-dnet** *URI*
Specifies a default namespace URI for element and type names

The namespace URI, if present, is used for any unprefixed QName appearing in a position where an element or type name is expected.

**-dnf** *URI*
Specifies a default namespace URI for function names

The namespace URI, if present, is used for any unprefixed QName appearing in a position where a function name is expected.

**-imm** *int*
Sets the integer math mode, which is a constant representing the level of precision required and whether overflow detection is required when working with xs:integer values

Valid values include:

**1** Values need only support the minimum precision required for a minimally conforming processor (18 digits).

**2** Values should support an arbitrary number of digits of precision; no overflow should occur.

**3** Values need only support the minimum precision required for a minimally conforming processor (18 digits); but any overflow condition should be detected and error FOAR0002 should be raised.

**-v** Prints the version of the compiler

**-h** Prints the usage statement

*xpathfile*
Full path to a file containing an XPath expression to be compiled

**-i** Forces the compiler to read the XPath expression from standard in

The following is a basic example of compiling an XPath expression using the CompileXPath tool:

– Windows `compileXPath.bat -pkg com.examples -dir C:\XPath\output C:\XPath\simpleXPath.txt`
This compiles the XPath expression provided in `C:\XPath\simpleXPath.txt` and places the resulting files in `C:\XPath\output\com\examples`.

– AIX HP-UX Linux Solaris `./compileXPath.sh -pkg com.examples -dir /var/XPath/output /var/XPath/simpleXPath.txt`
This compiles the XPath expression provided in `/var/XPath/simpleXPath.txt` and places the resulting files in `/var/XPath/output/com/examples`.

- **Compile an XQuery expression**

**Location**
The product includes the following script that sets up the environment and invokes the tool.

– Windows *app_server_root*\bin\compileXQuery.bat

– AIX HP-UX Linux Solaris *app_server_root*/bin/compileXQuery.sh

## Syntax

Windows

```
compileXQuery.bat
      -out output
      -dir directory
      -pkg package
      [-func name=funcName type=funcType argtype=argType...] ...
      -baseURI URI
      -dnet URI
      -dnf URI
      -imm int
      -bsp int
      -csm int
      -cnmi int
      -cnmp int
      -eso int
      -ordm int
      -v
      -h
      { xqueryfile... | -i }
```

AIX HP-UX Linux Solaris

```
./compileXQuery.sh
      -out output
      -dir directory
      -pkg package
      [-func name=funcName type=funcType argtype=argType...] ...
      -baseURI URI
      -dnet URI
      -dnf URI
      -imm int
      -bsp int
      -csm int
      -cnmi int
      -cnmp int
      -eso int
      -ordm int
      -v
      -h
      { xqueryfile... | -i }
```

## Parameters

**-out** *output*

Uses the name *output* as the base name for the generated classes

By default, the base name is XQueryModule.

This option is ignored if compiling multiple expressions.

**-dir** *directory*

Specifies a destination directory for the generated classes

The default is the current working directory.

**-pkg** *package*

Specifies a package name prefix for all generated classes

The default is the Java default package.

**-func name=***funcName* **type=***funcType* **argtype=***argType*

Adds a function binding to the static context for a single item

This simply declares the function, and a method object for the function also must be bound to the dynamic context at execution time.

*funcName*

Specifies the name of the function (expressed localPart,namespaceURI)

*funcType*

Specifies the return type of the function (expressed localPart,namespaceURI)

*argType*
Specifies the types of the function arguments (expressed localPart,namespaceURI) and is optional

This option can be used multiple times.

If the value of any option contains a blank space, enclose it in quotation marks.

This option can be used multiple times.

For example:

```
-func name=getId,http://example.org type=integer,http://www.w3.org/2001/XMLSchema argtype=string,http://www.w3.org/2001/XMLSchema
```

**-baseURI** *URI*
Specifies the base URI of the containing element

**-dnet** *URI*
Specifies a default namespace URI for element and type names

The namespace URI, if present, is used for any unprefixed QName appearing in a position where an element or type name is expected.

**-dnf** *URI*
Specifies a default namespace URI for function names

The namespace URI, if present, is used for any unprefixed QName appearing in a position where a function name is expected.

**-imm** *int*
Sets the integer math mode, which is a constant representing the level of precision required and whether overflow detection is required when working with xs:integer values

Valid values include:

**1** Values need only support the minimum precision required for a minimally conforming processor (18 digits).

**2** Values should support an arbitrary number of digits of precision; no overflow should occur.

**3** Values need only support the minimum precision required for a minimally conforming processor (18 digits); but any overflow condition should be detected and error FOAR0002 should be raised.

**-bsp** *int*
Specifies the boundary space policy

Valid values include:

**1** Preserve white spaces

**2** Strip white spaces

This is the default value.

**-csm** *int*
Specifies the construction mode

Valid values include:

**1** Preserve

The type of a constructed element node is xs:anyType, and all attribute and element nodes copied during node construction retain their original types.

This is the default value.

**2** Strip

The type of a constructed element node is xs:untyped, all element nodes copied during node construction receive the type xs:untyped, and all attribute nodes copied during node construction receive the type xs:untypedAtomic.

**-cnmi** *int*
Specifies the inherit part of the copy-namespaces

Valid values include:

**1** Inherit

Inherit mode should be used in namespace binding assignment when an existing element node is copied by an element constructor.

This is the default value.

**2** No inherit

No-inherit mode should be used in namespace binding assignment when an existing element node is copied by an element constructor.

**-cnmp** *int*
Specifies the preserve part of the copy-namespaces

Valid values include:

**1** Preserve

Preserve mode should be used in namespace binding assignment when an existing element node is copied by an element constructor.

This is the default value.

**2** No preserve

No-preserve mode should be used in namespace binding assignment when an existing element node is copied by an element constructor.

**-eso** *int*
Specifies the empty sequence order

Valid values include:

**1** Greatest

**2** Least

This is the default value.

**-ordm** *int*
Specifies the ordering mode

Valid values include:

**1** Ordered results are to be returned by certain path expressions, union, intersect, and except expressions, as well as FLWOR expressions that have no order by clause

This is the default value.

**2** Unordered results are to be returned by certain path expressions, union, intersect, and except expressions, as well as FLWOR expressions that have no order by clause

**-v** Prints the version of the compiler

**-h** Prints the usage statement

*xqueryfile*
Full path to a file containing an XQuery expression to be compiled

**-i** Forces the compiler to read the stylesheet from standard in

The following is a basic example of compiling an XQuery expression using the CompileXQuery tool:

- Windows `compileXQuery.bat -pkg com.examples -dir C:\XQuery\output C:\XQuery\simpleXQuery.txt`

  This compiles the XQuery expression provided in `C:\XQuery\simpleXQuery.txt` and places the resulting files in `C:\XQuery\output\com\examples`.

- AIX HP-UX Linux Solaris `./compileXQuery.sh -pkg com.examples -dir /var/XQuery/output /var/XQuery/simpleXQuery.txt`

  This compiles the XQuery expression provided in `/var/XQuery/simpleXQuery.txt` and places the resulting files in `/var/XQuery/output/com/examples`.

## Precompiling using ANT tasks

You can use the TaskCompileXPath, TaskCompileXQuery, and TaskCompileXSLT ANT tasks as alternatives to using the CompileXPath, CompileXQuery, and CompileXSLT commands.

### About this task

**ANT task elements:**

**argType**

This element indicates the types of the function arguments expressed in terms of the localpart and namespaceURI.

**Parameters specified as nested elements:**

**localpart**

A nested localpart element must be specified to provide the local part of the qualified name.

**namespaceURI**

A nested namespaceURI element can be specified to indicate the namespaceURI.

**Example:**

```
<argType>
  <localpart>boolean</localpart>
  <namespaceURI>"http://www.w3.org/2001/XMLSchema"</namespaceURI>
</argType>
```

**baseURI**

This element specifies the base URI of the containing element.

**Example:**

```
<baseURI>"http://www.ibm.com/Los Angeles"</baseURI>
```

**bsp** This element specifies the Boundary Space Policy.

Valid values include:

- 1 = preserve white spaces
- 2 = strip white spaces

The default value is 2 (strip white spaces).

**Example:**

```
<bsp>1</bsp>
```

**cnmi** This element specifies the inherit part of the copy-namespaces.

Valid values include:

- 1 = inherit

  Inherit mode should be used in namespace binding assignment when an existing element node is copied by an element constructor.
- 2 = no inherit

  No-inherit mode should be used in namespace binding assignment when an existing element node is copied by an element constructor.

The default is 1 (inherit).

**Example:**

```
<cnmi>2</cnmi>
```

**cnmp** This element specifies the preserve part of the copy-namespaces.

Valid values include:

- 1 = preserve

  Preserve mode should be used in namespace binding assignment when an existing element node is copied by an element constructor.
- 2 = no preserve

  No-preserve mode should be used in namespace binding assignment when an existing element node is copied by an element constructor.

The default is 1 (preserve).

**Example:**

```
<cnmp>2</cnmp>
```

**cpm** This element specifies an alternate XPath Compatibility Mode.

Valid values are:

- Latest
- 1.0
- 2.0

For example: use 1.0 for compatibility with XPath Version 1.0.

The default is 2.0.

**Example:**

```
<cpm>1.0</cpm>
```

**csm** This element specifies the Construction Mode.

Valid values include:

- 1 = preserve

  The type of a constructed element node is xs:anyType, and all attribute and element nodes copied during node construction retain their original types.
- 2 = strip

  The type of a constructed element node is xs:untyped, all element nodes copied during node construction receive the type xs:untyped, and all attribute nodes copied during node construction receive the type xs:untypedAtomic.

The default value is 1 (preserve).

**Example:**

```
<csm>2</csm>
```

**dir** This element specifies a destination directory for the executables.

The default is the current working directory.

If the value contains a blank space, enclose it in quotation marks.

**Example:**

```
<dir>C:/precompiledXSLT</dir>
```

**dnet** This element specifies a default namespace URI for element and type names.

The namespace URI, if present, is used for any unprefixed QName appearing in a position where an element or type name is expected.

**Example:**

```
<dnet>http://example.org/ibm</dnet>
```

**dnf** This element specifies a default namespace URI for function names.

The namespace URI, if present, is used for any unprefixed QName appearing in a position where a function name is expected.

**Example:**

```
<dnf>http://my.org</dnf>
```

**eso** This element specifies the Empty Sequence Order.

Valid values include:

- 1 = greatest
- 2 = least

The default value is 2 (empty sequences least).

**Example:**

```
<eso>1</eso>
```

**function**

For the CompileXSLT, CompileXPath, and CompileXQuery tasks, this element defines and binds a function to the static context for a single item. Note that this simply declares the function, and a Method object for the function must also be bound to the dynamic context. Note: this element can be specified multiple times.

**Parameters specified as nested elements:**

**name** A nested name element must be specified to indicate the name of the function.

**type** A nested type element must be specified to indicate the type of the function.

**argType**

A nested argType element can be specified to indicate the types of the function arguments.

This element is optional and can be specified multiple times.

**Example:**

```
<function>
  <name>
    <localpart>la</localpart>
    <namespaceURI>"http://www.ibm.com/Los Angeles"</namespaceURI>
  </name>
  <type>
    <localpart>boolean</localpart>
    <namespaceURI>http://www.w3.org/2001/XMLSchema</namespaceURI>
  </type>
</function>
```

**imm** This element sets the integer math mode, which is a constant representing the level of precision required and whether overflow detection is required when working with xs:integer values.

Valid values include:

- 1 = values need only support the minimum precision required for a minimally conforming processor (18 digits)
- 2 = values should support an arbitrary number of digits of precision; no overflow should occur

- 3 = values need only support the minimum precision required for a minimally conforming processor (18 digits) but any overflow condition should be detected and error FOAR0002 raised

**Example:**

```
<imm>2</imm>
```

**inputfile**

This element specifies the full path to a file containing an XSL, XPath, or XQuery to be compiled.

**Example:**

```
<inputfile>C:/XSLT/simple.xsl</inputfile>
```

**localpart**

This element indicates the local part of a qualified name.

**Example:**

```
<localpart>la</localpart>
```

**name** This element indicates the name of the function or variable (expressed in terms of the localpart and namespaceURI).

In the case of a variable that is in no namespace the namespace URI should be omitted.

**Parameters specified as nested elements:**

**localpart**

A nested localpart element must be specified to provide the local part of the qualified name.

**namespaceURI**

A nested namespaceURI element can be specified to indicate the namespaceURI.

**Example:**

```
<name>
  <localpart>la</localpart>
  <namespaceURI>"http://www.ibm.com/Los Angeles"</namespaceURI>
</name>
```

**namespaceURI**

This element indicates the namespaceURI part of a qualified name.

If the value contains a blank space. enclose it in quotation marks.

**Example:**

```
<namespaceURI>"http://www.ibm.com/Los Angeles"</namespaceURI>
```

**ns** This element specifies a namespace for use during static processing.

The value should be specified as prefix=URI.

If the value contains a blank space, enclose it in quotation marks.

This element can be used multiple times.

**Example:**

```
<ns>my=http://www.example.com/examples</ns>
```

**ordm** This element specifies the Ordering Mode.

Valid values include:

- 1 = ordered results are to be returned by certain path expressions, union, intersect, and except expressions, and FLWOR expressions that have no order by clause
- 2 = unordered results are to be returned by certain path expressions, union, intersect, and except expressions, and FLWOR expressions that have no order by clause

The default value is 1 (ordered).

**Example:**

```
<ordm>2</ordm>
```

**out** This element specifies the name of the generated executable.

The default executable name is XSLTModule, XPathModule, or XQueryModule depending on the corresponding task.

This option is ignored if compiling multiple files.

**Example:**

```
<out>sample</out>
```

**dir** This element specifies a destination directory for the executables. Default is the current working directory.

If the value contains a blank space, enclose it in quotation marks.

**Example:**

```
<pkg>com.mycompany.precompiled</pkg>
```

**schema**

This element specifies a schema document that will be used to populate the in-scope schema definitions.

This element can be used multiple times.

**Example:**

```
<schema>C:/samples/xpath/variousTypesNodeTest.xsd</schema>
```

**type** This element indicates the type of the function or variable expressed in terms of the localpart and namespaceURI.

**Parameters specified as nested elements:**

**localpart**

A nested localpart element must be specified to provide the local part of the qualified name.

**namespaceURI**

A nested namespaceURI element can be specified to indicate the namespaceURI.

**Example:**

```
<type>
  <localpart>boolean</localpart>
  <namespaceURI>"http://www.w3.org/2001/XMLSchema"</namespaceURI>
</type>
```

**variable**

This element defines and binds a variable to the static context for a single item.

This simply declares the variable, and a value must be bound to the dynamic context.

This element can be specified multiple times.

**Parameters specified as nested elements:**

**name** A nested name element must be specified to indicate the name of the variable.

**type** A nested type element must be specified to indicate the type of the variable.

**Example:**

```
<variable>
  <name>
    <localpart>booleanVar</localpart>
  </name>
  <type>
    <localpart>boolean</localpart>
    <namespaceURI>http://www.w3.org/2001/XMLSchema</namespaceURI>
  </type>
</variable>
```

## Procedure

- **Use TaskCompileXPath**

  This task can be used to precompile one or more XPath expressions. The output will be a set of Java classes that subsequently can be used to execute the expressions without the performance overhead of dynamic compilation.

  **Parameters specified as nested elements:**

  **out** A nested **out** specifies the name of the generated executable.

  The default executable name is XPathModule.

  **dir** A nested **dir** specifies a destination directory for the executables.

  The default is the current working directory.

  **pkg** A nested **pkg** specifies a package name prefix for all generated classes.

  The default is the Java default package.

  **cpm** A nested **cpm** specifies an alternate XPath Compatibility Mode.

  **ns** A nested **ns** specifies a namespace for use during static processing.

  **schema**
  A nested **schema** specifies a schema document that will be used to populate the in-scope schema definitions.

  **function**
  A nested **function** definition can be specified.

  This will create a function binding to the static context for a single item.

  **variable**
  A nested **variable** definition can be specified.

  This will add a variable binding to the static context for a single item.

  **baseURI**
  A nested **baseURI** specifies the base URI of the containing element.

  **dnet** A nested **dnet** specifies a default namespace URI for element and type names.

  **dnf** A nested **dnf** specifies a default namespace URI for function names.

  **imm** A nested **imm** sets the integer math mode, which is a constant representing the level of precision required and whether overflow detection is required when working with xs:integer values.

  **inputfile**
  A nested **inputfile** specifies the full path to a file containing XPath expression to be compiled.

  **Note:** This element is required and can be used multiple times.

  **Example:**

```
<target name="testXPath">
  <taskdef name="compileXPath" classname="com.ibm.xml.xapi.ant.TaskCompileXPath"/>
  <compileXPath>
    <out>sample</out>
    <dir>"C:/precompiledXPath"</dir>
    <pkg>com.mycompany.precompiled</pkg>
    <variable>
      <name>
        <localpart>booleanVar</localpart>
      </name>
      <type>
        <localpart>boolean</localpart>
        <namespaceURI>http://www.w3.org/2001/XMLSchema</namespaceURI>
      </type>
```

```
    </variable>
    <inputfile>C:/XPath/xpath.txt</inputfile>
  </compileXPath>
</target>
```

- **Use TaskCompileXQuery**

  This task can be used to precompile one or more XQuery expressions. The output will be a set of Java classes that subsequently can be used to execute the expressions without the performance overhead of dynamic compilation.

  **Parameters specified as nested elements:**

  **out** A nested **out** specifies the name of the generated executable.

  The default executable name is XQueryModule.

  **dir** A nested **dir** specifies a destination directory for the executables.

  The default is the current working directory.

  **pkg** A nested **pkg** specifies a package name prefix for all generated classes.

  The default is the Java default package.

  **function**
  A nested **function** definition can be specified.

  This will create a function binding to the static context for a single item.

  **baseURI**
  A nested **baseURI** specifies the base URI of the containing element.

  **dnet** A nested **dnet** specifies a default namespace URI for element and type names.

  **dnf** A nested **dnf** specifies a default namespace URI for function names.

  **imm** A nested **imm** sets the integer math mode, which is a constant representing the level of precision required and whether overflow detection is required when working with xs:integer values.

  **bsp** A nested **bsp** specifies the Boundary Space Policy.

  **csm** A nested **csm** specifies the Construction Mode.

  **cnmi** A nested **cnmi** specifies the inherit part of the copy-namespaces.

  **cnmp** A nested **cnmp** specifies the preserve part of the copy-namespaces.

  **eso** A nested **eso** specifies the Empty Sequence Order.

  **ordm** A nested **ordm** specifies the Ordering Mode.

  **inputfile**
  A nested **inputfile** specifies the full path to a file containing an XQuery expression to be compiled. Note: this element is required and can be used multiple times.

  **Example:**

```
<target name="testXQuery">
  <taskdef name="compileXQuery" classname="com.ibm.xml.xapi.ant.TaskCompileXQuery"/>
  <compileXQuery>
    <out>sample</out>
    <dir>"C:/precompiledXQuery"</dir>
    <pkg>com.mycompany.precompiled</pkg>
    <inputfile>C:/XQuery/xquery.sq</inputfile>
  </compileXQuery>
</target>
```

- **Use TaskCompileXSLT**

  This task can be used to precompile one or more stylesheets. The output will be a set of Java classes that subsequently can be used to execute transformations without the performance overhead of dynamic compilation.

**Parameters specified as nested elements:**

**out** A nested **out** specifies the name of the generated executable.

The default executable name is XSLTModule.

This element is ignored if compiling multiple stylesheets.

**dir** A nested **dir** specifies a destination directory for the executables.

The default is the current working directory.

**pkg** A nested **pkg** specifies a package name prefix for all generated classes.

The default is the Java default package.

**function**

A nested **function** definition can be specified.

This will create a function binding to the static context for a single item.

**baseURI**

A nested **baseURI** specifies the base URI of the containing element.

**imm** A nested **imm** sets the integer math mode, which is a constant representing the level of precision required and whether overflow detection is required when working with xs:integer values.

**inputfile**

A nested **inputfile** specifies the full path to a file containing an XSL stylesheet to be compiled.

**Note:** This element is required and can be used multiple times.

**Example:**

```
<target name="testXSLT">
  <taskdef name="compileXSLT" classname="com.ibm.xml.xapi.ant.TaskCompileXSLT"/>
  <compileXSLT>
    <out>sample</out>
    <dir>"C:/precompiledXSLT"</dir>
    <pkg>com.mycompany.precompiled</pkg>
    <function>
      <name>
        <localpart>la</localpart>
        <namespaceURI>"http://www.ibm.com/Los Angeles"</namespaceURI>
      </name>
      <type>
        <localpart>boolean</localpart>
        <namespaceURI>http://www.w3.org/2001/XMLSchema</namespaceURI>
      </type>
    </function>
    <inputfile>C:/XSLT/simple.xsl</inputfile>
  </compileXSLT>
</target>
```

## Precompiling in Java

You can use the XCompilationFactory interface and its various compile and load methods to compile an expression, query, or stylesheet in advance. The Java classes can be loaded at execution time, therefore avoiding the cost of compilation in the application run time.

### Procedure

- Retrieve the XCompilationFactory by calling the getCompilationFactory method on the XFactory class.

  An XCompilationFactory instance is associated with a particular XFactory instance, so they share registered schemas. If a new schema is registered with the XFactory instance; therefore, it is visible to the associated XCompilationFactory instance.
- Create a new XCompilationParameters instance by calling the XCompilationFactory newCompilationParameters method, passing in the base class name to use for the generated classes.

  Configure the parameters further by using the set methods described in this table.

*Table 352. Valid set methods.*

*These set methods are defined in the XCompilationParameters interface and are valid for generating a precompiled executable.*

| Set Methods Valid for Generating a Precompiled Executable | Description | Default |
|---|---|---|
| setPackageName | Specify the package name for the generated classes.<br><br>The value must be a valid Java package name. | Java default package |
| setDirectoryName | Specify the directory to which the generated classes should be written.<br><br>The directory must exist. | Current working directory as retrieved by calling the Java System.getProperty method with the property user.dir |

The setClassLoader method is only valid when loading the generated classes using one of the load methods. If the class loader is set at compile time, it is ignored.

- Use one of the compile methods on the XCompilationFactory, passing in the XCompilationParameters, to generate the precompiled executable.

  The compile methods use the XStaticContext just like the XFactory prepare methods to configure prepare-time settings. Note that compilation is implied when the compile methods are used; therefore, changing the use-compiler setting through the XStaticContext setUseCompiler method has no effect on these methods. If no static context is specified, the default settings are used.

### Example

The following is a basic example of precompiling an XPath expression.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Get the compilation factory
XCompilationFactory compileFactory = factory.getCompilationFactory();

// Create the compilation parameters
XCompilationParameters params = compileFactory.newCompilationParameters("MyXPath");
params.setPackageName("org.example.myxpath");

// Generate the compiled classes
compileFactory.compileXPath("/doc/item[@id > 3000]", params);
```

Appropriate compile methods are available for XQuery and XSLT as well.

## Loading a precompiled executable

You can use the XCompilationFactory interface and its various load methods to load a precompiled expression, query, or stylesheet. These load methods load the Java classes and return an XPathExecutable, XQueryExecutable, or XSLTExecutable object respectively.

### Procedure

- Retrieve the XCompilationFactory by calling the getCompilationFactory method on the XFactory class.

  An XCompilationFactory instance is associated with a particular XFactory instance, so they share registered schemas. If a new schema is registered with the XFactory instance, therefore, it is visible to the associated XCompilationFactory instance.
- Create a new XCompilationParameters instance by calling the XCompilationFactory newCompilationParameters method, passing in the base class name of the classes to be loaded.

  Configure the parameters further by using the set methods described in this table.

*Table 353. Valid set methods.*

*These are set methods that are defined in the XCompilationParameters interface and are valid for loading a precompiled executable.*

| Set Methods Valid for Loading a Precompiled Executable | Description | Default |
|---|---|---|
| setPackageName | Specify the package name of the classes to load. | Java default package |
| setClassLoader | Specify the class loader to use. | Class loader that was used to load the processor |

The setDirectoryName method is not valid when loading a precompiled executable because the classpath is used to search for the classes. If the directory name is set, it is ignored. The setDirectoryName method can be used when generating precompiled executables to specify the directory to which you want to write the classes.

- Use one of the load methods on the XCompilationFactory, passing in the XCompilationParameters, to load the precompiled executable.

### Example

The following is a basic example of loading a precompiled XPath expression.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Get the compilation factory
XCompilationFactory compileFactory = factory.getCompilationFactory();

// Create the compilation parameters
XCompilationParameters params = compileFactory.newCompilationParameters("MyXPath");
params.setPackageName( "org.example.myxpath");

// Load the executable
XPathExecutable executable = compileFactory.loadXPath(params);

// Create the input source
StreamSource input = new StreamSource("simple.xml");

// Execute the XPath expression
XSequenceCursor cursor = executable.execute(input);
```

Appropriate load methods are available for XQuery and XSLT as well.

## Using resolvers

You can use this information to help you to use resolvers.

### Procedure

- Use source and result resolvers.
- Register a collection resolver.
- Register a schema resolver.
- Use an unparsed text resolver.

### Using source and result resolvers

You can use this information to help you to use source and result resolvers.

#### Procedure

- Use a source resolver at prepare time.
- Use a source resolver at execution time.
- Use a result resolver at execution time.

***Using a source resolver at prepare time:***

By specifying a source resolver at the time that an executable is being prepared, you can tell the processor how to interpret the URIs referenced at that time.

**Procedure**

Specify a source resolver at the time an executable is being prepared.
This tells the processor how to interpret the URIs referenced at that time, in a stylesheet's xsl:import and xsl:include directives for example.
The default source-resolution behavior is to interpret relative URIs in terms of the base URI of the expression, query, or stylesheet if the base URI is available or to interpret them as file paths relative to the current working directory if the base URI is not available. Absolute URIs are used unchanged.
To change this behavior, write a Java class that implements the XSourceResolver interface and register it with the XStaticContext before preparing the stylesheet.
The following is a basic example of how to register the source resolver.

```
XFactory factory = XFactory.newInstance();

// Register the source resolver with the static context
XStaticContext staticContext = factory.newStaticContext();
XSourceResolver sourceResolver=new ASourceResolver(replacementBase);
staticContext.setSourceResolver(sourceResolver);

// Prepare the sylesheet
XSLTExecutable executable = factory.prepareXSLT(new StreamSource(stylesheetFile), staticContext);

XDynamicContext dynamicContext = factory.newDynamicContext();

// Execute the stylesheet
XSequenceCursor cursor = executable.execute(new StreamSource(inputFile), dynamicContext);
```

***Using a source resolver at execution time:***

By specifying a source resolver at the time that an executable is being executed, you can tell the processor how to interpret the URIs referenced at that time.

**Procedure**

Specify a source resolver at the time that an executable is being executed.
This tells the processor how to interpret the URIs referenced at that time, in calls to the fn:doc() or document() functions for example.
The default source-resolution behavior is to interpret relative URIs in terms of the base URI of the expression, query, or stylesheet if the base URI is available or to interpret them as file paths relative to the current working directory if the base URI is not available. Absolute URIs are used unchanged.
To change this behavior, write a Java class that implements the XSourceResolver interface and register it with the XDynamicContext before executing the expression, query, or stylesheet.
The following is a basic example of how to register the source resolver.

```
XFactory factory = XFactory.newInstance();

XStaticContext staticContext = factory.newStaticContext();

// Prepare the stylesheet
XSLTExecutable executable = factory.prepareXSLT(new StreamSource(stylesheetFile), staticContext);

XDynamicContext dynamicContext = factory.newDynamicContext();
// Register the source resolver with the dynamic context
XSourceResolver sourceResolver=new ASourceResolver(replacementBase);
dynamicContext.setSourceResolver(sourceResolver);

// Execute the XPath expression
XSequenceCursor cursor = executable.execute(new StreamSource(inputFile), dynamicContext);
```

***Using a result resolver at execution time:***

By specifying a result resolver at execution time, you can tell the processor how to redirect output URIs specified in the executable.

### Procedure

To activate a result resolver, register it with the dynamic context before calling execute().
Result resolvers perform essentially the same function as source resolvers, but on the output side of the processor. They allow you to intercept and redirect output URIs specified in the executable, such as xsl:result-document directives in a stylesheet.
The default resolution behavior is to use the base output URI to resolve result documents if the URI reference is relative. Absolute URIs are used unchanged.
The following is a basic example of a result resolver.

```
class AResultResolver implements XResultResolver
{
    String _replacementBase;

    public AResultResolver(String replacementBase)
    {
      _replacementBase=replacementBase;
    }

    // Resolve URIs by loading the resource as an XSLT stylesheet
    // and evaluating it - return the result as the Source to use
    public Result getResult(String href, String base) {
      String rebasePrefix="rebase://";

      if(href.startsWith(rebasePrefix))
      {
       href=href.substring(rebasePrefix.length());
       base=_replacementBase;
      }

      java.net.URI baseURI;
      Result result=null;
      try {
         // Get base URI object
          baseURI = new java.net.URI(base);
          // Resolved relative reference against base URI
          URI resolvedURI = baseURI.resolve(href);
          // Try to read...
          result = new StreamResult(resolvedURI.toString());
      } catch (java.net.URISyntaxException use) {
          throw new RuntimeException(use);
     }

      return result;
    }
}
```

The following is a basic example of registering and using the resolver.

```
XFactory factory = XFactory.newInstance();

XStaticContext staticContext = factory.newStaticContext();

// Prepare the stylesheet
XSLTExecutable executable = factory.prepareXSLT(new StreamSource(stylesheetFile), staticContext);

XDynamicContext dynamicContext = factory.newDynamicContext();
// Register the result resolver with the dynamic context
XResultResolver resultResolver=new AResultResolver(replacementBase);
dynamicContext.setResultResolver(resultResolver);

// Execute the XPath expression
XSequenceCursor cursor = executable.execute(new StreamSource(inputFile), dynamicContext);
```

## Registering a collection resolver

You can register implementations of the XCollectionResolver interface with the XDynamicContext.

### Procedure

Register a collection resolver with the dynamic context.
The XCollectionResolver implementation registered with the XDynamicContext is used at execution time to retrieve the collection of nodes associated with the URI provided in calls to the fn:collection method. If no collection resolver is registered with the XDynamicContext then calls to fn:collection will result in a recoverable error and the empty sequence is used for the collection.
Note that the collection resolver and the fn:collection function are not meant to resolve document URIs. The source resolver and fn:doc function should be used for this purpose.

### Example

The following is a basic example of using a collection resolver.

```
XFactory factory = XFactory.newInstance();

// Prepare the XPath expression
XPathExecutable executable = factory.prepareXPath("count(collection('typeA-typeB'))"

// Register the collection resolver with the dynamic context
XCollectionResolver collectionResolver = new ACollectionResolver(factory);
XDynamicContext dynamicContext = factory.newDynamicContext();
dynamicContext.setCollectionResolver(collectionResolver);

// Execute the XPath expression
XSequenceCursor cursor = executable.execute(dynamicContext);
```

The following is a basic example of an XCollectionResolver implementation.

```
public class ACollectionResolver implements XCollectionResolver {

    private XFactory m_factory;

    public ACollectionResolver(XFactory factory) {
        m_factory = factory;
    }

    public XSequenceCursor getCollection(String uri, String base) {

        // Get the default collection
        if (uri.equals("")) {
            return getCollection("default", base);
        }

        // Get the requested collection
        ArrayList<XItemView> list = new ArrayList<XItemView>();
        StringTokenizer tokenizer = new StringTokenizer(uri, "-");
          XSequenceCursor cursor = null;
          while (tokenizer.hasMoreTokens()) {
              String token = tokenizer.nextToken();
              XSequenceCursor temp = getNodes(new StreamSource("collections.xml"), "/doc/" + token);
              if (cursor == null) {
                  cursor = temp;
              } else {
                  cursor = cursor.append(temp);
              }
          }
        return cursor;
    }

     private XSequenceCursor getNodes(Source source, String expression) {
         XPathExecutable executable = m_factory.prepareXPath(expression);
         XSequenceCursor cursor = executable.execute(source);
         return cursor;
     }

}
```

## Registering a schema resolver

The XSchemaResolver interface can be implemented and the implementation registered with the XFactory to override the default schema resolution behavior. This includes resolution of imports for schemas registered with XFactory using the registerSchema method and resolving schemas imported in XSLT stylesheets using the xsl:import-schema declaration.

### About this task

The default behavior for resolving imports within a schema is to use the base URI of the schema to resolve the imported schema's location. The default behavior for XSLT schema imports is to use the base URI of the xsl:import-schema declaration to resolve the location specified in the declaration.

### Procedure

Use the setSchemaResolver method on the XFactory class to register a schema resolver.
The getSchema method returns an instance of the java.util.List interface. This is because the definitions of the schema components for a particular namespace can be split across several distinct schema

documents. You can use the getSchema method to return all the schema documents for the particular target namespace associated with all the specified location hints.

### Example

The following is a basic example of using a schema resolver.

```
XFactory factory = XFactory.newInstance();

// Set validating to true.
factory.setValidating(true);

// Create the schema resolver and register it with the factory.
factory.setSchemaResolver(new ASchemaResolver(replacementBase));

// Prepare the stylesheet.
XSLTExecutable executable = factory.prepareXSLT(new StreamSource(stylesheetFile));

// Execute the transformation.
Source source = new StreamSource(inputFile);
Result result = new StreamResult(System.out);
executable.execute(source, result);
```

The following is a basic example of an XSchemaResolver implementation.

```
class ASchemaResolver implements XSchemaResolver
{
    String _replacementBase;

    public ASchemaResolver(String replacementBase)
    {
        _replacementBase=replacementBase;
    }

    // Resolve URI, returning the Source that URI represents.
    // Implements the "rebase:" pseudo-scheme.
    public List<? extends Source> getSchema(String namespace, List<String> locations, String baseURI) {
        String rebasePrefix="rebase:";

        List<StreamSource> list = new ArrayList<StreamSource>();
        for (int i = 0; i < locations.size(); i++) {
            String href = locations.get(i);
            String base = baseURI;
            if(href.startsWith(rebasePrefix)) {
                href=href.substring(rebasePrefix.length());
                base=_replacementBase;
            }

            java.net.URI uri;
            StreamSource source=null;
            try {
                // Get base URI object
                uri = new java.net.URI(base);
                // Resolved relative reference against base URI
                URI resolvedURI = uri.resolve(href);
                // Try to read...
                source = new StreamSource(resolvedURI.toString());
            } catch (java.net.URISyntaxException use) {
                throw new RuntimeException(use);
            }

            list.add(source);
        }
        return list;
    }
}
```

## Using an unparsed text resolver

The XUnparsedTextResolver interface can be implemented and the implementation registered with the XDynamicContext to override the default resolution behavior for resources loaded through the XSLT unparsed-text function.

### About this task

The default resolution behavior for resources loaded through the XSLT unparsed-text function is to resolve relative URIs based on the base URI from the static context. If the base URI is not available, the current working directory is used. Absolute URIs are used unchanged.

### Procedure

Use the setUnparsedTextResolver method on the XDynamicContext interface to register an unparsed text resolver.

### Example

The following is a basic example of using an unparsed text resolver.

```
XFactory factory = XFactory.newInstance();

// Prepare the stylesheet.
XSLTExecutable executable = factory.prepareXSLT(new StreamSource(stylesheetFile));

// Create the dynamic context and set the unparsed text resolver.
XDynamicContext dynamicContext = factory.newDynamicContext();
AnUnparsedTextResolver resolver = new AnUnparsedTextResolver(replacementBase);
dynamicContext.setUnparsedTextResolver(resolver);

// Execute the transformation.
Source source = new StreamSource(inputFile);
Result result = new StreamResult(System.out);
executable.execute(source, dynamicContext, result);
```

The following is a basic example of an unparsed text resolver implementation.

```
class AnUnparsedTextResolver implements XUnparsedTextResolver
{
    String _replacementBase;

    public AnUnparsedTextResolver(String replacementBase)
    {
        _replacementBase=replacementBase;
    }

    // Resolve URI, returning the resource that URI represents.
    // Implements the "rebase:" pseudo-scheme.
    public String getResource(String href, String encoding, String base) {
        String rebasePrefix="rebase:";

        if (href.startsWith(rebasePrefix)) {
            href = href.substring(rebasePrefix.length());
            base = _replacementBase;
        }

        try {
            // Get base URI object
            URI uri = new java.net.URI(base);
            // Resolved relative reference against base URI
            URI resolvedURI = uri.resolve(href);
            // Try to read...
            URL url = resolvedURI.toURL();
            URLConnection urlCon = url.openConnection();
            BufferedInputStream stream = new BufferedInputStream(urlCon.getInputStream());
            StringBuffer buffer = new StringBuffer();
            int s;
            while ((s = stream.read())!= -1) {
                // Do any character manipulation here.
                buffer.append((char)s);
            }
            return buffer.toString();
        } catch (Exception e) {
            throw new RuntimeException(e);
        }
    }
}
```

## Using resolvers in a J2EE context

When loading artifacts in a Java 2 Platform, Enterprise Edition (J2EE) context, you should consider the special implications that apply when loading resources from local deployment artifacts.

### About this task

Loading local resources—through Class.getResource and Class.getResourceAsStream—from J2EE deployment artifacts such as EARs, WARs, and library JAR files can introduce issues when loading related XML artifacts. Loading an initial local resource using these mechanisms will succeed, but artifacts loaded from the initial resource typically will fail to load without specific consideration.

Here is an example of loading documents at execution time from a stylesheet using the XPath fn:doc function. In this case, the default behavior is to resolve documents based on the base URI from the static context.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="2.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
 <xsl:output method="xml" version="1.0" encoding="UTF-8" indent="yes"/>

 <xsl:variable name="names" select="doc('names.xml')"/>

 <xsl:template name="loadnames">
  <xsl:copy-of select="$names"/>
 </xsl:template>

</xsl:stylesheet>
```

If this is loaded with the following Java code in a J2EE environment:

```
// create the factory
XFactory factory = XFactory.newInstance();

// load the XSLT file from a local resource within a J2EE deployment artifact
StreamSource source = new StreamSource(XSLTDocFunction.class.getResourceAsStream("/samplexslts/doc.xsl"));

// Create an XSL transform executable
XSLTExecutable xslTransform = factory.prepareXSLT(source);

// Create the result
Result result = new StreamResult(new ByteArrayOutputStream());

// Create a dynamic context specifying the XSLT initial template
XDynamicContext dc = factory.newDynamicContext();
dc.setXSLTInitialTemplate(new QName("loadnames"));

// Execute the transformation
xslTransform.execute(dc, result);
```

you will receive the following error:

```
IXJXE0364W: FATAL ERROR:  IXJXE0774E: [ERR 0693][ERR FODC0005]
The URI string 'names.xml' does not map to an available document.
```

The reason for this error is that in loading the initial XML artifact (doc.xsl), no static content was established for the base URI. In this case, the processor will fall back to looking in the current working directory, which is meaningless in a J2EE environment.

There are three possible ways to fix this situation. Here are the first two:

- Set the baseURI in the static context.

  Adjusting to set the baseURI on the static context would look like this example:

```
// create the factory
XFactory factory = XFactory.newInstance();

// set the baseURI in the static context
URL dataURL = XSLTSchemaAware.class.getResource("/samplexslts/doc.xsl");
XStaticContext staticContext = factory.newStaticContext();
staticContext.setBaseURI(dataURL.toString());

// load the XSLT file from a local resource within a J2EE deployment artifact
StreamSource source = new StreamSource(XSLTDocFunction.class.getResourceAsStream("/samplexslts/doc.xsl"));

// Create an XSL transform executable
XSLTExecutable xslTransform = factory.prepareXSLT(source, staticContext);

// Create the result
Result result = new StreamResult(new ByteArrayOutputStream());

// Create a dynamic context specifying the XSLT initial template
XDynamicContext dc = factory.newDynamicContext();
dc.setXSLTInitialTemplate(new QName("loadnames"));

// Execute the transformation
xslTransform.execute(dc, result);
```

- Load the resource in a way that allows the processor to know the baseURI.

  Adjusting to load the resource in a way that allows the processor to know the baseURI by passing the absolute URL to the StreamSource constructor would look like the following example:

```
// Create the factory
XFactory factory = XFactory.newInstance();
```

```
// Create the source from a URL
URL dataURL = XSLTSchemaAware.class.getResource("/samplexslts/doc.xsl");
StreamSource source = new StreamSource(dataURL.toString());

// Create an XSL transform executable for the expression
XSLTExecutable xslTransform = factory.prepareXSLT(source);

// Create the result
ByteArrayOutputStream baos = new ByteArrayOutputStream();
Result result = new StreamResult(baos);

// Create a dynamic context specifying the XSLT initial template
XDynamicContext dc = factory.newDynamicContext();
dc.setXSLTInitialTemplate(new QName("loadnames"));

// Execute the transformation
xslTransform.execute(dc, result);
```

These two approaches described will work well when all XML artifacts are in a single J2EE deployment unit, but they will fail if XML artifacts are split across J2EE deployment units because there is no single baseURI for all of the XML artifacts.

To have complete control over XML artifact loading to support cases such as artifacts spread across multiple deployment units, use resolvers to completely control loading behavior.

### Procedure

Implement the appropriate resolvers and register those resolvers into the static or dynamic context as appropriate.
These XML artifact loading recommendations apply within a J2EE context for all XML artifacts supported by resolvers such as XML documents (fn:doc(), document()), stylesheets (xsl:include, xsl:import), unparsed text, and XML schemas (XSLT import-schema).

## Using external variables and functions

You can use this information to help you to use external variables and functions.

### Procedure

- Use external variables.
- Use external functions.

### Using external variables

The XML API allows you to access external variables from XPath and XQuery expressions as well a stylesheet parameters from XSLT stylesheets.

#### About this task

External variables are useful when your XML processing depends on information that is not contained in an input document. If you are writing an application that allows users to search for books by title in a library that is stored as XML, for example, you could prepare a single XQuery expression to find books in the library that uses a variable for the book title to be matched. The resulting XQueryExecutable object can be used for each search that the user submits by binding the submitted book title to the variable. The details of using external variables and stylesheet parameters are presented in separate articles for XPath, XQuery, and XSLT.

#### Procedure

- Use external variables with XPath.
- Use external variables with XQuery.
- Set parameters with XSLT.

***Using external variables with XPath:***

When using an XPath expression that uses external variables, supply (or bind) values for each variable using an XDynamicContext instance and optionally declare the types of the variables using an XStaticContext instance.

### Procedure

- When preparing an XPath expression that uses external variables, declare the types of the variables using an XStaticContext instance.

  This step is optional. If a variable is not declared, the processor assumes its type is item()*. In other words, the value of the variable can be a sequence of any length consisting of items of any type. Declaring a type for your variables can help the processor detect some usage errors statically during preparation.

  The XStaticContext interface has two declareVariable methods that each have two parameters—one for the name, and one for the type of the variable. The name is always provided as a QName object, but the type can be a QName or an XSequenceType.

*Table 354. XStaticContext declareVariable methods.*

*The following table explains when to use each form of the declareVariable method.*

| Method Signature | Purpose |
|---|---|
| declareVariable(QName name, QName type) | Use when value of the variable is a single atomic value<br><br>The QName must refer to a built-in type or a global type declared in a schema that has been registered on the XFactory instance used to create the XStaticContext instance. If the QName refers to a non-atomic type, then the processor will treat the variable as having the type element(*, ns:type), where ns:type is the given QName. The XTypeConstants interface has convenient constants available that provide a QName object for each built-in type. |
| declareVariable(QName name, XSequenceType type) | Use when value of the variable is a single node or a sequence of atomic values or nodes |

  The following example shows how to prepare an XPath expression that uses variables, with two declared in the static context and one not declared.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create a new static context from the factory
XStaticContext staticContext = factory.newStaticContext();

// Define QNames for the names of the variables to be declared
final QName taxRate = new QName("taxRate");
final QName partNumbers = new QName("partNumbers");

// Declare a variable called "taxRate" as an xs:float
staticContext.declareVariable(taxRate, XTypeConstants.FLOAT_QNAME);

// Obtain an XSequenceTypeFactory instance from the factory
XSequenceTypeFactory typeFactory = factory.getSequenceTypeFactory();

// Define a sequence type for a sequence of xs:integer values
XSequenceType integerSequence = typeFactory.atomic(XTypeConstants.INTEGER_QNAME, XSequenceType.OccurrenceIndicator.ZERO_OR_MORE);

// Declare a variable called "partNumbers" as a sequence of xs:integer values
staticContext.declareVariable(partNumbers, integerSequence);

// Create an XPath expression that uses the declared variables, as well as another variable "discount"
// that the processor will assume has type item()*
String expression = "sum(for $partNumber in $partNumbers return /inventory/part[@num=$partNumber]/@price) * (1 - $discount) * (1 + $taxRate)";

// Prepare the XPath expression
XPathExecutable xpath = factory.prepareXPath(expression, staticContext);
```

- To execute an XPath expression that uses external variables, supply (or bind) values for each variable using an XDynamicContext instance.

  An error is raised if you do not supply a value for a variable that is used when executing the XPath expression.

  The XDynamicContext has a number of bind, bindItem, and bindSequence methods. Each has two parameters, where the first is a QName object corresponding to the name of the parameter and the second is the value.

*Table 355. XDynamicContext bind, bindItem, and bindSequence methods.*

*The following table explains when to use each form of the XDynamicContext bind, bindItem, and bindSequence methods.*

| Method | Purpose |
|---|---|
| bind | Use when binding a single atomic value<br><br>There is one form of this method for each of the Java types that is used in the standard mapping of built-in types to Java types. There are two additional forms—one that takes a node and one that takes a source. These are used for binding any node from a DOM tree and parsing a new source to yield a document node, respectively. |
| bindItem | Use when binding a single item as an XItemView object<br><br>An XItemView object can be obtained from the result of executing another expression or constructed using an XItemFactory instance. |
| bindSequence | Use when binding sequences of less than or greater than one item<br><br>There is one form of this method for each of the Java types that is used in the standard mapping of built-in types to Java types; each accepts an array of values the given type.<br><br>There is an additional form that takes an XSequenceCursor. An XSequenceCursor can be the result of executing another expression or can be constructed using an XItemFactory instance. |

The following example executes the XPath expression prepared in the first example, first binding values for each of the variables it uses.

```
// Create a new dynamic context from the factory
XDynamicContext dynamicContext = factory.newDynamicContext();

// Bind an atomic value for the "taxRate" and "discount" variables
dynamicContext.bind(taxRate, 0.13f);
dynamicContext.bind(new QName("discount"), 0.40);

// Bind a sequence of atomic values for the "partNumbers" variable
dynamicContext.bindSequence(partNumbers, new int[] {2, 1, 2, 3, 2});

// Create an XML input document
String xml = "<inventory>" +
"<part num='1' price='9.99'/>" +
"<part num='2' price='4.47'/>" +
"<part num='3' price='12.99'/>" +
"</inventory>";
StreamSource source = new StreamSource(new StringReader(xml));

// Execute the expression
XSequenceCursor result = xpath.execute(source, dynamicContext);
```

### *Using external variables with XQuery:*

When using an XQuery expression that uses external variables, supply (or bind) values for each variable using an XDynamicContext instance and optionally declare the types of the variables using an XStaticContext instance.

### Procedure

- When preparing an XQuery expression that uses external variables, declare the types of the variables using an XStaticContext instance.

  Declaring the variable in the XStaticContext is optional. If a variable is not declared, the processor assumes that its type is item()*. In other words, the value of the variable can be a sequence of any length consisting of items of any type. Declaring a type for your variables can help the processor detect some usage errors statically during preparation.

  The XStaticContext interface has two declareVariable methods that each have two parameters—one for the name, and one for the type of the variable. The name is always provided as a QName object, but the type can be a QName or an XSequenceType.

*Table 356. XStaticContext declareVariable methods.*

*The following table explains when to use each form of the declareVariable method.*

| Method Signature | Purpose |
|---|---|
| declareVariable(QName name, QName type) | Use when value of the variable is a single atomic value<br><br>The QName must refer to a built-in type or a global type declared in a schema that has been registered on the XFactory instance used to create the XStaticContext instance. If the QName refers to a non-atomic type, then the processor will treat the variable as having the type element(*, ns:type), where ns:type is the given QName. The XTypeConstants interface has convenient constants available that provide a QName object for each built-in type. |
| declareVariable(QName name, XSequenceType type) | Use when value of the variable is a single node or a sequence of atomic values or nodes |

XQuery also allows variables to be declared in the prolog of an XQuery expression. The following XQuery expression uses two variables, one declared in the prolog and one not.

```
declare namespace xs = "http://www.w3.org/2001/XMLSchema";
declare variable $searchTerms as xs:string+ external;

<table>
    <tr><td>Title</td><td>Author</td></tr>
    {
        for $book in /library/book
        let $value := $book/@*[local-name()=$searchField]
        where exists(for $term in $searchTerms return if (contains($value, $term)) then true() else ())
        return
            <tr>
                <td>{ string($book/@title) }</td>
                <td>{ string($book/@author) }</td>
            </tr>
    }
</table>
```

The variable not declared in the XQuery expression itself can be optionally declared using an XStaticContext instance to provide the processor with type information.

The following example shows how to prepare the above XQuery expression, providing a type for the variable not declared in the XQuery expression itself. It assumes that the expression is accessible using the xquerySource source object.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create a new static context from the factory
XStaticContext staticContext = factory.newStaticContext();

// Define a QName for the name of the variable to be declared
final QName searchField = new QName("searchField");

// Declare a variable called "searchField" as an xs:string
staticContext.declareVariable(searchField, XTypeConstants.STRING_QNAME);

// Prepare the XQuery expression
XQueryExecutable xquery = factory.prepareXQuery(xquerySource, staticContext);
```

- To execute an XQuery expression that uses external variables, supply (or bind) values for each variable using an XDynamicContext instance.

  An error is raised if you do not supply a value for a variable that is used when executing the XQuery expression.

  The XDynamicContext has a number of bind, bindItem, and bindSequence methods. Each has two parameters, where the first is a QName object corresponding to the name of the parameter and the second is the value.

*Table 357. XDynamicContext bind, bindItem, and bindSequence methods.*

*The following table explains when to use each form of the XDynamicContext bind, bindItem, and bindSequence methods.*

| Method | Purpose |
|---|---|
| bind | Use when binding a single atomic value<br><br>There is one form of this method for each of the Java types that is used in the standard mapping of built-in types to Java types. There are two additional forms—one that takes a node and one that takes a source. These are used for binding any node from a DOM tree and parsing a new source to yield a document node, respectively. |
| bindItem | Use when binding a single item as an XItemView object<br><br>An XItemView object can be obtained from the result of executing another expression or constructed using an XItemFactory instance. |
| bindSequence | Use when binding sequences of less than or greater than one item<br><br>There is one form of this method for each of the Java types that is used in the standard mapping of built-in types to Java types; each accepts an array of values the given type.<br><br>There is an additional form that takes an XSequenceCursor. An XSequenceCursor can be the result of executing another expression or can be constructed using an XItemFactory instance. |

The following example executes the XQuery expression prepared in the first example, first binding values for each of the variables it uses.

```
// Create a new dynamic context from the factory
XDynamicContext dynamicContext = factory.newDynamicContext();

// Bind an atomic value for the "searchField" variable
dynamicContext.bind(searchField, "title");

// Bind a sequence of atomic values for the "searchTerms" variable
dynamicContext.bindSequence(new QName("searchTerms"), new String[] {"Lost", "Gables"});

// Create an XML input document
String xml = "<library>" +
"<book title='Lost in the Barrens' author='Farley Mowat'/>" +
"<book title='Anne of Green Gables' author='L. M. Montgomery'/>" +
"</library>";
StreamSource source = new StreamSource(new StringReader(xml));

// Execute the expression
XSequenceCursor result = xquery.execute(source, dynamicContext);
```

### *Setting parameters with XSLT:*

To use parameters in an XSLT stylesheet, declare the parameters as global parameters in the stylesheet itself.

### Procedure

- Use the as attribute to declare a type for the parameter.

  The following stylesheet declares two parameters, explicitly giving one of them a type.

```
<?xml version="1.0"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
                xmlns:xs="http://www.w3.org/2001/XMLSchema"
                exclude-result-prefixes="xs"
                version="2.0">

  <xsl:param name="targetDate" as="xs:date"/>
  <xsl:param name="window" select="3"/>

  <xsl:template match="/">
    <table>
      <tr><td>Task</td><td>Due</td><td>Status</td></tr>

      <xsl:apply-templates select="todo-list/task[xs:date(@due) le $targetDate + xs:dayTimeDuration(concat('P', $window, 'D'))]">
          <xsl:sort select="@due"/>
      </xsl:apply-templates>
    </table>
  </xsl:template>
```

```
  <xsl:template match="task">
    <tr>
      <td><xsl:value-of select="."/></td>
      <td><xsl:value-of select="format-date(xs:date(@due), '[MNn] [D1o]')"/></td>
      <td>
          <xsl:choose>
          <xsl:when test="xs:date(@due) lt $targetDate">OVERDUE by
             <xsl:value-of select="days-from-duration($targetDate - xs:date(@due))"/> day(s)</xsl:when>
          <xsl:otherwise>Due in <xsl:value-of select="days-from-duration(xs:date(@due) - $targetDate)"/> day(s)</xsl:otherwise>
          </xsl:choose>
      </td>
    </tr>
  </xsl:template>

</xsl:stylesheet>
```

- Prepare an XSLT stylesheet with global parameters in exactly the same way as any other stylesheet because there is no need to declare anything in the static context.

  Assuming that the stylesheet above is available using the xsltSource Source object, the code below prepares the stylesheet.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Prepare the XSLT stylesheet
XSLTExecutable xslt = factory.prepareXSLT(xsltSource);
```

- To execute an XSLT stylesheet that uses parameters, supply (or bind) values for each parameter using an XDynamicContext instance.

  You must supply a value for any required parameters or an error is raised. For other parameters, if you do not supply a value, a default value is used—either one supplied in the stylesheet or a zero-length string.

  The XDynamicContext has a number of bind, bindItem, and bindSequence methods. Each has two parameters, where the first is a QName object corresponding to the name of the parameter and the second is the value.

*Table 358. XDynamicContext bind, bindItem, and bindSequence methods.*

*The following table explains when to use each form of the XDynamicContext bind, bindItem, and bindSequence methods.*

| Method | Purpose |
|---|---|
| bind | Use when binding a single atomic value<br><br>There is one form of this method for each of the Java types that is used in the standard mapping of built-in types to Java types. There are two additional forms—one that takes a Node object and one that takes a Source object. These are used for binding any node from a DOM tree and parsing a new source to yield a document node, respectively. |
| bindItem | Use when binding a single item as an XItemView object<br><br>An XItemView object can be obtained from the result of executing another expression or constructed using an XItemFactory instance. |
| bindSequence | Use when binding sequences of less than or greater than one item<br><br>There is one form of this method for each of the Java types that is used in the standard mapping of built-in types to Java types; each accepts an array of values the given type.<br><br>There is an additional form that takes an XSequenceCursor. An XSequenceCursor can be the result of executing another expression or can be constructed using an XItemFactory instance. |

  The following example executes the XSLT stylesheet prepared in the first example, first binding values for each of the parameters it will use. It assumes that a Result object called xsltResult has already been created.

```
// Create an xs:date value for the "targetDate" parameter with date "April 10, 2009"
XMLGregorianCalendar date = DatatypeFactory.newInstance().newXMLGregorianCalendarDate(2009, 4, 10, DatatypeConstants.FIELD_UNDEFINED);

// Create a new dynamic context from the factory
XDynamicContext dynamicContext = factory.newDynamicContext();

// Bind an atomic value for the "targetDate" parameter
dynamicContext.bind(new QName("targetDate"), date);

// Bind an atomic value for the "window" parameter
dynamicContext.bind(new QName("window"), 7);
```

```
// Create an XML input document
String xml = "<todo-list>" +
"<task due='2009-03-31' completed=''>File Quarterly Report</task>" +
"<task due='2009-05-04' completed='2009-04-22'>Review candidate resumes</task> +
"<task due='2009-04-16' completed=''>Order stock</task>" +
"<task due='2009-05-01' completed=''>Buy concert tickets</task>" +
"</todo-list>";
StreamSource source = new StreamSource(new StringReader(xml));

// Execute the stylesheet
xslt.execute(source, dynamicContext, xsltResult);
```

## Using external functions

The XML API allows you to use external functions with XPath, XQuery, and XSLT.

### About this task

You can define external functions when you want to use operations that are difficult or impossible to express directly by core functions defined in functions and operators, additional functions defined in the XSLT specification, constructor functions named after an atomic type, stylesheet functions defined using xsl:function declaration of XSLT, or user-defined functions in XQuery. Please note that external functions cannot be used to override built-in functions. For example, suppose you are using an external function, my:power(arg1 as xs:double, arg2 as xs:double), to calculate the value of the first argument raised to the power of the second argument; you could write a Java method taking two Java primitive double arguments that performs the calculation. The details of using external functions are presented in separate articles.

### Procedure

- Use external functions with XPath.
- Use external functions with XQuery.
- Use external functions with XSLT.

#### *Using external functions with XPath:*

When using an XPath expression that uses external functions, declare the function signatures using an XStaticContext instance and supply (or bind) a Java implementation for each function using an XDynamicContext instance.

#### Procedure

1. When preparing an XPath expression that uses external functions, declare the function signatures using an XStaticContext instance.

   The XStaticContext interface has two declareFunction methods that each have three parameters—one for the name, one for the return type of the function, and an array for the types of the arguments. The name is always provided as a QName object, but the types can be QNames or XSequenceTypes. The function name, return type, and argument types must uniquely identify the function.

*Table 359. XStaticContext declareFunction methods.*

*This table explains when to use each form of the declareFunction method.*

| Method Signature | Purpose |
|---|---|
| declareFunction(QName name, QName type, QName[] argTypes) | Use when the return value and arguments of the function are all single atomic values<br><br>The type QNames must refer to built-in types or global types declared in a schema that has been registered on the XFactory instance used to create the XStaticContext instance. If a QName refers to a non-atomic type, the processor will treat it as the type element(*, ns:type), where ns:type is the given QName. The XTypeConstants interface has convenient constants available that provide a QName object for each built-in type. |
| declareFunction(QName name, XSequenceType type, XSequenceType[] argTypes) | Use when any of the arguments or the return value of the function is a node or a sequence of atomic values or nodes |

The following example shows how to prepare an XPath expression that uses an external function.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create a new static context
XStaticContext staticContext = factory.newStaticContext();

// Declare a namespace for the function
staticContext.declareNamespace("my", "http://myfunc");

// Create a QName for the name of the function
QName methodQName = new QName("http://myfunc", "pow");

// Declare the function on the static context
staticContext.declareFunction(methodQName, XTypeConstants.DOUBLE_QNAME, new QName[]{XTypeConstants.DOUBLE_QNAME, XTypeConstants.DOUBLE_QNAME});

// Create an XPath executable for the expression
XPathExecutable executable = factory.prepareXPath("sum(/polynomial/term/(my:pow(2, @power) * @coefficient))", staticContext);
```

2. To execute an XPath expression that uses external functions, supply (or bind) the Java methods that implement the functions using an XDynamicContext instance.

   Use Java reflection to obtain a java.lang.reflect.Method object for the function. If the method is an instance method, an instance object is required when binding this function.

   An error is raised if you do not supply a Java method for a function that is used when executing the XPath expression.

   The XDynamicContext has two bindFunction methods. Each requires a QName object corresponding to the name of the function and a Method object identifying the Java method that will provide the implementation for the function.

*Table 360. XDynamicContext bindFunction methods.*

*This table explains when to use each form of the XDynamicContext bindFunction methods.*

| Method Name | Purpose |
|---|---|
| bindFunction(QName qname, Method method) | Use when binding a static method |
| bindFunction(QName qname, Method method, Object instanceObject) | Use when binding an instance method |

The following example executes the XPath expression prepared in the first example, first binding a method for the function it uses. In this example, the static pow(double a, double b) method of the java.lang.Math class is used to provide the implementation for the external function.

```
// Create a new dynamic context
XDynamicContext dynamicContext = factory.newDynamicContext();

// Retrieve the java.lang.reflect.Method object for this function
Method method = Math.class.getMethod("pow", Double.TYPE, Double.TYPE);

// Bind the function to the dynamic context
dynamicContext.bindFunction(methodQName, method);

// Create an XML input document
String xml = "<polynomial>" +
"<term power='2' coefficient='3'/>" +
"<term power='1' coefficient='-2'/>" +
"<term power='0' coefficient='1'/>" +
"</polynomial>";
StreamSource source = new StreamSource(new StringReader(xml));

// Execute the expression
XSequenceCursor result = executable.execute(source, dynamicContext);

// Serialize the result to System.out
result.exportItem(new StreamResult(System.out));
```

### *Using external functions with XQuery:*

When using an XQuery expression that uses external functions, declare the function signatures either in the XQuery prolog as external functions or using an XStaticContext instance. Supply (or bind) a Java implementation for each function using an XDynamicContext instance.

## Procedure

1. When preparing an XQuery expression that uses external functions, declare the function signatures in the XQuery prolog or using an XStaticContext instance.

   The XStaticContext interface has two declareFunction methods that each have three parameters—one for the name, one for the return type of the function, and an array for the types of the arguments. The name is always provided as a QName object, but the types can be QNames or XSequenceTypes. The function name, return type, and argument types must uniquely identify the function.

*Table 361. XStaticContext declareFunction methods.*

*This table explains when to use each form of the declareFunction method.*

| Method Signature | Purpose |
|---|---|
| declareFunction(QName name, QName type, QName[] argTypes) | Use when the return value and arguments of the function are all single atomic values<br><br>The type QNames must refer to built-in types or global types declared in a schema that has been registered on the XFactory instance used to create the XStaticContext instance. If a QName refers to a non-atomic type, the processor will treat it as the type element(*, ns:type), where ns:type is the given QName. The XTypeConstants interface has convenient constants available that provide a QName object for each built-in type. |
| declareFunction(QName name, XSequenceType type, XSequenceType[] argTypes) | Use when any of the arguments or the return value of the function is a node or a sequence of atomic values or nodes |

The following XQuery expression uses three functions, two of which are declared in the prolog.

```
declare namespace xs = "http://www.w3.org/2001/XMLSchema";
declare namespace trig = "http://www.example.org/trigonometry";
declare function trig:arctan($ratio as xs:double) as xs:double external;
declare function trig:sin($angle as xs:double) as xs:double external;

<ramps>
{
    for $ramp in ramps/ramp
    let $angleRadians := trig:arctan($ramp/height div $ramp/base)
    let $angle := trig:toDegrees($angleRadians)
    let $length := $ramp/height div trig:sin($angleRadians)
    return
        element ramp
        {
            $ramp/height,
            $ramp/base,
            element angle { $angle },
            element length { $length }
        }
}
</ramps>
```

Assuming that the query above is available using the xquerySource Source object, the code below prepares the query. The function that was not declared in the query itself, trig:toDegrees, is declared on the XStaticContext instance.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create a new static context
XStaticContext staticContext = factory.newStaticContext();

// Declare a namespace for the functions
staticContext.declareNamespace("trig", "http://www.example.org/trigonometry");

// Create a QName for the trig:toDegrees function
QName toDegreesQName = new QName("http://www.example.org/trigonometry", "toDegrees");

// Declare the function on the static context
staticContext.declareFunction(toDegreesQName, XTypeConstants.DOUBLE_QNAME, new QName[]{XTypeConstants.DOUBLE_QNAME});

// Create an XQuery executable for the query
XQueryExecutable executable = factory.prepareXQuery(xquerySource, staticContext);
```

2. To execute an XQuery expression that uses external functions, supply (or bind) the Java methods that implement the functions using an XDynamicContext instance.

   Use Java reflection to obtain a java.lang.reflect.Method object for the function. If the method is an instance method, an instance object is required when binding this function.

An error is raised if you do not supply a Java method for a function that is used when executing the XQuery expression.

The XDynamicContext has two bindFunction methods. Each requires a QName object corresponding to the name of the function and a Method object identifying the Java method that will provide the implementation for the function.

*Table 362. XDynamicContext bindFunction methods.*

*This table explains when to use each form of the XDynamicContext bindFunction methods.*

| Method Name | Purpose |
|---|---|
| bindFunction(QName qname, Method method) | Use when binding a static method |
| bindFunction(QName qname, Method method, Object instanceObject) | Use when binding an instance method |

The following example executes the XQuery expression prepared in the first example, first binding methods for the functions it uses. In this example, the static atan, sin, and toDegrees methods of the java.lang.Math class are used to provide the implementations for the external functions.

```
// Create a new dynamic context
XDynamicContext dynamicContext = factory.newDynamicContext();

// Retrieve the java.lang.reflect.Method object for the trig:toDegrees function
Method toDegreesMethod = Math.class.getMethod("toDegrees", Double.TYPE);

// Bind the function to the dynamic context
dynamicContext.bindFunction(toDegreesQName, toDegreesMethod);

// Create QNames for the trig:arctan and trig:sin functions
QName arctanQName = new QName("http://www.example.org/trigonometry", "arctan");
QName sinQName = new QName("http://www.example.org/trigonometry", "sin");

// Retrieve the java.lang.reflect.Method objects for the trig:arctan and trig:sin functions
// then bind them to the dynamic context
Method arctanMethod = Math.class.getMethod("atan", Double.TYPE);
Method sinMethod = Math.class.getMethod("sin", Double.TYPE);
dynamicContext.bindFunction(arctanQName, arctanMethod);
dynamicContext.bindFunction(sinQName, sinMethod);

// Create an XML input document
String xml = "<ramps>" +
"<ramp><base>4</base><height>4</height></ramp>" +
"<ramp><base>4</base><height>3</height></ramp>" +
"<ramp><base>10</base><height>2</height></ramp>" +
"</ramps>";
StreamSource source = new StreamSource(new StringReader(xml));

// Execute the query
XSequenceCursor result = executable.execute(source, dynamicContext);

// Serialize the result to System.out
result.exportItem(new StreamResult(System.out));
```

### *Using external functions with XSLT:*

When using an XSLT stylesheet that uses external functions, declare the function signatures using an XStaticContext instance and supply (or bind) a Java implementation for each function using an XDynamicContext instance.

### Procedure

1. When preparing an XSLT stylesheet that uses external functions, declare the function signatures using an XStaticContext instance.

   The XStaticContext interface has two declareFunction methods that each have three parameters—one for the name, one for the return type of the function, and an array for the types of the arguments. The name is always provided as a QName object, but the types can be QNames or XSequenceTypes. The function name, return type, and argument types must uniquely identify the function.

   A stylesheet function could have the same name as an external function. If the stylesheet function has an override attribute with the value of yes, any reference to that function name in the stylesheet is a reference to the stylesheet function; if it has an override attribute with the value of no, it is a reference to the external function.

*Table 363. XStaticContext declareFunction methods.*

*This table explains when to use each form of the declareFunction method.*

| Method Signature | Purpose |
|---|---|
| declareFunction(QName name, QName type, QName[] argTypes) | Use when the return value and arguments of the function are all single atomic values<br><br>The type QNames must refer to built-in types or global types declared in a schema that has been registered on the XFactory instance used to create the XStaticContext instance. If a QName refers to a non-atomic type, then the processor will treat it as the type element(*, ns:type), where ns:type is the given QName. The XTypeConstants interface has convenient constants available that provide a QName object for each built-in type. |
| declareFunction(QName name, XSequenceType type, XSequenceType[] argTypes) | Use when any of the arguments or the return value of the function is a node or a sequence of atomic values or nodes |

The following stylesheet uses an external function referred to by the QName ext:pow.

```
<?xml version="1.0"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
                xmlns:ext="http://www.example.com/functions"
                version="2.0">

    <xsl:output method="text"/>

    <xsl:template match="polynomial">
        <xsl:variable name="p" select="."/>

        <xsl:for-each select="1 to 5">
            <xsl:text>x = </xsl:text>
            <xsl:value-of select="."/>
            <xsl:text>; </xsl:text>
            <xsl:value-of select="for $t in $p/term return concat($t/@coefficient, 'x^', $t/@power)"
                          separator=" + "/>
            <xsl:text> = </xsl:text>
            <xsl:value-of select="sum($p/term/(ext:pow(current(), @power) * @coefficient))"/>
            <xsl:text>&#xA;</xsl:text>
        </xsl:for-each>
    </xsl:template>

</xsl:stylesheet>
```

Assuming that the stylesheet above is available using the xsltSource Source object, the code below prepares the stylesheet.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create a new static context
XStaticContext staticContext = factory.newStaticContext();

// Declare a namespace for the function
staticContext.declareNamespace("ext", "http://www.example.com/functions");

// Create a QName for the name of the function
QName methodQName = new QName("http://www.example.com/functions", "pow");

// Declare the function on the static context
staticContext.declareFunction(methodQName, XTypeConstants.DOUBLE_QNAME, new QName[]{XTypeConstants.DOUBLE_QNAME, XTypeConstants.DOUBLE_QNAME});

// Create an XSLT executable for the stylesheet
XSLTExecutable executable = factory.prepareXSLT(xsltSource, staticContext);
```

2. To execute an XSLT stylesheet that uses external functions, supply (or bind) the Java methods that implement the functions using an XDynamicContext instance.

   Use Java reflection to obtain a java.lang.reflect.Method object for the function. If the method is an instance method, an instance object is required when binding this function.

   An error is raised if you do not supply a Java method for a function that is used when executing the XSLT stylesheet.

   The XDynamicContext has two bindFunction methods. Each requires a QName object corresponding to the name of the function and a Method object identifying the Java method that will provide the implementation for the function.

*Table 364. XDynamicContext bindFunction methods.*

*This table explains when to use each form of the XDynamicContext bindFunction methods.*

| Method Name | Purpose |
|---|---|
| bindFunction(QName qname, Method method) | Use when binding a static method |
| bindFunction(QName qname, Method method, Object instanceObject) | Use when binding an instance method |

The following example executes the XSLT stylesheet prepared in the first example, first binding a method for the function it uses. In this example, the static pow(double a, double b) method of the java.lang.Math class is used to provide the implementation for the external function.

```
// Create a new dynamic context
XDynamicContext dynamicContext = factory.newDynamicContext();

// Retrieve the java.lang.reflect.Method object for this function
Method method = Math.class.getMethod("pow", Double.TYPE, Double.TYPE);

// Bind the function to the dynamic context
dynamicContext.bindFunction(methodQName, method);

// Create an XML input document
String xml = "<polynomial>" +
"<term power='2' coefficient='3'/>" +
"<term power='1' coefficient='-2'/>" +
"<term power='0' coefficient='1'/>" +
"</polynomial>";
StreamSource source = new StreamSource(new StringReader(xml));

// Execute the stylesheet
XSequenceCursor result = executable.execute(source, dynamicContext);

// Serialize the result to System.out
result.exportItem(new StreamResult(System.out), executable.getOutputParameters());
```

# Creating items and sequences

You can use this information to help you to create items and sequences using the XItemFactory as well as to use sequence types.

## Procedure

- Create items and sequences using the XItemFactory.
- Use sequence types.

## Creating items and sequences using the XItemFactory

You can use XItemFactory to create new items and sequences of items of different types.

### Procedure

- Use the getItemFactory method in the XFactory class to create instances of XItemFactory and call the appropriate item method to create an item of a specific type.

  An item itself can be a node or an atomic value such as an integer, string, or boolean.

  The following is an example of using the XItemFactory to create new items of different types.

```
// Create an XFactory
XFactory factory = XFactory.newInstance();

// Create an XItemFactory
XItemFactory itemFactory = factory.getItemFactory();

// Create a new atomic item of a type which is the default mapping of the xs:string built-in type to java.lang.String
XItemView stringItem = itemFactory.item("Lets see");

// Create a new atomic item of type int
XItemView intItem = itemFactory.item(3, XTypeConstants.INT_QNAME);

// Create a new atomic item of type boolean
boolean boolValue = false;
XItemView booleanItem = itemFactory.item(boolValue, XTypeConstants.BOOLEAN_QNAME);

 // Create Node type
DocumentBuilderFactory dbf = DocumentBuilderFactory.newInstance();
DocumentBuilder db = dbf.newDocumentBuilder();
// Parse the input file
Document doc = db.parse(INPUT_File);
```

```
Node node = doc.getFirstChild();
XItemView item =itemFactory.item(node)

 // Create a new item of complex type from a Source
StreamSource source = new StreamSource(INPUT_File);
XItemView complexItem = itemFactory.item(source);
```

As shown in the example, you can use item method with one argument as the value of the method and the type is evaluated based on the mapping rules between built-in types and Java types.

- Use the getItemFactory method in the XFactory class to create instances of XItemFactory and call the appropriate sequence method to create an XSequenceCursor that represents a sequence of items providing cursor access to the items in the sequence.

  The following is an example of using XItemFactory to create a homogeneous sequence.

```
// Create an XFactory
XFactory factory = XFactory.newInstance();

// Create an XItemXFactory
XItemFactory itemFactory =xfactory.getItemFactory();

//Create a sequence of int values
XSequenceCursor intSeq = xfactory.sequence(new int[]{1,2,3});

//Create a sequence of String values
XSequenceCursor stringSeq = xfactory.sequence(new String[]{"This", "is", "a", "test"},XTypeConstants.STRING_QNAME );
```

The following is an example of using the XItemFactory to create a sequence of items of different types.

```
// Create an XFactory
XFactory factory = XFactory.newInstance();

// Create an XItemXFactory
XItemFactory itemFactory = factory.getItemFactory();

//Create an Array of the newly created items
XItemView[] items = new XItemView[2];
items[0] =itemFactory.item(boolValue, XTypeConstants.BOOLEAN_QNAME);
items[1] = itemFactory.item(intValue, XTypeConstants.INT_QNAME);

// Create a sequence of items
XSequenceCursor seq = itemFactory.sequence(items);
```

## Using sequence types

You can use sequence types when declaring variables for the return or parameter types of functions.

### About this task

In the XML API, sequence types are represented using XSequenceType objects. XSequenceType objects can represent the same set of sequence types as the SequenceType syntax defined in XPath 2.0. XSequenceType objects are created through the XSequenceTypeFactory interface. You can obtain an instance of XSequenceTypeFactory using the getSequenceTypeFactory() method on an XFactory instance.

### Procedure

- XSequenceTypeFactory has several methods for creating XSequenceType instances.

  Each method on the XSequenceTypeFactory interface has an XSequenceType.OccurrenceIndicator parameter except for emptySequence(). OccurrenceIndicator is an enum that represents the cardinality of the sequence; ZERO_OR_ONE corresponds to "?" in SequenceType syntax, ZERO_OR_MORE to "*", ONE_OR_MORE to "+", and ONE to no occurrence indicator for sequences of exactly one item.

- The XSequenceTypeFactory interface methods use QNames to refer to the names of nodes such as elements and attributes, and also to types and global element and attribute declarations.

  QNames representing types must refer to built-in types or to types defined in schemas that have been registered with the same XFactory instance used to obtain the XSequenceTypeFactory instance. Similarly, QNames representing global element or attribute declarations must refer to global declarations present in schemas that have been registered with the same XFactory instance.

## Example

*Table 365. XSequenceTypeFactory methods and examples of sequence types.*

*The following table lists each method of the XSequenceTypeFactory and gives examples of the sequence types (using SequenceType syntax) that each can create.*

| Method Signature | Example Sequence Types | Comments |
|---|---|---|
| emptySequence() | empty-sequence() | |
| item(OccurrenceIndicator cardinality) | item()* | |
| atomic(QName typeName, OccurrenceIndicator cardinality) | xs:integer | "sc:type" is a QName referring to a user-defined schema type. |
| | sc:type+ | |
| documentNode(OccurrenceIndicator cardinality) | document-node()? | |
| documentNodeWithElement(QName elementNameOrWildcard, QName typeName, boolean nillable, OccurrenceIndicator cardinality) | document-node(element()) | "ns:elem" is a QName representing an element name, and "sc:type" is a QName referring to a user-defined schema type.<br><br>The elementNameOrWildcard and typeName parameters are optional; use null if the element name or type does not matter. |
| | document-node(element(ns:elem))? | |
| | document-node(element(*, sc:type?)) | |
| documentNodeWithSchemaElement(QName elementName, OccurrenceIndicator cardinality) | document-node(schema-element(sc:elemDecl)) | "sc:elemDecl" is a QName referring to a global element declaration in a schema. |
| element(QName elementNameOrWildcard, QName typeName, boolean nillable, OccurrenceIndicator cardinality) | element(*) | "ns:elem" is a QName representing an element name, and "sc:type" is a QName referring to a user-defined schema type.<br><br>The elementNameOrWildcard and typeName parameters are optional; use null if the element name or type does not matter. |
| | element(ns:elem, sc:type)* | |
| attribute(QName attributeNameOrWildcard, QName typeName, OccurrenceIndicator cardinality) | attribute()+ | "ns:attrib" is a QName representing an attribute name.<br><br>The attributeNameOrWildcard and typeName parameters are optional; use null if the attribute name or type does not matter. |
| | attribute(ns:attrib) | |
| | attribute(ns:attrib, xs:string)? | |
| schemaElement(QName elementName, OccurrenceIndicator cardinality) | schema-element(sc:elemDecl)* | "sc:elemDecl" is a QName referring to a global element declaration in a schema. |
| schemaAttribute(QName attributeName, OccurrenceIndicator cardinality) | schema-attribute(sc:attribDecl) | "sc:attribDecl" is a QName referring to a global attribute declaration in a schema. |
| processingInstruction(QName piNCName, OccurrenceIndicator cardinality) | processing-instruction()? | "pinst" is an NCName representing the name of a processing instruction. |
| | processing-instruction("pinst") | |
| | processing-instruction(pinst) | |
| comment(OccurrenceIndicator cardinality) | comment() | |
| text(OccurrenceIndicator cardinality) | text()+ | |
| node(OccurrenceIndicator cardinality) | node()* | |

The following example shows how to create XSequenceType objects to represent various sequence types. Some of the results refer to types and declarations from a schema. The example assumes that the schema is available through the schemaSource source object.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Obtain an XSeqeuenceTypeFactory instance
XSequenceTypeFactory stFactory = factory.getSequenceTypeFactory();

// Create a sequence type for a sequence of xs:integer values: "xs:integer*"
XSequenceType integerSequenceType = stFactory.atomic(
        XTypeConstants.INTEGER_QNAME,
        XSequenceType.OccurrenceIndicator.ZERO_OR_MORE);

// Create a sequence type for a single node: "node()"
XSequenceType nodeType = stFactory.node(OccurrenceIndicator.ONE);

// Define a constant for the target namespace of a schema containing user-defined types and declarations
final String targetNamespace = "http://www.example.org/schema/";

// Register the schema with the XFactory
factory.registerSchema(schemaSource);
```

```
// Create a sequence type for exactly one document node with an element of type "employeeRecord" from the schema:
// "document-node(element(*, ns:employeeRecord))"
XSequenceType employeeRecordDocumentType = stFactory.documentNodeWithElement(
        null,
        new QName(targetNamespace, "employeeRecord"),
        false,
        XSequenceType.OccurrenceIndicator.ONE);

// Create a sequence type for an optional attribute matching the attribute declaration "type" in the schema:
// "schema-attribute(ns:type)?"
XSequenceType optionalEmployeeType = stFactory.schemaAttribute(
        new QName(targetNamespace, "type"),
        XSequenceType.OccurrenceIndicator.ZERO_OR_ONE);

// Create a sequence type for one or more atomic values of type "telephoneNumber" from the schema:
// "ns:telephoneNumber+"
XSequenceType telephoneNumbersType = stFactory.atomic(
        new QName(targetNamespace, "telephoneNumber"),
        XSequenceType.OccurrenceIndicator.ONE_OR_MORE);
```

Contents of sample schema:

```
<?xml version="1.0" encoding="UTF-8"?>
<schema xmlns="http://www.w3.org/2001/XMLSchema" xmlns:ns="http://www.example.org/schema/" targetNamespace="http://www.example.org/schema/">
    <complexType name="employeeRecord">
        <sequence>
            <element name="name" type="string"></element>
            <element name="id" type="int"></element>
            <element name="telephone" type="ns:telephoneNumber"></element>
        </sequence>
        <attribute ref="ns:type"></attribute>
    </complexType>

    <simpleType name="telephoneNumber">
        <restriction base="string">
            <pattern value="\d{3}-\d{3}-\d{4}"></pattern>
        </restriction>
    </simpleType>

    <element name="employee" type="ns:employeeRecord"></element>

    <simpleType name="employeeType">
        <restriction base="string">
            <enumeration value="full-time"></enumeration>
            <enumeration value="part-time"></enumeration>
            <enumeration value="seasonal"></enumeration>
        </restriction>
    </simpleType>

    <attribute name="type" type="ns:employeeType"></attribute>
</schema>
```

# Working with collations

XSLT stylesheets and expressions in XQuery and XPath can refer to collations using collation URIs. A collation is a set of culture-specific rules that define how text should be sorted and which differences between two pieces of text are considered significant and which insignificant.

## Before you begin

This article assumes some basic familiarity with the java.util.Locale and java.text.Collator classes.

## About this task

The processor does not interpret the collation URI in any way -- it treats a collation URI merely as a sort of name for the instance of the Java Collator class that is associated with that URI. The XML API provides mechanisms for specifying what will be the default collation URI at preparation-time and for associating an instance of the Java Collator class with a collation URI at execution-time.

All collation URIs specified through the XML API must be absolute URI references. In an XSLT stylesheet or an XQuery or XPath expression, any relative URI reference that is used in a context where a collation URI is required will be resolved against the base URI from the static context for that expression -- that will ensure that even relative URI references in the stylesheet or expression can be matched with the absolute URI references specified through the XML API.

**Limitations:**

- If a collation URI is bound with an instance of the Java Collator class that is not an instance of java.text.RuleBasedCollator, certain operations will not be permitted with that collation URI. In particular, the fn:starts-with, fn:ends-with, fn:contains, fn:substring-before and fn:substring-after functions are not supported with that collation URI.
- All instances of Collator that are currently included with the Java runtime environment are also instances of java.text.RuleBasedCollator, so this is for most purposes only a theoretical limitation. However, it is something to be aware of if an application defines its own instances of the Java Collator class or defines subclasses the Collator class that are not also instances of java.text.RuleBasedCollator.

## Procedure

- Declare the default collation URI.

  You can specify what collation URI you want to use as the default for string comparison operations by using the method setDefaultCollation method on the XStaticContext interface. The default collation URI from the XStaticContext interface will be used as the collation URI in string comparison operations that do not explicitly specify a collation URI.

  An XQuery expression can override the default collation URI specified on the XStaticContext interface with the declare default collation declaration. Similarly, an XSLT stylesheet can override the default collation URI with the [xsl:]default-collation attribute. XPath does not provide a means of overriding the default collation URI. However, any XPath or XQuery expression or XSLT stylesheet that performs string comparison operations can specify an explicit collation URI to override the default collation URI.

  If you do not explicitly specify a default collation on any instance of the XStaticContext interface you supply when you prepare your XSLT stylesheet or your XQuery or XPath expression, the default collation URI for the stylesheet or expression will be the Unicode code-point collation URI: http://www.w3.org/2005/xpath-functions/collation/codepoint/.

  You can use the Unicode code-point collation in situations where characters must be identical Unicode characters to be considered to be equal. The lexicographical ordering defined by this collation is determined by the Unicode code points of the characters -- that is, by their positions on the Unicode code charts. As such, using the Unicode code-point collation will yield much better performance than collations that perform string comparisons in a culture-specific manner, but its unlikely to give very satisfactory results for sorting operations.

  The following is a simple example showing how to specify the default collation URI on an instance of the XStaticContext interface.

```
// Setting of default collation URI is not changed - default remains
// the Unicode code point collation URI
XFactory factory = XFactory.newInstance();
XPathExecutable maxPath1 = factory.prepareXPath("max($var)");

// A new default collation URI is specified in the static context
// That URI is used in any string comparison for which no other
// explicit collation URI is specified
XStaticContext sc = factory.newStaticContext();
sc.setDefaultCollation("http://example.org/my-collation");
XPathExecutable maxPath2 = factory.prepareXPath("max($var)", sc);
```

- Bind a collation URI.

  The XML API provides two methods for binding collation URI with an instance of the Java Collator class for an execution. The bindCollation methods on the XDynamicContext method have two arguments: the first argument is a collation URI; the second is either instance of the java.text.Collator class or an instance of the java.util.Locale class. If an instance of the locale class is specified, the processor will use the instance of the Collator class that is appropriate for that locale.

  XSLT, XPath and XQuery define the concept of "Statically Known Collations." If a reference to a collation URI appears in an XSLT stylesheet or an XPath or XQuery expression, and the collation URI is not one of the Statically Known Collations, a static error is supposed to be reported in some circumstances. However, the processor treats all collation URIs as if they were in the set of Statically Known Collations. This is due to the fact that instances of the Java Collator class are not actually associated with collation URIs until execution time, so it is not possible for the processor to determine

statically which collation URIs are not known. Instead, the processor will report a dynamic error if a collation URI that is not bound to an instance of the Collator class is used in a stylesheet or expression.

You cannot bind the Unicode code-point collation URI to any instance of the Java Collator class. It is always implicitly bound with the Unicode code-point collation.

The following example demonstrates how you can bind a collation URI with a specific instance of the Java Collator class on an instance of the XDynamicContext interface.

```
XFactory factory = XFactory.newInstance();
XStaticContext sc = factory.newStaticContext();
// Set up a default collation URI
sc.setDefaultCollation("http://example.org/my-collation");

// Prepare an XPath expression that computes fn:max() using the
// collator associated with the default collation URI and again using
// the Unicode code point collation
String expr =
    "max($var)," +
    "max($var,'http://www.w3.org/2005/xpath-functions/collation/codepoint')";
XPathExecutable maxPath =
    factory.prepareXPath(expr, sc);
XDynamicContext dc = factory.newDynamicContext();
// Set the value of the variable $var
dc.bind(new QName("var"),
        new String[] {"encyclopaedia",
                      // U+00E6 is lower case latin ae ligature
                      "encyclop\u00E6dia",
                      "encyclopedia"});
// Set up a Collator for English that does not distinguish between
// capitals, lower-case letters and certain character variants
Collator english =
    (Collator) Collator.getInstance(Locale.ENGLISH).clone();
english.setStrength(Collator.SECONDARY);
// Evaluate the expression with that English collator associated with
// the default collation URI
dc.bindCollation("http://example.org/my-collation", english);
XSequenceCursor maxValues = maxPath.execute(dc);
// Print maximum values - expected results are
// encyclopedia for English collation and
// encyclop\u00E6dia for Unicode code point collation
if (maxValues != null) {
    do {
        System.out.println(maxValues.getStringValue());
    } while (maxValues.toNext());
}
```

# Executing using the command-line tools

You can use the ExecuteXSLT tool to execute a stylesheet, use the ExecuteXPath tool to execute an XPath expression, and use the ExecuteXQuery tool to execute an XQuery expression.

## Procedure

- **Execute XSLT**

### Location

The product includes the following script that sets up the environment and invokes the tool.

- Windows *app_server_root*\bin\ExecuteXSLT.bat
- AIX HP-UX Linux Solaris *app_server_root*/bin/ExecuteXSLT.sh

### Syntax

Windows

```
ExecuteXSLT.bat
      -outputfile file
      -baseURI URI
      -useCompiler
      -bindVar name=varName value=varValue
      -baseOutputURI URI
      -XSLTinitMode mode
      -XSLTinitTemplate template
      -v
      -h
      -input file
      stylesheet
```

AIX HP-UX Linux Solaris

```
./ExecuteXSLT.sh
      -outputfile file
      -baseURI URI
      -useCompiler
      -bindVar name=varName value=varValue
      -baseOutputURI URI
      -XSLTinitMode mode
      -XSLTinitTemplate template
      -v
      -h
      -input file
      stylesheet
```

**Parameters**

**-outputfile** *file*
Specifies that output should go to the specified file

By default, the output is sent to standard out.

**-baseURI** *URI*
Specifies the base URI of the containing element

**-useCompiler**
Specifies compiler modes

If this parameter is not specified, the default behavior is to use interpreted mode.

**-bindVar name=***varName* **value=***varValue*
Bind an atomic value to a variable (XPath, XQuery) or a param (XSLT)

The value must be valid for the type that was specified in the static context (XPath), in the query (XQuery), or in the stylesheet (XSLT) for the same name.

*varName*
Name of the variable (expressed localPart,namespaceURI)

**Notes:**

- If the variable is in no namespace, the namespace URI should be omitted.
- If the value of any option contains a blank space, enclose it in quotation marks.
- Localpart is a required value.

*varValue*
Variable value

The -bindVar option can be used multiple times.

For example:

```
-bindVar name=la,"http://www.ibm.com/Los Angeles" value="some value"
```

**-baseOutputURI** *URI*
Specifies the base URI to use when resolving result documents

The default is either the base URI for the main result document or the current working directory.

This option only applies when working with XSLT.

**-XSLTinitMode** *mode*
Specifies a mode to use as the initial mode in an XSLT transformation (expressed localPart,namespaceURI)

This option only applies when working with XSLT.

For example:

```
-XSLTinitMode la,"http://www.ibm.com/Los Angeles"
```

**-XSLTinitTemplate** *template*

Specifies a named template to use as the initial template in an XSLT transformation (expressed localPart,namespaceURI)

If a named template is not set, the initial template is determined by the initial mode, context node, and template matching rules.

This option only applies when working with XSLT.

For example:

```
-XSLTinitTemplate la,"http://www.ibm.com/Los Angeles"
```

**-v** Prints the version of the tool

**-h** Prints the usage statement

**-input** *file*

Specifies the full path to a file containing an XML artifact against which the stylesheet will be executed

*stylesheet*

Specifies the full path to a file containing the XSL stylesheet

The following is a basic example of executing a stylesheet using the ExecuteXSLT tool:

– Windows `ExecuteXSLT.bat -input C:\sampledata\sample.xml C:\stylesheets\simple.xsl`

This executes the `C:\stylesheets\simple.xsl` stylesheet and places the resulting output on standard out.

– AIX HP-UX Linux Solaris `./ExecuteXSLT.sh -input /var/sampledata/sample.xml /var/stylesheets/simple.xsl`

This executes the `/var/stylesheets/simple.xsl` stylesheet and places the resulting output on standard out.

- **Execute an XPath expression**

**Location**

The product includes the following script that sets up the environment and invokes the tool.

– Windows *app_server_root*\bin\ExecuteXPath.bat

– AIX HP-UX Linux Solaris *app_server_root*/bin/ExecuteXPath.sh

**Syntax**

Windows

```
ExecuteXPath.bat
      -outputfile file
      -cpm mode
      -ns prefix=URI
      -schema URI
      [-var name=varName type=varType] ...
      -baseURI URI
      -dnet URI
      -useCompiler
      -bindVar name=varName value=varValue
      -v
      -h
      -input file
      xpathfile
```

AIX HP-UX Linux Solaris

```
./ExecuteXPath.sh
      -outputfile file
      -cpm mode
      -ns prefix=URI
      -schema URI
      [-var name=varName type=varType] ...
      -baseURI URI
```

```
-dnet URI
-useCompiler
-bindVar name=varName value=varValue
-v
-h
-input file
xpathfile
```

**Parameters**

**-outputfile** *file*
Specifies that output should go to the specified file

By default, the output is sent to standard out.

**-cpm** *mode*
Specifies an alternate XPath compatibility mode

Valid values are Latest, 1.0, and 2.0.

The default is 2.0.

**-ns** *prefix*=*URI*
Specifies a namespace for use during static processing

If the value of any option contains a blank space, enclose it in quotation marks.

This option can be used multiple times.

**-schema** *URI*
Specifies any schema document that is used to populate the in-scope schema definitions

This option can be used multiple times.

**-var name=***varName* **type=***varType*
Adds a variable binding to the static context for a single item

This simply declares the variable, and a value also must be bound to the XDynamicContext.

*varName*
Indicates the name of the variable (expressed localPart,namespaceURI)

If the variable is in no namespace, the namespace URI should be omitted.

Localpart is a required value.

*varType*
Indicates the type of the variable (expressed localPart[, namespaceURI])

If the value of any option contains a blank space, enclose it in quotation marks.

This option can be used multiple times.

For example:

```
-var name=la,"http://www.ibm.com/Los Angeles" type=boolean,http://www.w3.org/2001/XMLSchema
```

**-baseURI** *URI*
Specifies the base URI of the containing element

**-dnet** *URI*
Specifies a default namespace URI for element and type names

The namespace URI, if present, is used for any unprefixed QName appearing in a position where an element or type name is expected.

**-useCompiler**
Specifies compiler modes

If this parameter is not specified, the default behavior is to use interpreted mode.

**-bindVar name=***varName* **value=***varValue*
Bind an atomic value to a variable (XPath, XQuery) or a param (XSLT)

The value must be valid for the type that was specified in the static context (XPath), in the query (XQuery), or in the stylesheet (XSLT) for the same name.

*varName*
Name of the variable (expressed localPart,namespaceURI)

**Notes:**

- If the variable is in no namespace, the namespace URI should be omitted.
- If the value of any option contains a blank space, enclose it in quotation marks.
- Localpart is a required value.

*varValue*
Variable value

The -bindVar option can be used multiple times.

For example:

```
-bindVar name=la,"http://www.ibm.com/Los Angeles" value="some value"
```

**-v** Prints the version of the tool

**-h** Prints the usage statement

**-input** *file*
Specifies the full path to a file containing an XML artifact against which the XPath expression will be executed

*xpathfile*
Specifies the full path to a file containing the XPath expression

The following is a basic example of executing an XPath expression using the ExecuteXPath tool:

- Windows `ExecuteXPath.bat -input C:\sampledata\sample.xml C:\XPath\simpleXPath.txt`
  This executes the XPath expression provided in `C:\XPath\simpleXPath.txt` and places the resulting output on standard out.
- AIX HP-UX Linux Solaris `./ExecuteXPath.sh -input /var/sampledata/sample.xml /var/XPath/simpleXPath.txt`
  This executes the XPath expression provided in `/var/XPath/simpleXPath.txt` and places the resulting output on standard out.

- **Execute an XQuery expression**

  **Location**

  The product includes the following script that sets up the environment and invokes the tool.

  - Windows *app_server_root*\bin\ExecuteXQuery.bat
  - AIX HP-UX Linux Solaris *app_server_root*/bin/ExecuteXQuery.sh

  **Syntax**

  Windows

```
ExecuteXQuery.bat
      -outputfile file
      -baseURI URI
      -dnet URI
      -useCompiler
      -bindVar name=varName value=varValue
```

```
-v
-h
-input file
xqueryfile
```

AIX HP-UX Linux Solaris

```
./ExecuteXQuery.sh
      -outputfile file
      -baseURI URI
      -dnet URI
      -useCompiler
      -bindVar name=varName value=varValue
      -v
      -h
      -input file
      xqueryfile
```

## Parameters

**-outputfile** *file*
Specifies that output should go to the specified file

By default, the output is sent to standard out.

**-baseURI** *URI*
Specifies the base URI of the containing element

**-dnet** *URI*
Specifies a default namespace URI for element and type names

The namespace URI, if present, is used for any unprefixed QName appearing in a position where an element or type name is expected.

**-useCompiler**
Specifies compiler modes

If this parameter is not specified, the default behavior is to use interpreted mode.

**-bindVar name=***varName* **value=***varValue*
Bind an atomic value to a variable (XPath, XQuery) or a param (XSLT)

The value must be valid for the type that was specified in the static context (XPath), in the query (XQuery), or in the stylesheet (XSLT) for the same name.

*varName*
Name of the variable (expressed localPart,namespaceURI)

**Notes:**

- If the variable is in no namespace, the namespace URI should be omitted.
- If the value of any option contains a blank space, enclose it in quotation marks.
- Localpart is a required value.

*varValue*
Variable value

The -bindVar option can be used multiple times.

For example:

```
-bindVar name=la,"http://www.ibm.com/Los Angeles" value="some value"
```

**-v** Prints the version of the tool

**-h** Prints the usage statement

**-input** *file*
Specifies the full path to a file containing an XML artifact against which the XQuery expression will be executed

*xqueryfile*
Full path to a file containing the XQuery expression

The following is a basic example of executing an XQuery expression using the ExecuteXQuery tool:

– Windows `ExecuteXQuery.bat -input C:\sampledata\sample.xml C:\XQuery\simpleXQuery.txt`
This executes the XQuery expression provided in `C:\XQuery\simpleXQuery.txt` and places the resulting output on standard out.

– AIX HP-UX Linux Solaris `./ExecuteXQuery.sh -input /var/sampledata/sample.xml /var/XQuery/simpleXQuery.txt`
This executes the XQuery expression provided in `/var/XQuery/simpleXQuery.txt` and places the resulting output on standard out.

# Using a message handler and managing exceptions

You can use this information to help you to use a message handler and mange exceptions.

## Procedure

- Use a message handler.
- Manage exceptions.

## Using a message handler

The default behavior for prepare-time and execution-time processing errors and other messages is to print the messages to System.err and for nonrecoverable errors to raise an XProcessException as well. If an error occurs at prepare time, the processor attempts to continue preparation and signal all errors before generating an XProcessException; but no executable is produced. At run time, execution stops at the first occurrence of an error situation.

### Procedure

Change the handling of errors by registering an implementation of XMessageHandler to the XStaticContext (for prepare-time errors and other messages) or the XDynamicContext (for execution-time errors and other messages).
The XMessageHandler interface consists of a single report method that has the following parameters:

**level** One of the following enumerators defined in the XMessageHandler interface:

**INFO** Indicates that the error is simply informational and will not affect the result

This is also used for the XSLT message instruction when the terminate attribute evaluates to "no."

**WARNING**
Indicates a warning

The processor recovers from a warning situation, but the result might not be what was expected.

**ERROR**
Indicates a recoverable error

The processor might recover from this error for the purpose of signaling additional errors, but no result is produced.

**FATAL_ERROR**
Indicates a nonrecoverable error

The processor cannot recover from this error. It is also used for the XSLT message instruction when the terminate attribute evaluates to "yes."

**TRACE**
Indicates that the message was generated by a call to the XPath fn:trace function

**message**
Error message

**location**
Source location as an XSourceLocation if available

In general, the source location is not available for execution-time errors.

**cause** Original exception that caused the error if available

If the input document is invalid, for example, the XML parser generates an exception that is passed to the report method through this parameter.

**errorItems**
Items that were specified for the error-object parameter to the XPath fn:error function

The implementation of XMessageHandler can present the errors and other messages as desired, such as writing to a log file rather than sending the messages to System.err. It may also be more strict and stop compilation or execution after any error including recoverable errors by generating an exception. Because the report method has no throws clause, the exception must be unchecked. The implementation might also choose to ignore informational and warning messages. In short, registering an XMessageHandler allows the application to configure message handling to suit its purposes.
Note that in the case of a nonrecoverable error, if the registered message handler does not generate an exception, an XProcessException is raised by the processor.

## Managing exceptions

Various exceptions might occur. Unless otherwise indicated, all exceptions extend RuntimeException and thus are unchecked.

### Procedure

- Manage **XProcessException**.

  This exception occurs when the processor finds a nonrecoverable error when preparing or executing an expression, query, or stylesheet as described in the specifications for each language.

  If there are multiple errors at prepare time, the processor attempts to report all of the errors and only generates an XProcessException at the end of preparation or if it reaches a point where it cannot continue. At execution time, however, the first error results in an XProcessException and the end of execution.

  In general, XProcessExceptions should not occur if the expression, query, or stylesheet is syntactically and semantically valid and also valid for the types of input documents that it is meant to process.

  An XProcessException also occurs for an XSLT message instruction where the terminate attribute evaluates to "yes."

  This is the default behavior for handling processing errors and other messages. Applications can register an implementation of the XMessageHandler interface at prepare time or execution time to modify the default behavior.
- Manage an **XViewException**.

  This exception is raised for incorrect use of the XML API itself such as calling one of the XNodeView methods on an item that is atomic.

  See the API documentation for more information about when this exception can occur.
- Manage a **NullPointerException**.

  This exception is raised when a null value is passed to an API method where null is not allowed, such as passing a null prefix or namespace to the XStaticContext declareNamespace method.

See the XML API documentation for more information about when this exception can occur.

- Manage an **IllegalArgumentException**.

  This exception is raised when an invalid value is passed to an API method, such as calling the XStaticContext setXPathCompatibilityMode method with a value other than one of the predefined settings.

  See the XML API documentation for more information about when this exception can occur.

- Manage **exceptions generated by XFactory.newInstance**.

  The newInstance method on the XFactory class loads the XFactory implementation class and creates a new instance; therefore, any of the following checked exceptions might occur:

  – ClassNotFoundException
  – IllegalAccessException
  – InstantiationException

  These exceptions would likely result if there is a classpath problem or a Java security issue.

# Appendix. Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

## Default product locations (distributed)

The following file paths are default locations. You can install the product and other components or create profiles in any directory where you have write access. Multiple installations of WebSphere Application Server - Express products or components require multiple locations. Default values for installation actions by root and nonroot users are given. If no nonroot values are specified, then the default directory values are applicable to both root and nonroot users.

*app_client_root*

*Table 366. Default installation root directories for the Application Client for IBM WebSphere Application Server.*

*This table shows the default installation root directories for the Application Client for IBM WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppClient` (Java EE Application client only)<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\Program Files\IBM\WebSphere\AppClient` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppClient` (Java EE Application client only)<br>Windows `C:\IBM\WebSphere\AppClient` |

*app_server_root*

*Table 367. Default installation directories for WebSphere Application Server.*

*This table shows the default installation directories for WebSphere Application Server - Express.*

| User | Directory |
|---|---|
| Root | AIX `/usr/IBM/WebSphere/AppServer`<br>HP-UX Linux Solaris `/opt/IBM/WebSphere/AppServer`<br>Windows `C:\Program Files\IBM\WebSphere\AppServer` |
| Nonroot | AIX HP-UX Linux Solaris *user_home*`/IBM/WebSphere/AppServer`<br>Windows *user_home*`\IBM\WebSphere\AppServer` |

*component_root*
: The component installation root directory is any installation root directory described in this topic. Some programs are for use across multiple components—in particular, the Web Server Plug-ins, the Application Client, and the IBM HTTP Server. All of these components are part of the product package.

*gskit_root*
: IBM Global Security Kit (GSKit) can now be installed by any user. GSKit is installed locally inside the installing product's directory structure and is no longer installed in a global location on the

© IBM Corporation 2005

target system. The following list shows the default installation root directory for Version 8 of the GSKit, where *product_root* is the root directory of the product that is installing GSKit, for example IBM HTTP Server or the web server plug-in.

AIX HP-UX Linux Solaris

*product_root*/gsk8

Windows

*product_root*\gsk8

### *profile_root*

*Table 368. Default profile directories.*

*This table shows the default directories for a profile named profile_name on each distributed operating system.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/AppServer/profiles/*profile_name*<br>HP-UX Linux Solaris /opt/IBM/WebSphere/AppServer/profiles/*profile_name*<br>Windows C:\Program Files\IBM\WebSphere\AppServer\profiles*profile_name* |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/AppServer/profiles<br>Windows *user_home*\IBM\WebSphere\AppServer\profiles |

### *plugins_root*

*Table 369. Default installation root directories for the Web Server Plug-ins.*

*This table shows the default installation root directories for the Web Server Plug-ins for WebSphere Application Server.*

| User | Directory |
|---|---|
| Root | AIX /usr/IBM/WebSphere/Plugins<br>HP-UX Linux Solaris /opt/IBM/WebSphere/Plugins<br>Windows C:\Program Files\IBM\WebSphere\Plugins |
| Nonroot | AIX HP-UX Linux Solaris *user_home*/IBM/WebSphere/Plugins<br>Windows C:\IBM\WebSphere\Plugins |

### *wct_root*

*Table 370. Default installation root directories for the WebSphere Customization Toolbox.*

*This table shows the default installation root directories for the WebSphere Customization Toolbox.*
